VII Comparing LFG with other linguistic theories

Preface

This handbook is the result of discussions which began in late 2018 among many of the handbook authors, who felt that a wide-coverage handbook of LFG would be very useful for practitioners of LFG as well as for people wanting to learn more about various aspects of the theory. We originally planned to finish the handbook by mid-2021, but, as with many things, the COVID-19 pandemic got in the way, and the number of originally planned chapters had to be reduced. We are nevertheless delighted with the results, and we anticipate that the handbook will be an essential resource for work in LFG for many years to come.

This handbook has been a community effort in the best sense, with involvement and input from handbook contributors at every stage of the process. I have been extremely grateful to all of the contributors for their flexibility, good humor, perseverance, and very hard work. At an early stage, Annie Zaenen and Nigel Vincent provided very helpful suggestions for the overall organization of the handbook. As always, Tracy Holloway King provided sage advice, and help with Latex conversion at crucial moments. Bozhil Hristov went far beyond the call of duty in proofreading many of the handbook chapters. We have also benefited greatly from the helpful advice and expert technical assistance of the editorial team, Sebastian Nordhoff and Felix Kopecky, and the vision of Stefan Müller and his team in establishing Language Science Press as an essential resource for linguistics.

Reviewers' suggestions and advice were crucial in improving the content and presentation of the chapters. All of the handbook authors also acted as reviewers for other handbook chapters, and we are grateful to them for taking on this work. Most authors reviewed two other handbook chapters, but the following authors took on reviewing responsibility for more than two chapters, and we are grateful to them for this extra effort: Ash Asudeh, Avery Andrews, Dag Haug, John Lowe, Peter Sells, and Tracy Holloway King. We also relied on a large team of external reviewers who provided very useful comments and feedback. Most external reviewers reviewed only one chapter, but we extend special thanks to those who reviewed more than one chapter: Amanda Thomas, Doug Arnold, and especially Joey Lovestrand, who contributed three reviews. We are particularly grateful to a team of Oxford graduate students who provided very detailed and helpful comments on the introductory chapters: Shuting Chen, Wilson Lui, Yiwei Si, Eden Watkins, and Xiulin Yang. For very helpful comments on the glossary, we are grateful to Ron Kaplan, Elaine Ui Dhonnchadha, Bozhil Hristov, Rachel Nordlinger, Hannah Booth, Nigel Vincent, György Rákosi, Alex Alsina, and Tibor Laczkó. We are also grateful to the Press's very competent and helpful team of proofreaders for their careful work on all of the chapters.

As always, I am grateful to Ken Kahn for all kinds of support as this handbook came together.

Oxford, October 2023 Mary Dalrymple

Part I

Overview and introduction

Chapter 1

Introduction to LFG

Oleg Belyaev

Lomonosov Moscow State University, Institute of Linguistics of the Russian Academy of Sciences, and Pushkin State Russian Language Institute

This chapter provides a general summary of the architecture of LFG. It is mainly focused on describing the two main syntactic levels, c- and f-structure, and the projection architecture used in LFG in general. It also describes the notation for defining the range of possible c-structures and their corresponding f-structures. Core syntactic mechanisms such as structure sharing and X-bar theory are also briefly covered.

1 Introduction

In this chapter, I aim to summarize the main syntactic levels of LFG, constituent structure (c-structure) and functional structure (f-structure), while providing a general overview of the foundational features of this framework. In Section 2, I briefly describe the basic architecture of LFG and the overall role played by each of the syntactic levels. In Section 3, I describe the c-structure model used in standard LFG, its understanding of constituency, and the role of X′ theory. In Section 4, the notion of f-structure is introduced, together with notational conventions and a system of mapping c-structure to f-structure. In Section 5, I show how the basic system of c- and f-structure can be extended to include other levels of projection that comprise the architecture of LFG.

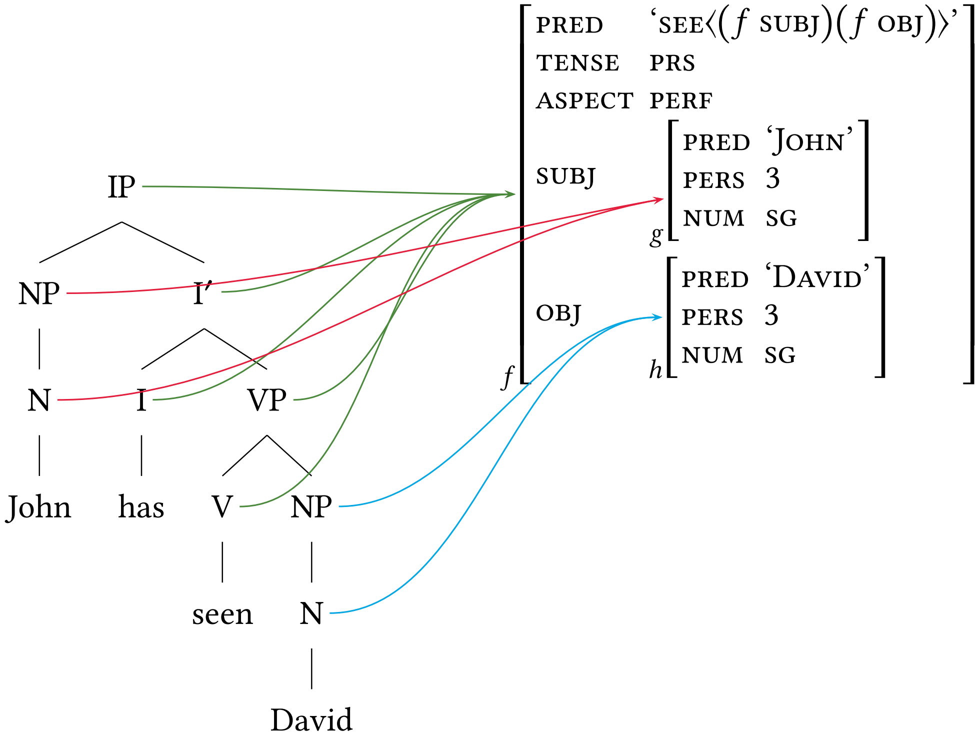
2 The basic architecture of LFG

At the core of LFG architecture as it was originally proposed in Kaplan & Bresnan (1982) is the split of syntax into two levels: constituent structure, or **c-structure**,

Oleg Belyaev. 2023. Introduction to LFG. in Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 3–22. Berlin: Language Science Press. DOI: 10.5281/zenodo.10185934

and functional structure, or **f-structure**. The correspondence function $\phi(x)$ maps every c-structure node to an f-structure. As an example, consider the LFG analysis of the sentence *John has seen David* in (1), where the mapping function is represented by the arrows.

(1)



As seen in (1), the two parallel structures are substantially different: c-structure is a phrase structure tree that represents word order and hierarchical embedding, while f-structure is a feature-value structure that represents predicate-argument relations and the grammatical features of all the major parts of the sentence. Features appear as atomic values of f-structure attributes, while arguments and adjuncts appear as f-structures embedded as values of attributes such as SUBJ and OBJ in (1); which arguments can and, indeed, have to appear in the f-structure is specified in the value of the PRED attribute. While the mapping between the two structures follows certain constraints imposed both by the formal metalanguage and theoretical considerations (on which see Belyaev 2023a [this volume] and Andrews 2023 [this volume], it is, in principle, language-specific: an LFG grammar consists of a set of rules and lexical entries that define the possible c-structures and their corresponding f-structures for a particular language.

This flexibility in the c- to f-structure correspondence ensures that each corresponds to a particular set of grammatical generalizations. Overall, f-structure is the main syntactic level that represents the predicates, their valencies and grammatical relations, as well as grammatical features such as number, case, aspect and gender. The majority of syntactic phenomena that have to do with feature assignment and feature checking are described using f-structure constraints; these include:

- feature government (case assignment, mood, constraints on the use of non-finite forms, etc.);
- agreement;
- anaphoric constraints;
- wh-movement, topicalization and other long-distance dependencies.

All generalizations that have to do with argument relations and grammatical features have to be stated in terms of f-structure. For instance, a constraint that requires the verb to agree with Spec,IP or to assign accusative case to Comp,VP would be complex and somewhat unnatural to formulate (although not impossible). It is much more simple and natural in LFG for such rules to refer to grammatical functions such as SUBJ and OBJ instead. This implies that the role of constituent structure is more restricted than in other frameworks; for the most part, c-structure constraints only capture generalizations related to word order and various embedding possibilities.

The correspondence architecture is not limited to syntax. Other projections that map c-structure nodes or f-structures to other structures (such as information structure, semantic structure, or prosody) have been proposed in the literature: see Section 5 for details.

3 C-structure

3.1 The notion of c-structure

C-structure (constituent structure) in LFG is a phrase structure tree. Possible trees are defined by a set of context-free statements ("phrase structure rules") of the type $A \rightarrow \alpha$, where A is a nonterminal symbol (representing some syntactic category), while α is a string of nonterminals or a single terminal. A simple set of rules that licenses the English sentence in (1) is given in (2).

(2) a. IP $\longrightarrow$ NP I′ b. I′ $\longrightarrow$ I VP c. VP $\longrightarrow$ V NP d. NP $\longrightarrow$ N

Such rules are well-established in modern linguistics since at least Chomsky (1957) and so hardly require further discussion. It should however be observed that, in LFG, these should not be understood as "rules" in the direct (procedural) sense, but rather a set of phrase structure principles that constrain hierarchical relations between mothers and daughters – crucially, not between levels further apart, such as granddaughters etc. Phrase structure grammars are one way of describing such principles that has proved most popular among LFG practitioners, but not the only way – possible alternatives are ID/LP rules (Falk 1983) and the specification language described in Potts (2002), which builds on the specification language in Blackburn & Gardent (1995).

The structures that are constrained in this way are not just strings,[1] but constituent structure trees whose nodes are individually mapped to f-structures, as shown in (1).

The syntax of phrase structure rules in LFG is somewhat more extensive than in many other frameworks, because the right-hand side α is allowed to be a regular expression and include such features as optionality (represented by parentheses around the symbol), disjunction (with the disjuncts in curly brackets, separated by either a vertical line (|) or a logical disjunction sign (∨): e.g. { NP | DP }), Kleene star (zero or more instances, NP*), Kleene plus (one or more instances, NP^+), and some other less frequently used expressions. Grammars where the right-hand side can include regular expressions are called extended context-free grammars or regular right part grammars and it is known (Woods 1970) that the set of languages they describe is the same as that of standard context-free grammar.

3.2 Main properties of c-structure

LFG is unique among all frameworks in the simplicity of its constituent structure representations. This is a deliberate design decision which is possible due to the parallel architecture approach of LFG. It has been widely accepted since Chomsky (1957) that context-free grammar is not by itself an adequate formalism for describing natural language; even if the majority of syntactic constructions can

---

[1] In fact, in the original version of LFG architecture introduced in Kaplan (1989), c-structure is itself a projection from the string. In recent LFG work, this idea has been developed in more detail by distinguishing between the *s-string* (the string of syntactic units) and the *p-string* (the string of phonological units), see Dalrymple & Mycock (2011) and Bögel 2023 [this volume] for more information.

indeed be described by context-free grammar (Pullum & Gazdar 1982), the descriptions required would be cumbersome, artificial and theoretically unenlightening as a model of human linguistic competence. Therefore, most grammars which use constituent structure as the main level of syntactic representation introduce additional mechanisms such as transformations in order to increase their expressive power. But such additions are not required in LFG because all phenomena that require more powerful mechanisms are dealt with at f-structure and other levels. C-structure remains limited to modeling basic word order facts, hierarchical embedding, and recursion, the phenomena for which phrase structure always was and remains the most adequate formal representation.

The advantage of this simplicity is that constituent structure in LFG has a clear empirical basis and can be determined for individual languages based on classic tests not obscured by additional considerations. For example, since there is no syntactic displacement, constituents in LFG are continuous by definition – apparently "discontinuous" material may eventually converge in one f-structure, but will still be split into separate constituents at c-structure.

By contrast, some constituency diagnostics which are valid in other frameworks are not valid in LFG. For example, since c-command is a phrase structure-based relation in mainstream transformational grammar, the existence of binding asymmetries between subjects and objects implies a configurational structure where the subject c-commands the object or vice versa. Thus Speas (1990: 137) argues that, within standard GB assumptions, flat structure predicts the existence of subject reflexives bound by their objects; since few such languages, if any, are actually found, existence of a hierarchical structure with a VP and a subject c-commanding the direct object is part of Universal Grammar.

In LFG, such a conclusion is a *non sequitur* because constraints on anaphoric relations, and other related phenomena, are formulated chiefly in terms of f-structure; sometimes in terms of information structure, semantics, or even linear precedence; but almost never in terms of c-structure configuration. Reference to c-command is possible in principle,[2] but it is largely useless as a source of valid generalizations due to the core assumptions of LFG: the cross-linguistic variability of c-structure, the universality[3] of grammatical functions at f-structure, and variation in the syntax-semantics interface.

---

[2] As, for example, in the definition of extended heads in Bresnan et al. (2016: 136). Note that this is a concept that is used to describe regularities in the c- to f-structure mapping, not a constraint on f-structure relations themselves.

[3] "Universality" here refers to universal availability, as in a grammatical toolbox (cf. Jackendoff 2002), not in the sense of mapping the same semantic roles to the same grammatical functions in all languages, or even in a single language. See Belyaev 2023b [this volume] for more detail.

Constituent structure representations in LFG are therefore rather "shallow" in that their makeup is determined by a limited set of empirical diagnostics mostly based on word order possibilities. These facts vary widely across languages, and so do c-structure rules and the resulting structures. While f-structures have a degree of universality (in the sense of sharing a single inventory of grammatical functions and broad similarity in the way analogous phenomena such as anaphora, coordination, agreement etc. are represented), c-structures are language-specific.

Still, even in c-structure there are certain basic theoretical constraints which are deemed to hold universally across languages. In mainstream LFG, these are ENDOCENTRICITY and LEXICAL INTEGRITY. The former is usually captured by a version of X-Bar Theory, which is generally the same as in GB (see Chomsky 1970, Jackendoff 1977) but less restrictive: no universal clause or NP structure, no universal mapping from X′-theoretic positions (specifier, complement) to grammatical functions are assumed; non-binary branching is allowed; various exceptions from endocentricity, most prominently the exocentric S node used in non-configurational languages are permitted. For more information on the version of X-Bar Theory used in LFG, see Belyaev 2023a [this volume] and Andrews 2023 [this volume].

Lexical integrity is another principle that has been assumed in LFG since its inception. At its core, this principle states that words are constructed from different elements and according to different rules than syntactic phrases, and that the internal structure of words is invisible to rules of syntax (Bresnan & Mchombo 1995: 181). In formal terms, this is usually interpreted such that the leaves of c-structure trees must be morphologically complete words (Bresnan et al. 2016: 92). For more detail on lexical integrity as it is used in LFG, the challenges it faces and proposed modifications, see Belyaev 2023a [this volume].

4 F-structure

4.1 Defining equations

As mentioned above, at the most basic level f-structures in LFG are a type of attribute-value structure.[4] However, unlike most other frameworks which deal

---

[4] Carpenter (1992) is the standard reference on the mathematical properties of such feature structures. However, the structures described by Carpenter are *typed*, which is a crucial difference from LFG f-structures, which are untyped and defined using a functional notation.

with this data type, the LFG formalism does not refer to f-structures as objects that can be manipulated and to which various operations can be applied. In contrast, an f-structure is thought of as a *function* that maps attributes (attribute names) to their values.[5]

From this perspective, describing an f-structure consists in defining the value y for each argument x in the function's domain (i.e. the set of attribute names). In LFG, attribute-value pairs are usually described using the notation of function application probably inspired by the Lisp programming language, i.e. the more conventional $f(x) = y$ is expressed as $(f\ x) = y$. Thus, for the f-structure f in (1), the value of the attribute $\textsc{tense}$ is defined by the equation $(f\ \textsc{tense}) = \textsc{prs}$. By way of example, the full (minimal) set of equations that describes the f-structure of (1) is provided in (3).

(3) $(f\ \textsc{pred}) = \text{‘}\textsc{see}\langle(f\ \textsc{subj})\ (f\ \textsc{obj})\rangle\text{’}$
$(f\ \textsc{tense}) = \textsc{prs}$
$(f\ \textsc{aspect}) = \textsc{perf}$
$(f\ \textsc{subj}) = g$
$(f\ \textsc{obj}) = h$

$(g\ \textsc{pred}) = \text{‘}\textsc{John}\text{’}$
$(g\ \textsc{pers}) = 3$
$(g\ \textsc{num}) = \textsc{sg}$

$(g\ \textsc{pred}) = \text{‘}\textsc{David}\text{’}$
$(g\ \textsc{pers}) = 3$
$(g\ \textsc{num}) = \textsc{sg}$

Sets of equations as in (3) are called f-descriptions. A valid f-structure of a sentence is an f-structure that *minimally* satisfies this sentence's f-description. Thus, the f-structure displayed in (1) is the minimal f-structure that satisfies (3); were one to add the attribute-value pair [mood indicative], (3) would still be satisfied, but the structure would no longer be minimal.

Since an f-structure function application produces attribute values, and, as seen in (1) and (3), these values can also be f-structures, it is possible to use nested function applications. Thus, since $(f\ \textsc{subj}) = g$, $((f\ \textsc{subj})\ \textsc{pers})$ is equivalent to $(g\ \textsc{pers})$ and has the value 3. By convention, function application is

---

[5] The term *f(unctional)-structure* can thus be understood in two ways: as a structure representing the "function" of words and phrases (as opposed to c-structure which represents "form") and, more formally, as a *function* proper. This set-theoretic understanding of f-structures is standard in the LFG literature, but f-structures can alternatively be modeled in terms of graph theory; an example of this approach is found in Kuhn (2003).

left associative, thus the parentheses can be omitted and the equation written as (f SUBJ PERS) = 3. Early on, LFG has also adopted an extension of function application called functional uncertainty (Kaplan & Zaenen 1989b), which allows replacing the right-hand side of the function application (the "path" of attribute names) by a regular expression; thus, (f COMP* SUBJ) denotes the value of the attribute SUBJ of f or an f-structure embedded in any number of COMP attributes within f. For a formal definition of functional uncertainty and a more detailed discussion, see Belyaev 2023a [this volume].

While it is possible to describe individual f-structures using sets of equations as in (3), it is obvious that such a system cannot serve as a basis for any regular description of grammar, as it lacks a way of specifying the mapping from words or phrases to the f-structures that represent them. In LFG, this task is mediated through c-structure; f-descriptions for individual sentences are constructed on the basis of ANNOTATED C-STRUCTURE RULES, which are described in the next section.

4.2 Annotated c-structure rules

The formal metalanguage introduced in Section 4.1 provides a way to describe abstract syntactic representations, but, used by itself, it does not allow describing actual grammars and making generalizations about linguistic notions. This is because f-structures should also be mapped to the building blocks of sentence structure – words and c-structure nodes – in a regular way. In other words, the correspondence function ϕ, introduced in Section 2, has to be defined. In LFG, this is done using ANNOTATED PHRASE STRUCTURE RULES. These rules contain additional statements, formulated in the functional description metalanguage, that specify the mapping from each node to the f-structure. In order to refer to the f-structure projections, the equations use the following additional notations:

(4) the current c-structure node: $*$
the immediately dominating c-structure node: $\hat{*}$

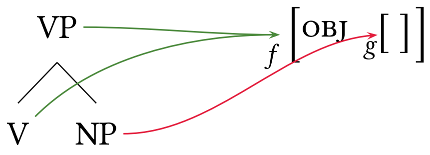
Using this notation, we can formulate phrase structure rules like the following:

$$(5)\quad \mathrm{VP} \longrightarrow \underset{\phi(\hat{*}) = \phi(*)}{\mathrm{V}} \quad \underset{(\phi(\hat{*})\ \textsc{obj}) = \phi(*)}{\mathrm{NP}}$$

In (5), the annotation for V stands for "this node (V) maps to the same f-structure as the dominating node (VP)", while the annotation for NP stands for "this node (NP) maps to the OBJ attribute of the f-structure of the dominating node (VP)".

The mapping that this rule defines is illustrated in (6). The nodes VP and V map to the same f-structure, labeled as f, while NP maps to the f-structure labeled as g – the direct object of the clause.

(6)



For convenience, $\phi(*)$ and $\phi(\hat{*})$ are usually replaced by the abbreviations ↓ (pronounced “down”) and ↑ (pronounced “up”), respectively. These metavariables are assumed to be the only way to refer to material up or down the tree in phrase structure rules; direct reference to “low-level” variables such as $*$ is generally not used in LFG analyses. The conventional representation of the rule in (5) is given in (7).

(7)	VP	⟶	V	NP
			↑=↓	(↑ obj)=↓

In the standard model of c-structure, lexical entries are nothing more than rules defining a preterminal node dominating a terminal node. However, they use a slightly different notation, where the word form is followed by its category and annotation, illustrated in (8).

(8)	*John*	N	(↑ pred)=‘John’ (↑ pers)=3 (↑ num)=sg

Since there is no further material down the tree, lexical entries typically only use the metavariable ↑ to provide information associated with the preterminal node. In some cases, ↓ is also used to draw subtle distinctions between information contributed by the word itself and the information contributed by the preterminal. For example, Zaenen & Kaplan (1995: 230) ingeniously map the verbal form to the pred value, while other grammatical features are assumed to be contributed by the V node. In practice, this possibility is seldom used.

The projection function ϕ maps c-structure nodes to f-structures, but one may also define an inverse correspondence ϕ^{-1} to proceed in the opposite direction. This function provides the set of c-structure nodes that map to the f-structure given as its argument. Note that the inverse projection is not a function, as the f- to c-structure relation is one-to-many. Inverse projections are used in f-descriptions in order to use c-structure features in f-structure constraints. For example, to check that the subject's f-structure maps to an NP, one may use the equation $\mathrm{NP} \in \mathrm{CAT}((\uparrow \textsc{subj}))$. This is seldom needed, because, by design, most constraints on f-structure attributes can be described solely in terms of f-structure. However, sometimes the inverse projection is indispensable, e.g. when formulating the notion of f-precedence (see Kaplan & Zaenen 1989a; also see Belyaev 2023a [this volume]) describing linear order conditions on anaphora (Rákosi 2023 [this volume]).

4.3 Well-formedness conditions

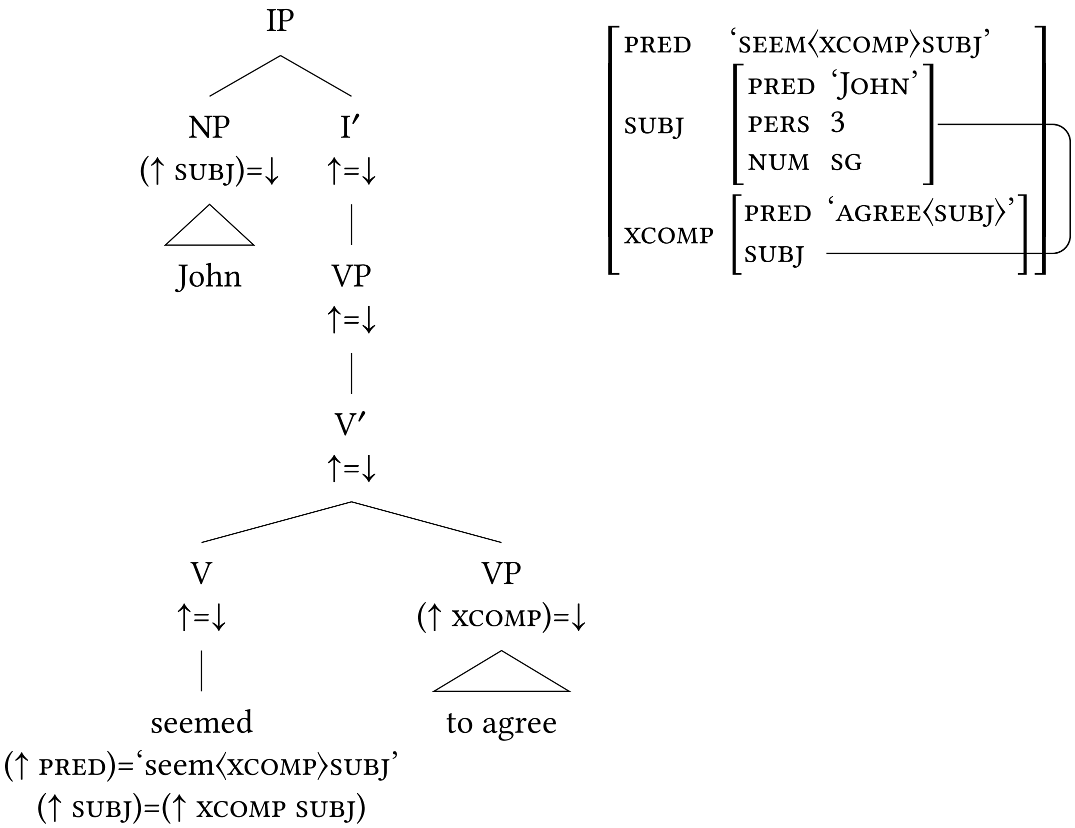
There are three conditions that any f-structure must satisfy in order to be treated as valid: Uniqueness (also known as Consistency), Completeness, and Coherence. Any f-structure that violates these conditions cannot be part of a valid analysis of any sentence. Uniqueness requires that each attribute have exactly one value – this actually follows from the notion of f-structure as a function, since a function, by definition, is a many-to-one or one-to-one mapping. Completeness requires that each argument listed in the PRED value of an f-structure (which is the locus of valency information) is present in the f-structure; Coherence, complementarily, requires that no extra arguments *not* listed in the PRED value are introduced. For more detail on how these conditions actually operate, see Belyaev 2023a [this volume].

4.4 Structure sharing and "movement"

Unlike transformation-based grammatical approaches, LFG has no special formal mechanism such as movement or Internal Merge to handle dependencies between different structural positions. The closest equivalent to such a mechanism is STRUCTURE SHARING, which consists in one f-structure being the value of two or more distinct attributes. The possibility of structure sharing follows from the general makeup of the formalism: If f-structures are functions and features are their arguments, it is expected that these structures are reentrant: a function can return the same value for different arguments. Since reentrancy is obviously required for the simplest cases such as reentrant atomic values, structure sharing is only a natural consequence of this property.

A classic example of the use of structure sharing to describe a movement-like process is the LFG analysis of raising. Raising verbs such as English *seem* are analyzed as having a non-thematic subject that is shared with the subject of the complement clause:

(9)



This correctly predicts that the raised subject appears as the argument of the matrix clause while being subcategorized for and assigned a semantic role in the complement clause. For more detail on control and raising, see Vincent 2023 [this volume].

It is important to note that while structure sharing is, in formal terms, the closest counterpart to movement in LFG, this does not mean that all phenomena that are treated via movement in transformational frameworks should involve structure sharing in LFG. This is because movement is normally the *only* mechanism for “non-canonical” or “displaced” positioning of material in transformational frameworks, while LFG draws a crucial distinction between c- and f-structure. Two sentences may differ in the c-structure while having the same f-structure – this is called SCRAMBLING and this is the most widespread mechanism of syntactic “displacement” in non-configurational languages or languages that allow mapping to the same grammatical function in different positions. For example, Arka (2003) proposes the following rule for S in Balinese:

(10) $$\text{S} \longrightarrow \left\{ \begin{array}{c|c} \text{VP} & \text{NP} \\ \uparrow=\downarrow & (\uparrow \textsc{gf})=\downarrow \end{array} \right\}^{*}$$

This allows any number of NPs to alternate with any number of VPs in any order; each NP may be freely assigned to any grammatical function. Therefore, sentences with the same predicate and the same set of NP arguments will have identical f-structures, with the only difference being found at c-structure. But no c-structure configuration will be considered as "basic" in any formal sense of the term.[6]

5 Additional levels of projection

C-structure and f-structure were originally thought of as the only levels of grammar in LFG: c-structure as a kind of "form" representation, and f-structure as a "functional" representation, in some sense reflecting semantics and having a degree of universality compared to c-structure. It quickly became clear, however, that these two levels are not enough to represent the full complexity of grammatical phenomena. First, semantics should be separate from f-structure to handle phenomena that are not represented in syntax, such as quantifier scope. Second, f-structure in its standard form is a collection of information of different types: purely morphological and morphosyntactic atomic features; grammatical functions; valency information (PRED features); and semantic information (if features such as ANIM are used to describe effects of animacy on grammatical marking). Third, f-structure simply cannot handle some phenomena, like prosody, which require a different kind of structure whose constituents are not equivalent to either c-structure constituents or f-structures.

A possible way to overcome these difficulties would be to extend the role of the existing c- and f-structure, which would mirror similar developments in transformational grammar, with its central role of constituent structure and the proliferation of functional projections (see Sells 2023 [this volume]). However, the architecture of LFG permits a more elegant solution. While the original system does only consist of c- and f-structure, there is nothing intrinsic about this binarity: the two are connected by a projection function ϕ that maps nodes to f-structure. It is possible to define other functions that would connect c- or f-structures to various other structures; thus, where $\phi(*)$ (abbreviated $\downarrow$) stands for the f-structure of the annotated node, $\mu(*)$ would be the morphosyntactic structure (m-structure) of

---

[6] Of course, even in non-configurational languages, certain word orders are often viewed as less marked compared to others. This is probably due to differences in information structure, which in modern LFG literature is usually treated as a separate level that may interact with other levels such as c-structure, f-structure, and prosody (Zaenen 2023 [this volume]; see also Dalrymple & Nikolaeva 2011). Crucially, an information structure difference between sentences does not automatically entail any difference at either c- or f-structure.

this c-structure node, and $\sigma(\phi(*))$ (abbreviated $\uparrow_\sigma$) would be the semantic structure (s-structure) that the f-structure that corresponds to this node maps to (if s-structure is viewed as projected from f-structure). The simultaneous description of two or more grammatical structures by the same rule or lexical entry is called CODESCRIPTION, which is the main principle governing the interaction of levels in LFG.

This modularity has been successfully used to model a number of grammatical levels, such that LFG, as it is currently practiced, is no longer centered around the interaction between c- and f-structure, although these still play a major role as the main syntactic representations. It is also crucial that LFG, by design, still retains a degree of "syntactocentricity" in that all additional projections are defined with reference to c-structure nodes. This is different from the notion of a truly parallel architecture advocated e.g. in Culicover & Jackendoff (2005), where each level of representation (specifically, in their model, syntax and semantics) is conceived of as a separate "combinatorially autonomous" system that is linked to other levels via a system of correspondence constraints. In LFG, only c-structure is combinatorial in this sense,[7] with possible trees defined directly through phrase structure rules; the content of other projections is not autonomously generated, but defined through phrase structure annotations that connect the elements of these projections to c-structure nodes. Thus, while c-structure is not as central as constituent structure in other frameworks, it acts as a "hub" that connects all the different levels of sentence structure together.[8]

There is currently no agreed-upon set of representational levels. Some, like s-structure or prosodic structure, are almost universally adopted and consistently interpreted in terms of projection. Others, like information structure (i-structure), are assumed by most authors, but specific interpretations vary: for example, i-structure is projected from c-structure in King (1997), Butt & King (1997), but

---

[7] C-structure rules are somewhat less central in approaches like Halvorsen (1983) and Andrews (2008), which use description by analysis, rather than the standard codescription approach, to describe the syntax-semantics interface: In these approaches, meaning is constructed on the basis of f-structure, without direct reference to c-structure. Even here, however, semantics is not a separate combinatorial system but is constructed on the basis of another structure which, in turn, is projected from c-structure; this still seems rather different from Culicover and Jackendoff's vision of parallel architecture.

[8] This flavour of syntactocentricity is far less radical than in mainstream generative grammar and may in fact be unavoidable in a (broadly) lexicalist framework, inasmuch as words are viewed as the "building blocks" of sentences. In fact, I am not aware of a fully developed and formalized implementation of any truly parallel architecture. There is no way around the fact that phonetic form is the only part of language that is directly available for perception; thus the part of grammar that is tasked with combining such "surface" elements into complete utterances – i.e. syntax in the narrow sense – will always have a special role.

from s-structure in the more recent proposal of Dalrymple & Nikolaeva (2011). Finally, some levels are specific to particular approaches and are not universally adopted, e.g. morphosyntactic structure (m-structure), viewed as projected from c-structure (Butt et al. 2004, Butt, Fortmann, et al. 1996) or f-structure (Sadler & Nordlinger 2004); or argument structure (a-structure), which is used in some approaches to argument mapping (Butt et al. 1997) but is viewed as redundant in some more recent proposals such as (Asudeh & Giorgolo 2012, Asudeh et al. 2014, Findlay 2016). One version of how the correspondence architecture might look is provided in (11).[9]

(11)

$$\begin{tikzcd}
& \text{p-structure} & \text{l-structure} & & \text{m-structure} & \text{i-structure} \\
\textbf{Form} \arrow[ur, "\beta"] \arrow[r, "\pi"] & \text{c-structure} \arrow[ur, "\lambda"] \arrow[rr, "\phi"] \arrow[dr, bend right, "\alpha"'] & & \text{f-structure} \arrow[ur, "\mu"] \arrow[r, "\sigma"] & \text{s-structure} \arrow[ur, "\iota"] \arrow[r, "\psi"] & \textbf{Model} \\
& & \text{a-structure} \arrow[ur, bend right, "\lambda'"'] & & &
\end{tikzcd}$$

To date, additional levels and projections that have been discussed and described in the LFG literature include the following (references to some of the proposals are given in parentheses; most have separate chapters in the handbook, which describe proposed representations in detail):

- argument structure (a-structure) (Butt et al. 1997), see Findlay et al. 2023 [this volume];
- semantic structure (s-structure) (Dalrymple 1999), see Asudeh 2023 [this volume];
- information structure (i-structure) (King 1997, Butt & King 1997, Dalrymple & Nikolaeva 2011), see Zaenen 2023 [this volume];
- prosodic structure (p-structure) (Dalrymple & Mycock 2011, Bögel 2012), see Bögel 2023 [this volume];
- morphological / morphosyntactic structure (m-structure), see (Butt et al. 2004, Sadler & Nordlinger 2004), Asudeh & Siddiqi 2023 [this volume];
- grammatical marking structure (g-structure) (Falk 2006);

---

[9] The argument structure projection functions α and λ' are from the proposal in Butt et al. (1997). In this approach, which is not universally accepted in the literature, the projection function ϕ is the composition $\alpha \circ \lambda'$. I use the label λ' to distinguish this from the projection function λ that maps c-structure to l-structure, specifying category labels (Lowe & Lovestrand 2020).

- l-structure, a level that represents complex categories of c-structure nodes in the approach of Lowe & Lovestrand (2020): see Belyaev 2023a [this volume].

6 Conclusion

In this chapter, I have described the main architectural notions of LFG – the c- and f-structures. LFG can be viewed as incorporating the best features of constituent-structure-based (at c-structure) and dependency-based (at f-structure) frameworks, while avoiding their main drawbacks. Frameworks that use phrase structure as the only syntactic representation require additional mechanisms such as transformations, multiple dominance or separate linearization to properly capture word order variation and feature constraints; LFG manages to keep c-structure relatively simple due to the fact that all feature interactions are captured at f-structure, without referring to constituent structure positions. At the same time, the fact that f-structure does not directly refer to individual words or phrase structure nodes allows adequately capturing word order variation while keeping predicate-argument representations fairly uniform across languages. I have also described how the core architecture may be extended to other projections beyond f-structure. Each of these modules captures a separate part of grammar (prosody, semantic structure, information structure, etc.) and has its own internal makeup. The modules are linked together using annotations of c-structure rules in the same way as f-structure is projected from c-structure. Hence, grammars in LFG are factorized into several distinct components, each of which is responsible for its own range of phenomena and largely operates according to its own principles, with c-structure serving as a "hub" tying all the components together.

Acknowledgements

I am grateful to Mary Dalrymple for her insightful comments on this chapter and painstaking editorial work. I would also like to thank Tina Bögel for some comments on an earlier draft of the chapter. Finally, I am grateful to two anonymous reviewers for their attentive reading of the chapter and useful comments. This research has been supported by the Interdisciplinary Scientific and Educational School of Moscow University "Preservation of the World Cultural and Historical Heritage".

Chapter 2

Core concepts of LFG

Oleg Belyaev

Lomonosov Moscow State University, Institute of Linguistics of the Russian Academy of Sciences, and Pushkin State Russian Language Institute

This chapter provides an in-depth coverage of the main features of the LFG framework, focusing mainly on its syntactic representations: c- and f-structure. The makeup of each level is discussed in detail. For c-structure, I describe the version of X′ theory used in LFG and the status of lexical integrity as a core principle of the framework. I discuss the notion of f-structure as a function/set of feature-value pairs that is used in the majority of LFG work; attribute value types and well-formedness conditions on f-structure (Uniqueness, Completeness and Coherence) are covered as well. I also describe the metalanguage for defining f-structures and the mapping from c- to f-structures, and note some linguistically relevant consequences of how this mapping is organized. Three proposed extensions of the standard architecture are also discussed: templates (constructions), minimal c-structure, and lexical sharing.

1 Introduction

This chapter provides a detailed survey of the main syntactic levels of LFG, constituent structure (c-structure) and functional structure (f-structure). It complements the more general introduction in Belyaev 2023b [this volume]. In Section 2, I describe the c-structure model used in standard LFG, its understanding of constituency, and the role of X′ theory. In Section 3, the notion of f-structure is discussed, including the metalanguage used for describing f-structures and constraints on possible f-structure. In Section 4, I discuss the mapping from c- to f-structure. Finally, in Section 5 I describe recently proposed modifications to the basic architecture of LFG that have not yet been universally accepted, but which may shape the development of this framework in the future.

Oleg Belyaev. 2023. Core concepts of LFG. in Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 23–96. Berlin: Language Science Press.
DOI: 10.5281/zenodo.10185936

2 C-structure

The nature of constituent structure (c-structure) in LFG and its main properties are summarized in Belyaev 2023b [this volume]. Briefly, c-structure is a phrase structure tree; constraints on possible trees are usually described via context-free rules as in (1). Other metalanguages are sometimes used as well.

(1) S ⟶ NP VP

An important feature of c-structure in LFG is that empty nodes are not usually employed. This is not a limitation imposed by the framework itself, but a theoretical decision. It is formally possible to define grammars with null terminal nodes in LFG: this is implemented in XLE (Crouch et al. 2011) and was used to capture long-distance dependencies in early versions of LFG (Kaplan & Bresnan 1982). However, since Kaplan & Zaenen (1989b) it has become a universal practice to capture long-distance dependencies through functional uncertainty at f-structure, and the use of empty categories at c-structure has become unnecessary (see Kaplan 2023 [this volume]). For more information on the formal features of c-structure in LFG, see Andrews 2023 [this volume].

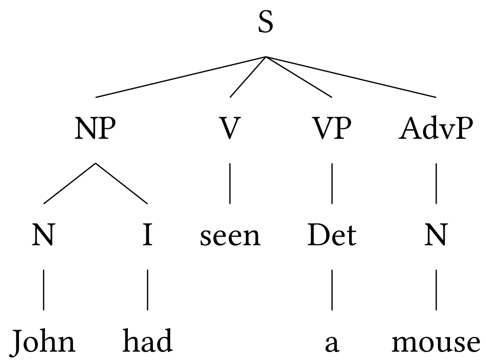
Without additional theoretical restrictions, context-free grammars allow far more possible phrase structure trees than actually attested in natural languages. In this section, I will focus on two main constraints on c-structure in LFG: X-Bar Theory and lexical integrity.

2.1 X′ Theory

Every theory of constituency based on phrase structure grammar faces what Everett (2015), in his review of Adger (2013), called “Lyons’ Problem”. Lyons (1968) famously asked what guarantees that NPs are headed by Ns, VPs are headed by Vs, etc., such that rules like VP ⟶ … V … or NP ⟶ … N … are allowed, but rules like NP ⟶ … V … are not.

Indeed, from the point of view of context-free rules, VP and V are atomic symbols that are not related to each other; labeling one of the daughters of NP as N is merely a convention, and nothing in the formalism excludes a hypothetical language with constituent structures like in (2) – “monsters” in Bresnan et al.’s (2016) terms.

(2)



Intuitively, there are many things that are wrong with this structure: an I head cannot be the daughter of NP; the VP cannot be headed by, or even immediately dominate, a Det; an AdvP cannot be headed by a noun.[1] The principle that prohibits this is called endocentricity; roughly stated, it means that the external distribution of a phrase (e.g. NP) is determined by the category of one and only one of its daughters, the head. Disallowing non-endocentric structures requires a theory of constituent structure labels that limits the range of available configurations. To this end, X-bar (X′) theory has been proposed in mainstream generative grammar (Chomsky 1970, Jackendoff 1977).

X′ theory enforces endocentricity by introducing the notion of projection and "bar level" and requiring that each non-maximal projection (X^0 and X′; X″, or XP, is usually assumed to be the maximum level of projection) be dominated by a node belonging to the same category, with the bar level either incremented by one or unchanged. The sisters of c-structure heads (complements, specifiers and adjuncts) have to be maximal projections or non-projecting words (on which see below).

One variant of X′ theory has been adopted in LFG from the very early days and continues to be used in most LFG work. An in-depth exposition of X′ theory as it is used in LFG, with certain additional theoretical innovations, can be found in Bresnan et al. (2016). The most important features of X′ theory as it is practiced in LFG are as follows. First, as in the original formulation, X′ theoretical constraints are viewed as constraints on phrase structure *rules*; the later GB view of a kind of universal "X′ schema" has not gained acceptance in LFG, primarily because

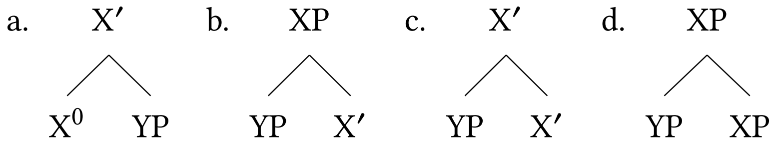
---

[1] Curiously, each of the features of this illustration *ad absurdum* has a counterpart in real languages: noun phrases do sometimes mark the tense of their clauses, verbs do mark the definiteness of their arguments, and bare nouns (although probably not nouns like 'mouse') are used adverbially. But there is broad consensus in theoretical lingustics that such phenomena are more exceptions than rules and should *not* be modeled by allowing the theory of phrase structure to license such configurations.

the architecture of the framework is fundamentally based on language-specific rules and does not allow such schemas.

Second, X′ theory in LFG allows for the following positions: complement (3a), specifier (3b), X′ adjunct (3c) and XP adjunct (3d).[2]

(3)



As in all versions of X′ theory, only maximal projections may appear in these positions.

There is some disagreement concerning the possibility of X′ adjunction: While most authors accept both kinds of adjunction, Toivonen (2003) only allows XP-adjunction (and head adjunction, see below) because in her theory only constituents of the same bar level may be adjoined.

The LFG literature also generally allows for multiple complements and specifiers dominated by the same mother node; thus, a sequence of several phrases instead of YP is possible in (3a–c); multiple adjuncts in one position are also usually allowed, even though this creates redundancy since this structure could always be replaced by multiple binary adjunction.

Third, LFG uses the following functional projections: DP for NPs, IP and CP for VPs. Some work also uses additional phrases, such as KP/CaseP for clitic case markers (Broadwell 2008). The number of functional positions is limited compared to mainstream theories, and this is not merely a stipulation: LFG requires all constituency in a given language to be empirically motivated in a way that is more narrow than in frameworks that represent the bulk of syntactic information in phrase structure (such as transformational frameworks). Specifically, heads may only be stipulated if there is actual lexical material that can occupy them; therefore, even the existence of projections such as CP or IP cannot be automatically assumed for all languages. More abstract projections such as TopicP or ForceP are not usually introduced because there are few suitable candidates for the status of heads of these phrases, and little distributional evidence to argue that their specifiers are distinct structural positions.

It turns out, in fact, that the set of functional projections listed above is fully adequate for the overwhelming majority of languages. Moreover, some categories, like DP, are not viewed as universal; authors, such as Sells (1994) for Japanese and

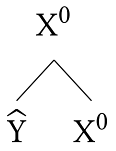
---

[2] The order of constituents is only an illustration; X′ theory itself does not impose any specific order.

Korean, even limit the number of projections to one (X') instead of the standard two.

Fourth, LFG admits non-projecting words, i.e. lexical items that do not project X' and XP levels and hence cannot have complements or specifiers; their maximum projection level is 0. The category of non-projecting words is marked as X^0. Toivonen (2003) develops a detailed theory of non-projecting words. Being maximal projections, they can appear at any non-head X' theoretic positions (i.e. specifier, complement, or adjunct), but the only dependents that they may have are X^0 adjuncts, which must themselves be non-projecting. Thus, an additional type of adjunction – head adjunction – is introduced into X' theory, illustrated in (4), where X^0 can also be $\widehat{X}$, but, crucially, $\widehat{Y}$ cannot be Y^0, as that would violate the principle that only maximal projections can appear in non-head positions.

(4)



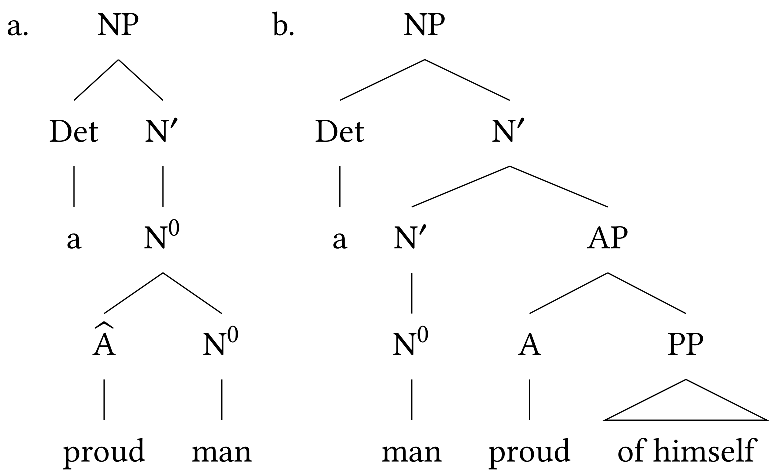
The theory of non-projecting words presented in Toivonen (2003) further requires that only same-level projections are adjoined; this effectively prohibits adjoining non-projecting words at X' or XP level, as well as any adjunction at X' level in languages where XP is the maximal projection (because only maximal projections can be adjuncts, as stated above). However, these more restrictive principles are not accepted by all authors who use non-projecting words in their analyses: for example, Spencer (2005) analyzes case markers in Hindi as $\hat{P}$ nodes adjoined to NP. X' adjunction also remains quite common in LFG analyses.

Sadler & Arnold (1994) use non-projecting words to account for the behaviour of English prenominal adjectives, which cannot have phrasal complements if they are prenominal; consider the contrast between (5a) and (5b), while (5c) is ungrammatical.

(5) a. a **proud** man
b. a man [**proud** of himself]
c. * a [**proud** of himself] man

Sadler and Arnold argue that this contrast is due to the fact that prenominal adjectives in English are non-projecting words with the category $\widehat{A}$ that are adjoined to N^0, while postnominal adjectives form AP and can therefore have complements. Thus the structure of (5a) is (6a), while the structure of (5b) is (6b).

(6)

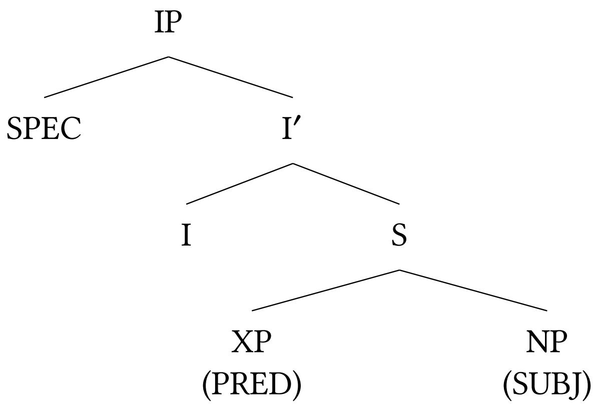


Finally, X′ theoretic principles are not viewed as fully universal in LFG. The most prominent exception is the exocentric category S.[3] This category does not have a "head" in the normal sense: it can be "headed" by a verb, but also by an adjective or another nonverbal predicate; this is why the term S is used instead of, for example, VP. The category S is most extensively used in nonconfigurational languages (see Andrews 2023 [this volume]), but this is not its exclusive role. Many languages have a fairly configurational structure overall but allow predicates of various categories to be embedded under a general "predicative marker", which sits in the I or C node. For example, Kroeger (1993: 119) proposes the phrase structure in (7) for Tagalog. The SPEC position can be optionally occupied by fronted constituents of several types (such as topics); the I node is occupied by an auxiliary or the finite verb; the predicate XP can be a VP in verbal sentences, but can also be AP or NP if the predicate is nonverbal. Hence, the structure is indeed non-endocentric, and the use of the label S is justified.

---

[3] Bresnan et al. (2016: 112ff.) present the category S and non-projecting words as effectively the *only* exceptions from standard principles of X′ theory. This, however, is a theoretical idealization insofar as it applies to actual LFG analyses, which routinely make us of *ad hoc* categories such as CL, CCL (for "clitic", "clitic cluster") in Bögel et al. (2010) and Lowe (2011). Such minor innovations do not seem to influence the overall theory in any meaningful way, since they deal with exceptional cases such as second-position clitics or language-specific, idiosyncratic linear order distributions. It is also conceivable that many of them could be converted to analyses that conform to X′ theoretic principles; for example, CCL could be treated as a phrase consisting of multiple $\widehat{\text{D}}$ head adjunction (if the clitics are pronominal).

(7)



Since c-structure is not the only level of representation in LFG and models only a subset of syntactic phenomena (word order, embedding), X′ theory does not do much by itself to limit the range of possible languages. Unlike frameworks such as GB, for which the theory was originally devised, X′ positions are not inherently or uniquely associated with specific syntactic or semantic functions – as a result, X′ theory, understood purely in terms of c-structure, is little else than a system of labeling nodes which allows us to generalize endocentricity at constituent structure level. In order to make it more meaningful, it should be augmented by a set of principles that determine the mapping of X′ positions to f-structure – such a system has been developed in LFG, and will be described in Section 4.3.

2.2 Lexical Integrity

As its name implies, Lexical Functional Grammar was originally conceived as a lexicalist framework, a term that has several meanings. In the most general sense, lexicalism implies that the features of individual syntactic elements (morphemes and wordforms) as well as their subcategorization frames are determined in the lexicon, and cannot be modified in the syntax (such as by promoting the direct object in a passive construction). Lexicalism in this sense requires no additional stipulation and is enforced by the LFG architecture itself: there are no transformations or other means to change the c-structure or f-structure features; syntax can only mutiply define lexical features, but cannot override them.[4]

---

[4] Kaplan & Wedekind (1993) introduced the restriction operator: $f\backslash_{A}$ denotes the f-structure f with the attribute A and its value removed. As suggested by an anonymous reviewer, this violates lexical integrity in the weak sense, because here the syntax effectively accesses an f-structure constructed otherwise (possibly by means of morphology) to retrieve some of its information. This operator is not widely employed but was used in several LFG analyses, notably in Asudeh (2012) and Falk (2010).

LFG is also lexicalist in another sense: it subscribes to the idea that the building blocks of syntax are not roots or affixes, but individual words that are constructed from different blocks and according to different rules than syntactic constituents.[5] Thus, the distinction between morphology and syntax in LFG is viewed as fundamental, which is against the views of many recent approaches, both formal (Bruening 2018) and typological (Haspelmath 2011).

This understanding of lexicalism is more formally termed LEXICAL INTEGRITY and has been given two formulations in LFG (8)–(9).

(8) Words are built out of different structural elements and by different principles of composition than syntactic phrases. (Bresnan & Mchombo 1995: 181)

(9) Morphologically complete words are leaves of the c[onstituent]-structure tree and each leaf corresponds to one and only one c[onstituent]-structure node. (Bresnan et al. 2016: 92)

The definition in (8) is rather broad and can be compatible with several different understandings of the morphology–syntax interface, as long as the border between the two levels in maintained in some way. The second definition (9) is more specific and is only compatible with one view of the interaction between morphology and syntax. For example, lexical sharing, which allows one word to correspond to two X^0 nodes (discussed in Section 5.2.2), is compatible with (8) but not with (9).

Interestingly, despite the rather strict definition in (9), much work in LFG uses the concept of "sublexical nodes", like in the rule for Greenlandic nouns in (10), from Bresnan et al. (2016: 368). This is formally incompatible with (9) because the preterminal nodes correspond to morphemes, not morphologically complete nodes.

(10) $\text{N} \longrightarrow \text{N}_{\text{stem}} \quad \text{N}_{\text{aff}}$

In practice, such analyses are rather harmless because in their predictions they are equivalent to analyses that strictly adhere to (9): since all morphology is sublexical, the position of individual affixes cannot have any syntactic relevance, as opposed to approaches like Distributed Morphology (Halle & Marantz 1993), where morphological features often occupy higher-level functional projections

---

[5] These two understandings of lexicalism are sometimes conflated, but they are actually independent: A framework may be lexicalist in the former sense, but consider the distinction between words and syntactic phrases to be ephemeral.

that can scope over syntactic phrases. However, the use of sublexical representations does raise the issue of how the individual contribution of morphemes to f-structure should be represented – standard LFG does not provide such a way, because words are viewed as complete, unsegmented bundles of morphosyntactic information. These issues are discussed in detail in Asudeh & Siddiqi 2023 [this volume].

3 F-structure

3.1 The notion of f-structure

As described in Belyaev 2023b [this volume], c-structure in LFG is complemented by an additional level of representation called f-structure. F-structure is an attribute-value structure that includes information on valency, grammatical functions, and the features of clauses and their syntactic arguments. An f-structure for the English sentence *John has seen David* is given in (11).

(11)

$$
{}_{f}\left[\begin{array}{ll}
\textsc{pred} & \text{‘}\textsc{see}\langle(f\ \textsc{subj})(f\ \textsc{obj})\rangle\text{’}\\
\textsc{tense} & \textsc{prs}\\
\textsc{aspect} & \textsc{perf}\\
\textsc{subj} & {}_{g}\left[\begin{array}{ll}\textsc{pred} & \text{‘John’}\\ \textsc{pers} & 3\\ \textsc{num} & \textsc{sg}\end{array}\right]\\
\textsc{obj} & \left[\begin{array}{ll}\textsc{pred} & \text{‘David’}\\ \textsc{pers} & 3\\ \textsc{num} & \textsc{sg}\end{array}\right]
\end{array}\right]
$$

F-structure is usually thought of as a set of attribute-value pairs, or a function that maps attribute names to their values. This understanding of f-structure has important implications for the architecture of LFG. Specifically, it implies that f-structures are solely and uniquely defined by their set of attribute-value pairs; there is no type system as in Carpenter (1992) or HPSG (Pollard & Sag 1994). Therefore, there is no such thing as two different f-structures having the same set of attributes and values; the notion of an empty f-structure is also problematic, because all empty structures are equivalent to each other.[6] This notion of

---

[6] Observe that the standard LFG notation does not even have a way to specify empty f-structures, on the tacit assumption that every non-vacuous f-structure would have at least one feature. However, the notion could be useful e.g. for expletive arguments that are not specified for any morphosyntactic features such as pers or case but simply appear to satisfy Completeness.

identity is somewhat mitigated by the uniqueness of pred values (Section 3.3.4), which ensures that any two independently introduced, semantically interpreted f-structures are formally distinct, even if they have the same lexical predicate and the same set of morphosyntactic features. However, not all f-structures have pred values; thus, for instance, all expletive subjects of the same form are described by the same f-structure, regardless of the clauses in which they occur. For example, all bundles of agreement features (agr) with the same set of values are identical to each other. One agr bundle may be required to be identical to another via agreement sharing (Haug & Nikitina 2015) in the f-description (using an equation such as (↑ agr)=(↑ subj agr)), but it will also be identical to all other such bundles elsewhere in the same sentence, if they occur. Counterintuitive though such results may seem, it is not clear whether they can lead to any undesirable effects in practice. The notion of identity of f-structures is important for understanding the concept of structure sharing (Section 3.3.3).

3.2 The metalanguage

3.2.1 Defining equations

The standard notation for describing f-structures are defining equations.These utilize the idea that f-structures are functions. For example, the value of the attribute tense of f-structure f in (11) can be defined by the equation (f tense)=prs. It is possible to use nested function applications; thus, since (f subj)=g, ((f subj) pers) is equivalent to (g pers) and has the value 3. By convention, function application is left associative, thus the parentheses can be omitted and the equation written as (f subj pers)=3.

Defining equations are grouped into f-descriptions. An f-description describes the *minimal* f-structure that satisfies all the equations included in the description. The default relation between equations forming an f-description is conjunction, but disjunction is also possible; for example, { (↑ subj pers)=1 | (↑ subj pers)=2 } means that the subject is defined as being either 1st or 2nd person.[7] For more examples and discussion of defining equations, see Belyaev 2023b [this volume].

3.2.2 Constraining equations

The f-structure equations described above are all evaluated to construct the minimal complete and coherent f-structure that satisfies all of them together (if such

---

[7] Disjunction can be represented by either a vertical line (|) or a logical disjunction sign (∨); both notations are found in the literature.

an f-structure exists). In this sense, they are “constructive”, or DEFINING: informally, a defining equation introduces a feature value, regardless of whether it is the only such equation or the same value is defined elsewhere.

But sometimes it is necessary to check the value of a feature without actually assigning it. For example, a matrix verb might require its complement to have a specific mood value, such as subjunctive. A defining equation like ($\uparrow$ COMP MOOD)=SBJV also licenses a complement that is not marked for mood, i.e. does not have a lexically defined MOOD feature (e.g., it is non-finite), which probably leads to an incorrect prediction (unless additional constraints block the use of such forms in this context).

Defining equations also provide no way to capture purely negative requirements, i.e. to ensure that a feature *does not* have a specific value. Clearly, this is not equivalent to the disjunction of other possible values of the feature, since, first, absence of the feature also satisfies the negative condition; second, the disjunction would freely assign any feature value except for the disallowed one, which is definitely not what a negative constraint should do.

The need for such constraints is accounted for in LFG by allowing a special class of equations, CONSTRAINING EQUATIONS. These equations are special in that they do not participate in constructing the f-structure of the sentence. In contrast, they are only evaluated once the minimal f-structure satisfying all defining equations has been constructed. Then, violation of a constraining equation leads to ungrammaticality.

The simplest type of constraining equations involve equality relations; these are annotated in the same way as defining equations, but with a subscript *c*, e.g.: $(f\ a) =_c \mathrm{X}$. To illustrate how constraining equations work, consider the following f-descriptions and their corresponding f-structures:

(12) a. $$\begin{array}{lcl}(f\ \mathrm{A}) & = & \mathrm{X}\\ (f\ \mathrm{B}) & = & \mathrm{Y}\\ (f\ \mathrm{A}) & =_c & \mathrm{X}\end{array} \rightarrow {}_f\!\begin{bmatrix}\mathrm{A} & \mathrm{X}\\ \mathrm{B} & \mathrm{Y}\end{bmatrix}$$ (constraining equation satisfied)

b. $$\begin{array}{lcl}(f\ \mathrm{B}) & = & \mathrm{Y}\\ (f\ \mathrm{A}) & =_c & \mathrm{X}\end{array} \nrightarrow {}_f\!\begin{bmatrix}\mathrm{B} & \mathrm{Y}\end{bmatrix}$$ (constraining equation not satisfied)

In (12a), the constraining equation is satisfied because the feature value is defined elsewhere. By contrast, in (12b) the constraining equation is not satisfied because A has no value, and a value cannot be assigned by a constraining equation.

Note that constraining equations serve as a good illustration of the LFG principle of separation between description and the object being described. Just as multiple feature definitions are not represented in the f-structure, there is also no trace of constraining equations having been "checked" in (12a). The only thing a constraining equation does is to put constraints on permissible structures; it does not contribute to the structures themselves.

The other two types of constraining equations are existential and negative constraints. Existential equations check that a feature has *any* value rather than testing for a specific value. They are written as simple function applications: $(f\,a)$ means that the f-structure f must have the feature a with any value; the absence of an equality statement indicates that we are dealing with an existential constraint. Negative constraints check that a feature does not have a given value ($(f\ a) \neq x$; this is compatible with the feature having no value) or has no value ($\neg(f\ a)$; this is called a negative existential constraint).

Constraining equations are also implicitly introduced by conditional statements of the form $X \Rightarrow Y$. These are, by definition (Bresnan et al. 2016: 61, Dalrymple et al. 2019: 168), equivalent to a disjunction: $\neg A \vee (A_c \wedge B)$.

Off-path constraints are conceptually similar to conditional statements in that they are used to restrict function application to apply only to f-structures satisfying additional conditions on their features. For example,

$$(f \quad \underset{(\rightarrow \mathrm{B}) =_c y}{\mathrm{A}} \quad \mathrm{C}) = x$$

means that the value x is only assigned to the feature C of the f-structure $(f\ \mathrm{A})$ if $(f\ \mathrm{A})$ has an attribute B with the value y. If only constraining equations are used in such statements (as assumed in some of the literature), they could all in principle be rewritten as conditional statements (provided that local names are used: see Section 3.2.5), but the notation is more cumbersome. This is indeed assumed in some LFG literature, and perhaps most prominently in the XLE implementation (Crouch et al. 2011), where defining equations cannot be used in off-path constraints (see Patejuk & Przepiórkowski 2014: 7 for a discussion). However, in spite of their name, the theoretical literature (Bresnan et al. 2016: 65, fn. 26, Dalrymple et al. 2019: 230) unanimously suggests that off-path constraints can be constructive, and this feature is used in some LFG analyses.[8] Off-path constraints are especially important for Functional Uncertainty expressions (Section 3.2.3), where a path may be a regular expression with many elements and the direct use of conditional statements is impractical.

It is clear from the discussion above that while the concept of constraining equations appears rather simple, it actually introduces some additional complexity into the system. Instead of just evaluating an f-description that consists of a

---

[8] I am thankful to an anonymous reviewer for drawing my attention to this fact.

set of defining equations, the resolution of a valid f-structure for a sentence must proceed through two steps: (a) evaluation of defining equations; (b) evaluation of constraining equations. The notion of constraining equations has also raised concerns about the metatheoretical status of LFG grammars; in particular, Pullum (2013) and Blackburn & Gardent (1995) have argued that constraining equations introduce a degree of procedurality into the framework, which is incompatible with the notion of model-theoretic syntax. However, the specific implications of this procedurality have never been systematically studied. It is clear that many, perhaps most, grammars that use constraining equations could be rewritten without them, but with more notational complexity: for example, by requiring every f-structure to have certain attributes, introducing "empty" attribute values (i.e. treating "no value" as one of the values for atomic features), and so on. Thus the issue might, in the end, be more of notation rather than substance, as suggested, in fact, in the conclusion to Blackburn & Gardent (1995).

3.2.3 Functional uncertainty

The basic LFG architecture outlined in the preceding sections is adequate to handle most phenomena that are relevant to the local structure of clauses and noun phrases, such as argument selection and realization, modification, and word order. However, it is missing a component that could handle unbounded dependencies of any kind, i.e. those dependencies between elements of a sentence that are not tied to any specific structural position. For example, consider the behaviour of "cyclic" extraction from complement clauses. This process is in principle unbounded: an interrogative might be extracted from the matrix clause (13a), from the complement clause (13b), from the complement of the complement (13c), etc.

(13) a. **Who** does John like _?
b. **Who** does John think Mary likes _?
c. **Who** does John believe David thinks Mary likes _?

For (13a), one might write an f-structure equation annotating the extracted NP node such as (↑ OBJ)=↓, and augment it with a disjunction for each other available grammatical function – which, by itself, is not very elegant, but seems to adequately account for the facts. To capture (13b), another set of equations must be added to the disjunction, this time with COMP before OBJ: (↑ COMP OBJ)=↓, etc. This already seems like a rather artificial solution, but when (13c) is considered, yet another disjunction is required: (↑ COMP COMP OBJ)=↓, etc. Clearly, the sequence of COMP's can be arbitrarily large (if memory constraints and other extralinguistic considerations are not taken into account), and any grammatical framework must account for such boundless iteration. LFG, in its basic form described above, clearly cannot do so.

Intuitively, what is required is to allow generalizing over sets of functional equations, specifically, introducing disjunction to allow selecting different GFs, and arbitrary iteration of comp. This is achieved by the notion of functional uncertainty, introduced to LFG in Kaplan & Zaenen (1989b). In a nutshell, functional uncertainty extends the LFG notion of function application by allowing function names – x in a statement like $(f\ x)$ – to be regular expressions. Thus, a single f-structure equation may correspond to a (possibly infinite) set of statements. More formally, functional uncertainty defines function application as in (14).

(14) $(f\ \alpha) = v$ holds if and only if f is an f-structure, α is a set of strings, and for some s in the set of strings α, $(f\ s) = v$.

Thus, the distribution in (13) can be captured by a single equation, such as in the following rule for extracted interrogatives:

(15)
$$\begin{array}{lcc} \text{CP} \longrightarrow & \text{NP} & \text{C}' \\ & (\uparrow \textsc{dis}) = \downarrow & \uparrow=\downarrow \\ & (\uparrow \textsc{comp}^{*}\ \{\textsc{obj} \mid \textsc{obj}_{\theta} \mid \textsc{obl}_{\theta}\}) = \downarrow & \end{array}$$

The disjunction in the NP annotation is typically abbreviated as gf, which stands for “any grammatical function” – but which GFs exactly can appear in a given position is construction-specific; for example, adjuncts may or may not be included in the list of gfs. In general, so-called “island constraints” are typically captured in LFG as constraints on paths in functional uncertainty equations (Kaplan & Zaenen 1989b). This correctly predicts that what counts as an “island” varies across languages and across different constructions within the same language.

3.2.4 Inside-out function application and functional uncertainty

Standard function application in LFG is “outside-in”: an expression $(f\ a)$ refers to a feature that belongs to the f-structure f or at any deeper level of embedding. This presupposes a “top-down” style of describing and constraining f-structures. However, it may sometimes be useful to describe constraints on the *external* distribution of an f-structure: for instance, limit the range of attributes it may occupy, or define some features of “sister” f-structures, i.e. f-structures that occupy different attributes in the containing f-structure (e.g., subj constraining attributes of obj). For this, LFG uses an additional mechanism called inside-out

EXPRESSIONS. Inside-out expressions use the same parenthetical notation as ordinary LFG notation, but the f-structure now acts as an argument rather than as a function. Formally, inside-out expressions are defined as follows:

(16) $(a\ f) = g$ holds if and only if g is an f-structure, a is a symbol, and the pair $\langle a, f \rangle \in g$.

Informally, this definition means that $(a\ f)$ refers to an f-structure g (or set of f-structures) whose attribute a has f as its value. For example, in (17), $(\textsc{a}\ g) = f$ holds because $(f\ \textsc{a}) = g$ is satisfied.

(17) $_f\begin{bmatrix}\textsc{a} & _g\begin{bmatrix}\textsc{b} & x\end{bmatrix}\end{bmatrix}$

Functional uncertainty can also be extended to cover inside-out expressions by replacing a in the definition above by a regular expression α. The formal definition is as follows:

(18) $(\alpha\ f) \equiv g$ if and only if g is an f-structure, α is a set of strings, and for some s in the set of strings α, $(s\ f) = g$.

Inside-out function application is by its nature a rather limited formal device compared to "outside-in" function application. It is mainly used either to constrain the grammatical functions that an f-structure may occupy, or to constrain the features of a higher-level f-structure. Importantly, it cannot actually be used as the main mechanism of constructing f-structures. For example, one may formulate a defining equation such as $((\textsc{a}\ f)\ \textsc{a}) = f$ to force f to appear in grammatical function A. But this definition will produce an "orphaned" f-structure which can only be integrated with other f-structures by additional "outside-in" statements, which, in turn, make such an inside-out statement redundant.

Which grammatical phenomena is inside-out functional uncertainty used to model? Perhaps the simplest is the restriction of certain grammatical forms to certain syntactic positions. For example, if nominative marking in a given language is always associated with the grammatical function SUBJ, one may avoid referring to a feature CASE, instead adding (SUBJ ↑) to the lexical entries of all nominative nouns. This correctly ensures that nominative nouns are only used in those positions which the grammar defines as being associated with subjects.

Another phenomenon where inside-out function application plays a role is agreement on modifiers. For example, Russian adjectives agree in gender and number with their heads. In standard LFG terms, this means that they are lexically annotated to co-define (together with the head noun) the features CASE and

NUM of the f-structures whose ADJUNCT position they occupy. An adjective like *krasnaja* 'red' (fem. sg.) might have the following lexical entry:[9]

(19) *krasnaja* Adj $(\uparrow \textsc{pred}) = \text{`}\textsc{red}\text{'}$
$((\textsc{adj} \in \uparrow)\ \textsc{num}) = \textsc{sg}$
$((\textsc{adj} \in \uparrow)\ \textsc{gend}) = \textsc{fem}$

A somewhat more exotic phenomenon that inside-out functional uncertainty succeeds at capturing is "case stacking" in Australian languages, where NP-internal dependents are marked not only with the case that indicates their position within this NP, but also for the case that indicates the position of this NP at a higher level. Nordlinger (1998) develops a theory called Constructive Case[10] to account for this behaviour; "stacked" cases are treated as denoting the case values of the f-structures that contain the noun as their complement, via the mechanism of inside-out functional uncertainty.

3.2.5 Local names

F-structures in annotated rules are typically referred to relative to the nodes in the phrase structure rule, i.e. using paths that begin in the metavariables ↑ or ↓. This is sufficient if these paths are uniquely and unambiguously resolved; the relevant reference may just be repeated in all equations that use it. But in some cases functional annotations do not uniquely identify f-structures that should be referred to. This most frequently occurs when functional uncertainty is involved (described in Section 3.2.3), i.e. when paths are regular expressions that can resolve to different f-structures. Another example is when the same set of rules can apply to different f-structures, either in free variation or subject to additional conditions. Consider a hypothetical language where verbal agreement morphology can alternatively define the person and number features of the subject or direct object.[11] In this case, it is of course possible to introduce disjunction of two sets of equations, as in (20), but this clearly misses the crucial generalization that the same features are defined in both disjuncts.

---

[9] The set membership symbol ∈ may be used in inside-out statements just as well as it can be used in outside-in statements. $(\textsc{a} \in f) = g$ entails that $(g\ \textsc{a} \in) = f$, which is notationally equivalent to $f \in (g\ \textsc{a})$. See Section 3.3.3.

[10] "Constructive" is, in fact, somewhat of a misnomer: as shown above, inside-out statements cannot actually "construct" anything, but can only test for feature values of f-structures that have already been constructed.

[11] This example is actually not so hypothetical: such an analysis of Dargwa is proposed in Belyaev (2013), where person-number agreement can be associated with either subject or object, and the choice is then "filtered" using a set of OT constraints.

(20) { (↑ subj pers) = 1
(↑ subj num) = sg
| (↑ obj pers) = 1
(↑ obj num) = sg }

A more economical way to formulate this constraint is to introduce a temporary label for the f-structure involved – a local name – and then refer to this name in the two equations assigning person and number features. Normal names in LFG, by convention, are written with an initial % and assigned using the standard equation operators, as in (21):

(21) { %agr = (↑ subj) | %agr = (↑ obj) }
(%agr pers) = 1
(%agr num) = sg

While local names are not very frequent in LFG analyses, their use is essential for some phenomena where there is a need to consistently refer to an f-structure whose identity is not uniquely deducible from its path (set members, functional uncertainty, etc.).

3.2.6 F-precedence

The basic architecture of LFG is devised to be modular, such that different linguistic phenomena are accounted for at separate levels. In the interaction between c- and f-structure, c-structure is exclusively concerned with linear order and hierarchical embedding, while f-structures do not reflect linear order or constituent structure in any way. Therefore, linear order is relevant for most morphosyntactic constraints only in a limited way, insofar as it distinguishes between different c- to f-structure mappings (such as, for example, in English, where Spec,IP is mapped to subject and precedes the verb and Comp,VP). Without extensions to the standard LFG notation, there is no way to state a constraint like "the verb agrees in person and number with whatever NP stands to its left", because agreement features are the domain of f-structure, and functional equations can only refer to f-structure functions, not linear or constituent-based positions.

However, in certain cases linear order does seem to play a role in determining constraints on syntactic relations. A well-known example is the availability of discourse anaphora between adverbial clauses and main clauses: If the antecedent precedes the pronoun, coreference is possible regardless of which clauses the two are located in (22), while cataphora (backwards anaphora) is only possible if the cataphor stands in the subordinate clause (23).

(22) a. [When John$_{\mathrm{i}}$ came], I saw him$_{\mathrm{i}}$.
b. I saw John$_{\mathrm{i}}$ [when he$_{\mathrm{i}}$ came].

(23) a. [When he$_{\mathrm{i}}$ came], I saw John$_{\mathrm{i}}$.
b. * I saw him$_{\mathrm{i}}$ [when John$_{\mathrm{i}}$ came].

Such behaviour has been generalized since Langacker (1969) as "precede-and-command".[12] Coindexation is possible if at least one of the following is true: the antecedent c-commands[13] the pronoun; the antecedent precedes the pronoun.

Similar constraints operate in other languages. For example, Mohanan (1982) argues that in Malayalam, pronouns *must* follow their antecedents. In LFG, such constraints can be captured using the relation of F-PRECEDENCE (Kaplan & Zaenen 1989a), which is a way of introducing linear order constraints in f-structure using the inverse projection ϕ^{-1}, which maps f-structures to the corresponding c-structure nodes.

(24) f *f-precedes* g ($f <_f g$) if and only if for all $n_1 \in \phi^{-1}(f)$ and for all $n_2 \in \varphi^{-1}(g)$, n_1 c-precedes n_2.

The formal definition in (24)[14] essentially means that an f-structure f_1 f-precedes f_2 iff all c-structure constituents that map to f_1 linearly precede the constituents that map to f_2. Given this definition, anaphoric constraints such as precede-and-command may be formulated as the requirement that the pronoun's antecedent f-precede the pronun.

Note that f-precedence is a rather straightforward relation if an f-structure corresponds to a single constituent. In more complex situations, such as when discontinuous constituents are involved, or one of the elements does not have a c-structure exponent, its application is not so intuitive. In particular, in the latter case, null elements f-precede and are f-preceded by all other elements in the sentence, because one of the sets n_1, n_2 is empty. This property of f-precedence is used to analyze the behaviour of null anaphora in languages like Malayalam (Mohanan 1982) or Japanese (Kameyama 1985), where null pronouns behave differently from full pronouns. For such languages, the definition in (24), combined

---

[12] The relevance of linear order has been hotly contested in the literature on anaphora, especially in mainstream transformational grammar; for a recent take on precede-and-command, see Bruening (2014). This is not relevant for our discussion, though, as within LFG no one ever argued against linear-order constraints on anaphora.

[13] In LFG, c-command is replaced by outranking on the grammatical function hierarchy: see Rákosi 2023 [this volume].

[14] C-precedence requires that all daughter nodes of a node precede all daughter nodes of another node – essentially a linear precedence relation for c-structure constituents.

with the generalization in the preceding paragraph, correctly predicts that linear order does not influence the anaphoric requirements of null pronouns (Dalrymple et al. 2019: 257).

An alternative definition of f-precedence, that leads to a different treatment of null pronouns, is proposed in Bresnan et al. (2016: 213):

(25) f f-precedes g if and only if the rightmost node in $\phi^{-1}(f)$ precedes the rightmost node in $\phi^{-1}(g)$.

Under this definition, null pronouns in fact do not f-precede and are not f-preceded by any constituent, because their inverse projections lack a rightmost node. To capture the data of Japanese or Malayalam using this definition, a different, negative formulation of the precedence binding constraint should be used: "The domain of a binder *excludes* any pronominal that f-precedes it" (Bresnan et al. 2016: 213, emphasis mine), i.e. the pronoun *must not* f-precede its antecedent. For more information on f-precedence and linear order constraints on anaphora in general, see Rákosi 2023 [this volume].

Thus, the use of inverse projection does allow a degree of influence of linear order on syntactic constraints, in a limited way (as intended): linear order may serve as an additional constraint on relations formulated in f-structure terms, but does not serve as the only or as the main factor determining these relations.

3.3 Attribute value types

3.3.1 General remarks

The system of attribute values in the core LFG architecture is very straightforward. There are only three types of values: atomic values, semantic forms and other f-structures (of which sets are a special instance).

The simplicity of this system follows from the fact that, as mentioned above, LFG has no type system for f-structures. This means that the list of potential attributes and their values for any given f-structure is defined only by annotated phrase structure rules and lexical entries. Thus, there is nothing in the formal architecture or in any part of an LFG grammar that would prohibit a "clausal" f-structure to have the feature CASE or a "nominal" f-structure to have the feature TENSE; such constraints are only implicit in the way these f-structures are constructed and mapped from c-structure nodes.

Similarly, the attributes themselves are not by default associated with any specific value type: LFG grammars by themselves contain no stipulation of possible attributes and the values they may take. Only grammatical function values are required to be f-structures, and PRED values to be semantic forms due to Completeness and Coherence (see Section 3.4). Nothing prevents the value for CASE or PERS to be an f-structure rather than an atomic value; in fact, the former option has been used in analyses such as Dalrymple & Kaplan (2000).

This simplicity of the type system may be viewed as an advantage, as it simplifies the LFG metalanguage without introducing unnecessary redundancy (see Asudeh & Toivonen 2006: 412ff. for a criticism of the Minimalist feature system). There are few problems that a more complex type system would solve, as the architecture of a well-defined grammar typically prevents f-structures from being assigned incorrect attribute values. Still, sometimes it is necessary to check that an f-structure belongs to a given type – for example, whether it is nominal or clausal. LFG provides several ways to do so: one might directly check the category of the corresponding c-structure node using an inverse projection (Section 4.1), or check for certain characteristic attributes (such as CASE for nominals or TENSE for finite clauses) using constraining equations. The latter method, however, is error-prone, as the grammar writer has to ensure that all relevant f-structures have these attributes. This issue can be partly remedied using templates (Asudeh et al. 2013), but templates are an optional, purely notational device; care must be taken that templates are used consistently.

Another solution has been implemented in XLE, which allows the grammar writer to optionally use FEATURE DECLARATIONS to describe the restrictions on feature values (Crouch & King 2008). This is a robust system which, if employed properly, can provide grammars with a higher degree of generalization while also decreasing the number of accidental errors in feature descriptions. Unfortunately, it is virtually unknown in the LFG theoretical literature, being meant as an engineering solution rather than a theoretical proposal and limited to computational work that uses XLE (see Forst & King 2023 [this volume] for more detail).

3.3.2 Atomic values

The simplest type of attribute value is an atomic value: essentially a token that represents a given value of a grammatical feature (e.g. ACC for the feature CASE, PRESENT for the feature TENSE, etc.). There is no single agreed-upon set of "standard" features and the valid values they might take: in principle, it is the task of the grammar writer or analyst to determine the set of features required to describe a particular language.

In current LFG practice, there is, however, a set of informal conventions on the general inventory of atomic features. These fall into two types. The first type are morphosyntactic features of the same kind as those standardly used in typology and descriptive grammars: features such as CASE, TENSE, ASP, PERS, etc. An overview of the use of features in syntactic and morphological description can be found in Corbett (2012).

The second type are more technical features that are specific to the LFG understanding of specific syntactic phenomena. For example, Dalrymple (2001: 396ff.) uses the feature LDD (for Long-Distance Dependency) to mark whether an f-structure is available for extraction. If $(f\ \text{LDD}) = -$, the f-structure f cannot be in the path that specifies a long-distance dependency. This feature is checked by an off-path constraint (see Section 3.2.2). These and similar constraints are discussed in more detail in Kaplan 2023 [this volume].

Similarly, features such as PRONTYPE or NUCLEAR are used in Dalrymple (1993), Bresnan et al. (2016) to distinguish between different kinds of pronouns to account for the differences in binding constraints. See Rákosi 2023 [this volume] for more detail.

In spite of the theoretical significance and cross-linguistic ubiquity of such features as LDD and PRONTYPE, it is generally assumed that they are also not universal and not part of an innate grammatical blueprint (although, to my knowledge, this question has never been explicitly discussed in the literature). Thus, while Bresnan et al.'s (2016) approach to anaphora relies on grammar-wide constraints and distinguishes pronouns via their features, Dalrymple (1993) rather assumes that all binding constraints are lexically specified by the pronouns themselves. The latter point of view is supported by the cross-linguistic diversity of binding domains. It might be that both approaches are valid, but the efficiency of each depends on the language in question. Hence, like in many other domains, LFG as a framework is agnostic as to whether cross-linguistic similarities are due to innate, universal constraints or are a result of independent, functionally motivated convergence of grammars in the course of their evolution. Particular analyses can strike a balance between these two factors that explain cross-linguistic similarities.

3.3.3 F-structure

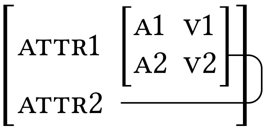
As seen in (11), f-structures can themselves serve as attribute values. F-structures are predominantly values of grammatical functions such as SUBJ, OBJ, etc., and discourse functions such as DIS (or TOPIC and FOCUS in earlier approaches; see Belyaev 2023a [this volume]). F-structures are sometimes also used to represent "compound" attribute values; for example, agreement features are sometimes represented as the “bundle” AGR in (26), and PRED values can be viewed as composite (Section 3.3.4).

(26)
$$\begin{bmatrix} \textsc{pred} & \text{‘}\textsc{house}\text{’} \\ \textsc{agr} & \begin{bmatrix} \textsc{pers} & 3 \\ \textsc{num} & \textsc{sg} \end{bmatrix} \end{bmatrix}$$

Just as different atomic-valued attributes can have identical values, one f-structure can also serve as a value for several attributes. This phenomenon is called STRUCTURE SHARING and is the closest LFG counterpart to the notion of “movement” in transformational frameworks; it is discussed in more detail in Belyaev 2023b [this volume]. This configuration can be visually represented in two ways: either the f-structure is fully spelt out in every occurence (27a), or only once – then the other occurences are connected by lines (27b) or coindexed (27c).

(27) a.
$$\begin{bmatrix} \textsc{attr1} & \begin{bmatrix} \textsc{a1} & \textsc{v1} \\ \textsc{a2} & \textsc{v2} \end{bmatrix} \\ \textsc{attr2} & \begin{bmatrix} \textsc{a1} & \textsc{v1} \\ \textsc{a2} & \textsc{v2} \end{bmatrix} \end{bmatrix}$$

b.



c.
$$\begin{bmatrix} \textsc{attr1} & {}_{f}\begin{bmatrix} \textsc{a1} & \textsc{v1} \\ \textsc{a2} & \textsc{v2} \end{bmatrix} \\ \textsc{attr2} & f \end{bmatrix}$$

Some grammatical phenomena, in particular coordination, adjunction and feature indeterminacy, are represented in LFG via set-valued attributes, as in (28).

(28)
$$f{:}\begin{bmatrix} \textsc{a} & \left\{ \begin{matrix} \begin{bmatrix} \textsc{distr1} & l \\ \textsc{distr2} & m \end{bmatrix} \\ \begin{bmatrix} \textsc{distr1} & l \\ \textsc{distr2} & n \end{bmatrix} \end{matrix} \right\} \end{bmatrix}$$

At first sight, this may appear to violate the notion of f-structure as a function, and the consequent Uniqueness constraint (Section 3.4.1). However, sets in LFG are not multiple values of a single attribute; they are rather viewed as a special kind of f-structure – a *hybrid object* that has both attributes that pertain to it as a whole and attributes whose value is determined based on the values of the set members. This is based on the distinction between DISTRIBUTIVE and NON-DISTRIBUTIVE features.[15] The value of a *distributive* feature for a set is determined as follows:

(29) If a is a *distributive* feature and s is a set of f-structures, then $(s\ a) = v$ holds if and only if $(f\ a) = v$ for all f-structures f that are members of the set s. (Bresnan et al. 1985, Dalrymple & Kaplan 2000)

A distributive feature for a set is only defined as having a value if it has this value in all f-structures in the set. Thus, for (28), the equation $(f\ \text{A DISTR1}) = \text{L}$ is true; conversely, no equation invoking the feature DISTR2 (such as $(f\ \text{A DISTR2}) = \text{M}$ or $(f\ \text{A DISTR2}) = \text{N}$) can be satisfied, since the set elements differ in the value of this feature. Crucially, there is no requirement that distributive features be the same for all elements of a set unless they have been invoked; the structure in (28) is valid as long as the grammar does not assign any value to $(f\ \text{A DISTR2})$.

While distributive features are resolved on the basis of their values for individual members of a set, *non-distributive* features apply to sets as a whole:

(30) If a is a *non-distributive* feature, then $(f\ a) = v$ holds if and only if the pair $\langle a, v\rangle \in f$. (Bresnan et al. 1985, Dalrymple & Kaplan 2000)

In (3.3.3), the value of the attribute A illustrates a set with a non-distributive feature.

(31)
$$f{:}\left[\text{A}\ \left[\begin{array}{l}\text{NDISTR}\ \ \text{N}\\ \left\{\begin{array}{l}\left[\text{NDISTR}\ \ \text{L}\right]\\ \left[\text{NDISTR}\ \ \text{M}\right]\end{array}\right\}\end{array}\right]\right]$$

This notation, standard in LFG work, is meant to represent that, while the feature NDISTR has the values L and M for the individual set members, it has the value N for the whole set. The equation $(f\ \text{A NDISTR}) = \text{N}$ is therefore satisfied regardless of the set members' values of NDISTR.

Distributive and non-distributive features in LFG are used to model different ways in which feature values are resolved and checked in coordination and similar structures. For example, number is typically viewed as non-distributive, because a coordinate NP triggers plural agreement regardless of the number features of its conjuncts. In contrast, case is usually distributive: when a case value is assigned to a coordinate phrase, it must be borne by all its conjuncts. The issue of sets and distributivity with respect to coordination is dealt with in Patejuk 2023 [this volume].

---

[15] This distinction is normally understood as being grammar-wide, or even universal; some authors have recently proposed treating distributivity as a property of *feature application*, not features as such; the most recent such account seems to be Przepiórkowski & Patejuk (2012), and similar ideas are explored in Belyaev et al. (2015) and Andrews (2018).

3.3.4 Semantic forms

A semantic form is a special type of attribute value that is exclusively assigned to the attribute pred. Semantic forms consist of the predicate name followed by the list of its syntactic arguments; arguments that are assigned thematic roles are written in angled brackets, while arguments that are not thematic (such as expletive subjects or “raised” subjects and objects) are written outside angled brackets. For example, the pred value for a transitive verb like ‘see’ will be ‘see ⟨subj obj⟩’. A verb like ‘rain’, which has no thematic arguments but an expletive subject, will have the pred value ‘rain⟨⟩subj’. Finally, an “object raising” verb like ‘believe’ will have the pred value ‘believe⟨subj⟩obj’: its subject is assigned a semantic role, while its object is not.

In the preceding paragraph, arguments were represented as mere lists of grammatical function names. This convention, which is followed in much LFG work (see e.g. Dalrymple 2001, Dalrymple et al. 2019), is but a simplification: arguments inside pred values are usually understood as direct references to the corresponding attribute values. Thus, in the left-hand side of (32), the pred value is represented as ‘see⟨(f subj) (f obj)⟩’. As observed in Kuhn (2003: 63), pred values as used in typical LFG representations can be viewed as shorthands for complex structures such as in the right-hand side of (32);[16] fn is an abbreviation for functor; sfid stands for “semantic form identifier”, on which see below. Similar structures are used in implemented parsers like the Xerox Grammar Writer’s Workbench (Kaplan & Maxwell 1996) and the Xerox Linguistic Environment (XLE, Crouch et al. 2011; see Forst & King 2023 [this volume]).

(32)
$$
{}_{f}\left[\begin{array}{ll}
\textsc{pred} & \text{‘}\textsc{see}\langle(f\ \textsc{subj})(f\ \textsc{obj})\rangle\text{’} \\
\textsc{subj} & \left[\begin{array}{ll} \textsc{pred} & \text{‘John’} \\ \textsc{num} & \textsc{sg} \\ \textsc{pers} & 3 \end{array}\right] \\
\textsc{obj} & \left[\begin{array}{ll} \textsc{pred} & \text{‘David’} \\ \textsc{num} & \textsc{sg} \\ \textsc{pers} & 3 \end{array}\right]
\end{array}\right]
=
\left[\begin{array}{ll}
\textsc{pred} & \left[\begin{array}{ll} \textsc{fn} & \textsc{see} \\ \textsc{argument1} & \\ \textsc{argument2} & \\ \textsc{sfid} & i \end{array}\right] \\
\textsc{subj} & \left[\begin{array}{ll} \textsc{pred} & \left[\begin{array}{ll} \textsc{fn} & \text{John} \\ \textsc{sfid} & j \end{array}\right] \\ \textsc{num} & \textsc{sg} \\ \textsc{pers} & 3 \end{array}\right] \\
\textsc{obj} & \left[\begin{array}{ll} \textsc{pred} & \left[\begin{array}{ll} \textsc{fn} & \text{David} \\ \textsc{sfid} & k \end{array}\right] \\ \textsc{num} & \textsc{sg} \\ \textsc{pers} & 3 \end{array}\right]
\end{array}\right]
$$

---

[16] I follow the representation used by Kuhn (2003), which does not distinguish between thematic and non-thematic arguments. In XLE, this is implemented by distinguishing between the attributes arg1, arg2, … for thematic arguments and notarg1, notarg2, …. for non-thematic arguments.

If semantic forms were just a bundle of a functor and one or more argument slots, there would be no need to treat them as a special argument value type. What distinguishes them from any other value is their *uniqueness*: each introduction of a PRED value is treated as unique. That is, whenever an expression like (f PRED)=‘FN’ introduces a new semantic form, it is assigned a unique identifier, even if it is lexically identical to another predicate. Thus the equivalence in (33): each PRED assignment is viewed as also introducing an invisible “index” to distinguish between individual PRED values. Thus, if atomic values can be introduced multiple times, PRED values cannot; different grammatical or discourse functions can have the same PRED value only through structure sharing,[17] when the whole f-structure is constrained to be identical. In XLE and other implemented versions of LFG, this uniqueness effect is achieved by including a special feature SFID in the PRED, that is assigned a unique value each time a PRED is introduced in the f-description.[18]

The uniqueness of PRED values is needed to prevent multiple introduction of arguments and will be discussed in Section 3.4.1.

(33)
$$\left\{ \begin{array}{l} (f\ \textsc{pred}) = \text{‘}\textsc{apple}\text{’} \\ (f\ \textsc{pred}) = \text{‘}\textsc{apple}\text{’} \end{array} \right\} \equiv \left\{ \begin{array}{l} (f\ \textsc{pred}) = \text{‘}\textsc{apple}_1\text{’} \\ (f\ \textsc{pred}) = \text{‘}\textsc{apple}_2\text{’} \end{array} \right\}$$

In current LFG research, PRED values mainly serve only to specify argument lists to satisfy Completeness and Coherence, and to provide unique “labels” for f-structures that have PREDs. Even this limited functionality is contested in the literature, with some authors proposing to abandon f-structures in favour of a purely semantic approach, see Section 3.4.4. Originally, however, PREDs were thought to have a more central role, providing a kind of link from syntax to semantics (Kaplan & Bresnan 1982). It is important to observe that PREDs are no

---

[17] Or, as an anonymous reviewer observes, through sharing of the PRED value itself, as e.g. in the analysis of adjective coordination in Belyaev et al. (2015).

[18] XLE extends standard LFG by allowing any atomic value to be unique – an *instantiated symbol* notated via a subscript following its name: VAL_. Thus in XLE, semantic forms do not seem to require any special machinery as such. However, an anonymous reviewer observes that if the left-hand side of (32) is indeed the abbreviation of its right-hand side, it should be possible to manipulate argument structure in the syntax via equations such as (↑ PRED ARGUMENT3)=↓. XLE seems to circumvent this by tacitly introducing a negative existential constraint that prevents any additional attributes from appearing in PRED except the ones included at its introduction. This includes both argument features and any other feature names: both the XLE version of the above statement and (↑ PRED FOO)=BAR lead to an existential constraint violation. It is also impossible to “construct” a semantic form using a set of separate statements for the individual features; thus even XLE does technically treat semantic forms as a special value type.

longer viewed in these terms in the LFG literature; the functor names are only arbitrary labels, and all semantic derivation is separate from syntax, being done through Glue Semantics, described in Asudeh 2023 [this volume].[19]

3.4 Well-formedness conditions

There are three conditions that any f-structure must satisfy in order to be treated as valid: Uniqueness (also known as Consistency), Completeness, and Coherence. Any f-structure that violates these conditions cannot be part of a valid analysis of any sentence, regardless of the rules of a particular grammar.

3.4.1 Uniqueness

3.4.1.1 Definition

Uniqueness (Consistency) is the requirement that every attribute in an f-structure must have a single value. Thus, the two equations in (34) do not describe any valid f-structure.

(34) Ill-formed f-structure:

$(f\ \textsc{a}) = \textsc{l}$
$(f\ \textsc{a}) = \textsc{m}$

$${}_{f}\begin{bmatrix} \textsc{a} & \begin{array}{c} \boxed{\textsc{l}} \\ \boxed{\textsc{m}} \end{array} \end{bmatrix}$$

It should be noted that Uniqueness is not, in fact, a constraint that needs to be stipulated separately: it follows from the notion of f-structure as a function, since a function maps arguments to single values (thus defining a one-to-one or many-to-one, but not a one-to-many or many-to-many correspondence).

3.4.1.2 Multiple specification of a value

Uniqueness does not in any way imply that multiple specification of an attribute value is ruled out. When the *same* value is assigned to an attribute two or more times, the resulting f-structure is valid, as seen in (35).

(35) $(f\ \textsc{a1}\ \textsc{a2}) = \textsc{l}$
$(f\ \textsc{a1}\ \textsc{a2}) = \textsc{l}$
$(g\ \textsc{a2}) = \textsc{l}$
$(g\ \textsc{a3}) = \textsc{m}$
$(f\ \textsc{a1}) = g$

$${}_{f}\begin{bmatrix} \textsc{a1} & {}_{g}\begin{bmatrix} \textsc{a2} & \textsc{l} \\ \textsc{a3} & \textsc{m} \end{bmatrix} \end{bmatrix}$$

---

[19] A kind of hybrid approach is proposed in Andrews (2008), which introduces a variant of Glue Semantics where meaning is at least in part derived from f-structure feature values; in this approach, PRED features do play a prominent role in semantic composition.

In (35), the attribute (g A2) is assigned its value three times and referred to in two different ways, but this "history" of its origin is not displayed in the resulting f-structure and is not recoverable from it in any way. This is an illustration of the LFG distinction between a *description* and the *object* that it describes, a crucial feature of LFG that separates it from most other frameworks, where syntactic constraints are usually encoded in the structure itself in one way or another.

Turning to a linguistically meaningful example, this distinction between description and object is manifest in the standard LFG approach to agreement (see Haug 2023 [this volume] for more detail). Agreement targets do not normally have a "copy" of their controller's features; they only lexically specify the same features that are separately specified by the controller. If there is a conflict, the resulting f-structure is invalid. If there is no conflict, the agreement features are displayed in the f-structure once and there is nothing in the f-structure indicating that agreement feature checking has taken place. Compare the Italian examples (49) and (50) below, which map to the same f-structure even though the person-number features are described in two positions in (49) but defined once in (50).

3.4.1.3 Uniqueness and PRED values

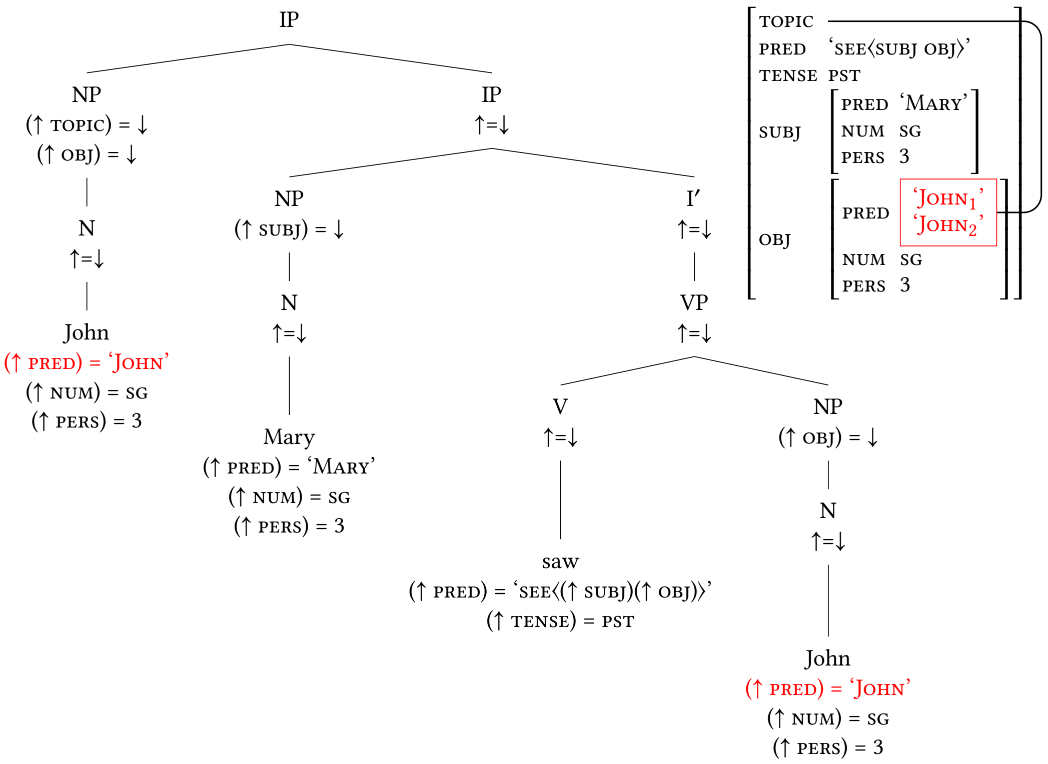
One place where multiple specification is virtually prohibited is PRED features, whose values are special objects called semantic forms. As described above in Section 3.3.4, each assignment of a PRED value is treated as a unique object; it is thus impossible to assign a PRED value more than once, even if the value to be assigned has the same functor name.

The reason why PRED values are treated in this way is to ensure that each argument position, and each predicative element in general, is instantiated by exactly one lexical head. Since there is no one-to-one correspondence between c-structure positions and f-structure functions, this cannot, in the general case, be ensured by phrase structure rules alone. Even in a configurational language like English, a displaced constitutent is not directly linked to its "original" (normal, unmarked) position at c-structure; consequently, the c- to f-structure correspondence allows introducing it twice, as in (36).[20]

---

[20] For the sake of exposition, I assume that the topicalized direct object appears as an IP adjunct – this carries no theoretical significance.

(36) Ill-formed f-structure for **John, Mary saw John*:

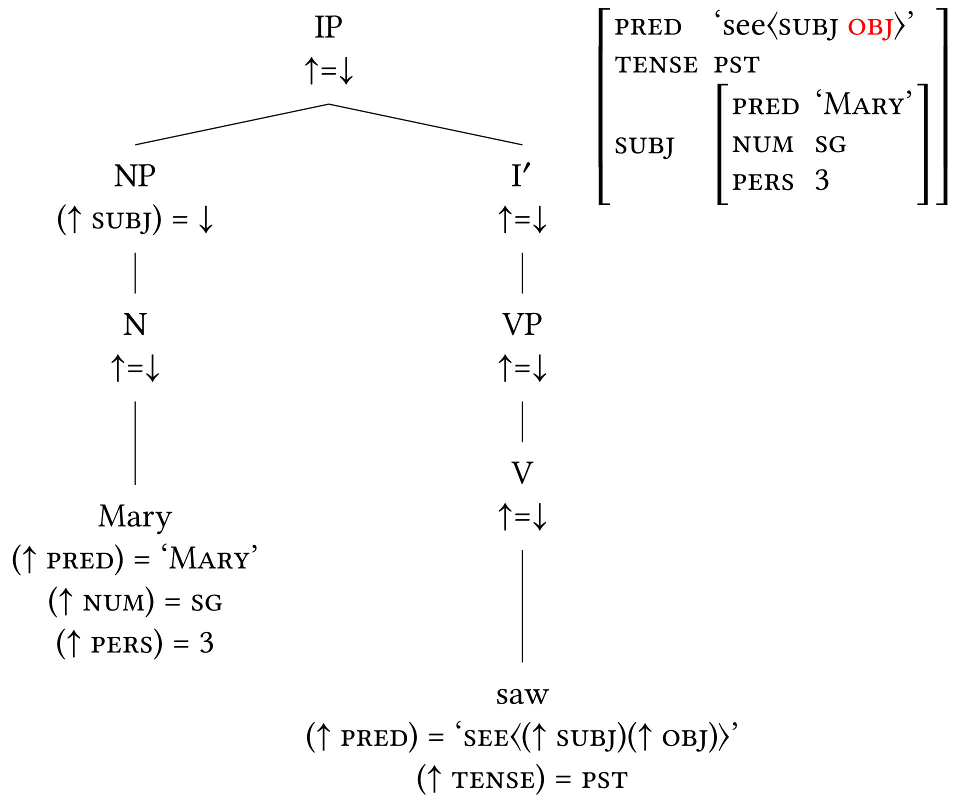


What ensures the ungrammaticality of (36) is precisely the uniqueness of PRED values. This effect is even more pronounced in non-configurational languages, where no c-structure position is tied to any grammatical function, and any number of NPs may be freely mapped to any grammatical function; see Andrews 2023 [this volume] for detail.

3.4.2 Completeness

The Completeness condition requires every grammatical function governed by the PRED value of a given f-structure to exist in this f-structure. In other words, all arguments of a predicate must be "filled" by f-structures. This disallows examples such as (37).

(37) Ill-formed f-structure for **Mary saw*:



C-structure rules cannot be conditioned by argument structure; hence, Completeness violation is the only reason why this sentence is ungrammatical. The c- to f-structure correspondence is otherwise entirely valid.

It is important to understand that completeness only refers to f-structure and has nothing to do with whether arguments are expressed overtly or covertly. Since LFG avoids empty nodes, covert subjects in pro-drop languages do not correspond to any c-structure NP or DP, but Completeness still has to be satisfied at f-structure. This is normally done via equations introducing the pronominal PRED of the subject in the verb's lexical entry: see (48) below.

An additional Completeness constraint has to do with the parameter of semantic argumenthood. It states that semantic arguments (i.e. those whose names stand within angled brackets in the PRED) have to themselves contain a PRED. Conversely, non-arguments (those whose names stand outside angled brackets) are required not to contain a PRED, unless these f-structures are arguments or adjuncts elsewhere (such as, for example, in raising constructions). This is meant to exclude, respectively, expletive arguments in positions where semantic roles are assigned (38), and meaningful NPs in expletive positions (39).

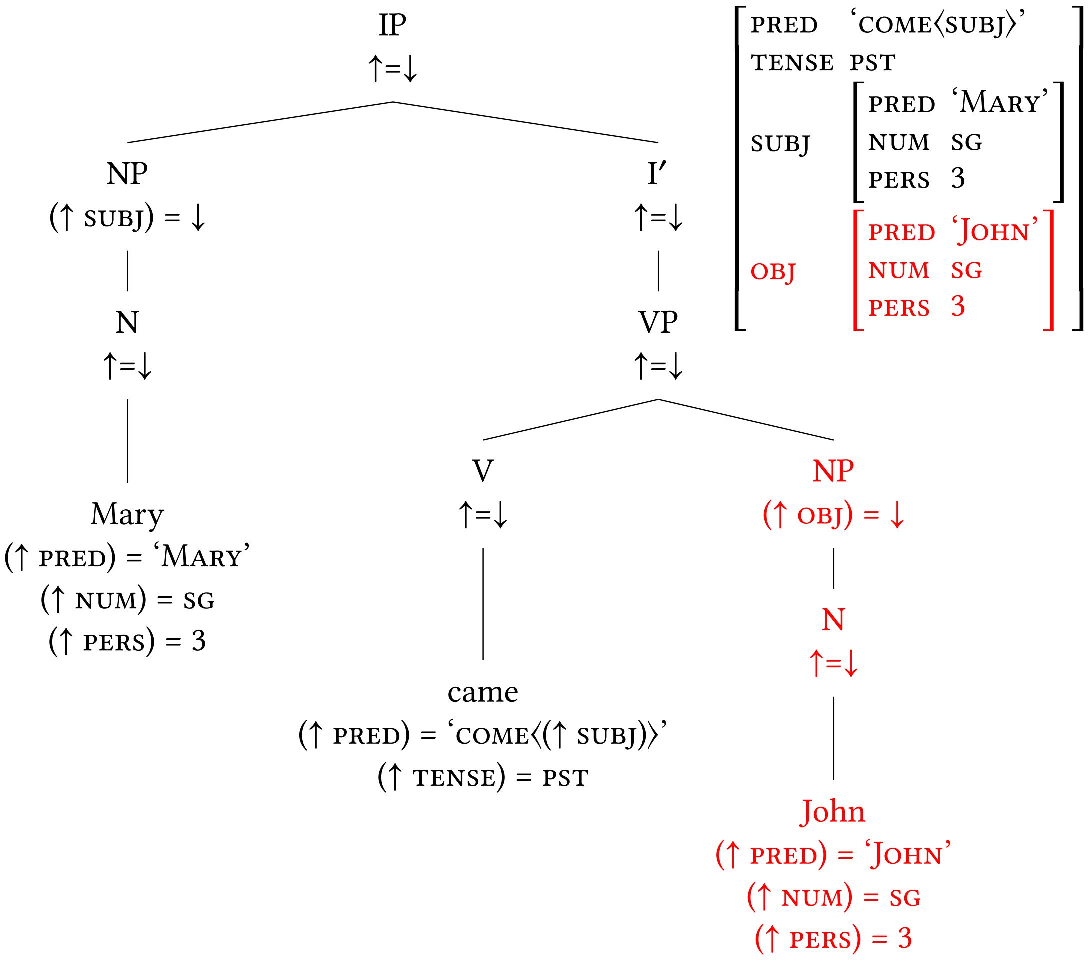
(38) *I saw **there**.

(39) ***The sky** rained.

3.4.3 Coherence

The Coherence condition is the converse of Completeness: no governable functions (i.e. f-structure functions representing grammatical functions such as subj, obj, etc., see Belyaev 2023a [this volume]) may appear in an f-structure without being listed in a pred value. This ensures that no "orphaned" arguments appear in an f-structure, disallowing examples such as (40).

(40) Ill-formed f-structure for **Mary came John*:



Here, again, the c- to f-structure correspondence itself is valid, but the resulting f-structure is incoherent.

The coherence condition only applies to argumental grammatical functions and does not say anything about adjuncts or discourse functions. Where these elements may appear is constrained by a separate condition called Extended Coherence (Bresnan et al. 2016: 63). Extended Coherence requires that the f-structure where adjuncts appear have a PRED value. This ensures that no adjuncts appear in PRED-less f-structures. Discourse / overlay functions (DIS in more recent approaches, TOPIC and FOCUS in earlier work) are required to be linked to a grammatical function in some way: either functionally (via structure sharing) or anaphorically. For more information on the differences between various types of grammatical functions, see Belyaev 2023a [this volume].

3.4.4 Redundancy of PRED?

The description of Completeness and Coherence in this chapter follows the traditional LFG model, which had little to say about semantics; therefore, all valency restrictions had to be modeled at f-structure. Since at least the papers in Dalrymple et al. (1993), Glue Semantics (see Asudeh 2023 [this volume]) has been gaining acceptance in LFG as the model of the syntax-semantics interface. Glue Semantics is resource-sensitive, which automatically ensures both Completeness and Coherence: Completeness, because all premises of the meaning constructor introducing the main predicate have to be saturated; Coherence, because no unused resources have to be left. The role of uniqueness of PRED for ensuring lack of multiple argument introduction / duplicate heads (Section 3.4.1) also follows from Glue semantics due to the fact that any resource can only be consumed once. Therefore, many authors, among others Kuhn (2001), Asudeh & Giorgolo (2012), Asudeh et al. (2014), have argued that PRED features in their original form are no longer necessary in LFG. At least argument lists can, for the most part, be safely dispensed with.[21] Many authors, therefore, continue to use PRED values but only include the name of the functor, not arguments in angled brackets; the remaining role of PRED values is only to provide an index for the f-structure, guaranteeing its uniqueness (that may be relevant for purely syntactic purposes that are not handled in semantics), and to provide information on the lexical content of its head.

---

[21] Non-thematic arguments like *it* in *it rained* might still be relevant insofar as they are not selected by any semantic predicate. However, these arguments may be forced to appear using existential constraining statements.

4 The c- to f-structure mapping

4.1 Annotated c-structure rules

The metalanguage discussed in the preceding section can describe individual f-structures, but cannot, by itself, generate or evaluate natural language expressions. F-descriptions must come from somewhere. The only generative component in LFG is c-structure; therefore, phrase structure rules must be coupled with some mechanism that specifies how the nodes in the c-structure tree are mapped to f-structures – the projection function ϕ. In LFG, this is normally done using ANNOTATED PHRASE STRUCTURE RULES where nodes at the right-hand side are supplemented by f-descriptions that reference the c- to f-structure mapping. This referencing is done by introducing two additional notational symbols:

(41) the current c-structure node: $*$
the immediately dominating c-structure node: $\hat{*}$

These are normally not used directly in LFG grammars; instead, two metavariables $\downarrow$ and $\uparrow$ are used, which signify the following:

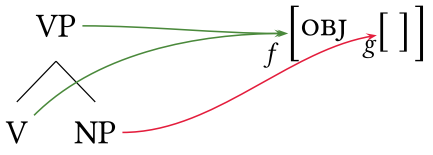
(42) $\downarrow = \phi(*)$ (the f-structure corresponding to the current c-structure node)
$\uparrow = \phi(\hat{*})$ (the f-structure corresponding to the immediately dominating c-structure node)

This notation allows formulating rules of the type:

(43) $$\text{VP} \longrightarrow \underset{\uparrow=\downarrow}{\text{V}} \qquad \underset{(\uparrow\ \text{OBJ})=\downarrow}{\text{NP}}$$

In (43), the annotation for V stands for “this node (V) maps to the same f-structure as the dominating node (VP)”, while the annotation for NP stands for “this node (NP) maps to the OBJ attribute of the f-structure of the dominating node (VP)”. The mapping that this rule defines is illustrated in (44). The nodes VP and V map to the same f-structure labeled as f, while NP maps to the f-structure labeled as g – the direct object of the clause.

(44)



The LFG metalanguage also allows for a notation for the inverse projection ϕ^{-1}, that maps f-structures to the c-structure node(s) that map to them. This mapping is one-to-many and thus, unlike the direct projection, not a function. For example, in (44), $\phi^{-1}(f)$ refers to two nodes: VP and V. The inverse projection is, by design, seldom used and, in fact, rarely required; but it is indispensable for certain construction which place selective requirements on the categorial status of their elements, such as the verb *wax* in examples like *wax poetical*, which is only compatible with an AP complement (the construction is discussed in Pollard & Sag 1994; for an LFG implementation, see Dalrymple et al. 2019: 6.10.3).

4.2 Some consequences of the mapping

4.2.1 Locality

The annotated rule format described in the preceding section is not merely a question of notation; it defines a rather rigid constraint on the way c-structure nodes can be mapped to f-structure. Namely, the mapping is strictly local: it can refer only to the nodes that are involved in a given phrase structure rule. It is not possible to freely traverse the tree and refer to, say, the node dominating the mother node, the child node of the current node, or the root node. LFG assumes that no linguistically meaningful generalizations can be captured using such "long-distance" references. For the majority of cases, this is clearly true, and consequently, there have been no serious attempts to extend the LFG metalanguage in this direction.[22]

However, the strict locality of c-structure to f-structure mapping does create problems for the analysis of certain idiomatic combinations – multi-word expressions (MWEs), as they are called in the literature. Such MWEs often span whole syntactic phrases, and the lexical constraints involved cannot be captured locally. One solution that has been proposed in LFG is to replaced the context-free c-structure by a variant of Tree-Adjoining Grammar (TAG), see Findlay (2017, 2019); this proposal is described in some detail in Findlay 2023 [this volume].

Within the local domain of c-structure rules, the mapping to f-structure is further constrained in that it is only possible to refer to the immediately dominating and current nodes, but not to any of the sister nodes. Unlike the locality constraint, this has been challenged in some LFG literature. For example, Dalrymple

---

[22] As observed by an anonymous reviewer, if ↑ and ↓ are only abbreviations of $\phi(\hat{*})$ and $\phi(*)$, it is possible to also use $\phi(\hat{\hat{*}})$ and so on, making annotated rules potentially non-local. As mentioned above, low-level "designators" like $*$ are not normally used in LFG analyses: grammars are expected to operate only with ↑ and ↓.

(2001: 120), Dalrymple et al. (2019: 222–223), developing the ideas of Nordlinger (1998), extend this notation by defining the metavariables <* and *> for "left sister of the current node" and "right sister of the current node", respectively; the corresponding f-structures are $\phi(<\!*)$ and $\phi(*\!>)$. Similarly, XLE defines the metavariables LS* and RS* for the same concepts.

The status of such innovations in the general LFG framework is uncertain. On the one hand, the analyses that introduce such notational conventions make convincing cases that they are necessary for analyzing certain phenomena, or at least vastly simplify such analyses. On the other hand, it is telling – and usually implied – that their use is somewhat exceptional and limited to a handful of specific phenomena. The fact that phrase structure nodes and lexical items do not refer to the information contributed by their left or right sisters in the vast majority of cases seems to be an important cross-linguistic generalization – one that is lost if this possibility is introduced in the formalism. If such formal devices are necessary, additional theoretical stipulations should supposedly constrain their use, but in practice, this possibility is almost never explored.

4.2.2 Monotonicity

As Bresnan et al. (2016: 73ff.) observe, the limitations of the metalanguage described above (even if additional designations like <* and *> are included) lead to several important consequences for grammatical architecture. Specifically, the locality of the c- to f-structure mapping leads to the monotonicity of information flow in the syntax: the f-structure of a larger fragment is always more specific than the f-structure of a smaller fragment.

Let us first consider what "being more specific" means for an f-structure. By definition, f-structures are sets of feature-value pairs. It is clear, then, that g in (45) is more specific than f, as it has exactly the same features and values as f and one additional feature.

(45)
$$ {}_{f}\begin{bmatrix} \textsc{a} & \textsc{x} \\ \textsc{b} & \textsc{y} \end{bmatrix} \qquad {}_{g}\begin{bmatrix} \textsc{a} & \textsc{x} \\ \textsc{b} & \textsc{y} \\ \textsc{c} & \textsc{z} \end{bmatrix} $$

Now consider a more complex case. In (46), f and g have the same features, but intuitively, g is more specific than f because the f-structure value of A in g is more specific than the value of A in f.

(46)
$$ {}_{f}\begin{bmatrix} \textsc{a} & \begin{bmatrix} \textsc{c} & \textsc{z} \end{bmatrix} \\ \textsc{b} & \textsc{y} \end{bmatrix} \qquad {}_{g}\begin{bmatrix} \textsc{a} & \begin{bmatrix} \textsc{c} & \textsc{z} \\ \textsc{d} & \textsc{m} \end{bmatrix} \\ \textsc{b} & \textsc{y} \end{bmatrix} $$

Thus, specificity can be defined recursively: g is at least as specific as f if for every attribute a in f, $(g\,a) = (f\,a)$ or $(g\,a)$ is at least as specific as $(f\,a)$ (Bresnan et al. 2016: 74). This relation is essentially equivalent to subsumption (Dalrymple et al. 2019: 240), and can be notated accordingly: $g \sqsupseteq f$ or $f \sqsubseteq g$ means that g is at least as specific as f, or f subsumes g.

Now recall that every f-description can in principle correspond to infinitely many f-structures that satisfy it. Let us, then, define $\phi(d)$ to be the smallest f-structure ϕ that satisfies d; this gives the mapping ϕ from the set of functional descriptions D to the set of f-structures F. This mapping is MONOTONIC: the larger the f-description d, the more specific the corresponding f-structure f. In other words, $\phi : D \rightarrow F$ has the property that if $d \subseteq d'$ and both d and d' have f-structure solutions, then $\phi(d) \sqsubseteq \phi(d')$.

This property of the mapping between f-descriptions and the corresponding f-structures follows from the nature of the f-structure equations: New equations can only specify additional information about the f-structure or check existing information; they cannot, as it were, "delete" existing feature values or otherwise make the structure less specific.

4.2.3 Fragmentability

Another feature of syntax in the LFG architecture that follows, in part, from monotonicity is FRAGMENTABILITY of language (Bresnan et al. 2016: 79–82). Recall that f-descriptions in annotated c-structure rules can only refer to the f-structures of the nodes involved in the rule (the node at the left side of the rule – the dominating node – and its daughters). This means that, the larger the tree, the longer its f-description; due to monotonicity, the f-structure of a larger tree fragment is, then, always more specific than the f-structure of any of its subtrees. Therefore, a valid f-structure can be constructed for any tree fragment dominating an arbitrary sequence of terminal nodes (a substring of a complete sentence), and this f-structure will not be overridden by any additional information that is contained in the complete sentence (unless it renders the f-structure ill-formed, in which case the sentence is ungrammatical).

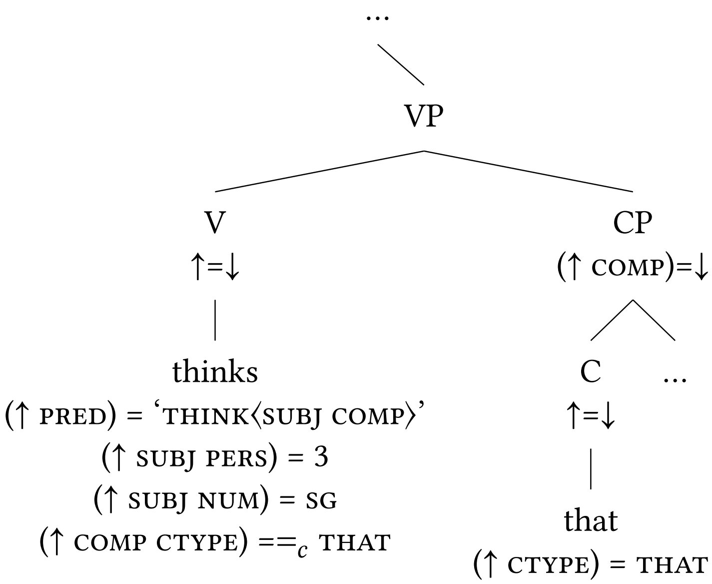
Note that this property of the c- to f-structure correspondence does not depend on whether the tree fragment corresponds to a sequence of terminal nodes in a complete sentence; it may even not be a constituent. Any sentence fragment is "self-contained" in the sense that its content is not modified by additional nodes in the tree.[23] Consider the c- and f-structures in (47). Here, the combina-

---

[23] Note, however, that a tree fragment may be ambiguous between two or more interpretations; this ambiguity may be resolved by further material in the tree.

tion "thinks that", which is not even a constituent in a fully formed sentence, contributes the argument structure of the matrix clause, the person and number features of the subject, and the complement type. It can be extended both upwards (with the addition of a subject) and downwards (with the addition of a complement clause), with f-structure information increasing monotonically in both cases.

(47)



$$\left[\begin{array}{ll} \text{PRED} & \text{`THINK}\langle\text{SUBJ COMP}\rangle\text{'} \\ \text{TENSE} & \text{PRS} \\ \text{SUBJ} & \left[\begin{array}{ll} \text{PERS} & 3 \\ \text{NUM} & \text{SG} \end{array}\right] \\ \text{COMP} & \left[\begin{array}{ll} \text{CTYPE} & \text{THAT} \end{array}\right] \end{array}\right]$$

Within the non-transformational architecture of LFG, the properties of monotonicity and fragmentability may seem trivial. But this is not so for transformational frameworks, where elements may be extracted from within constituents, thus violating the principle of fragmentability: sentence fragments may become modified during derivation, losing some of the information they initially contain. Fragmentability captures the fact that sentence fragments frequently occur in natural discourse and are parsed without effort by native speakers.

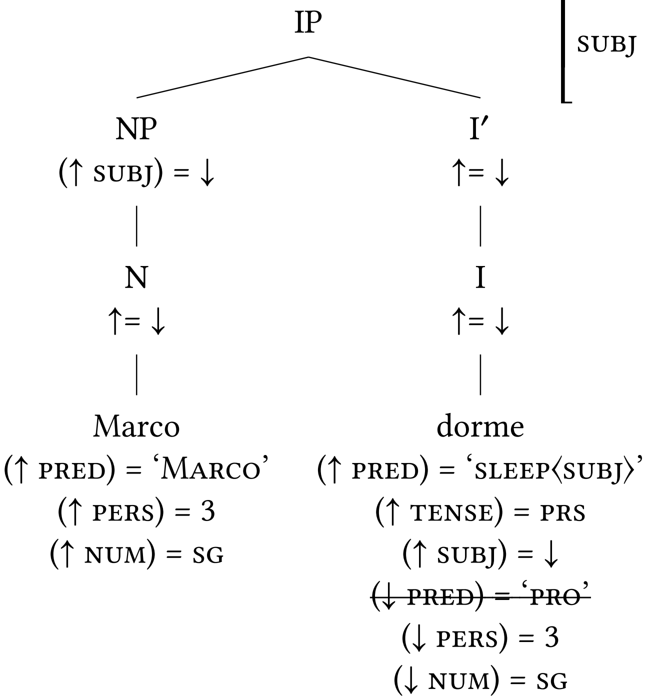
4.2.4 Non-configurationality

Another consequence of the mapping between c- and f-structure is NON-CONFIGURATIONALITY of language. This property means that information in the f-structure does not necessarily correspond to specific positions in the tree. Thus, features of a single constituent may be "collected" from several nodes or assigned several times in different positions. This is usually related to the interaction between syntactic and morphological encoding.

For example, in Italian, a pro-drop language, a third person singular verb form might be defined as in (48) – with the optional assignment of a pred feature to the subject (the standard analysis of pro-drop in LFG). If there is a subject NP in Spec,IP, this annotation is not selected, as it would lead to a pred conflict. If, however, there is no overt subject, this annotation *must* be used, because otherwise the resulting f-structure would violate Coherence: subj would have no pred value. Both options can be seen in (49) and (50).

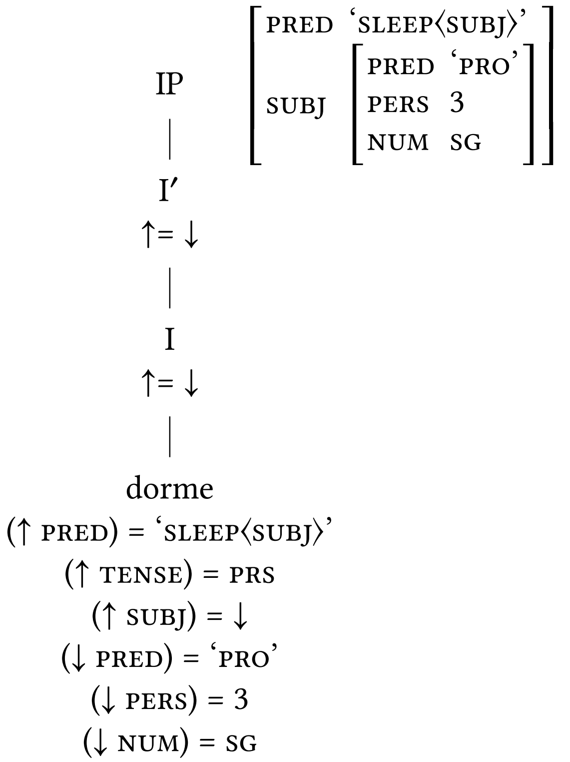
(48) *dorme* V (↑ pred) = ‘sleep⟨subj⟩’
(↑ tense) = prs
(↑ subj) = ↓
((↓ pred) = ‘pro’)
(↓ pers) = 3
(↓ num) = sg

(49)



$$\begin{bmatrix} \textsc{pred} & \text{‘}\textsc{sleep}\langle\textsc{subj}\rangle\text{’} \\ \textsc{subj} & \begin{bmatrix} \textsc{pred} & \text{‘Marco’} \\ \textsc{pers} & 3 \\ \textsc{num} & \textsc{sg} \end{bmatrix} \end{bmatrix}$$

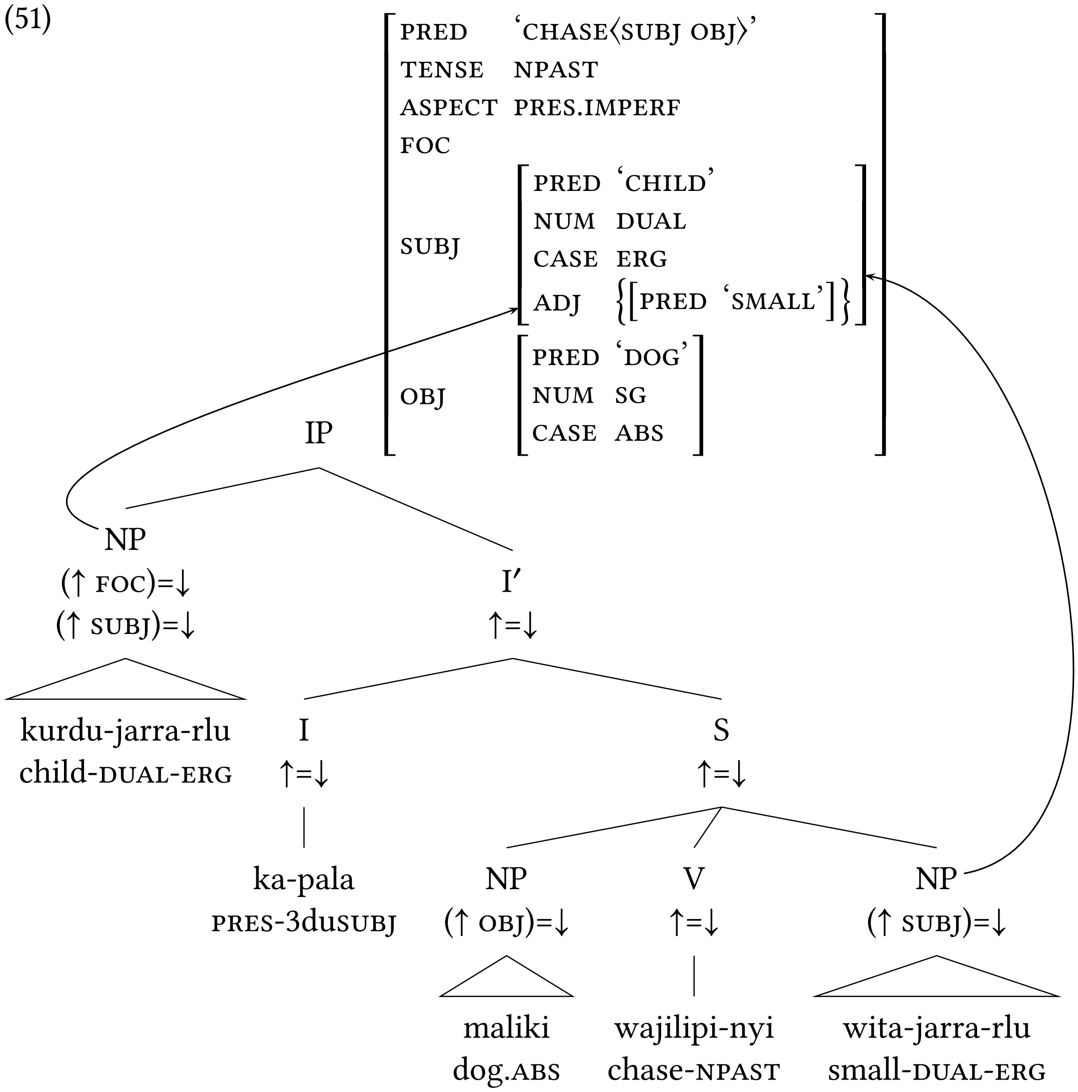
(50)



Thus, in Italian, the PERS and NUM features of the subject are always assigned at the I node, and they may also be assigned at the N head, if it is present. The PRED feature, in contrast, can be supplied either at the I node (if no overt head is present) or at the N node. This means that even in languages with relatively rigid word order and clausal phrase structure such as Italian (and English, although examples are less illustrative; see Bresnan et al. 2016), there is no universal mapping between c-structure positions and f-structure features.

"Non-configurationality" is usually understood in a more narrow sense, describing languages with no evidence for a hierarchical clause structure, such as Warlpiri (Hale 1983, Austin & Bresnan 1996). In (51), from Austin & Bresnan (1996: 229), two NPs, one having a head and the other only specifying an adjunct, map to the same f-structure function SUBJ. Thus information that is split at f-structure is collected together at f-structure.

(51)



These, of course, are only more radical manifestations of the phenomenon illustrated above. In Italian, the features of certain grammatical functions can be defined in different positions, but these positions, at least, are generally fixed, such that the overt subject, if present, occupies the Spec,IP postion, the full NP direct object occupies Comp,VP, and the verb provides the agreement and PRED features of the subject. In radically non-configurational languages, in contrast, there is no association between c-structure positions and grammatical functions at all: any NP daughter of the S node can be mapped to any grammatical function, and any category, not only the verb, can function as the predicate of the clause. Non-configurational syntax and its challenges are described in more detail in Andrews 2023 [this volume].

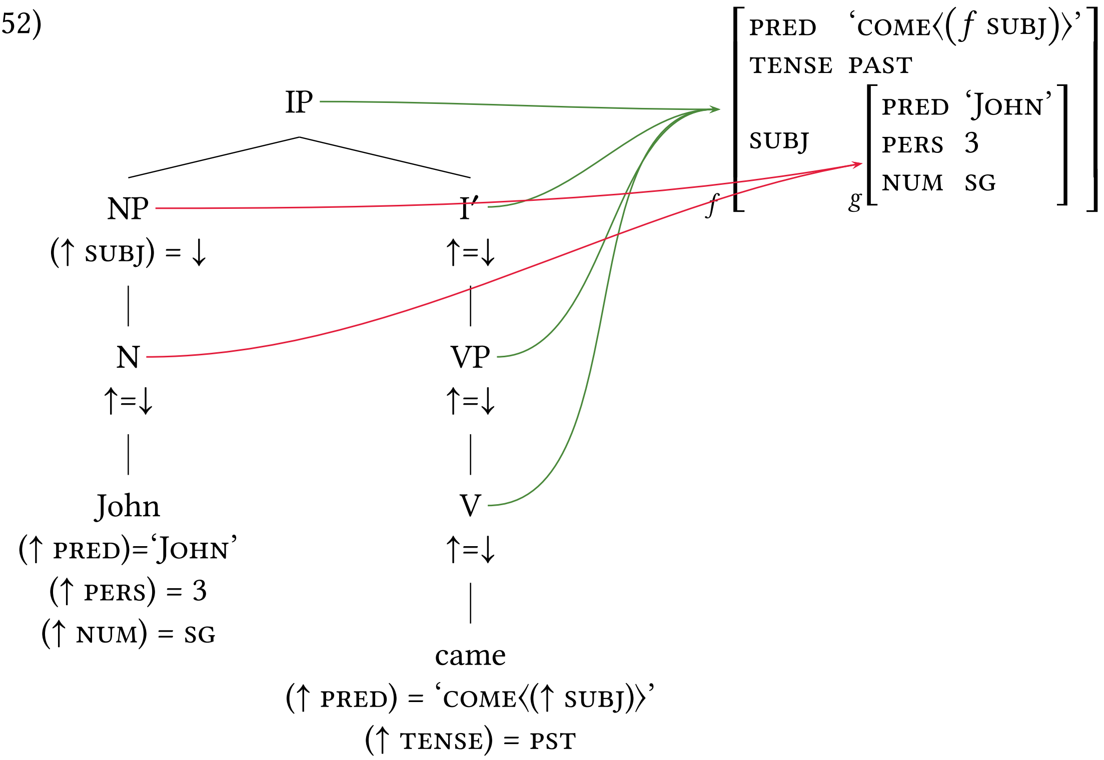
4.2.5 Equality, unification, and non-compositionality

As seen in Belyaev 2023b [this volume] and elsewhere above, statements specifying the equality of one f-structure to another – most prominently, ↑=↓ – play a key role in the LFG c- to f-structure mapping and syntactic analyses. These kinds of statements allow mapping more than one c-structure node to the same f-structure and permit structure sharing and the checking of compatibility of f-structure features. Equality in LFG is very similar in its effects to UNIFICATION found in many other non-transformational formalisms – such that LFG itself is included in the class of UNIFICATION-BASED GRAMMARS in Shieber (1986).

However, as Kaplan (1989: 8ff.) points out, there is a crucial difference between LFG grammars and most unification-based frameworks (GPSG, HPSG, etc.): namely, the distinction between linguistic representations and the *descriptions* of said representations. The clearest case of this distinction are constraining equations, which impose additional constraints on admissible f-structures which, if not violated, do not show up anywhere in the f-structure. Defining equations behave similarly: the same feature may be defined several times in the tree, but the f-structure will contain no trace of its "pedigree": only the resulting feature value will be included.

Another way in which LFG grammars are different from unification grammars is their NON-COMPOSITIONALITY. Even if a c-structure node is annotated with the "unificational" statement ↑=↓, the f-structure it maps to in the complete sentence may contain additional values that are introduced higher in the tree. Thus, in (52) the VP node maps to an f-structure that includes a SUBJ feature that is not introduced anywhere in the VP subtree.

(52)



In a single-tier unificational model like GPSG or HPSG, where the counterpart to f-structure information directly occupies phrase structure nodes together with categorial information, the flow of information would be different: The content of a dominating node would be a function of the content of its children, hence, information contained in VP would be a subset of the information contained in IP. In LFG, as discussed above, *f-descriptions* do indeed increase monotonically, and a *fragment* associated with a node like VP does indeed contain a subset of the information contained in a larger constituent. However, in the full structure, this is not the case: every node mapped to a given f-structure maps to *all* the information contained in this f-structure, even to the information that is introduced only higher above.

4.3 Regularities in the c- to f-structure correspondence

In Section 2.1, I briefly described X′ theory in the way that it is used in most LFG work. However, given that c-structure plays a limited role in LFG compared to the frameworks for which X′ theory was originally devised, in this form it amounts to little more than a system for labelling nodes. In order to give significance to the notion of being a head, a specifier, a complement, or an adjunct, X′ theory must be augmented by f-structure mapping principles.[24] A set of such principles is broadly accepted in LFG, although some details vary. For a more detailed exposition of X′ theory, see Dalrymple et al. (2019), Bresnan et al. (2016).

4.3.1 Heads

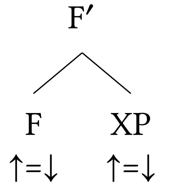
Headedness is a key concept of X′ theory; all projecting nodes, i.e. preterminal nodes (X^0) and intermediate projections (X′), are heads. We saw in all examples above that all projections of a single X′ category are mapped to the same f-structure, and this is for good reason: X-bar theory aims to model endocentricity, and so heads map to a "matrix" f-structure while specifiers, adjuncts, and complements (with the exception of functional categories) map to its dependents. Thus, heads are always annotated as ↑=↓. This principle was first proposed in Bresnan (1982a) and further developed in Zaenen (1983), where it is called the Head Convention. Additionally, XP is also annotated as ↑=↓ when other categories are adjoined to it.

This principle of head annotation allows us to formalize endocentricity as the requirement that every lexical category have a head (Bresnan et al. 2016), or, more correctly, an extended head (see below), because some phrases can have a lexically instantiated functional head but no lexically instantiated lexical head.

4.3.2 Complements

Complements are annotated differently depending on whether they are attached to functional or lexical heads. In essence, functional projections are little more than extensions of lexical projections, and generally map to the same f-structure: for example, CP, IP and VP map to the same clausal structure, while DP and NP map to the same nominal structure. Thus, complements of functional projections are f-structure co-heads, annotated as ↑=↓ (53). The heads of functional categories are known as extended heads of lexical categories; a formal definition of extended head can be found in Bresnan et al. (2016: 136).

(53)

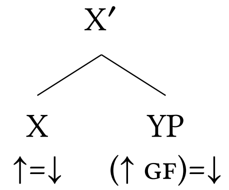


---

[24] It is by no means implied that these principles dictate the *only* annotations that can be associated with a given node: additional annotations are not only possible, but sometimes even required to produce a valid f-structure (for example, dis must usually be associated with a grammatical function).

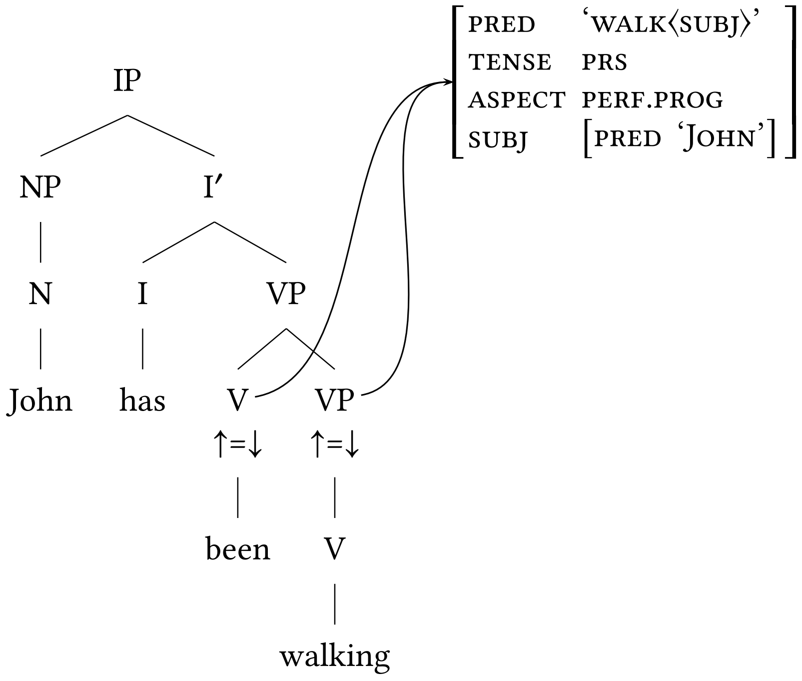
Complements of lexical projections are assigned to various functions of their heads' f-structures. Most typically these are, more specifically, grammatical functions, i.e. those functions that are governed by predicates and have no additional discourse significance (54); the label gf stands for "grammatical function" and includes such notions as subject (subj), direct object (obj), secondary object (obj$_\theta$) and oblique (obl$_\theta$). In Bresnan et al. (2016), this is formulated as a strict requirement that the complement may be any grammatical function except subj (which, in their model, is both a grammatical and a discourse function, see Belyaev 2023a [this volume]). However, this restricted understanding of lexical complements is not universally accepted. For example, Laczkó (2014) analyzes postverbal subjects in Hungarian as occupying the same position as postverbal direct objects, i.e. VP complements.

(54)



Complements of lexical heads may also behave in the same way as complements of functional projections, i.e. be annotated as ↑=↓. This possibility should be allowed for to handle cases where the same f-structure extends over more than two projections, e.g. in certain English auxiliary constructions (55), see Bresnan et al. (2016: 111).

(55)



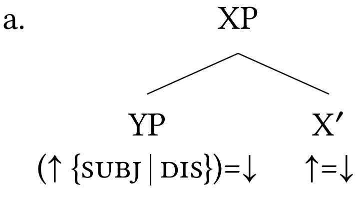
The higher VP in this case thus operates as a kind of intermediate functional projection. An alternative solution would be to introduce an additional functional projection for English, but this does not seem justified as the forms used in these positions are identical to V complements of simpler auxiliary constructions. At the same time, the X′ model itself is obviously too simplistic to describe the full system of constraints on the English system of verbal periphrasis. This requires reference to morphological features of c-structure nodes; see Forst & King 2023: Section 2.2 [this volume] for a discussion of complex c-structure categories which can encode such information.

4.3.3 Specifiers

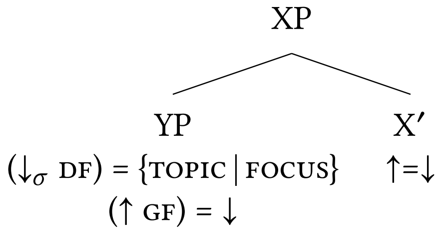
Specifiers are similar to complements in that they are mapped to f-structure positions in the f-structure of their heads. In the literature on LFG, there are two views on exactly what functions specifiers can be mapped to. The traditional approach as described in Dalrymple (2001), Bresnan et al. (2016) is that specifiers map to DISCOURSE FUNCTIONS (DF), which consist of TOPIC, FOCUS and SUBJ (which is unique in being simultaneously a grammatical function and a discourse function). However, a trend in much LFG work (King 1997, Butt & King 1997, Dalrymple & Nikolaeva 2011) is to eliminate information structure functions from syntax, instead relegating them to a separate projection, i-structure. Thus Dalrymple et al. (2019) instead propose that specifiers must be *either* syntactically prominent or prominent in information-structure terms. Syntactic prominence means that the f-structure of the specifier is either the subject, or it bears the overlay function DIS (which replaces the earlier TOPIC and FOCUS and handles long-distance dependencies). Discourse prominence means that the specifier occupies the discourse functions TOPIC or FOCUS at i-structure.[25] This question is discussed in more detail in Kaplan 2023 [this volume].

According to this approach, then, specifiers can be given annotations as in either (56a) or (56b):

(56) a.



b.



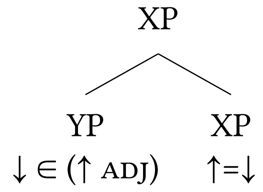
---

[25] In contemporary LFG, discourse functions are usually modeled not in f-structure but in a separate projection: see Kaplan 2023 [this volume] for more information. The notation in (56) follows the model of information structure in Dalrymple & Nikolaeva (2011).

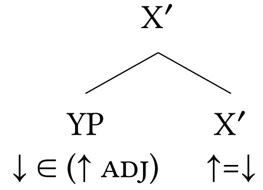
4.3.4 Adjunction

Unlike specifiers and complements, adjuncts may be freely iterated.[26] Naturally, then, they tend to be associated with the only grammatical function that is always set-valued,[27] ADJ (or XADJ), see (57). As new adjuncts are added to the tree, they get added to the adjunct set, thereby not violating uniqueness.

(57) a.



b.



C-structure adjuncts do not always map to f-structure adjuncts, however. Extraposed focused or topicalized material is often adjoined at c-structure, especially at XP level; it is then associated with an information structure function like TOPIC or FOCUS, a grammatical function, and the overlay function DIS.

Some analyses also use adjunction as the main mechanism of introducing grammatical functions, not only adjuncts, into the f-structure, without them having any special information structure role. A prominent example is the analysis of Japanese and Korean in Sells (1994, 1995). Building on the ideas of Fukui (1986), Sells proposes that the maximal projection in Japanese and Korean is X′, and that the main sentence-building operation is the adjunction of verbal arguments and adjuncts to V′, and nominal dependents to N′. Adjunction of this sort can be described in LFG notation by rules such as (58), where GF is any grammatical function. Unlike flat structures of non-configurational languages, the resulting structures like (59), from Korean, are binary-branching, but the use of unrestricted adjunction of this kind ensures that the order of constituents is free.

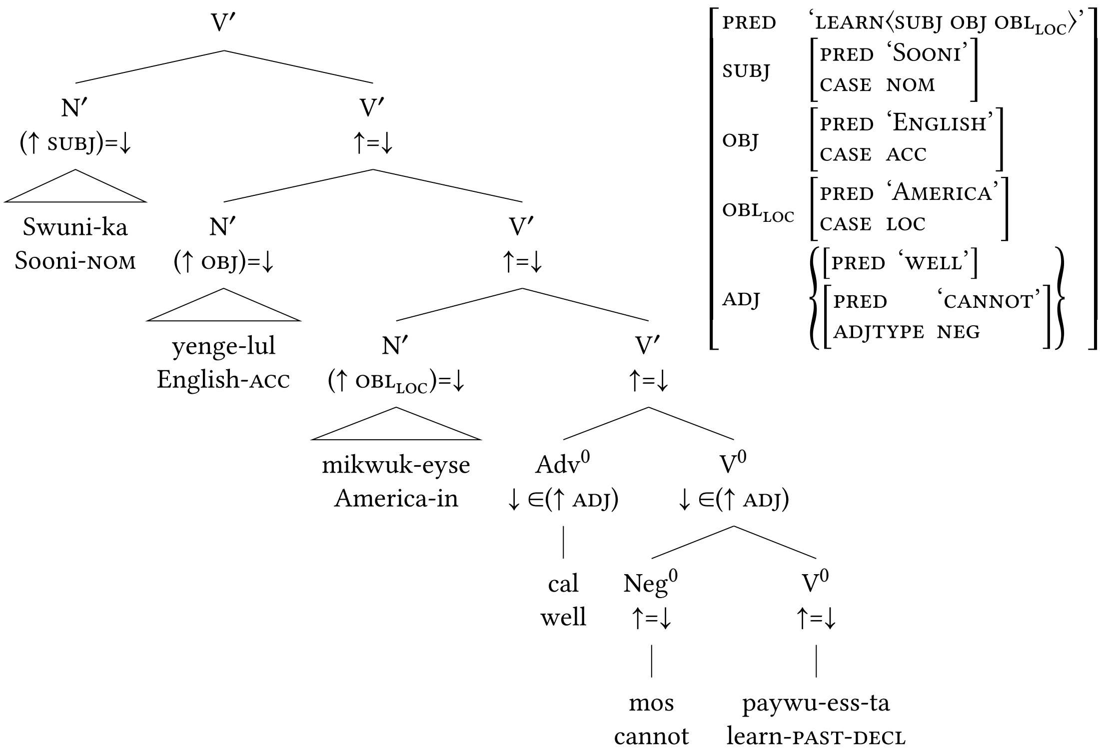
---

[26] As noted in Section 2.1, some versions of LFG X′ theory allow multiple complements or specifiers. However, this is not the same as adjunct iterations, because, if multiple complements or specifiers are used in a grammar, these receive different annotations, thereby not causing a conflict. In contrast, multiple application of the same adjunct rule will lead to a uniqueness violation if it selects the same grammatical function.

[27] Due to the possibility of coordination, all grammatical functions can be set-valued. However, this requires the use of a special syntactic configuration at c-structure, whereas adjuncts are set-valued "by definition".

(58) $$\begin{array}{llll} \text{X}' & \longrightarrow & \text{Y}' & \text{X}' \\ & & (\uparrow \textsc{gf}){=}\downarrow & \uparrow{=}\downarrow \end{array}$$ (Sells 1994: 354)

(59)



‘Sooni did not learn English well in America.’ (Sells 1994: 355)

4.3.5 The category S

As discussed above, the category S, being by definition exocentric, does not have a head in the X′-theoretic sense. This does not mean, however, that it has no head in the sense of c- to f-structure mapping, i.e. no node that is annotated as ↑=↓. In fact, S usually includes at least one such node that represents the predicate; for example, in (7), representing the clause structure of Tagalog, the predicative XP is annotated as ↑=↓, which causes the f-structure of the clause to be unified with the f-structure of the predicate, regardless of what its c-structure category may be.[28] Moreover, unlike X′-theoretic structures, a nonconfigurational S node can have more than one head: for example, a V node representing the lexical verb

---

[28] The actual developed analysis can be somewhat more complex, as there are several views on nonverbal predication in LFG, and the (non-)identity of its structure to that of verbal predications.

and an Aux node representing an auxiliary that contributes tense, agreement and other grammatical information.

It is remarkable that S is the only systematic exception from the X′ schema[29] that is admitted in mainstream LFG, at least in theory. While the use of S for both nonconfigurational and "partially non-endocentric" languages like Tagalog or Irish is universally accepted as a valid and theoretically solid decision, there has been no discussion of exocentric NPs or other categories in the literature. Whether this represents a lack of empirical evidence for such structures in languages of the world, or is simply the result of a lack of focus and a kind of predetermined conviction, is not clear.

4.3.6 Optionality of c-structure positions

Now that X′ theory is supplemented by f-structure well-formedness constraints and annotation principles, we can introduce an additional feature of LFG c-structures: ECONOMY OF EXPRESSION, which amounts to optionality of most nodes, because the relevant grammatical constraints are for the most part captured at f-structure. This broad principle is formulated in the most radical way in Bresnan et al. (2016: 90), who state that *all* nodes (including nonbranching intermediate X′ projection nodes, heads, complements and specifiers) are optional:

(60) ECONOMY OF EXPRESSION:
All syntactic phrase structure nodes are optional and are not used unless required by independent principles (completeness, coherence, semantic expressivity). (Bresnan et al. 2016: 90)

Note that this is a *theoretical* principle whose *formal* implementation is a separate issue, partly discussed in Section 5.2.1. For example, in the standard phrase stucture rule formalism, the notions of complement and specifier crucially depend on the presence of intermediate X′ nodes, even if these are redundant in the sense of unary branching. Thus, as Dalrymple et al. (2015) observe in their detailed discussion of economy of expression, this principle leads to a proliferation of rules, such as in (61).

(61) X′ ELISION (Dalrymple et al. 2015: 384)
If an LFG grammar G_G contains an annotated rule of the form

---

[29] It is also the only consistent exception from endocentricity, although, as an anonymous reviewer observes, the X′ theory elaborated in Bresnan et al. (2016) only requires endocentricity for lexical, not functional, projections (p. 137), thereby allowing, among other things, the standard treatment of mixed categories (Bresnan et al. 2016: 311ff.).

$$\begin{array}{cccccc} \mathrm{XP} & \longrightarrow & \alpha & \mathrm{X}' & \beta \\ & & & \uparrow=\downarrow & \end{array}$$

it also contains a rule of the form

$$\begin{array}{cccccc} \mathrm{XP} & \longrightarrow & \alpha & \mathrm{X} & \beta \\ & & & \uparrow=\downarrow & \end{array}$$

In general, Dalrymple et al. (2015) conclude that economy of expression is plausible as an informal principle that emerges through the interaction of other, more basic principles, and that grammars, in general, tend to obey; but it is not plausible as a formal principle to be incorporated into the theory of grammar, because it not only introduces additional complexity into the framework, but also fails to account for cases of genuine non-optionality (such as, for example, in configurational languages where certain nodes are obligatory regardless of independent principles).

Still, the degree of optionality commonly allowed in LFG grammars is rather large and certainly greater than what is assumed by most other phrase-structure-based frameworks. I will now go through each of the X′ theoretic categories and show why they can be optional (except adjuncts, because these are optional by definition, by virtue of the rules that introduce them).

4.3.6.1 Complements and specifiers

Complements and specifiers not only can but must, as a rule, be optional because the c-structure does not contain any valency information and there is no way to verify at c-structure if, for example, the verb has a direct object. Thus, the rule in (43), repeated in (62), will hold for all English sentences, but the NP complement will only be licensed in transitive clauses.

(62) $$\mathrm{VP} \longrightarrow \begin{array}{c} \mathrm{V} \\ \uparrow=\downarrow \end{array} \left(\begin{array}{c} \mathrm{NP} \\ (\uparrow \textsc{obj})=\downarrow \end{array} \right)$$

If the verb is transitive (i.e. its PRED feature has OBJ in the list of arguments), omitting the complement will result in a violation of Completeness (unless the object is introduced in another position). By contrast, if the verb is intransitive, introducing the object here will lead to a Coherence violation, because the grammatical function OBJ will not be selected by any argument.

Optionality of complement and specifier positions, and c-structure positions where arguments are introduced in general, is also required because the material that they “canonically” contain may be displaced elsewhere, for example, to a position designated for wh-movement or information structure function. In this case, only one position must be filled, otherwise conflict of PRED values will lead to a Uniqueness violation. Thus (43) may produce a single V node even in a transitive clause, provided that the direct object is introduced in another position (such as wh-movement *Whom did you see?* or topicalization *John, I saw.*).

4.3.6.2 Heads

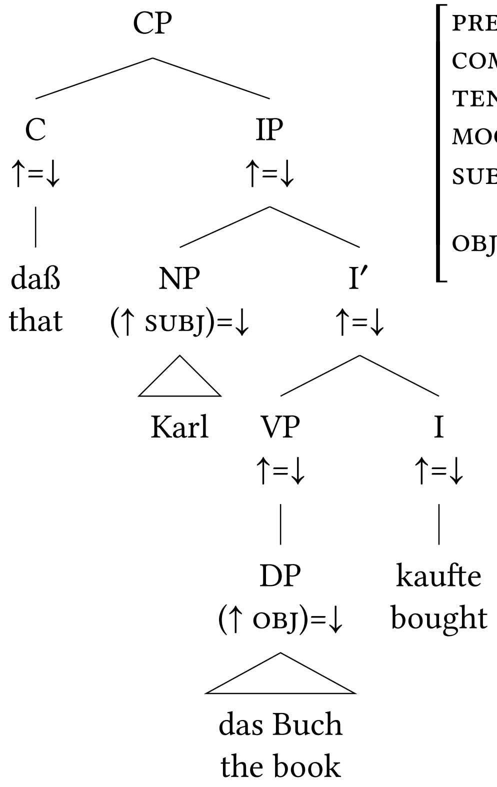
Similarly, c-structure heads can be optional in LFG because of Completeness and Coherence. PRED features are almost always[30] introduced by head nodes, i.e. nodes carrying the unificational annotation ↑=↓. Therefore, a structure lacking a head (without its PRED features introduced elsewhere) will be PRED-less and will not be able to include any grammatical functions, because that would violate Coherence.

Headless XPs are quite widespread at clause level; their role is to account for variation in head positions in configurational languages. For example, in English lexical verbs always appear in V, but the I head can be filled or not depending on whether the verb form is periphrastic or synthetic. In German and other V2 languages, the distribution is more complex: the V head is only occupied if the verb form is periphrastic, and the auxiliary, or the finite verb in synthetic forms, stands in the I node in subordinate clauses (63) and in the C node in main clauses (64). Examples are from Bresnan et al. (2016: 448–450).

---

[30] It is technically possible to introduce a PRED feature in a different position. For example, the annotation of a complement or specifier might include an additional annotation like (↑ OBJ PRED)='PRO'. I am not aware of any analyses utilizing this possibility; "external" PRED assignment normally only happens in verbal heads assigning PRED features to pro-dropped subjects and in similar such structures. However, Mary Dalrymple (p.c.) points out that such annotations seem to be required in asyndetic relative clauses like *The man John saw*, where the pronominal OBJ in the relative clause has to be introduced by a phrase structure rule since there is no lexical material that could plausibly contribute its content.

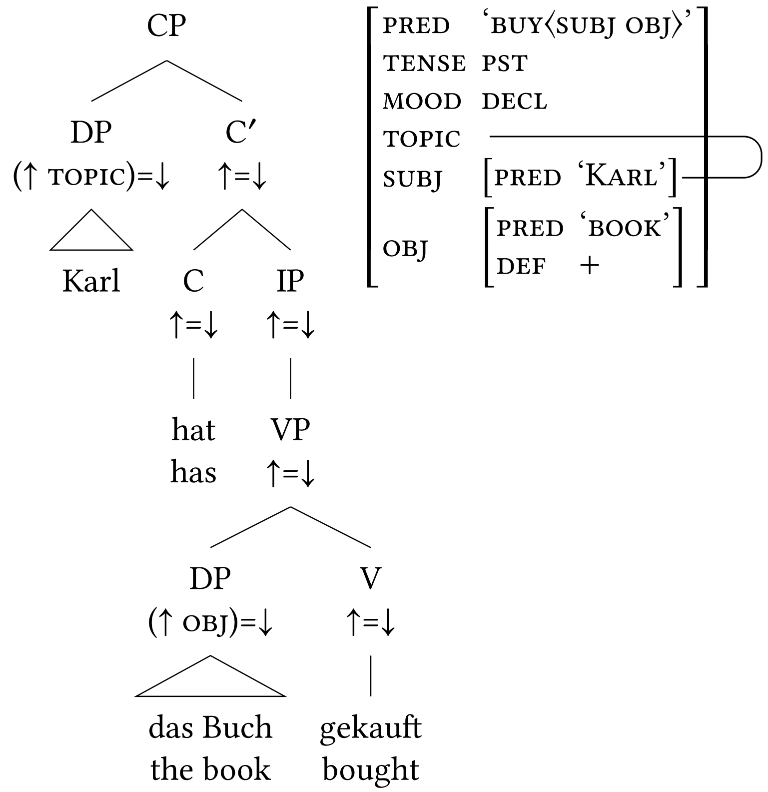
(63)



$$\left[\begin{array}{ll} \textsc{pred} & \text{‘buy}\langle\textsc{subj obj}\rangle\text{’} \\ \textsc{comptype} & \textsc{that} \\ \textsc{tense} & \textsc{past} \\ \textsc{mood} & \textsc{decl} \\ \textsc{subj} & \left[\begin{array}{ll} \textsc{pred} & \text{‘}\textsc{Karl}\text{’} \end{array}\right] \\ \textsc{obj} & \left[\begin{array}{ll} \textsc{pred} & \text{‘}\textsc{book}\text{’} \\ \textsc{def} & + \end{array}\right] \end{array}\right]$$

‘that Karl bought the book’

(64)



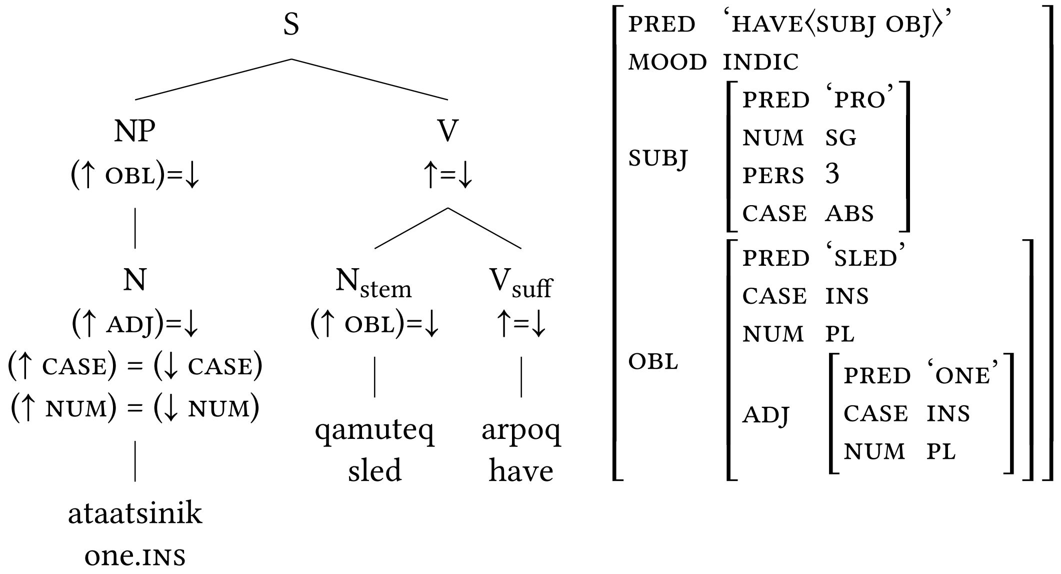
‘Karl has bought the book.’

This analysis corresponds quite closely to the standard view of German word order in GB / Minimalism, such as Vikner (1995). The key difference is that there is no verb movement in LFG; verbs and auxiliaries are always “base-generated” in C, I, or V depending on clause types and the verb form. The correct word order is ensured by feature licensing; multiple occurences of a verb form or verbless sentences are excluded at f-structure through Uniqueness and Coherence.

Another type of headless XP occurs in languages which allow freely discontinuous constituents, like the example from Warlpiri in (51) above. Non-configurational languages like Warlpiri allow freely assigning any grammatical function to Spec,IP (which is additionally interpreted as a focus) and to any NP children of S. Hence, two or more NPs might be mapped to the same grammatical function; if there is no PRED clash or case mismatch, the resulting sentences will be grammatical and these multiple NPs will be mapped to the same f-structure. For more information on non-configurational languages, see Andrews 2023 [this volume].

Finally, headless constituents appear in certain instances of incorporation, such as in West Greenlandic (65), where an incorporated noun head can have non-incorporated dependents (here, agreeing in instrumental case with the incorporated argument).

(65) Greenlandic (Bresnan et al. 2016: 446)



‘I have one sled.’

5 Extensions of the core architecture

The core architecture of LFG has remained remarkably stable since the framework was first introduced in Bresnan (1982a); the only major innovations are the introduction of various additional projections, briefly described in Belyaev 2023b: Section 5 [this volume], and functional uncertainty (earlier LFG used traces to model long-distance dependencies). Nevertheless, there have been proposals to alter and extend the core architecture, mainly from three directions: to adopt a view of c-structure different from context-free grammar; to introduce construction-based approaches to LFG using templates; to eliminate PRED values, fully relegating their work to semantics. None of these approaches have been adopted by mainstream LFG practitioners, with the exception of templates, which have gained some acceptance. Nevertheless, these proposals may represent venues in which LFG could develop in the future.

5.1 Constructions and LFG: Templates

In many ways, LFG is close in spirit to other non-transformational frameworks such as HPSG (Pollard & Sag 1994) or various versions of construction grammar (see Hoffmann & Trousdale 2013). All these frameworks, unlike mainstream generative grammar, are not committed to cross-linguistically universal structures and instead define syntactic rules on a language-by-language basis. However, LFG is crucially different from these other approaches in lacking any concept comparable to the notion of construction. The basic building blocks of syntax are phrase structure rules and lexical entries (which formally are a subtype of phrase structure rules); there is a general set of principles governing the mapping from phrase structure positions to f-structure. It is, of course, possible to define separate phrase structure rules and lexical entries to handle specific phenomena and constructions, but these will not be formally related to other rules – there is no hierarchy of phrase structure rules that would allow defining, for example, an exceptional subtype of a specifier rule. In general, most theoretical principles in LFG (such as the principles of c- to f-structure mapping described above) are formulated in such a way as to define a structure that obtains by default, but which can be overriden in individual languages. This is at odds with the main tenets of construction-based approaches, where no general or universal principles or structures are usually assumed, and each construction hierarchy is language-specific.

Furthermore, while it is possible to define rules that are specific to individual constructions or lexical items, it is impossible to directly define a construction that spans more than the scope of one phrase structure rule (e.g., a specific combination of a specifier, head and complement). Of course, the same effect may be achieved by using combinations of defining and constraining equations, as in analyses of idioms; for an example, see Falk (2001: 77). But such analyses do not treat idioms or constructions as theoretical objects in their own right; the collocation is only enforced by the combination of equations acting at different levels.

These “limitations” related to the c-structure to f-structure correspondence are not necessarily disadvantages of the LFG system: they are the result of a conscious design decision that influences the way LFG analyses are structured; in most cases, it is possible to account for “construction-based” phenomena in LFG, but the description will be different than in Construction Grammar and related frameworks. However, there are certainly genuine cases of construction-specific phenomena, such as so-called multi-word expressions (MWEs); these are difficult to describe in standard LFG. A possible, but radical, solution is the replacement of context-free grammar by Tree-Adjoining Grammar (TAG) at c-structure, as described in Findlay 2023 [this volume].

Another reason why some counterpart to the notion of construction might be useful in LFG is that f-structure equations associated with rules and lexical items are not generalized in any way. Thus, nouns may have annotations such as (↑ NUM)=SG and (↑ NUM)=PL, and verbs, (↑ TENSE)=PST, but nothing in the grammar *requires* nouns and verbs to introduce these equations, and there is no place where such generalizations are stated explicitly – in effect, they are only the result of consistency on the part of the grammar writer.[31] This limitation, again, cannot be overcome using a kind of type inheritance system common to construction-based approaches, because that would require a "hierarchy" of f-descriptions. But f-descriptions are only sets of expressions, not objects that can be manipulated or inherit information from each other.

A possible compromise between the description-based approach of LFG and constructions, explored in Asudeh et al. (2013), is based on the use of templates – bundles of grammatical descriptions extensively used in computational LFG, such as in XLE, but also in some theoretical work (Dalrymple et al. 2004, Asudeh 2012). Templates are basically symbols that serve as shorthands for f-descriptions that are substituted for the template call wherever it is invoked in an f-description. For example, the combination of third person and singular number agreement, highly relevant for English grammar, can be abbreviated as the template 3sg (66). This template can then be called as in (67). Furthermore, just like an f-description, a template can be negated; thus, as Asudeh et al. (2013: 19) propose, English unmarked present-tense forms can be naturally captured as in (68a), which resolves to (68b).[32]

(66) 3sg ≡[33] (↑ subj pers)=3
(↑ subj num)=sg

(67) *laughs* V (↑ pred) = 'laugh⟨subj⟩'
@3sg

(68) a. *laugh* V (↑ pred) = 'laugh⟨subj⟩'
¬@3sg

b. *laugh* V (↑ pred) = 'laugh⟨subj⟩'
{ (↑ subj pers) ≠ 3
| (↑ subj num) ≠ sg }

---

[31] Note that in LFG, this issue is distinct from the issue of permissible f-structure attributes and values discussed in Section 3.3. The two are, of course, related, and would have been the same issue in other frameworks, but not in LFG, where, as discussed above, structures are distinct from the descriptions that license them. An LFG grammar may not generalize over *structures* directly (unless feature declarations are used), but it may well generalize over *descriptions*.

[32] Note that such negation tacitly changes the equation type from defining to constraining, because negative statements can only be constraining. This change is not formally problematic, but care should be taken to ensure that other parts of grammar, which may depend on these defining equations, are not compromised.

[33] Asudeh et al. (2013) use := for template assignment, which is a standard assignment operator in some programming languages (e.g. Pascal), also used in computer science.

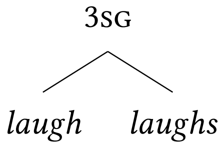
Templates can also be parametric, with parameters supplied in parentheses, as in programming languages. When a template is called, all mentions of each parameter are replaced by the string given in the parentheses. Note that this is done via simple string substitution,[34] and the parameters can be any kind of symbol; often, a reference to an f-structure, but not necessarily. For example, Asudeh et al. (2013) define the following template for intransitive verbs:

(69) INTRANS(P) ≡ (↑ PRED) = ‘P⟨SUBJ⟩’

(70) *laughs* V @INTRANS(LAUGH)
@3SG

Templates by themselves are not theoretical objects: they are a simple mechanism for reusing common parts of f-descriptions. Nevertheless, if used consistently, they can serve as a powerful mechanism for capturing generalizations in grammatical structure. In particular, a kind of hierarchy of templates can be defined if the use of a template in a lexical item, phrase structure rule, or in another template is viewed as inheritance from that template. For example, both *laugh* and *laughs* inherit from the 3SG template:[35]

(71)



Asudeh et al. (2013) use this template system to develop a detailed analysis of the traversal / result construction (*Smithy drank his way through university*, Jackendoff 1992, Goldberg 1995) in English, Swedish, and Dutch. Since this seminal work, templates have been widely used in LFG literature, although their adoption is not universal. Importantly, an advantage of the template-based approach to constructions is that they only introduce a purely notational convention; they

---

[34] For this reason, if the parameter is an f-structure reference, it may be ambiguous within a template if it includes Functional Uncertainty. To ensure that the same f-structure is referred to in all expressions, the template should first assign the parameter to a local name.

[35] This may seem counterintuitive, given that *laugh* is not a third person singular form. However, inheritance in this approach is purely a matter of calling a template in the f-description: it does not matter in what context it is called (under negation, in disjunction, etc.). This graph captures the intuition that the English unmarked Present Simple form is defined with reference to the third person singular features (as opposed to, e.g., being a disjunction of all alternative person-number combinations). Note that “inheritance” here is purely a matter of visualization and metagrammatical analysis; it has no special status in the formalism itself.

do not change the architecture of LFG in any way. Thus template-based analyses are fully compatible with non-template-based ones.

This simplicity can also be perceived as a disadvantage, in that constructions are not "first class citizens" of the theory: the template mechanism is unconstrained, and its use is fully optional. However, this follows the overall spirit of LFG: As seen above, the core architecture and metalanguage are relatively unconstrained and certainly more expressive than is needed for the purposes of describing natural languages. Constraints on possible languages are meant to be captured by theoretical generalizations (such as the regularities of c- to f-structure mapping described in Section 4.3) that are not part of the formal framework itself. Likewise, templates only serve as a useful mechanism of generalizing over f-descriptions; what these templates should look like and how consistently they should be used are theoretical decisions that should be viewed as additional constraints on LFG grammars, not part of the formal architecture itself.

5.2 Modifications of c-structure

Compared to developments in other frameworks, such as Minimalism (cf. Adger 2013), there have been few advances in the development of constituent structure in LFG. Apart from the introduction of non-projecting words in Toivonen (2003), the version of X′ theory used in most LFG work is the same as the original version developed in transformational grammar. However, there have been several alternative approaches to c-structure proposed in the literature, some relatively minor while others quite radical. In this section, I will describe two approaches – minimal c-structure (Lovestrand & Lowe 2017) and lexical sharing (Wescoat 2002). Another modification (Findlay 2017, 2019), which replaces context-free grammar with tree-adjoining grammar (TAG) while preserving core features of the LFG formalism, is described in Findlay 2023 [this volume]. Several categorial grammar-based approaches have been proposed (Oehrle 1999, Muskens 2001, Kokkonidis 2007), but have not gained much traction, possibly because they are no longer compatible with standard LFG and have to be regarded as separate, though related, frameworks.

5.2.1 Minimal c-structure

Lovestrand & Lowe (2017) propose a modification of X′ theory to account for two shortcomings that they perceive in its standard LFG version. First, X′ categories and projection levels are stipulated by the theory but not actually represented as discrete features; in formal terms, c-structure node labels are just monolithic symbols, even though they are given a theoretical interpretation. Second, consistent application of X′ theoretic principles leads to many redundant nodes, e.g. unary branching X′ nodes have to be used if an XP has a complement but no specifier or adjuncts. This redundancy is sometimes eliminated by appealing to economy of expression, either by “pruning” the superfluous nodes (Bresnan et al. 2016) or by introducing additional rules into the grammar (such as XP ⟶ X ZP in addition to XP ⟶ X′ YP and X′ ⟶ X ZP). However, both solutions introduce additional complexity into LFG and could be avoided. Third, some analyses work with fewer than two levels of X′ structure: for example, Bresnan et al. (2016: 130) take Welsh IP to lack a specifier, dominating only I and S. Sells (1994, 1995) similarly assumes that all phases in Japanese and Korean have X′ as their maximal projection. This kind of “deficiency” is not formalized in traditional X′ theory.

An earlier attempt to refine X′ theory in LFG is Marcotte (2014), which, however, has been criticized in Lovestrand & Lowe (2017) for failing to account for some common syntactic structures, such as adjunction and non-projecting words. Lovestrand and Lowe propose, following Kaplan (1989), that additional categorial features are projected in a separate feature structure (l-structure) via the function λ. L-structure contains the features L (for Level) and P (for Projection) that represent the “current” bar level of the node and the maximal level that this particular phrase has in the sentence. C-structure itself only contains syntactic category information; thus X, X′, and XP are all represented as X. Lovestrand and Lowe then define a set of templates and rule schemas that describe all the positions allowed by X′ theory. For example, the template EXT in (72a) is a conjunction of the tem1lates LPM (72b) and LP (72c), which mean that the annotated node is a maximal projection (LP) that is a daughter of a maximal projection (LPM). This applies to specifiers and adjuncts. The template HEADX (73a) is used on all X′ theoretic heads and consists of the templates LDOWN (73b) and PUD (73c), which mean that, first, the bar-level of the annotated node is lower than the level of the mother by 1; (b) the maximal projection level is inherited from the head to the overall structure. These templates allow us to define the specifier rule template in (74).[36]

(72) templates for specifier

a. EXT ≡ @LPM ∧ @LP

b. LPM ≡ $(\hat{*}_{\lambda}\ \mathrm{L}) = (\hat{*}_{\lambda}\ \mathrm{P})$

c. LP ≡ $(*_{\lambda}\ \mathrm{L}) = (*_{\lambda}\ \mathrm{P})$

---

[36] For clarity, conjunction is explicitly represented as ∧ in (72a) and (73a).

(73) templates for head

a. HEADX ≡ @LDOWN ∧ @PUD

b. LDOWN ≡ $\{(*_{\lambda}\ \text{L}) = 0 \wedge (\hat{*}_{\lambda}\ \text{L}) = 1 \ \mid\ (*_{\lambda}\ \text{L}) = 1 \wedge (\hat{*}_{\lambda}\ \text{L}) = 2\,\}$

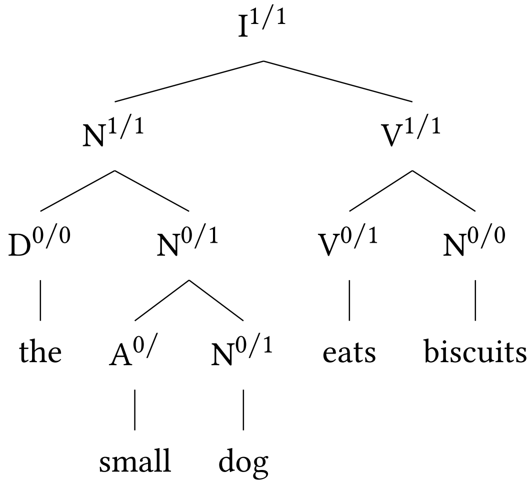
c. PUD ≡ $(\hat{*}_{\lambda}\ \text{P}) = (*_{\lambda}\ \text{P})$

(74) specifier rule

$$\text{X} \longrightarrow \underset{\text{@EXT}}{\text{Y}} \quad \underset{\text{@HEADX}}{\text{X}}$$

The application of this approach leads to c-structures notated as in (75), where the superscript numbers are shorthand for L/P feature values of the node.

(75)



In this example, prenominal A in English is treated as a non-projecting category, hence it lacks the P feature altogether.[37] It is seen from this example that the "maximal" projection level (P) is inherited bottom-up and represents the highest projection that the phrase has in this specific sentence. For example, the specifier noun phrase *the small dog* has a specifier, hence its dominating node has the category $\text{N}^{1/1}$, while the complement *biscuits* has no modifiers, and its head is only $\text{N}^{0/0}$. Thus the system results in minimal c-structures solely by using standard LFG mechanisms of templates and projections, without employing additional formal devices such as Economy of Expression.

---

[37] While Lovestrand and Lowe assume no DP in English, D is not treated as a non-projecting word: in their theory, *'s* possessors can attach to D as internal arguments (complements).

5.2.2 Lexical sharing

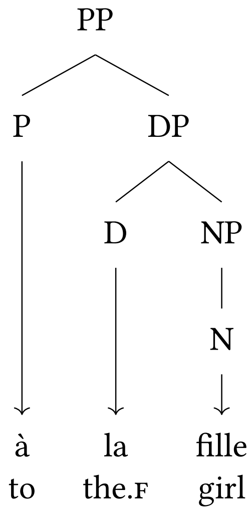
The principle of lexical integrity, and the general idea that there is a definite boundary between morphology and syntax, has long been criticized in the generative literature (perhaps the most recent such attempt is Bruening 2018) and, recently, in typological approaches (see Haspelmath 2011). Not all of the objections to lexicalism are necessarily applicable to LFG, but one persistent problem is the putative existence of syntactic structure where one lexical item (either completely idiosyncratic or derived in the morphology) occupies two or more syntactic heads. One example are preposition-determiner contractions in languages like French and German (Wescoat 2007): Items like French *au* [o] 'to the (masculine)' (⟵ *à* + *le*) are clearly idiosyncratic, historically motivated mergers of the preposition and the article (compare *à le faire* 'to do it', where *le*, identical in form to the masculine singular definite article, is the object proclitic of *faire* 'do', and thus does not trigger merger), but syntactically, they obey all the constraints that are independently imposed on prepositions and determiners in the language.

To account for such phenomena, Wescoat (2002) proposed LEXICAL SHARING: a modification of the LFG architecture to allow a single word (supplied by the lexicon) to occupy more than one c-structure node. In Wescoat's system, lexical items are no longer part of c-structure; category nodes like N, V, I (preterminals in the standard system) are now terminal nodes that are mapped, via the projection function λ, to morphological words that comprise an ordered list at a separate level of representation, l-structure.[38] In the simplest and most common case, each terminal c-structure node corresponds to exactly one word:

---

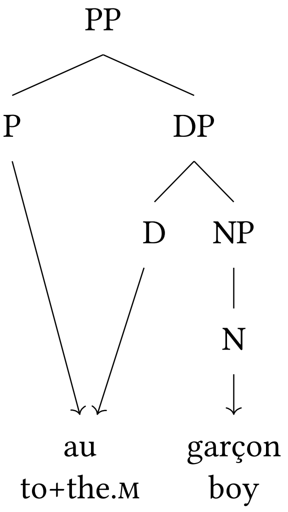
[38] It is unfortunate that the same name of the level and the projection function were independently used in Lovestrand & Lowe's (2017) proposal of minimal c-structure, which creates confusion. However, as will be shown below, Wescoat's approach can be integrated into the contemporary LFG architecture without stipulating an additional level.

(76)



Lexical sharing occurs when two or more terminal c-structure nodes are mapped to one morphological word:

(77)



To avoid excessive reorderings, Wescoat puts a constraint on the correspondence between c-structure and l-structure which he calls the *order preservation axiom*: For all n_1 and n_2 in the set of terminal nodes, if $\lambda(n_1)$ precedes $\lambda(n_2)$, then n_1 precedes n_2. This means that words cannot be reordered. It also follows from this axiom that only adjacent nodes may be shared. Thus lexical sharing is, in fact, rather constrained and does not seem to introduce much additional complexity into the system.

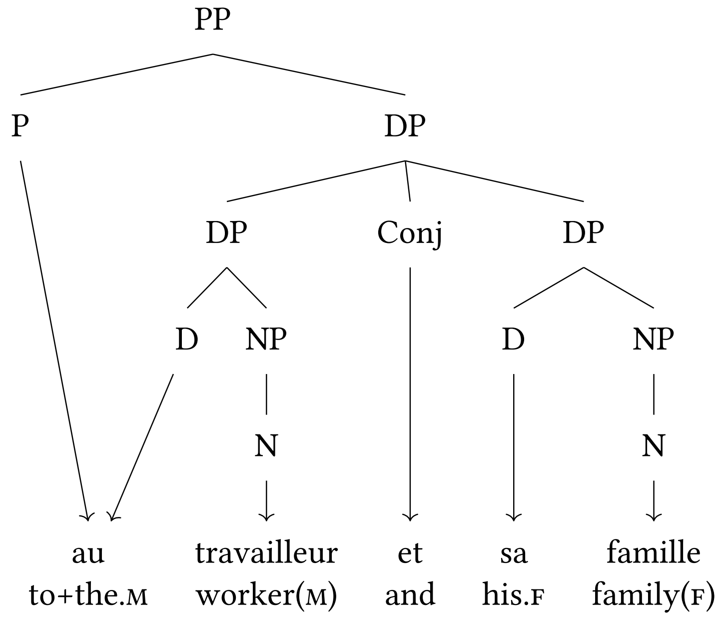
Lexical entries in lexical sharing analyses are defined as in (78), with each node having a separate f-description. The syntactic analysis then proceeds according to the standard f-structure rules defined by the grammar; lexical sharing configurations are licensed if a word is defined as coinstantiating adjacent nodes.

(78) *au* ⟵

P	D
(↓ PCASE)=TO	(↓ SPEC)=DEF
⇓=↓	(↓ GEND) $=_c$ M
	(↓ NUM) $=_c$ SG

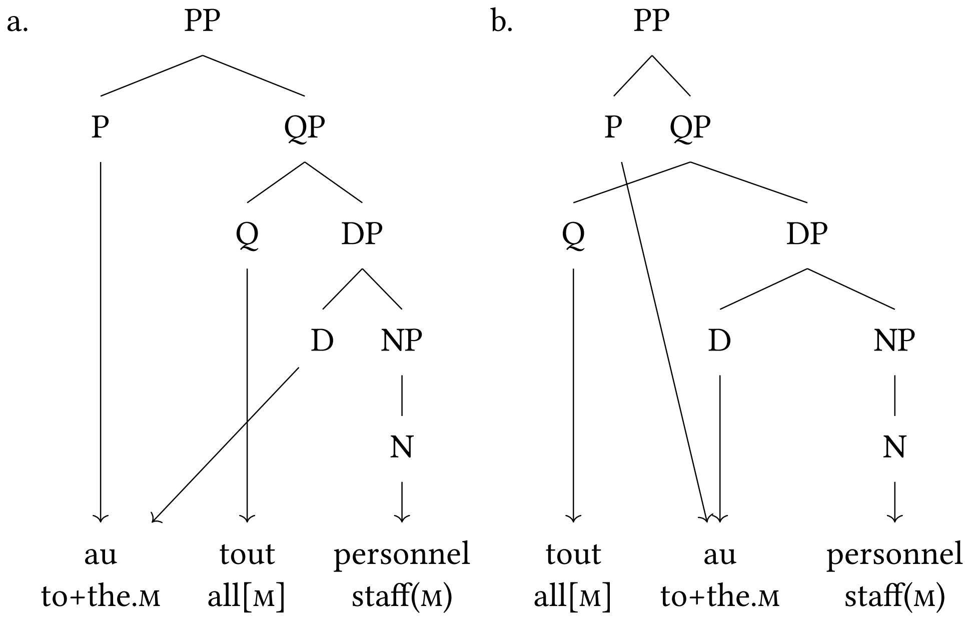
This correctly predicts the scope difference between the preposition and definite article in examples like (79). The order preservation axiom also predicts that structures like (80a) and (80b) are ungrammatical, because the shared nodes are not adjacent; the only possible word order is (81).

(79)



‘to the worker and his family’

(80) Ill-formed c-structures:



(81) á tout le personnel
to all[м] the.м staff
'to all the staff'

Note that Wescoat assumes that the correspondence function ϕ should have l-structure in its domain, hence the use of ↓ in annotations, instead of ↑ in standard LFG analyses. This assumption also motivates the symbol ⇓; this stands for the abbreviation $\phi(\lambda(\downarrow))$, i.e. "the f-structure of the lexical exponent of the current node" – this is needed to determine which of the co-instantiated f-structures the word itself maps to. However, this is not actually required, and Lowe (2016), in his analysis of the English "Saxon genitive" *'s*, proposed a modification of lexical sharing that dispenses with both these additional notations and integrates the proposal into modern mainstream LFG. Lowe observes that Wescoat's "l-structure" in fact serves the exact same function as the s-string – the set of morphosyntactic words that map to terminal c-structure nodes – in the LFG projection architecture, including the recent proposal of Dalrymple & Mycock (2011). Ordinarily, the s-string in LFG maps to terminal tree nodes that are occupied by morphosyntactic words; lexical sharing can be implemented by assuming that the c-structure tree terminates in category labels (preterminals), to which elements of the s-string are mapped. The replacement of l-structure by the s-string means that the symbol ⇓ and all the related machinery is no longer needed, because s-structure does not map to f-structure.[39] For the same reason, lexical entries use ↑, as in normal LFG, instead of ↓.[40] In Lowe's version of lexical sharing, the entry in (78) will look as follows:

(82) *au*: P D
P (↑ PCASE) = TO
D (↑ SPEC) = DEF
(↑ GEND) $=_c$ M
(↑ NUM) $=_c$ SG

While lexical sharing has been used to analyze several phenomena, including auxiliary reduction (Wescoat 2005), preposition-determiner contractions (Wescoat 2007), suspended affixation (Broadwell 2008, Belyaev 2014, 2021), endoclitics (Wescoat 2009), and morphologically bound complementation (Panova 2020), it has not been adopted as part of mainstream LFG, mainly, it seems, due to its apparent violation of lexical integrity and the potential to vastly increase the number of possible analyses. Indeed, if unconstrained, lexical sharing can be used to produce structures where every morphological category has its separate functional projection that is shared with the lexical head, reminiscent of Distributed Morphology (DM, Halle & Marantz 1993). However, as both Broadwell (2008) and Lowe (2016) observe, lexical sharing can be constrained to be used only when there is independent syntactic evidence in favour of a separate lexical head. Under this interpretation, lexical sharing analyses present an advantage over non-lexicalist analyses in that functional heads like CaseP or NumP are only stipulated as needed; for example, in Broadwell's (2008) analysis of suspended affixation, there is an empirical difference between languages where case is realized by a coinstantiated head (these allow suspended affixation) and languages where it is purely morphological (these do not); this opposition is lost in non-lexicalist approaches, where other, arguably less intuitively plausible mechanisms have to be used, such as a constraint on coordinating sub-CaseP constituents, feature deletion (Kharytonava 2012), or morphological ellipsis (Erschler 2012).

Furthermore, as mentioned in Section 2.2, lexical sharing does not really violate lexical integrity as formulated in Bresnan & Mchombo (1995), see (8), i.e. as

---

[39] This seems rather harmless, because lexical sharing entries overwhelmingly just use ⇓=↓ on one of the nodes, which doesn't seem to influence anything. However, Wescoat (2007) does use constraints on the l-structure to f-structure mapping to model certain limitations on preposition-determiner contractions in German.

[40] In fact, while standard LFG allows using ↓ in lexical entries, this model does not. This means that analyses that make use of ↓ in lexical entries, such as the Italian example in (48), have to be reformulated to use ↑. In most cases, this should not influence anything, although the definition and application of f-precedence might require some modification.

the general principle that words are built from different blocks and according to different rules than syntactic units. Indeed, syntax does not have any access to internal word structure in lexical sharing analyses, and coinstantiated nodes map to words as complete units, not to morphemes, disembodied features, or anything similar.[41] This gives lexical sharing analyses a distinct flavour that separates them from both mainstream LFG analyses and from truly non-lexicalist analyses that situate morphemes or features in functional projections (which have also been proposed in LFG: see Melchin et al. 2020 for a DM-like approach to LFG morphology). Notably, it still allows an independent morphological module (usually described in LFG in terms of a lexicalist realizational framework like PFM, see Belyaev (2021) and Asudeh & Siddiqi 2023 [this volume]) to do its work.

6 Conclusion

In this article, I have tried to summarize the state of the art of the core syntactic representations of LFG – the c- and f-structures. While the understanding of various phenomena has considerably changed in almost all areas of grammar (for example, in semantics and information structure: see Asudeh 2023 [this volume] and Zaenen 2023 [this volume]), the formal underpinnings of LFG have remained remarkably stable over the years. The only fundamental innovation to the original c- and f-structure architecture of Kaplan & Bresnan (1982) is the introduction of functional uncertainty in Kaplan & Zaenen (1989b). Since then, new levels of projection were introduced, and the architecture extended in various ways, but the core mechanisms of c- and f-structure – notation, featurehood, even the basic set of GFs – have remained constant. This serves as an impressive testimony of the versatility of the architecture proposed in Kaplan & Bresnan (1982), and its remarkable suitability to describing natural languages.

The architecture of LFG is both similar to that of other constraint-based frameworks and very different from them in various ways. The main difference is the parallel architecture of LFG, and the related emphasis on the distinction between descriptions (a set of syntactic constraints) and the structures that are licensed by

---

[41] In fact, from a certain perspective this might be viewed as a disadvantage of lexical sharing analyses in that they fail to capture the fact that coinstantiated material usually corresponds to a well-defined, segmental, agglutinatively attached element of the wordform. For example, Ossetic affixal case features are realized on the Case head, while stem-based ones are realized on N (Belyaev 2014, 2021). I am not aware of any analyses where coinstantiated heads encode features that are realized by stem change, suppletion, or apophony. This fact might be explained diachronically, however, since lexical sharing usually reflects an ongoing process of (de)grammaticalization.

these descriptions. While constructions and lexical entries are *structures* in most other frameworks, in LFG they are sets of *statements* that describe a range of possible structures. This architectural feature enables LFG to make use of mechanisms such as functional uncertainty and inside-out application, which are unavailable in other frameworks.

While the empirical coverage of LFG work is impressive, and a number of important developments are now taking place in several theoretical directions, not all areas of syntax have been researched to the same extent. The focus on f-structure and the view of GFs as theoretical primitives has prompted a lot of fruitful and insightful work on subjects and other core grammatical relations. Functional uncertainty and structure sharing have also proved to be efficient mechanisms for describing long-distance dependencies. The notion of sets and feature distributivity allow for elegant analyses of coordination – an area traditionally underrepresented in mainstream syntactic frameworks. In contrast, c-structure has seen much less attention,[42] although here important developments are also taking place. The notion of lexical integrity, assumed as a stipulation early in the history of LFG, has not been extensively discussed and refined, in spite of numerous challenges. These challenges will have to be dealt with if LFG is to compete with other frameworks for the originally envisaged role of "a theoretically justified representation of the native speaker's linguistic knowledge" (Kaplan & Bresnan 1982).

Acknowledgements

I am grateful to two anonymous reviewers, whose comments made a significant contribution to the final form of this chapter, and to Mary Dalrymple for her attentive reading and insightful comments. This research has been supported by the Interdisciplinary Scientific and Educational School of Moscow University "Preservation of the World Cultural and Historical Heritage".

---

[42] The reason for this might be that the range of phenomena handled by c-structure is much less than those handled by f-structure, as c-structure only directly models word order and embedding. However, as an anonymous reviewer observes, c-structure in LFG is analogous to Merge in Minimalism, being the main generative component that connects different projections together while also providing codescription for the semantics. This role can hardly be described as minor, but the existing model handles this purpose rather adequately.

Chapter 3

Grammatical functions in LFG

Oleg Belyaev

Lomonosov Moscow State University, Institute of Linguistics of the Russian Academy of Sciences, and Pushkin State Russian Language Institute

Grammatical functions (GFs) such as subject and object play a central role in the architecture of LFG, which makes it quite different from most other formal theories of grammar. In this chapter, I discuss the motivation behind this design decision and the ways in which grammatical functions are distinct from each other: their classification and the properties of certain individual GFs, namely subjects, sentential complements (COMP) and possessors. I also discuss the status of so-called overlay or discourse functions, which serve to specify the status of GFs with respect to additional syntactic constraints.

1 Introduction

One of the distinguishing features of LFG is that grammatical functions (GFs) are first-class citizens of syntactic structure. The set of available GFs is viewed as universal, and each GF is associated with a distinct set of structural properties. Some syntactic rules and generalizations refer to individual GFs directly; others refer to their relative ranking, but, unlike GB/Minimalism (Sells 2023 [this volume]) or HPSG (Przepiórkowski 2023 [this volume]), the ranking itself is directly stipulated and is secondary to grammatical function status. The list of grammatical functions used in most LFG work includes subjects (SUBJ), direct objects (OBJ), secondary objects (OBJ_θ or OBJ2), obliques (OBL_θ), and adjuncts (ADJ), which are familiar from traditional grammar but given more exact definitions in LFG. This list is not arbitrary; it is motivated by the classification of grammatical functions into ungovernable (ADJ) vs. governable functions, terms (SUBJ and OBJ) vs. non-terms, semantically restricted (OBJ_θ and OBL_θ) vs. unrestricted; each class is associated with a distinct expected pattern of behaviour. The list of basic GFs is also

Oleg Belyaev. 2023. Grammatical functions in LFG. in Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 97–161. Berlin: Language Science Press. DOI: 10.5281/zenodo.10185938

motivated by the regularity of mapping between semantic roles and their syntactic expression: the cross-classification of GFs into two binary features [±*o*] and [±*r*] and the mapping principles assumed in Lexical Mapping Theory (Bresnan & Kanerva 1989) correctly predict both the regular mappings and their possible permutations. More unusually, LFG also treats certain specialized grammatical functions – namely, clausal complements (COMP), possessors (POSS) and sometimes nonverbal predicates (PREDLINK) – as theoretical primitives on par with subjects and objects.

LFG also uses OVERLAY FUNCTIONS to represent the locus of long-distance dependencies like wh-extraction. These do not formally belong to the class of grammatical functions, but are similar in that they are occupied by the same f-structures that represent clausal participants. In earlier versions of LFG, most overlay functions were called "discourse functions" and also represented information structure notions such as topic and focus. In modern LFG, there is usually a separate level for information structure, and there is no need to duplicate it at f-structure. Instead, a single function, here called DIS, is used for all long-distance dependencies; some authors postulate additional overlay functions to model other grammatical information, such as PIVOT for "pivots" in Falk (2006). To the extent that overlay functions are related to grammatical functions, they will be discussed in this chapter; further information on overlay functions with respect to long-distance dependencies is found in Kaplan 2023 [this volume].

In this chapter, I summarize the key elements of the LFG understanding of grammatical functions. In Section 2, I briefly discuss the formal status of grammatical functions and their role as syntactic primitives in LFG. In Section 3, I describe the main mechanism through which grammatical functions obtain their distinctive properties – their hierarchical ordering and cross-classification. In Section 4, I turn to individual grammatical functions – subjects, objects, and obliques – and discuss their distinctive properties that do not follow from their classification or ranking in the hierarchy. Finally, in Section 5, I discuss overlay functions, which represent additional functions that link clausal participants to the wider sentential or discourse context.

2 General concepts

Grammatical functions in LFG represent all kinds of relations that syntactic dependents may have to their predicates. This includes both grammatical relations like subject, object, or adjunct and additional functions – so-called overlay functions – that situate the event participant in some wider cross-clausal or discourse context (e.g. dis for dislocated – usually topicalized or focalized – elements, or relpro for relative pronouns). The values of grammatical functions are normally also event participants – thus, in the words of Bresnan et al. (2016), grammatical functions can be called "the 'relators' of c-structure to a[rgument]-structure" (p. 94). However, this is not always the case: adjuncts do not appear at argument-structure, and expletive arguments, like *it* in *It rains*, are purely syntactic and do not correspond to any semantic argument.

In formal terms, a grammatical function is any f-structure attribute that has an f-structure as its value[1] and whose occurence is governed by Completeness, Coherence, and Extended Coherence. Completeness requires that features listed as arguments in a pred feature value appear within the same f-structure as this pred. Coherence prevents governable gfs (see Section 3.3) from appearing in f-structures where they are not listed in the pred value. Extended Coherence restricts the occurence of *non-governable* gfs: adjuncts and overlay functions. Adjuncts can only appear in f-structures that have a pred feature (regardless of its value), while overlay functions like dis (for dislocated constituents), relpro (relative pronouns), topic, and focus (see Section 5) must be linked to non-overlay functions through structure sharing or anaphora.

For example, (1) represents the f-structure of the sentence *Peter met Paul in Rome*. The value of the feature pred includes, in angled brackets, the list of arguments that are required by the verb *meet* – in English, this is a transitive verb that selects a subject and an object. These arguments appear as the features subj and obj that have f-structures representing the NPs *Peter* and *Paul* as their values. The PP *in Rome* is not selected by the verb (its occurrence is not obligatory) and is represented as an element of the set-valued feature adj, for adjunct. The preposition *in*, which contributes semantic content, has its own f-structure with the feature pred whose value defines a valency for obj. The nouns *Peter*, *Paul* and *Rome* do not require any syntactic arguments, and hence their pred feature values lack a list of arguments in angle brackets. For more detail on how arguments and adjuncts are licensed at f-structure, see Belyaev 2023a [this volume].

---

[1] F-structures appear as values not exclusively with gfs. For example, many authors, among others Alsina & Vigo (2014) and Haug & Nikitina (2015), use the function agr as a "bundle" of agreement features that is an f-structure that never has a pred value and that is neither an argument nor an adjunct.

(1)
$$\left[\begin{array}{ll}
\textsc{pred} & \text{‘}\textsc{meet}\langle\textsc{subj}, \textsc{obj}\rangle\text{’} \\
\textsc{tense} & \textsc{past} \\
\textsc{subj} & \left[\begin{array}{ll} \textsc{pred} & \text{‘Peter’} \\ \textsc{pers} & 3 \\ \textsc{num} & \textsc{sg} \end{array}\right] \\
\textsc{obj} & \left[\begin{array}{ll} \textsc{pred} & \text{‘Paul’} \\ \textsc{pers} & 3 \\ \textsc{num} & \textsc{sg} \end{array}\right] \\
\textsc{adj} & \left\{\left[\begin{array}{ll} \textsc{pred} & \text{‘}\textsc{in}\langle\textsc{obj}\rangle\text{’} \\ \textsc{obj} & \left[\begin{array}{ll} \textsc{pred} & \text{‘Rome’} \\ \textsc{pers} & 3 \\ \textsc{num} & \textsc{sg} \end{array}\right] \end{array}\right]\right\}
\end{array}\right]$$

The fact that dependents are represented as values of f-structure *features* is not at all trivial. The term “grammatical relations” used in typology implies that arguments and clauses are viewed as *objects* literally linked to each other via *relations*. Thus, where LFG has $(f\ \textsc{subj}) = g$ (f is a function, SUBJ is an argument, g is the feature value), the intuitive tradition would rather have $\textsc{subj}(f) = g$ (SUBJ is a function, f is an argument, g is the value). The LFG view has certain interesting consequences for the handling of many syntactic phenomena. For example, the Coordinate Structure Constraint (Ross 1967) has no special status in the framework – its effects are of exactly the same nature as the scoping of grammatical features (such as mood or case) over conjuncts in coordinate structures. This is a direct consequence of the fact that grammatical functions such as SUBJ or OBJ are features in exactly the same sense as grammatical features such as CASE or MOOD; for more information, see Patejuk 2023 [this volume].

A core tenet of LFG is that grammatical functions are theoretical primitives; their set is universal and their properties are not derived from other, more fundamental principles.[2]

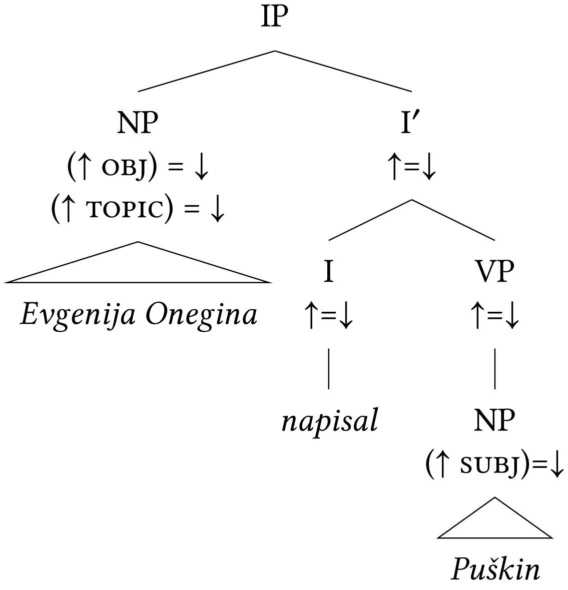
Viewing GFs as primitives amounts to saying that neither phrase structure relations nor semantics are sufficient to account for all the properties of individual arguments. As discussed in Belyaev 2023b [this volume] and Andrews 2023 [this volume], the mapping from c-structure to grammatical functions is relatively unconstrained. X′ Theory, in formulations like that of Bresnan (2001) and Bresnan

---

[2] Lexical Mapping Theory (Bresnan & Kanerva 1989) is sometimes interpreted as involving the decomposition of grammatical functions into bundles of two binary features: [±*r*], [±*o*], cf. e.g.: “Basic argument functions are not atomic but decomposable into features” (Kibort 2014). Under this view, it is these features that are primitives, instead of GFs. But lexical mapping theory can also be interpreted as a classification rather than an actual decomposition; this is the position taken, for example, in the Oxford Reference Guide to LFG (Dalrymple et al. 2019).

et al. (2016), does impose certain restrictions, but these are very general and do not impose any specific mapping. For example, it is assumed that complements of lexical projections map to grammatical functions, but no specific mapping is enforced: the complement of VP does not have to map to obj, but can map to any grammatical function, even subj. Thus in King (1995), all postverbal (contrastive) foci in Russian, including subjects (2), are analyzed as VP complements.

(2) Russian (Slavic > Indo-European)
Evgenija Onegina napisal **Puškin**
E.:acc O.:acc wrote P.:nom
'It was **Pushkin** who wrote "Eugene Onegin".'



In fact, a consistent mapping cannot be assumed even in so-called configurational languages like English: while in English declarative sentences, objects appear in Comp of VP, the arrangement changes in interrogative sentences, where objects occupy the clause-initial position (Spec of CP or CP adjunct) but the Comp of VP is left empty. Since LFG uses no transformations or any similar mechanism, this has to be accounted for by positing a notion of grammatical function independent from c-structure position.

Grammatical functions are also distinct from semantic roles. A patient, for example, may map to either obj (in the active voice) or subj (in the passive), as evidenced by its syntactic properties (e.g. control of verb agreement, reflexive binding). In LFG, these two sentence types are defined as two different *lexical mappings* between semantic roles and gfs. While in terms of argument structure, i.e. the mapping from semantic roles to gfs, the passive is treated as derivative to the active, at f-structure passive subjects are genuine, first-class subjects that are not derived from objects in any sense.

Finally, grammatical functions cannot be equated to case marking or another argument encoding mechanism, such as verb agreement. First of all, there are many languages which completely lack both agreement and case marking, but which nevertheless display evidence for grammatical functions. Thus Mandinka (Mande > Niger-Congo), which lacks both case marking and verbal indexing, nevertheless displays a distinction between the subject (sole argument of intransitive verbs, i.e. S in typological terminology, and the agent of transitive verbs, i.e. A) and all other arguments in a number of different constructions (Creissels 2019). For instance, pronominal resumption in relative clauses is only available for non-subject arguments. In (3a) and (3b), subjects (S and A arguments, respectively) are relativized, and the resumptive pronoun *à* cannot appear in the subordinate clause in the normal subject position; the subject is represented by a gap. In contrast, in (3c), it is the object that is relativized, and the pronoun *à* may (optionally) appear in the object position after the verb.

(3) Mandinka (Mande > Niger-Congo: Creissels 2019: 339)

a. S relativized: resumption ungrammatical
mùs-ôo **míŋ** (***à**) táa-tá fàr-ôo tó
woman-DET REL 3SG go-COMPL.POS rice.field-DET LOC
'the woman **who** went to the rice field'

b. A relativized: resumption ungrammatical
mùs-ôo **míŋ** (***à**) yè fǎaŋ-ó tǎa
woman-DET REL 3SG COMPL.POS cutlass-DET take
'the woman who took the cutlass'

c. P relativized: resumption possible
fǎaŋ-ò **míŋ** mùs-ôo yè **à** tǎa
cutlass-DET REL woman-DET COMPL.POS 3SG take
'the cutlass that the woman took'

Furthermore, case marking or agreement do not always consistently identify specific grammatical functions. For example, in Icelandic (Andrews 1982) agreement is always with the nominative argument, but subjects can be non-nominative. Many languages with differential object marking (DOM) allow nominative objects (Dalrymple & Nikolaeva 2011). For example, in Ossetic, human objects are normally genitive-marked (4a) and inanimate objects are nominative-marked (4b), i.e. the case marking of subjects and objects can be identical.

(4) Ossetic (Iranian > Indo-European)

a. Human P: genitive
alan **šošlan-ə** fet:-a
S.-GEN see.PFV-PST.3SG
'Alan saw **Soslan**.'

b. Inanimate P: nominative
alan **št'ol** fet:-a
table see.PFV-PST.3SG
'Alan saw **a/the table**.'

Of course, this is not to say that grammatical functions never systematically correspond to any syntactic or morphological marking; if they did not, there would be no means of identifying them. The point of treating grammatical functions as primitives is that we *cannot*, as a general rule, reduce them to any other linguistic phenomena such as case marking or word order. This logic is in line with the general spirit of LFG, which can be termed "anti-reductionist" in that it strives to factorize grammatical phenomena into distinct notions responsible for distinct patterns of behaviour, which may or may not correlate systematically across languages. Thus, in the LFG treatment of argument encoding, constituent structure, semantic roles, and case marking are all formally independent from each other. The framework itself puts no constraints on their relationship; it is the task of the theorist to establish how exactly they can or cannot correlate, both cross-linguistically and within individual languages.

We also have to assume, as a working hypothesis, that individual grammatical functions are associated with core sets of syntactic properties that are relatively stable across languages. If this is not the case, then using such terms as "subject" or "direct object" as anything more than convenient language-internal labels is not justified. This issue is still at the centre of much typological discussion, cf. the overview in Bickel (2010). In many syntactic frameworks, grammatical functions only exist, at best, in the form of an ordering relation among arguments – this is true at least for most variants of HPSG (Pollard & Sag 1994, Müller et al. 2021) and Simpler Syntax (Culicover & Jackendoff 2005, Varaschin 2023 [this volume]). Thus, in recent versions of HPSG there is a list ARG-ST (or DEPS) containing all verbal arguments; the subject is the first element of this list, the direct object, the second, and so on, generally according to the Keenan–Comrie hierarchy (Keenan & Comrie 1977). In many instances, both approaches make the same predictions, because in LFG the GF hierarchy also plays a major role (see Section 3.2); for example, in both LFG (Rákosi 2023 [this volume]) and HPSG (Müller 2021), anaphoric relations are licensed by the relative ranking of verbal arguments. But the key practical difference is that in HPSG or Simpler Syntax, distinctive properties are not associated with individual grammatical functions. For example, in LFG it is possible to analyze sentences as having only a subject (SUBJ) and a secondary object (OBJ_θ, without a primary OBJ) when the "second-ranking" argument is deemed to lack features commonly associated with direct objects. This is done, for example, for certain classes of predicates in Plains Cree (Dahlstrom 2009) and for unmarked direct objects in differential object marking systems in the analysis of Dalrymple & Nikolaeva (2011). Even subjectless sentences are possible if the highest-ranking argument lacks properties that are associated with subjecthood (Kibort 2006). The standard LFG analysis of complementation (Section 4.3) also relies on the grammatical functions COMP and XCOMP (for clausal complements) being distinct from OBJ (Dalrymple & Lødrup 2000, Alsina et al. 2005). All of this would be impossible if grammatical functions were just an issue of ranking.

While GFs have been a cornerstone of LFG since its inception, a variant of this framework without the traditional notion of GF is also conceivable. Such an attempt was made in Patejuk & Przepiórkowski (2016), who propose replacing features such as SUBJ, OBJ and ADJUNCT with an ordered set DEPS in the style of HPSG. A detailed counterargument to this proposal can be found in Kaplan (2017).

In the following sections, I will describe the standard view of grammatical functions in current LFG: their inventory, their classification, and the properties of the core grammatical functions.

3 The classification of grammatical functions

3.1 General remarks

LFG generally operates with the following set of grammatical functions (with the addition of overlay functions, which will be discussed in Section 5):

(5)	SUBJ	subject
	OBJ	object
	OBJ_θ	secondary object
	OBL_θ	oblique
	COMP (XCOMP)	complement (closed/open)
	PREDLINK	nonverbal predicate in copular constructions
	ADJ (XADJ)	adjunct (closed/open)
	POSS	possessor

The θ in OBJ$_\theta$ and OBL$_\theta$ represents the particular semantic role that is filled by the argument. For example, a secondary object and an oblique with the semantic role Goal will be called OBJ$_{\text{GOAL}}$ and OBL$_{\text{GOAL}}$, respectively. Thus OBJ$_\theta$ and OBL$_\theta$ are not individual GFs but "families" of GFs associated with particular semantic roles, but sharing some common properties. The main motivation for this will be discussed in Section 3.5.

As discussed above, GFs in LFG are theoretical primitives on a par with such entities as constituents, or morphosyntactic or phonological features. Such primitives are never given definitions or identified on the basis of a fixed set of tests or criteria; rather, they are associated with a set of properties and used as building blocks for hypotheses whose predictions are to be tested. But this does not mean that the list of GFs in (5) is completely arbitrary. On the contrary, in the following sections I will show how the core GFs (SUBJ, OBJ, OBJ$_\theta$, OBL$_\theta$, ADJ) are mostly distinguished on the basis of three classifications: ungovernable (ADJ) vs. governable, term (SUBJ, OBJ, OBJ$_\theta$) vs. non-term, semantically unrestricted (SUBJ, OBJ) vs. restricted. This only leaves the distinction between SUBJ and OBJ – two semantically unrestricted terms – unspecified, but these can be distinguished on the basis of the subject having a higher structural priority.

This classification is complemented by a different but related cross-classification from the Lexical Mapping Theory (LMT, Bresnan & Kanerva 1989) based on two features: [$\pm r$] (for "(semantically) restricted") and [$\pm o$] (for "objective"), seen in (6).

(6)

	$-r$	$+r$
$-o$	SUBJ	OBL$_\theta$
$+o$	OBJ	OBJ$_\theta$

This classification produces a markedness hierarchy of grammatical functions: SUBJ [$-r$, $-o$] < OBJ [$-r$, $+o$], OBL$_\theta$ [$+r$, $-o$] < OBJ$_\theta$ [$+r$, $+o$] (Bresnan & Moshi 1990). This hierarchy, together with the mapping principles, ensures the correct default mapping of semantic roles to grammatical functions. It also predicts the possible ways of remapping grammatical functions in passives, causatives and applicatives, although the details differ across variants (e.g. some versions of LMT allow mapping agents to OBJ and some do not). It should be stressed that LMT does not *directly* provide evidence for the set of grammatical functions, because in LFG the theory of f-structure and the theory of the mapping from semantic roles to f-structure are formally independent: one can analyze GFs without adopting any particular theory of how they are mapped to semantic roles. But indirectly, the cross-classification of core GFs can serve as an independent justification for their inventory. For more information on mapping principles in LFG, see Findlay et al. 2023 [this volume].

3.2 Functional hierarchy

The most fundamental distinction between grammatical functions is the universal functional hierarchy in (7), which is the LFG version of the Keenan-Comrie Hierarchy (Keenan & Comrie 1977).[3]

(7) SUBJ > OBJ > OBJ_θ > COMP, XCOMP > OBL_θ > ADJ, XADJ

The Keenan-Comrie Hierarchy was originally devised as a typological hierarchy that constrains the range of possible grammatical functions that the relativized argument can occupy in the relative clause. It is now widely acknowledged that the same hierarchy can determine a number of grammatical processes within a single language. Phrase-structure-based frameworks try to account for such generalizations by reducing the hierarchy to differences in phrase structure configuration. For example, asymmetries in anaphoric binding are typically described in terms of c-command (Chomsky 1982). In LFG, most such constraints, if they are indeed syntactic,[4] are described in terms of f-structure.[5] Thus, the relation of c-command is replaced by the relation of outranking in the hierarchy in (7): see Rákosi 2023 [this volume].

---

[3] The difference from Keenan and Comrie is mainly in the terminology (OBJ_θ for what they call indirect object), but also in the split between OBJ and (X)COMP and the addition of adjuncts at the bottom of the hierarchy. Objects of comparison are not viewed as a special grammatical function in LFG and are therefore not included. Also, while Keenan and Comrie include genitive possessors, this is not done in LFG because possessors do not directly compete with clausal arguments and are somewhat special; they are discussed in Section 4.4.

[4] For many phenomena, it is not easy to decide whether the constraints should be formulated in terms of syntax, semantics, or both; in many ways this rests on the particular theories of the two and the syntax–semantics interface. For example, while mainstream generative grammar is notoriously syntactocentric, Simpler Syntax represents another extreme, where syntactic structure includes only a very basic notion of grammatical relations, and most of the work that is done by f-structure is assigned to a (very elaborate) semantic structure. As an illustration of the relationship between Culicover and Jackendoff's approach and LFG, Belyaev (2015) shows that the criteria that Culicover & Jackendoff (1997) consider to be semantic are captured at the f-structure level in LFG.

[5] It has been argued that anaphora is sometimes directly constrained by linear precedence, e.g. for Malayalam in Mohanan (1982). In LFG, this has been modeled using the f-precedence relation (Kaplan & Zaenen 1989, also see Belyaev 2023a [this volume]) by essentially stating that the c-structure nodes that map to the f-structure of the antecedent must precede the c-structure nodes that map to the f-structure of the anaphoric expression. Notably, the starting point is still the f-structure and the c-structure is only accessed through inverse mapping.

3.3 Governable and ungovernable GFs

As stated above, most GFs are GOVERNABLE: that is, in LFG terms, they must appear in the list of arguments in the PRED value of their f-structure in order to be licensed. The PRED value is usually that of a verb or other clausal predicate, as in (8), which is the f-structure of the sentence *Mary ran quickly*.

(8)

$$\left[\begin{array}{ll} \text{PRED} & \text{‘RUN}\langle\text{SUBJ}\rangle\text{’} \\ \text{TENSE} & \text{PAST} \\ \text{SUBJ} & \left[\begin{array}{ll}\text{PRED} & \text{‘Mary’}\\ \text{PERS} & 3 \\ \text{NUM} & \text{SG}\end{array}\right] \\ \text{ADJ} & \left\{\left[\begin{array}{ll}\text{PRED} & \text{‘QUICKLY’}\end{array}\right]\right\}\end{array}\right]$$

In this sentence, SUBJ is a governable GF that appears in the argument list in PRED. The f-structure for *quickly* appears as the value of the GF ADJ, which is ungovernable and is not licensed by the PRED value.

If a governable GF is included in the list of arguments in PRED but has no value, Completeness is violated; conversely, if a governable GF is present but not included in the list, Coherence is violated. Modifiers (ADJ and XADJ) are the only GFs which are ungovernable. The only condition on their occurence is that the f-structure in which they appear should have *some* PRED value.[6]

Determining the status of the dependents of a given predicate is not trivial in general, but especially in LFG because of its rigid separation between levels. Two distinctions are especially important for LFG: between semantic and syntactic argumenthood, because semantic arguments are not necessarily expressed as arguments in syntax, and vice versa (Section 3.3.1), and between arguments and adjuncts in syntax, whose status does not necessarily correlate with semantic argumenthood and adjuncthood (3.3.2).

3.3.1 Semantic and syntactic arguments

First of all, one must clearly differentiate between *semantic* argumenthood and *syntactic* argumenthood. Syntactic arguments may have no semantic counter-

---

[6] This constraint is part of *extended coherence* (Bresnan et al. 2016), which is not accepted by all LFG practitioners as a universal well-formedness condition. While the notion that only f-structures with PRED values can have modifiers is intuitively plausible, it is difficult to find empirical justification for this condition on adjuncts, since PRED-less f-structures normally correspond either to expletive pronouns or heads of categories like P, which both tend not to attach any modifiers at c-structure. Violation of extended coherence might be relevant for languages where some adpositions have PRED values and some do not; only the former would then be able to have adjuncts.

parts; such is the case of subjects of verbs like *rain*, or “raised” subjects and objects like *John* in *John seemed to come* or *David* in *I saw David come* (functionally controlled in LFG terms). In LFG, such “non-arguments” are notated as being outside the angled brackets in the argument list of the PRED feature value, e.g. ‘RAIN⟨ ⟩SUBJ’ or ‘BELIEVE⟨SUBJ XCOMP⟩OBJ’. This effectively makes f-structure include semantic information. As discussed in Belyaev 2023a [this volume], in modern Glue Semantics-based approaches, it is possible to either completely eliminate PRED features from the syntax or at least remove semantic role information, which would make the separation between syntax and semantics more clear-cut.

Conversely, a semantic argument might have no syntactic expression. For example, unspecified object deletion or antipassivization can turn a transitive verb into an intransitive one that only has a single argument, the agent (*We ate a meal.* ⟶ *We ate.*). The semantic predicate ‘eat’, and the corresponding real-life event, clearly have a patient participant regardless of whether it is syntactically expressed, and this omitted participant will be interpreted in some way. But there is broad consensus in the literature (see Melchin 2019) that unspecified objects are not present in syntax in any form. In LFG, this means that they are both absent as constituents in c-structure, and as GFs in f-structure, because f-structure is a syntactic level that does not directly reflect the thematic roles of the arguments.[7]

It is important to distinguish such cases of true omission of semantic arguments at f-structure from cases where arguments do not overtly appear at c-structure but are still present at f-structure. Two widespread cases when this occurs are pro-drop (like in Italian *ha vinto* lit. ‘has won’ = ‘s/he has won’) and raising (*John seems to have won*, where *to have won* appears to lack a subject). The “little *pro*” analysis of null subjects in languages like Italian has been assumed at least since Perlmutter (1971) and is supported by much empirical evidence, such as the possibility of controlling PRO, serving as the antecedent of anaphors, controlling agreement etc. that is well-known from basic syntax textbooks and need not be repeated here. This evidence is also valid in LFG and leads one to conclude that while *pro* is not needed at c-structure, it has to be present at f-structure in subject position. Similarly, “raised” (functionally controlled) arguments overtly appear in main clauses but still have to satisfy the subcategorization constraints of the embedded clause. In the LFG analysis of raising, one f-structure is shared

---

[7] The mapping from semantic roles to GFs is handled in LFG by a separate component, Linking Theory. In the most widespread variant of Linking Theory, Lexical Mapping Theory, unspecified object deletion is captured by suppressing the realization of the patient argument, i.e. preventing it from being mapped to any GF. See Findlay et al. 2023 [this volume] for further explanation.

between the main clause subject or object and the subject of the embedded clause. Therefore, both components of the functional control relation are present in the syntax as arguments of their respective clauses; see Section 4.3.2 and Vincent 2023 [this volume] for more detail.

3.3.2 Arguments and adjuncts

In one form or another, the problem of arguments vs. adjuncts is relevant for all grammatical frameworks, but LFG is special in that it treats the syntactic distinction between arguments and adjuncts as fully separate from the homonymous semantic distinction. The syntactic distinction between arguments and adjuncts also does not exist in other frameworks in the same form; for example, the HPSG approach is typically to include all verbal dependents in an ordered list DEPS. This means that semantic subcategorization and semantic obligatoriness cannot be used as reliable criteria by themselves: it was shown above that semantic arguments might not correspond to any GF in syntax. Similarly, some analyses treat passive agents as adjuncts, in spite of their semantic argumenthood. The issue is further complicated by the fact that additional, derived arguments that are not present in the lexical entry of the predicate can be introduced in the syntax (Needham & Toivonen 2011). Hence, criteria for distinguishing between arguments and adjuncts must be purely syntactic.

The main empirical difference between arguments and adjuncts can be formulated in terms of Dowty's (1982) *subcategorization test*: modifiers, but not arguments, can be omitted. In a theory like LFG which uses no empty heads (see Belyaev 2023a [this volume]), this criterion is clearly not general enough, because grammatical functions that are present at f-structure may lack a realization at c-structure, e.g. under pro-drop (see Section 3.3.1 above). Normally, the presence of such "null" elements like *pro* and their features is reflected in the morphology through agreement or argument incorporation, although some languages, like Japanese, are notorious for allowing almost unrestricted pro-drop — for these languages, distinguishing between arguments and adjuncts using the subcategorization test is especially problematic.

Another truly syntactic criterion is that adjuncts can be freely multiplied in any number, whereas arguments cannot (Kaplan & Bresnan 1982: 40):

(9) The girl handed the baby a toy **on Tuesday**$_{\text{ADJ}}$ **in the morning**$_{\text{ADJ}}$.

(10) * The girl saw **the baby**$_{\text{OBJ}}$ **the boy**$_{\text{OBJ}}$.

Crucially, the multiplication test is only relevant for adjuncts *of the same type*. While a clause may have at most one subject and object, it may have several obliques or indirect objects (as elaborated in sections 3.5.2 and 3.5.3 below). But there can still be only one indirect object or oblique with the same semantic role:

(11) * John went to Moscow to Red Square.

Other criteria have to do with the specific understanding of grammatical functions in LFG, their relative ordering and the licensing of long-distance dependencies. For example, some pronouns, such as the reflexive pronoun *seg selv* in Norwegian, are specifically limited in their coreference to coarguments (Hellan 1988), and therefore cannot occur in adjunct position. The examples in (12) are cited from Dalrymple et al. (2019). In (12a) this reflexive is a direct object that is coreferent to the subject – both are arguments. Similarly, in (12b), the reflexive is used in a PP that is an oblique argument selected by the verb 'tell'. But in (12c), the prepositional phrase containing the reflexive is not an argument of the predicate and thus it cannot have the subject as its antecedent. Thus the cut-off point in the hierarchy in (7) for *seg selv* is just to the left of ADJ, XADJ.

(12) Norwegian (Germanic > Indo-European)

a. Jon forakter **seg selv**.
Jon despises self
'Jon$_i$ despises **himself**$_i$.'

b. Jon fortalte meg **om** **seg selv**.
Jon told me about self
'Jon$_i$ told me **about himself**$_i$.'

c. * Hun kastet meg **fra** **seg selv**.
she threw me from self
('She$_i$ threw me away **from herself**$_i$.')

It is also widely assumed in the literature that wh-extraction from adjuncts is impossible (Pollard & Sag 1987, Huang 1982, Rizzi 1990). However, this constraint does not seem to be cross-linguistically universal, or at least it does not apply to all types of modifiers. For example, while in English extraction from clausal adjuncts is prohibited (13), extraction from PPs is allowed (14).

(13) * **Which man** did John leave when he saw __?

(14) **Which bed** did David sleep **in** __?

3.4 Terms and non-terms

Another distinction is between core arguments, or terms, and non-core arguments, or non-terms.

(15) $\underbrace{\textsc{subj} > \textsc{obj} > \textsc{obj}_\theta}_{\text{terms}} > \textsc{comp}, \textsc{xcomp} > \textsc{obl}_\theta > \textsc{adj}, \textsc{xadj}$

There is no universal set of tests that distinguishes between terms and non-terms, but a number of constructions in different languages are systematically sensitive to this distinction; see Alsina (1993) for a detailed discussion of termhood. Some of these constraints are discussed in the following sections.

3.4.1 Agreement

In many languages, verb agreement seems to be only possible with terms, that is, subjects, objects or secondary objects. The idea goes back at least to Johnson (1977: 157), where it is called the Agreement Law. It has the same status in Relational Grammar (Frantz 1981). Agreement with subjects is very widespread; many languages also have (obligatory or optional) agreement with direct objects; the map in WALS (Siewierska 2013) cites 193 languages with both subject (A/S) and object (P) agreement out of a sample of 378. Object-only (or rather, P/S) agreement is considerably less common, exhibited by only 24 languages in the above-mentioned sample. Indexing other arguments is even more rare, but some languages, like Basque (isolate), also agree with secondary objects. As seen in (16), finite ditransitive verbs in Basque agree with the ergative (SUBJ), absolutive (OBJ) and dative ($\textsc{obj}_\theta$) arguments in person and number.

(16) Basque (isolate)
d-a-kar-ki-da-zu
3SG.ABS-PRS-bring-DAT-1SG.DAT-2SG.ERG
'you bring it to me' (Hualde et al. 2003: 209)

From current LFG literature, it is unclear whether the restriction of agreement to terms is a theoretical postulate or an empirical observation, since the termhood of agreement controllers is usually confirmed by independent syntactic evidence.

3.4.2 Control

Cross-linguistically, only terms tend to be controllers or controllees in control constructions, both lexically determined (clausal complements) and not (clausal adjuncts). For instance, Kroeger (1993) shows that in Tagalog, only terms can be anaphoric controllees[8] in participial complement constructions and controllers in adjunct constructions. According to Kroeger, voice suffixes in Tagalog promote any argument to subject status, and the erstwhile subject (the agent) becomes an obj$_\theta$ (see an illustration in (23) below).[9] Thus, (17) illustrates the verb 'read' in the active voice; the controller is the subject. In (18), the verb 'read' is marked by the "object voice" suffix: the Patient is promoted to subject status and carries the nominative proclitic *ang=*. The controllee is still the Agent, which in this example is demoted to obj$_{\text{AG}}$. Finally, (19) shows that obliques, i.e. arguments that are not subjects, direct objects or demoted agent-like arguments in voice constructions, cannot be controllees, even if they have the same semantic role Agent.

(17) Tagalog (Malayo-Polynesian > Austronesian)
In-abut-an ko siya=ng [nagbabasa ___$_{\text{subj}}$ ng=komiks
pfv-find-dv 1sg.gen 3sg.nom=comp av.ipfv.read gen=comics
sa=eskwela].
dat=school
'I caught him reading a comic book in school.' (Kroeger 1993, via Dalrymple et al. 2019: 16)

(18) In-iwan-an ko siya=ng [sinusulat ___$_{\text{obj}_{\text{AG}}}$ ang=liham].
pfv-leave-dv 1sg.gen 3sg.nom=comp ipfv.write.ov nom=letter
'I left him writing the letter.' (Kroeger 1993, via Dalrymple et al. 2019: 16)

(19) *In-abut-an ko si=Luz na [ibinigay ni=Juan
pfv-find-dv 1sg.gen nom=Luz link iv.ipfv.give gen=Juan
ang=pera ___$_{\text{obl}_{\text{GOAL}}}$].
nom=money
('I caught Luz being given money by Juan.') (Kroeger 1993, via Dalrymple et al. 2019: 16)

Similarly, Kibrik (2000) argues that in Archi (Lezgic > East Caucasian), any of the core arguments / terms (subject or direct object) can be the controllee in control constructions.

---

[8] On the distinction between anaphoric and functional control ("raising") in LFG, see Section 4.3.2 below and Vincent 2023 [this volume].

[9] Such arguments must be treated as secondary objects because they are marked by the same genitive proclitic *ng=* that marks direct objects, which do not change their mapping when an agent is demoted.

3.4.3 Reflexivization

Kibrik (2000) in fact claims that not only control constructions, but most constructions in Archi do not single out any argument beyond the term vs. non-term distinction. He shows that possessive reflexives can be controlled by the subject or direct object (i.e. A, S or P), in any direction (20a), but not by non-core-arguments (21).

(20) Archi (Lezgic > East Caucasian)

Therefore, while subject-oriented reflexives are found in many languages (see Dalrymple 1993 and Rákosi 2023 [this volume]), Archi is different in having subject *and* object, i.e. term-oriented, reflexives.

3.5 Semantically restricted and unrestricted arguments

The classification of GFs into terms and non-terms allows us to distinguish between subjects, objects and all other grammatical functions. But the difference between "primary" and "secondary" objects (OBJ and OBJ$_\theta$) remains undefined.

This distinction is captured by another classification of GFs into semantically restricted and unrestricted arguments:

(22) $$\underbrace{\text{SUBJ} > \text{OBJ}}_{\text{semantically unrestricted}} > \text{OBJ}_\theta > \text{COMP}, \text{XCOMP} > \text{OBL}_\theta > \text{ADJ}, \text{XADJ}$$

As mentioned above, θ in the GF names OBJ_θ and OBL_θ stands for a particular thematic role that is filled by this argument. Thus they are families of GFs, each of which is associated with a particular semantic role: OBL_{GOAL}, $\text{OBJ}_{\text{THEME}}$, etc. In this, they are contrasted with subjects (SUBJ) and direct objects (OBJ), which do not have this additional qualifier attached to them.

The specific list of thematic roles is not agreed upon in LFG. In the case of OBJ_θ and OBL_θ, it is not even clear whether the roles that appear in θ are universal or language-specific (the fact that θ is often equivalent to the PCASE value supplied by an adposition suggests the latter). For more information on the mapping from thematic roles to GFs, see Findlay et al. 2023 [this volume].

A consequence of the distinction between semantically restricted and semantically unrestricted GFs is the fact that only the latter can be non-arguments at the semantic level; the former must be assigned some thematic role. This, in turn, predicts that, first, arguments lacking any semantic role (expletives or dummy arguments) like English *it* or *there* (such as in *It rained*) can only appear in subject or direct object position; second, that "raising" (functional control in LFG terms) is only possible when the matrix clause position is SUBJ or OBJ.

In what follows, I will discuss the motivation for treating each of these GFs as semantically restricted or unrestricted in detail.

3.5.1 Unrestricted GFs

3.5.1.1 Subjects One of the key features of subjects is that they are not restricted to one semantic role (Fillmore 1968). The semantic unrestrictedness of subjects is perfectly illustrated by the existence of passive constructions: the same lexical verb can have either the Agent (in the active voice) or the Patient (in the passive voice) as its subject. Some languages go even further and allow promoting any argument to subject status if it has discourse prominence, or for syntactic reasons. One such language is Tagalog, where the voice suffix on the verb determines which argument bears the SUBJ GF, according to the analysis in Kroeger (1993):

(23) Tagalog (Greater Central Philippine > Austronesian)

a. active voice
B<um>ili **ang=lalake** ng=isda sa=tindahan.
<PRF.AV>buy NOM=man GEN=fish DAT=store
'**The man** bought fish at the store.'

b. objective voice
B<in>ili-∅ ng=lalake **ang=isda** sa=tindahan.
<PRF>buy-OV GEN=man NOM=fish DAT=store
'The man bought **the fish** at the store.'

c. dative voice
B<in>ilih-an ng=lalake ng=isda **ang=tindahan**.
<PRF>buy-DV GEN=man GEN=fish NOM=store
'The man bought the fish **at the store**.'

d. instrumental voice
Ip<in>am-bili ng=lalake ng=isda **ang=pera**.
<PFV>IV-buy GEN=man GEN=fish NOM=money
'The man bought fish **with the money**.'

e. benefactive voice
I-b<in>ili ng=lalake ng=isda **ang=bata**.
BV-<PRF>buy GEN=man GEN=fish NOM=child
'The man bought fish **for the child**.'

The formal marking of the subject is also not usually directly derived from its semantic role. We saw above that in Tagalog, the subject always receives the nominative preposition *ang*. In languages where non-canonical subject marking is possible, there is still no consistent association between case marking and the semantic role of the subject. For example, Icelandic oblique subjects are never agent-like, but the choice of the case marker does not otherwise consistently correlate with particular semantic roles (Jónsson 2003). Even among Daghestanian (East Caucasian) languages, where experiencer subjects are regularly marked by dative instead of ergative, there is some variation as to which case is selected by which verb; for example, in Gubden Dargwa, the verb 'see' selects ergative case and the verb 'want' selects dative case, while in the closely related Khuduts Dargwa both verbs have dative subjects (Ganenkov 2013: 246).[10] In short, sub-

---

[10] It is worth mentioning that some Daghestanian languages have been argued to lack the subject grammatical function. As mentioned above, Kibrik (2000) argued that in Archi, only core arguments (terms in LFG) can be distinguished, but there is no evidence for the privileged status of either of the core arguments. The universality of subjects is discussed in Section 4.2.4.

jects are usually consistently encoded regardless of their semantic role, and when there is variation in marking, it is usually lexical and idiosyncratic.

3.5.1.2 Direct Objects Direct objects, too, are not associated with specific semantic roles. While direct objects are never agents in English, they can still have a range of semantic roles: Patient (*John ate* ***the cookie***), Stimulus (*John saw* ***David***), Experiencer (*It surprised* ***me***), Theme (*I gave* ***the book*** *to John*). Just like Tagalog can promote various arguments to subjects, some languages allow promoting arguments to direct objects via so-called applicative constructions. One such language is Hakha Lai (Tibeto-Burman > Sino-Tibetan), which I describe following Peterson (2007: 15ff.). In Hakha Lai, verbs agree with two core arguments – subjects and objects – of transitive verbs, as in (24).

(24) Hakha Lai (Tibeto-Burman > Sino-Tibetan)
ʔan-kan-thoʔŋ
subj.3pl-obj.1pl-hit
'They hit us.' (Peterson 2007: 16)

It can be reasonably assumed that, in LFG terms, the argument indexed by the first prefix is subj, while the argument indexed by the second prefix is obj.

Hakha Lai also has a range of applicative suffixes that introduce additional morphologically unmarked arguments into the verb's argument structure. One such marker is the benefactive / malefactive suffix *-piak*. When this suffix is used, it is the newly introduced argument that occupies the obj position, as seen from the agreement pattern in (25). The verb agrees with the first person singular benefactive argument ('on me') and not with the third person singular patient ('wood slab').

(25) ʔaa! tleem-pii khaa maʔ-tii tsun taar-nuu=niʔ
interj wood.slab-aug deic dem-do deic old-woman=erg
ʔa-**ka**-khaʔŋ-piak=ʔii…
subj.3sg-obj.1sg-burn-mal=conn
'Ah, the old woman burned the big slab of wood on me, and…'
(Peterson 2007: 17)

3.5.2 Obliques

The reason for treating obliques as semantically restricted and a family of functions is that, unlike subjects and objects, their marking will always vary depending on their semantic role. For example, Goals in English use the preposition *to* (as in *Mary went to London*), while Sources use the preposition *from* (*David came from Paris*). This justifies treating OBL as a family of functions rather than a single GF.

Another reason for this architectural decision is that there may be multiple obliques in one clause. In English, this can be illustrated by sentences like *John moved from London to Paris*, where *from London* can be analyzed as $\text{OBL}_{\text{SOURCE}}$ and *to Paris* as OBL_{GOAL}. This can be disputed, however, because either of the obliques, or both, can be omitted; thus Zaenen & Crouch (2009) propose doing away with OBL altogether, replacing OBL with set-valued ADJ. In other languages, however, the evidence for multiple OBL arguments can be more compelling. Dahlstrom (2014) shows that in the Algonquian language Meskwaki, obliques are strictly positioned immediately before the verb (26), while other arguments (subjects, objects, secondary objects and complement clauses) appear postverbally, as illustrated in (27), where 'Wisahkeha' is analyzed as a direct object by Dahlstrom.

(26) Meskwaki (Algonquian > Algic)
aˑkwi **nekotahi** wiˑh-nahi-ihaˑ-yanini
not anywhere FUT-be.in.habit.of-go(thither)-2/NEG
'You will never go **anywhere**.' (Dahlstrom 2014: 57)

(27) iˑni=keˑhi=ipi=meko eˑh-awataw-aˑči wiˑsahkeˑh-ani
then=and=HRSY=EMPH AOR-take.OBJ2.to-3>3′/AOR W.-SG
metemoˑh-eˑh-a
old.woman-DIM-SG
'And right then, it's said, the old woman took it to Wisahkeha.'
(Dahlstrom 2014: 58)

In Meskwaki, obliques are not optional but required by verbal stems or preverbs. For example, all verbs of quotation require an oblique argument. Therefore, the participants that Dahlstrom terms "obliques" cannot be analyzed as adjuncts in terms of LFG.

Dahlstrom further demonstrates that additional oblique arguments may be associated with preverbs (which can be viewed as a kind of applicative marker) or compounded verb stems. When more than one oblique appears in a clause, all must precede the verb, and each oblique argument must be adjacent to the associated root or preverb.

(28) awitameko **keˑkoˑhi** iši– **ateškaˑwi** –išawihkapa
not.POT=EMPH any.way thus– with.delays –thus.happen.to.S-2/POT
'You would not have experienced delays in any way.' (Dahlstrom 2014: 64)

In (28), *ateška·wi* is associated with the verb stem, while *ke·ko·hi* satisfies the valency introduced by the preverb *iši-*. The special position of each of these obliques seems to present compelling evidence for treating them as separate (though related) semantically restricted GFs.

3.5.3 Secondary objects

Among all the main GFs, secondary objects are perhaps the most difficult to characterize. They are similar to objects in being terms, and to obliques in being semantically restricted. But these classifications are not easily translatable into specific empirical properties. We have seen above that arguments analysed as secondary objects are similar to direct objects in being terms, which allows them to trigger verbal agreement and act as controllees. But these criteria do not always serve to distinguish OBJ$_\theta$; for example, neither applies to English. Another property of secondary objects, which likens them to obliques, is their semantic restrictedness.

Secondary objects were originally thought of as occupying a single GF OBJ2 (Kaplan & Bresnan 1982) and identified on the basis of constructions like (29) in English and other Germanic languages like Icelandic. In English, the identification of OBJ2 is straightforward due to the fact that it is the only argument apart from subject and direct object that is not marked by a preposition (which is a feature of obliques) and also due to the alternation of the double object construction in (29) with the oblique dative construction in (30). Thus, the same thematic roles map to two constructions that differ both in word order and case / preposition marking. This means that at least three different GFs must be distinguished: OBJ, OBL$_\theta$ and OBJ$_\theta$.

(29) John gave [Mary]$_{\text{OBJ1}}$ [a book]$_{\text{OBJ2}}$.

(30) John gave [a book]$_{\text{OBJ1}}$ [to Mary]$_{\text{OBL}}$.

The fact that *Mary* is indeed the direct object in (29), even though it is called an “indirect object” in traditional grammar (due to its dative semantics), can be seen from the fact that in the passive version of (29), it is the recipient that is promoted to subject status (31).

(31) a. Mary was given a book.
     b. * A book was given Mary.

Passivization is not a *direct* criterion for objecthood, because in LFG the passive is a lexical process and not a syntactic transformation (Dalrymple et al. 2019: 28).

But indirectly, lexical mapping constraints do determine which arguments can be passivized. Objects can be passivized because they are inherently classified as [−*r*], and, in the absence of a higher-ranking argument, fill the subj gf which is defined as [−*o*, −*r*]. Secondary objects, in contrast, cannot be passivized because they are inherently defined as [+*o*]. This is one of the key features of secondary objects as opposed to direct objects.

In English, the label obj2 may indeed be appropriate, because there can be only one secondary object, and this object is connected to only one semantic role (Theme). But other languages make much wider use of secondary object functions, such that there may be several obj$_\theta$s, each of which is restricted to a different semantic role. For example, Bresnan & Moshi (1990) analyze Kichaga (Bantu) as having verbal indexing of multiple thematically restricted objects, each of which has its own slot in the verb form:

(32) Kichaga (Bantu)
n-ä-lꜝé-kú-shí-kí-kóṛ-í-à
focus-1subj-pst-17obj-8obj-7obj-cook-appl-fv
‘She/he cooked it with them there.’ (Bresnan & Moshi 1990: 151)

Of the three object prefixes in this example, only the instrumental object (8obj-) is unrestricted; the other two are thematically objects that occupy the grammatical functions obj$_{\text{loc}}$ (17obj-) and obj$_{\text{patient}}$ (7obj-).

Another use of obj2 / obj$_\theta$ is to capture the difference between case-marked (topical) and unmarked objects in languages with Differential Object Marking (DOM), where the direct object can either be marked by a special (accusative) case or left unmarked (as discussed in Section 2; also see Butt 2023 [this volume]). According to Dalrymple & Nikolaeva (2011), in many such systems, accusative-marked direct objects have the gf obj, while unmarked objects are obj$_\theta$. The same distinction may be reflected in agreement patterns: Dalrymple & Nikolaeva (2011) show that in Ostyak (Ob-Ugric > Uralic), objects that trigger agreement are obj while objects that do not are obj$_\theta$. With respect to case marking, an opposite viewpoint is taken by Butt & King (1996), who treat focal, unmarked objects as obj. It may be that different patterns are observed in different languages. It is also possible that in some languages, the distinction is not reflected by any overt case marking or agreement; the theory itself does not constrain this in any way.

3.5.4 Universality

From these examples it is clear that secondary objects are very similar to obliques in being semantically restricted and covering a similar set of semantic roles. Secondary objects have to be recognized only in those languages where there is evidence that some arguments are more prominent than obliques (e.g. in case marking, verb morphology, or anaphora) but less prominent than direct objects. Not all grammars involve such fine-grained distinctions, and in this sense $\textsc{obj}_\theta$ is probably not universal.

In contrast, $\textsc{obl}_\theta$ as it is understood and used in LFG is, in effect, architecturally necessary,[11] because subj and obj provide only two positions, which is not enough to map all possible thematic roles that verbs may have.

Finally, it is theoretically possible that some languages do not make use of the gf obj. Such a language would have only one semantically unrestricted function, subj; all other arguments would be $\textsc{obj}_\theta$s or $\textsc{obl}_\theta$s with various semantic roles. It would also lack a passive, because, under Lexical Mapping Theory, passivization depends on the presence of a second $[-r]$ argument that is promoted to subject status. In effect, this would be a language where most semantic roles are directly encoded in the syntax, i.e. there is a one-to-one correspondence between gfs and thematic roles, except for one unrestricted argument. This idea has been discussed in two distinct flavours. Börjars & Vincent (2008) consider whether the obj vs. $\textsc{obj}_\theta$ distinction should be abandoned as such (i.e. all objects in all languages are $\textsc{obj}_\theta$s). In contrast, Lander et al. (2021) make this proposal for the specific case of West Circassian (West Caucasian). West Circassian, a polysynthetic language, has a rather unusual system of applicative prefixes that is unlike the more typologically common system discussed above for Hakha Lai: see (25) above. In Hakha Lai, additional arguments introduced by applicative morphology are promoted to obj status, while the erstwhile object is demoted to $\textsc{obj}_\theta$. In West Circassian, applicative prefixes simply introduce additional arguments without altering the status of existing arguments. The absolutive argument is not indexed on the verb and the corresponding full NP (if present) bears Absolutive case. All other arguments are introduced by prefixes and their full NP counterparts bear Oblique case. For example, in (33) the Absolutive Patient is ‘dishes’ (*laʁe-xe-r*) and has no corresponding verbal prefix. The three other arguments bear Oblique case: ‘boy’ (*č̣’ale-m*) corresponds to the prefix *jə-*, ‘girl’ (*pŝaŝe-m*) corresponds to *∅-r-* and ‘you’ is expressed only by the prefix *b-də-*.[12]

---

[11] Assuming that $\textsc{obj}_\theta$ is not universal. Logically speaking, if the language only draws a distinction between subj, obj, and all other arguments, it does not matter whether the latter are called $\textsc{obj}_\theta$ or $\textsc{obl}_\theta$.

[12] The colours represent the morphemes and f-structures associated with the arguments of the clause, for easier comprehension. The ergative subject (‘boy’) is in red, the oblique-marked recipient (’to the girl’) is in brown, and the caseless comitative pronoun (’with thee’) is in blue.

(33) West Circassian (West Caucasian)
č̣’ale-m$_i$ pŝaŝe-m$_j$ laʁe-xe-r we$_k$
boy-OBL girl-OBL dish-PL-ABS you.SG
qə-b-$_k$də-∅-$_j$r-jə-$_i$tə-ʁe-x
DIR-2SG.IO-COM-3SG.IO-DAT-3SG.ERG-give-PST-PL
‘The boy gave the dishes to the girl with you (sg.).’ (Lander et al. 2021: 226)

Lander et al. (2021) argue for a syntactically ergative analysis of West Circassian, showing that the Absolutive argument has privileged status in certain constructions; it is assigned the grammatical function SUBJ. In contrast, they find no evidence for a distinction between different types of indexed arguments and analyze them all as OBJ$_\theta$: ergative agents are OBJ$_{\text{AGENT}}$, recipients are OBJ$_{\text{RECIP}}$, instrumentals are OBJ$_{\text{INSTR}}$ etc. Thus the sentence (33) gets the f-structure (34) in their analysis.

(34)
$$\left[\begin{array}{ll}
\text{PRED} & \text{‘GIVE}\langle\text{SUBJ, OBJ}_{\text{AG}}\text{, OBJ}_{\text{GOAL}}\text{, OBJ}_{\text{COM}}\rangle\text{’} \\
\text{TENSE} & \text{PAST} \\
\text{DIR} & \textit{Qə} \\
\text{SUBJ} & \left[\begin{array}{ll} \text{PRED} & \text{‘DISH’} \\ \text{PERS} & 3 \\ \text{NUM} & \text{PL} \end{array}\right] \\
\text{OBJ}_{\text{AG}} & \left[\begin{array}{ll} \text{PRED} & \text{‘BOY’} \\ \text{PERS} & 3 \\ \text{NUM} & \text{SG} \end{array}\right] i \\
\text{OBJ}_{\text{GOAL}} & \left[\begin{array}{ll} \text{PRED} & \text{‘GIRL’} \\ \text{PERS} & 3 \\ \text{NUM} & \text{SG} \end{array}\right] j \\
\text{OBJ}_{\text{COM}} & \left[\begin{array}{ll} \text{PRED} & \text{‘PRO’} \\ \text{PERS} & 2 \\ \text{NUM} & \text{SG} \end{array}\right] k
\end{array}\right]$$

According to Lander et al., West Circassian does make use of the grammatical function OBL$_\theta$ for those arguments that are not indexed and are marked by postpositions, but there is no need for the grammatical function OBJ in this language.

4 Individual GFs

4.1 General remarks

In the preceding section, I described the cross-classification of grammatical functions according to three parameters: governability, termhood and semantic restrictedness. This subdivides the main GFS into four classes: (1) SUBJ and OBJ (governable semantically unrestricted terms); (2) OBJ_θ (governable semantically restricted term); (3) OBL_θ (governable semantically unrestricted non-term); (4) ADJ (ungovernable). However, this is not enough to characterize all the grammatical functions for the following reasons. First, (X)COMP and POSS, being restricted to rather specific syntactic configurations, do not readily fit into this picture: while (X)COMP is certainly governable, it is not clear whether it is a term; as for POSS, while it is certainly semantically unrestricted, it is not clear whether it is a term and whether it is, in fact, governable. Secondly, the distinction between SUBJ and OBJ remains unspecified.[13] Thirdly, the cross-classification of grammatical functions is not meant to explain all of their properties: even grammatical functions like OBJ_θ, whose existence is predicted by the cross-classification itself, may have individual properties that do not follow from their class membership.

Therefore, in this section, I will proceed from the "big picture" drawn above towards characterizing the unique properties of some of the more distinct grammatical functions in LFG, sometimes together with other GFS in order to provide a better contrast. Subjects are opposed to all other grammatical functions and will be discussed separately in Section 4.2. Many LFG approaches treat clausal complementation and nonverbal predication similarly, and both are discussed in Section 4.3. The treatment of possessors in LFG is rather special: in many ways they are like subjects, but they are also sometimes viewed as being ungovernable, likening them to adjuncts instead. Accordingly, they are given a separate treatment in Section 4.4.

4.2 Subjects

All grammatical frameworks that have any notion of grammatical function assign a special status to the subject. Its properties are mainly derived from its position at the top of the functional hierarchy, and are discussed in Section 4.2.1. The centrality of the subject also raises the question of its universality, which can be approached from three different perspectives. First, is the subject universal across sentences within a single language, i.e. do all sentences have to have a subject (Section 4.2.2)? Secondly, do all languages map semantic arguments to subjects in the same way? For example, do ergative languages employ the same mapping as accusative languages? This is discussed in Section 4.2.3. Finally, is

---

[13] As mentioned above, Lexical Mapping Theory classifies them both as semantically unrestricted [$-r$], but OBJ is "objective" [$+o$] while SUBJ is not [$-o$]. But this distinction only plays a role in mapping thematic roles to grammatical functions; it is not relevant for the actual syntactic properties of subjects and objects, which is the focus of this chapter.

the notion of subject universal at all – are there languages where no single argument can be identified as the priority target of most syntactic relations and processes (Section 4.2.4)?

4.2.1 Core properties

The subject can be characterized as the most prominent argument in the clause, both in terms of the hierarchy in (7) and in that it is usually the sentence topic (at least in syntactically accusative languages). As with all other GFs, there is no specific set of tests that would define subjects cross-linguistically. Rather, being highest-ranking in the Keenan-Comrie hierarchy, they are expected to always participate in processes that are dependent on this hierarchy. More specifically, if a syntactic construction always targets only one argument of a clause, this argument is likely to be identified as the subject. Many tests for subjecthood have been proposed in the literature (for one summary, see Andrews 2007);[14] in the end, the particular set of diagnostics should be identified on a language-by-language basis.

One diagnostic is agreement. We have seen above that cross-linguistically, only terms can control agreement. But if any one term is the sole agreement controller in a language, this has to be the subject. Moravcsik (1978: 364) proposes a typological universal: if a language has agreement with anything other than an intransitive subject, it also has to exhibit agreement with the intransitive subject. Note that this universal is carefully formulated to include ergative languages (which only show S/P agreement) and does not automatically identify the subject in the "accusative" sense (A/S). I will return to the question of subjecthood in non-accusative languages below.

It also seems that only subjects can be "raised",[15] i.e. in LFG terms, shared (functionally controlled) with a term argument in the main clause. English only has subject-to-subject (35) and subject-to-object (36) raising.[16]

---

[14] Subject criteria that are commonly proposed in the literature include: case marking and agreement; ellipsis under coordination; binding of reflexive pronouns; control of null subjects (PRO) of infinitives and gerunds; selection in switch reference systems (same-subject / different-subject). Many more language-specific tests have been proposed as well.

[15] Based on cross-linguistic data, Falk (2006: 155-161) argues that only arguments bearing the grammatical function PIVOT (in accusative languages equal to SUBJ, see Section 4.2.3) can be controllees in functional control (raising) constructions, with the only exception being certain Polynesian languages. For the latter, he allows the possiblity of inside-out licensing of functional control, which does not obey his generalization on PIVOT.

[16] A reviewer proposes English sentences like *This book is tough to read* as potential counterexamples; however, Dalrymple & King (2000) argue that this construction involves anaphoric control rather than raising/functional control (see Section 3.4.2 above for a termhood constraint on anaphoric controllees in certain languages).

(35) **John** seemed [__ to agree].

(36) John believed **David** [__ to be crossing the street].

In Icelandic, the raising rule also applies to non-nominative ("quirky") subjects (Andrews 1982). Thus, in (37a–c) the verbs select accusative, dative and genitive subjects, respectively.

(37) Icelandic (Germanic > Indo-European)

a. **Drengina** vantar mat.
boys.DEF.ACC lacks food.ACC
'**The boys** lack food.'

b. **Barninu** batnaði veikin.
child.DEF.DAT recovered.from disease.DEF.NOM
'**The child** recovered from the disease.'

c. **Verkjanna** gætir ekki.
pains.DEF.GEN is.noticeable not
'**The pains** are not noticeable.'

This case marking is retained under raising in the main clause (38). These examples also illustrate how subjecthood is independent not only from semantic role, but also from case marking.

(38) a. Hann telur **mig** (í barnaskap sínum) [vanta peninga].
he believes me.ACC in foolishness his to.lack money.ACC
'He believes **me** (in his foolishness) to lack money.'

b. Hann telur **barninu** (í barnaskap sínum) [hafa
he believes child.DEF.DAT in foolishness his to.have
batnað veikin].
recovered.from disease.DEF.NOM
'He believes **the child** (in his foolishness) to have recovered from the disease.'

c. Hann telur **verkjanna** (í barnaskap sínum) [ekki gæta].
he believes pains.DEF.GEN in foolishness his not noticeable
'He believes **the pains** (in his foolishness) not to be noticeable.'

4.2.2 Subjectless sentences?

A persistent question in theoretical linguistics is whether subjects are universal — that is, if subjectless sentences exist. Note that the very fact that this is a valid question follows from the LFG assumption that GFs like SUBJ are theoretical primitives (even if they tend to be associated with a set of typical empirical diagnostics). Were the subject only defined as the highest-ranking argument in a list of ARGS (as in Simpler Syntax and some variants of HPSG), each clause would automatically have a "subject" as long as its predicate had any syntactic arguments. In LFG, subjects are also assumed to be, by and large, prominent in different senses (more on this below), but this does not entail that subjectless sentences cannot exist, if only at the periphery of grammar.

That being said, the Subject Condition in (39) is widely assumed to hold in LFG (Bresnan & Kanerva 1989) — as a theoretical stipulation, not as a consequence of the framework's architecture. Most versions of the Lexical Mapping Theory also predict that one of the arguments will always be mapped to SUBJ.

(39) Subject Condition:
Every verbal predicate must have a subject.

The Subject Condition certainly holds in English, as well as in many other languages. But is it universal? Examples like (40) from German and (41) from Russian at first sight seem to be exceptions to the Subject Condition.

(40) German (Germanic > Indo-European)
… weil getanzt wird
because danced become.PRS.3SG
'because there is dancing'

(41) Russian (Slavic > Indo-European)
menja tošnit
I.ACC nauseate.PRS.3SG
'I feel sick.'

The German example in (40) has an intransitive verb with no overt arguments, even though German is generally not a pro-drop language. The Russian verb in (41) only has an accusative experiencer argument; while Russian does allow null subjects, it does so in a limited number of contexts and always optionally, while here no nominative argument can be expressed. However, Berman (1999, 2003) argues that the agreement morphology indicates that German examples contain a null expletive subject with only pers and num features, and no pred value. The same analysis can be extended to the Russian data.

A more convincing case for subjectless sentences is found in the Polish examples like (42), discussed in Kibort (2006). In this construction, the verb stands in the infinitive form, thus having no agreement morphology. To Kibort, this indicates that such sentences are truly subjectless. The agent may be optionally expressed, but as an oblique prepositional argument — not as a subject.

(42) Polish (Slavic > Indo-European)
Słychać ją / jakieś mruczenie.
hear.inf her.acc some.n.acc murmuring(n).acc
'One can hear her/some murmuring.'

Subjectless sentences also appear in Lowe et al.'s (2021) analysis of the Sanskrit raising verb *śak* 'can'. When this verb is passivized, one of the possible outcomes is for the raised subject of the subordinate clause to stand in the instrumental case, while the object remains in the accusative:

(43) Sanskrit (Indo-Aryan > Indo-European)
rājabhī rāmaṃ hantuṃ na śakyate
kings.ins R.acc slay.inf not can.pass.3sg
'Rāma cannot be slain by the kings.'

Lowe et al. argue that in this construction the matrix clause has two arguments: the instrumental as obl$_\theta$ and the subordinate clause as xcomp, and thus it has no overt subject.[17]

Thus, the Subject Condition may not be universal as a general rule — although it does hold as an overall tendency, since subjectless constructions, if there are any, are usually found only at the periphery of grammar.

4.2.3 Subjects in non-accusative languages

The universality of subjects can also be questioned in a different way: Does the same mapping between thematic roles and gfs obtain in all languages? This has long been debated in the literature concerning ergative and other non-accusative types of alignment. Most ergative languages are in fact only morphologically ergative, that is, have ergative case marking while syntactically behaving in the

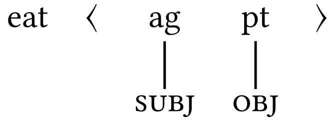
---

[17] Lowe et al. acknowledge that, if (x)comp is assumed not to exist as a separate gf (see Section 4.3.1), the clause itself will have to be treated as subj.

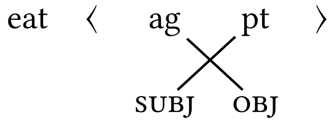
same way as accusative languages. But there are a few languages that have been claimed to be consistently syntactically ergative, e.g. Dyirbal (Dixon 1979), although this analysis is disputed, see Legate (2012); less common syntactic alignment types are attested as well. These facts call for an adjustment to the standard approach to argument mapping.

There are two basic proposals for treating non-accusative languages in LFG. One, developed in Manning (1996), is to preserve the standard set of gfs but map subj and obj to thematic roles in different languages in different ways. Thus, while intransitive verbs always have a single subj argument, transitive verbs in accusative languages map agents to subj and patients to obj (44a); in ergative languages, the mapping is reversed (44b).

(44) a. accusative



b. ergative



Thus, in ergative languages, the transitive agent (A) is obj while the transitive patient (P) is subj. This explains why the patient has subject-like properties in various constructions. Calling the agent a “direct object” is unfamiliar and confusing from a traditional perspective, which is why Manning proposes an alternative nomenclature of pivot (= subj) and core (= obj, for core argument) instead.

This approach works well for languages where one of the arguments fully “takes over” all syntactic properties of subjecthood. However, such languages are an exception rather than the norm. More commonly, subject properties are distributed between the transitive agent (A) and the absolutive argument (P): some constructions are aligned in the ergative way, while others are still oriented towards A. For example, in Ashti Dargwa (field data), gender agreement on the verb follows the ergative pattern (S/P), and can even be long-distance (45), which suggests syntactic ergativity. But reflexive binding still prefers the A argment, as in accusative languages (46).

(45) Ashti (Dargwa > East Caucasian)

di-l	[šin	**d**-eč:-ib]	ha<**d**>eχʷ-i
I(m)-erg	water(npl)	npl-drink.pfv-pcvb	<npl>finish.pfv-pret

‘I finished drinking water.’

(46) a. rasul-li **sin-na** **sa-w** w-aˁqˁ.aqˁ-ipːi
R.-ERG self-GEN self-M(ABS) M-hurt.PFV-PRF.3
'Rasul (erg.) hurt **himself** (abs.).'

b. * **sin-na** **sin-dil** rasul w-aˁqˁ.aqˁ-ipːi
self-GEN self-ERG R.(ABS) M-hurt.PFV-PRF.3
(intended translation: 'Rasul hurt himself.'; lit. 'Himself (erg.) hurt Rasul (abs.).')

Falk (2006) observes that cross-linguistically, subject properties tend to fall into two classes exactly along these lines: anaphoric prominence, switch-reference, null expression, control of PRO (anaphoric control) and some other properties such as the ability to serve as the imperative subject are almost always tied to A/S, even in ergative languages. At the same time, properties related to cross-clausal continuity – functional control, extraction properties, long-distance agreement – and certain secondary properties (external structural position in non-configurational languages, agreement) may be tied to different arguments of the clause in different languages.

Accordingly, Falk proposes to recast the traditional LFG grammatical function SUBJ as $\widehat{\text{GF}}$, which is the most prominent argument (A/S), while introducing the additional clausal continuity function PIVOT, which can be identified with either $\widehat{\text{GF}}$ or OBJ. Subjecthood properties are distributed between these two functions along the lines in (47).

(47) Subject properties according to Falk (2006)

$\widehat{\text{GF}}$	PIVOT
anaphoric prominence	extraction
anaphoric control	functional control
switch-reference	long-distance agreement
null expression	obligatory element
imperative subject	"external" structural position

Of these two functions, only $\widehat{\text{GF}}$ can be properly called a grammatical function: it replaces SUBJ in the argument lists of PRED feature values; in terms of Lexical Mapping Theory, it is this function that the most prominent argument on the semantic role hierarchy is mapped to. PIVOT always has to be structure-shared with one of the verbal arguments and is thus more correctly characterized as an overlay function (see Section 5).

All the diverse surface manifestations of pivot can be generalized in what Falk calls the Pivot Condition, informally summarized in (48). This condition means that all cross-clausal dependencies, if they are not stated in terms of special overlay functions for long-distance dependencies such as dis (for “dislocated”, or topic and focus in earlier approaches: see Section 5 and Kaplan 2023 [this volume]) must be tied to pivot. Thus pivot is the locus through which argument information is shared across clauses.

(48) Pivot Condition:
A path inward through f-structure into another predicate-argument domain or sideways into a coordinate f-structure must terminate in the function pivot. (Falk 2006: 78)

In English, and in other purely accusative languages, $\widehat{\text{gf}}$ and pivot are always occupied by the same f-structure. Falk calls such systems “uniform-subject”. In other languages, these do not always coincide — this class of languages is called “mixed-subject”. The mixed-subject class is not uniform. Its most widespread members are ergative languages, where pivot is identified with $\widehat{\text{gf}}$ in intransitive clauses and with obj in transitive clauses.

Given the facts in (45)–(46), Ashti Dargwa can be analyzed as a mixed-subject, ergative language, with the f-structure of a transitive sentence ‘the girl drank water’ as in (49).

(49)
$$\left[\begin{array}{ll} \text{PRED} & \text{‘DRINK}\langle\widehat{\text{GF}}\ \text{OBJ}\rangle\text{’} \\ \widehat{\text{GF}} & \left[\begin{array}{ll} \text{PRED} & \text{‘GIRL’} \\ \text{NUM} & \text{SG} \\ \text{GEND} & \text{F} \\ \text{CASE} & \text{ERG} \end{array}\right] \\ \text{OBJ} & \left[\begin{array}{ll} \text{PRED} & \text{‘WATER’} \\ \text{NUM} & \text{PL} \\ \text{GEND} & \text{N} \\ \text{CASE} & \text{ABS} \end{array}\right] \\ \text{PIVOT} & \rule{3cm}{0.4pt} \end{array}\right]$$

The Philippine type of alignment, illustrated in (23) above, where any argument can become the “subject” through voice morphology, is interpreted by Falk as promotion to pivot, as in (50); the most prominent argument, $\widehat{\text{gf}}$, does not change its mapping.

(50)	“Active voice”:	$(\uparrow \text{PIVOT})=(\uparrow \widehat{\text{GF}})$
	“Direct object voice”:	$(\uparrow \text{PIVOT})=(\uparrow \text{OBJ})$
	“Indirect object / locative voice”:	$(\uparrow \text{PIVOT})=(\uparrow \text{OBJ}_{\theta})$
	“Instrumental voice”:	$(\uparrow \text{PIVOT})=(\uparrow \text{OBL}_{\text{INS}})$
	…	

Some languages do not entirely fit the uniform- vs. mixed-subject distinction. In topic prominent languages like Acehnese, PIVOT is identified with any of the core arguments ($\widehat{\text{GF}}$ and OBJ) provided that it bears the information structure function TOPIC, according to Falk’s (2006: 172) interpretation of the data in Durie (1985). Thus Falk’s approach does not require PIVOT to be necessarily tied to particular argument functions.

4.2.4 Universality

Since Falk’s framework splits the traditional SUBJ into two grammatical functions that may be identified with different arguments in different languages and constructions, it follows that the subject in the traditional sense – i.e. a single highest-ranking grammatical function that dominates all syntactic rules and processes – is not universal. But we may also ask whether $\widehat{\text{GF}}$ and PIVOT are universal. There are two ways in which a language may be said to lack $\widehat{\text{GF}}$. One is that this language encodes thematic roles directly in the syntax. Such claims have been made for different languages in the literature, especially in the typological tradition. Falk (2006: 169) observes that in LFG terms, this amounts to saying that the language only has oblique GFS: OBL_{AGT}, OBL_{PAT}, etc. This, in turn, entails that the language would have no distinction between core and non-core arguments — a prediction that has empirical consequences. Evaluating such a possibility for Acehnese, one language that has been claimed to lack reference to grammatical relations in its grammar (Van Valin & LaPolla 1997), Falk concludes that its syntax does distinguish core functions from non-core functions and thus requires reference to $\widehat{\text{GF}}$. Similarly, Kibrik (2000), as mentioned in Section 3.4.3, argues that most constructions in Archi (Lezgic > East Caucasian) are only sensitive to the term (core argument) vs. non-term distinction. But there is one construction in Archi that is oriented towards A/S arguments (i.e. in Falk’s terms, $\widehat{\text{GF}}$): clausemate reflexivization. Nevertheless, the theoretical possibility of languages only having oblique arguments still exists and deserves to be investigated in more detail, although, based on the current state of our understanding, their existence does not seem likely.

Another sense in which a language may lack $\widehat{\text{GF}}$ is, conversely, if it draws a more fine-grained distinction between core arguments, i.e. does not unify the transitive agent (A) and the sole intransitive argument (S) in any way.[18] Again, this approach is widespread in the typological / functionalist tradition, a prominent example being Dixon (1994), who treats A, S and P as syntactic primitives. This is useful for purposes of typology and cross-linguistic comparison: A, S and P serve as valid comparative concepts in the sense of Haspelmath (2009). But applied to individual grammars, this distinction seems too fine-grained, failing to capture important generalizations. It is well-known, for example, that $\widehat{\textsc{gf}}$ outranks other arguments in anaphoric constructions in the overwhelming majority of languages, regardless of their other alignment patterns. Nor do “syntactically tripartite” languages with S, A and P having distinct, non-intersecting sets of properties seem to be attested.[19]

Thus, $\widehat{\textsc{gf}}$ is likely to be universal. A separate question is what a pivotless language could look like, and whether such languages exist. A pivotless language is *not* a language where the pivot cannot be readily identified with any grammatical function; it could be identified with the topic, as in Acehnese, or with the highest-ranking argument on the person hierarchy, as in some analyses of Ojibwe (Algonquian > Algic, Rhodes 1994). A pivotless language would rather lack constructions of the kind that are predicted to be pivot-sensitive by the Pivot Condition (48). For example, there would be no cross-clausal extraction, with all interrogatives and relatives being localized in their local domains; coreference in coordination and in other multiclausal constructions would similarly involve no pivot sensitivity. Falk argues that at least two languages, Choctaw and Warlpiri, qualify for pivotless status. Thus, unlike $\widehat{\textsc{gf}}$, pivot is not universal according to Falk.

Falk’s approach is insightful and makes a number of strong claims that deserve more thorough cross-linguistic investigation. It is widely accepted as the most

---

[18] Another possible complication for Falk’s theory, and the LFG view of grammatical relations in general, are so-called split-S languages, cf. Van Valin (1990), sometimes described as languages with active alignment, a view that goes back at least to Sapir (1911). In such languages, the marking of S depends on the properties of the clause or the predicate, such as agentivity, control, and telicity. Unaccusativity (Perlmutter 1978) is a related phenomenon inasmuch as it amounts to a difference between classes of intransitive verbs or intransitive subjects. It is not obvious that this difference in marking requires distinguishing between two different gfs. LFG work has tended to describe split intransitivity in terms of argument structure (cf. Bresnan & Zaenen 1990 on unaccusativity in English) or semantics (cf. Belyaev 2020 on split S marking on the verb in Ashti Dargwa). However, split intransitivity / active alignment still requires a more thorough and systematic treatment in LFG.

[19] Kibrik (1997: 323-326) claims that syntactically tripartite alignment is observed in Jacaltec (Mayan), based on the analysis in Van Valin (1981), who identifies multiple pivots in the language. However, Falk (2006: 93-94) interprets Jacaltec as syntactically ergative in terms of his LFG anlaysis instead.

adequate solution for ergativity and other syntactic alignments within LFG, although many authors still continue using the SUBJ-OBJ distinction for languages where Falk's fine-grained analysis is irrelevant, i.e. mainly in syntactically accusative languages. Falk's notion of $\widehat{\text{GF}}$ and PIVOT also has yet to be fully integrated with the recent developments in the relevant areas of LFG, such as Lexical Mapping Theory and semantic composition.

4.3 Complementation and nonverbal predication

In the preceding sections, I have mostly avoided discussing sentential complements, because their specialized grammatical function COMP stands apart from other grammatical functions in LFG. COMP is not readily classifiable in terms of termhood and semantic restrictedness, and its limitation to a single semantic type (clauses / states of affairs) is unusual for LFG. In fact, the very existence of (X)COMP as a separate GF has been questioned in the theoretical literature, as discussed in Section 4.3.1. In Section 4.3.2, I discuss the difference between closed (COMP) and open (XCOMP) complements. Nonverbal predication is also sometimes analysed using the grammatical function XCOMP, and therefore it is discussed under the same umbrella in Section 4.3.3.

4.3.1 The status of COMP

The status of COMP as a specialized grammatical function in LFG is controversial. From the beginning, it was assumed that *all* clausal complements are classified as COMP (Kaplan & Zaenen 1989, Bresnan et al. 2016). As a formal assumption, this idea is suspect: the spirit of LFG is generally to separate categorial and functional information, such that f-structure should not draw a distinction between NP and CP complements. For this reason, the very existence of COMP has been questioned, first in Alsina et al. (1996), who proposed that COMP can be replaced by OBJ.

One argument in favour of COMP is the fact that it can coexist with OBJ and OBJ_θ, as in (51).

(51) David bet $[\text{Chris}]_{\text{OBJ}}$ $[\text{five dollars}]_{\text{OBJ}_{\text{GOAL}}}$ $[\text{that he would win}]_{\text{COMP}}$.

As a further argument, Dalrymple & Lødrup (2000) show that while many clausal complements in English, German and Swedish do, indeed, behave like objects, others do not. For example, in German the complement of the verb 'believe' can be replaced by a pronoun and moved to clause-initial position (52); the latter option is also available for ordinary object NPs (53). In contrast, neither option is possible for complements of 'be happy' (54).

(52) German (Germanic > Indo-European)
a. Ich glaube [**dass** die Erde rund ist].
I believe that the earth round is
'I believe **that** the earth is round.'
b. Ich glaube es.
'I believe **it**.'
c. [**Dass** Hans krank ist] glaube ich.
that Hans sick is believe I
'**That** Hans is sick, I believe.'

(53) Einen Hund habe ich gesehen.
a dog have I seen
'A dog, I have seen.'

(54) a. Ich freue mich [**dass** Hans krank ist]
I gladden myself that Hans sick is
'I am happy that Hans is sick.'
b. * Ich freue mich **das** / **es**.
('I am happy it.')
c. * [**Dass** Hans krank ist] freue ich mich.
('**That** Hans is sick, I am happy.')

Dalrymple & Lødrup (2000) conclude that while clausal arguments of verbs like 'believe' do indeed bear the function OBJ in German, complements of verbs like 'be happy' should be recognized as genuine COMPs. However, Alsina et al. (2005) contest this conclusion by appealing to the data of Catalan and Spanish. They claim that both examples like (51) and the data cited by Dalrymple and Lødrup only show that OBJ alone is not enough to capture the behaviour of all types of clausal complements. But if some complements are treated as OBJ$_\theta$ and OBL$_\theta$, they can coexist with direct objects, and their syntactic properties can be adequately captured. A similar conclusion is reached in Forst (2006) for the German data.

This debate still continues in the LFG literature. Thus Belyaev et al. (2017) conclude that the syntax of complementation in Moksha Mordvin requires appealing to COMP in addition to OBJ and OBL$_\theta$. Moksha has object agreement morphology on transitive verbs. As discussed in Section 3.4 above, agreement is a feature of terms; clausal complements controlling agreement may thus be viewed as OBJ. In Moksha, there is a split according to this criterion. Factives control agreement, and they can also be replaced by pro-forms (55), like OBJ-complements in German, passivized, coordinated with nouns, and replaced by quantificational expressions.

(55) Moksha Mordvin (Mordvinic > Uralic)
factive complements

a. object agreement
učit'əl'-s' **sodas-in'ə /** *soda-s' [**što**
teacher-DEF.SG[NOM] know-NPST.3PL.O.3SG.S know-NPST.3SG COMP
pet'ɛ er' mejn'ɛ vor'g-əčn'-i urok-stə]
Peter every what.TMPR run.away-IPFV-NPST.3SG class-EL
'The teacher **knows** (SUBJ-OBJ) **that** Peter always misses classes.'

b. pronominalization
mon kunarə soda-jn'ə [što vas'ɛ
I[NOM] for.a.long.time know-PST.3.O.1SG.S COMP Basil[NOM]
ašč-əl' t'ur'ma-sə] — də mon-gə **t'ɛ-n'** soda-sa
be-PQP.3SG prison-IN yes I-ADD this-GEN know-NPST.3SG.O.1SG.S
'I have known (SUBJ-OBJ) for a long time that Basil had been in prison. – Yes, I know (SUBJ-OBJ) **it** too.'

Other complement clauses do not control matrix verb agreement, i.e. the verb only agrees with the subject. However, this class is not homogeneous. Some non-factive complements, such as the complement of 'fear', can be replaced by pronominal postpositional phrases or oblique case-marked pronouns — these can uncontroversially be classified as obliques (56). But complements of other non-factives, such as the verb 'say', cannot be replaced by a pronoun — an adverbial 'so' should be used instead (57). They also cannot be replaced by quantificational expressions or coordinated with a nominal argument. Belyaev et al. (2017) conclude that this latter class of complements, being distinct from both OBJ and OBL$_\theta$, should be assigned the grammatical function COMP.[20]

---

[20] Another option is available: these non-agreeing complements can be OBJ$_\theta$. This idea is appealing because Dalrymple & Nikolaeva (2011) analyze some unmarked direct objects in DOM systems as OBJ$_\theta$. In Moksha, which displays DOM, direct objects can be nominative (unmarked) or genitive. Indeed, it is unmarked direct objects in Moksha that are similar to complements of verbs like 'say': they do not trigger agreement, cannot be used with quantifiers; pronominal objects are always case-marked, etc. However, it is not clear whether unmarked and genitive direct objects in Moksha should be assigned to different grammatical functions: for instance, a marked and an unmarked direct object can be coordinated (Natalia Serdobolskaya, p.c.). In contrast, complements of verbs like 'say' cannot be coordinated with a noun phrase (Belyaev et al. 2017). Thus for Moksha the answer depends on whether unmarked direct objects in this language are OBJ$_\theta$s and on whether the coordination facts can be given an alternative explanation.

(56) Moksha Mordvin (Mordvinic > Uralic)
non-factive ‘fear’: pronominalization
mon dumand-an [što vas’ɛ af pastupanda-v-i]
I[NOM] think-NPST.1SG COMP Basil[NOM] NEG enter-PASS-NPST.3SG
institut-u — mon tožə **t’a-də** pel’-an
institute-LAT I[NOM] also that-ABL fear-NPST.1SG
‘I think (SUBJ) that Basil will not enter the university. — I am afraid (SUBJ) **of that** as well.’

(57) non-factive ‘say’: no pronominalization
nu mon **t’aftə** / *t’ɛ-n’ af dumand-an
well I[NOM] thus this-GEN NEG think-NPST.1SG
{Context: ‘Basil is so smart, he will surely pass the exams with excellent marks!’ —} ‘Well, I do not think (SUBJ) **so** / *that.’

Not all languages with object agreement or indexing draw such a sharp distinction between different complement types, however. West Circassian (West Caucasian, polysynthetic), for example, treats most clausal complements in the same way as NP arguments, which is consistent with this language’s weak distinction between nouns and verbs (Letuchiy 2016).

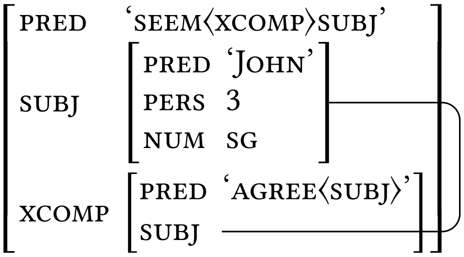
Significant differences between clausal complements and “nominal” grammatical functions such as SUBJ and OBJ have also been described for Russian in Letuchiy (2012). Overall, the data strongly suggest that COMP should at least be recognized as a possible GF for clausal complements, although the extent to which languages use this possibility seems to vary. The semantic differences between OBJ and COMP complement clauses should also be investigated in more detail.

4.3.2 Open and closed complements

We mentioned above that clausal complements in LFG are split into two grammatical functions: COMP and XCOMP. The former is called ‘closed’, the latter ‘open’. Closed clausal complements are, in principle, fully self-contained and have their own subjects (e.g. finite complement clauses); the latter do not have a subject, which has to be structure shared with an argument of another clause. Open complements (XCOMP) appear in structures called FUNCTIONAL CONTROL, which involves structure sharing of an argument of the matrix clause and an argument (usually the subject) of the subordinate clause. Functional control is generally used to represent so-called raising constructions, as in (35), repeated here, with the f-structure in (58).

(35) **John** seemed [__ to agree].

(58)

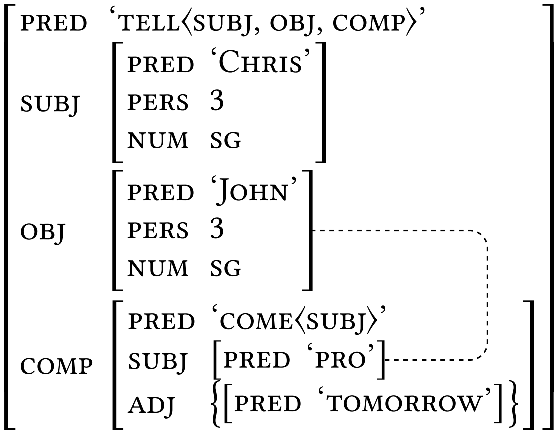


Functional control in LFG is opposed to anaphoric control, which is often employed to analyse the construction known as Equi or simply control in English, see (59).[21]

(59) Chris told John$_i$ [(PRO$_i$) to come tomorrow].

Anaphoric control involves no structure sharing but only a covert pronominal subject in the subordinate clause (PRO); accordingly, complements whose subject is anaphorically controlled are treated as closed (COMP). The f-structure of (59) is shown in (60), where the dashed line indicates coreference.

(60)



It is not clear if the distinction between COMP and XCOMP is really needed to account for the behaviour of control constructions. After all, equations that enforce structure sharing automatically ensure that the subject of the complement clause is overtly expressed only once: double expression would cause a PRED conflict. F-structure does not take the linear order or c-structure position of elements

---

[21] The discussion here presents a simplified view of the issue. In some LFG work, functional control is not limited to raising constructions but is also used in the analysis of some or all of the constructions traditionally called Equi or control. See Vincent 2023 [this volume] for detailed information on control and raising in LFG.

into account, therefore it does not matter, in principle, *where* the argument is expressed. This means that LFG allows Backward Raising constructions as in the West Circassian (61) by default (Sells 2006). In (61), the “raised” NP is overtly expressed only in the subordinate clause, which is seen in its case marking: the ergative is selected by the verb ‘lead’. The main clause subject, if it were overt, would have been in the absolutive (as seen in the crossed out pronoun).

(61) West Circassian (West Caucasian)

~~a-xe-r~~	[a-xe-me	se	s-a-š’e-new]
dem-pl-abs	dem-pl-erg.pl	1sg.abs	1sg.abs-3pl.erg-lead-inf

∅-fjež’a-ʁe-x
3abs-begin-pst-3pl.abs
‘They began to lead me.’ (Potsdam & Polinsky 2012: 76)

The English counterpart to this example would be **Began* [*they to lead me*] (or, to provide an uncontroversial example of raising, **Seem they to come*). The ungrammaticality of such examples requires independent explanation (for example, English xcomps are expressed by VPs at c-structure, which do not have a subject position). See Vincent 2023: §7 [this volume] for further discussion of LFG analyses of backwards raising.

Similarly, anaphoric control is typically analyzed as coreference that is syntactically enforced through equations like (↑ subj index) = (↑ comp subj index)[22] and, possibly, (↑ comp subj pred)=‘pro’. If the latter equation is present, an overt subject in the complement clause is precluded due to pred conflict. If it is not, argument expression is only constrained by general anaphoric requirements, which is why Backward Control (Polinsky & Potsdam 2002) is impossible in most languages due to Principle C violations (see Rákosi 2023 [this volume] for details on Principle C).

Crucially, such constraints follow from universal considerations, functional equations and general principles of individual grammars, but not from complements being xcomp rather than comp. Thus, it is not clear whether the traditional distinction between comp and xcomp is anything more than a useful notational convention; both could be said to refer to the same GF.

---

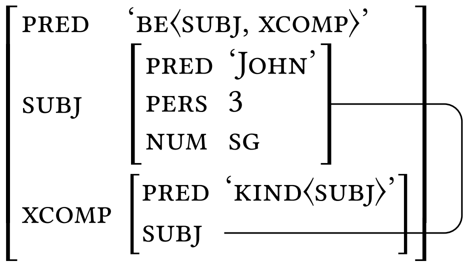
[22] In an approach where coreference is a semantic relation, such as Haug (2013), it cannot be enforced directly in the f-structure, but it can be done via a Glue meaning constructor (Haug 2014, Asudeh 2023 [this volume]).

4.3.3 Nonverbal predication

Traditionally, XCOMP was used in LFG to represent nonverbal predicates, treating them as arguments of copular verbs such as *be*, as in (62).

(62) a. John is kind.

b.



$$\left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{be}\langle\textsc{subj, xcomp}\rangle\text{'} \\ \textsc{subj} & \left[\begin{array}{ll} \textsc{pred} & \text{`John'} \\ \textsc{pers} & 3 \\ \textsc{num} & \textsc{sg} \end{array}\right] \\ \textsc{xcomp} & \left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{kind}\langle\textsc{subj}\rangle\text{'} \\ \textsc{subj} & \end{array}\right] \end{array}\right]$$

This effectively makes the nonverbal predicate into a kind of small clause. The main problem with this approach is that all lexical items that can serve as predicates must have two subcategorization frames, because in normal contexts at least nouns, and possibly adjectives (if they are not assumed to be predicated of their head noun), do not have a valency for SUBJ. As observed in Dalrymple et al. (2004), another problem for this approach is that clauses that already have subjects may function as predicates, as in the sentence *The problem is that John came.* Such clauses have no open subject position to share with the matrix subject.

The main alternative is to replace XCOMP with a special grammatical function PREDLINK (Butt et al. 1999), which is not an open complement GF and therefore does not have to share a subject valency, see (63) for *John is kind* and (64) for *The problem is that John came.*

(63)

$$\left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{be}\langle\textsc{subj, predlink}\rangle\text{'} \\ \textsc{subj} & \left[\begin{array}{ll} \textsc{pred} & \text{`John'} \\ \textsc{pers} & 3 \\ \textsc{num} & \textsc{sg} \end{array}\right] \\ \textsc{predlink} & \left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{kind}\text{'} \end{array}\right] \end{array}\right]$$

(64)

$$\left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{be}\langle\textsc{subj, predlink}\rangle\text{'} \\ \textsc{subj} & \left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{problem}\text{'} \\ \textsc{det} & \textsc{def} \\ \textsc{pers} & 3 \\ \textsc{num} & \textsc{sg} \end{array}\right] \\ \textsc{predlink} & \left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{come}\langle\textsc{subj}\rangle\text{'} \\ \textsc{subj} & \left[\begin{array}{ll} \textsc{pred} & \text{`John'} \\ \textsc{pers} & 3 \\ \textsc{num} & \textsc{sg} \end{array}\right] \end{array}\right] \end{array}\right]$$

One drawback of the PREDLINK approach compared to the XCOMP approach is related to the fact that in languages with adjective agreement, such as Russian (65), the predicative adjectives agree in gender with the subject. In (65a), the word *komnata* 'room' is feminine, and therefore the predicative adjective *malen'kaja* is feminine. In (65b) *dom* 'house' is masculine, and the adjective is also masculine.

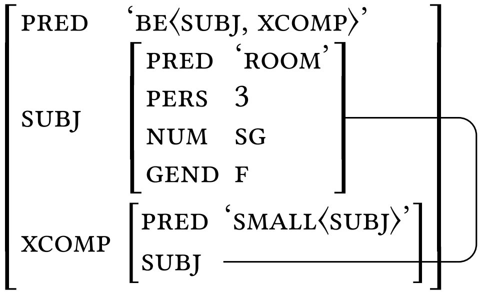
(65) Russian (Slavic > Indo-European)

a. Komnata byla malen'kaja.
room(F).SG.NOM was.F.SG small.F.SG.NOM
'The room was small (f.).'

b. Dom byl malen'kij.
house(M).SG.NOM was.M.SG small.M.SG.NOM
'The house was small (m.).'

This is straightforward to capture in the XCOMP approach, because the adjective has its own local subject with which it can agree: see (66).

(66)

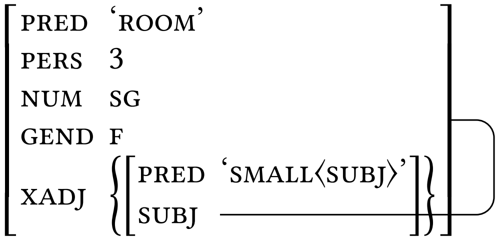


Adnominal adjectives like in (67a) can be treated in the same way by using a cyclic f-structure (67b) (see Haug & Nikitina 2012), requiring only one agreement pattern in the lexical entry (68).

(67) Russian (Slavic > Indo-European)

a. malen'kaja komnata
small(F).SG.NOM room(F).SG.NOM
'small room'

b.



(68) *malen'kaja* A (↑PRED) = 'SMALL⟨SUBJ⟩'
(↑ SUBJ NUM) = SG
(↑ SUBJ GEND) = F

In the PREDLINK approach, agreement rules will have to be more complex, utilizing inside-out functional expressions as in (69a) for adnominal adjectives and (69b) for predicative adjectives.

(69) a. ((ADJ ∈ ↑) NUM) = SG
b. ((PREDLINK ↑) SUBJ NUM) = SG

Yet another approach is to unify the f-structure of the nonverbal predicate with the f-structure of the clause (via ↑=↓); this is proposed in Dalrymple et al. (2004) for languages like Japanese, where predicative adjectives do not require a copula (70).

(70) Japanese (Japonic)
a. hon wa akai
book TOPIC red
'The book is red.'
b. $\left[\begin{array}{ll} \text{PRED} & \text{`RED}\langle\text{SUBJ}\rangle\text{'} \\ \text{SUBJ} & \left[\text{PRED `BOOK'}\right] \end{array}\right]$

In Japanese, this analysis is quite reasonable because adjectives are morphologically a subclass of verbs. It is plausible to assume that even adnominal adjectives have subjects, and thus always have PRED values like 'RED⟨SUBJ⟩'. But for languages like Russian, where adjectives inflect like nouns, there is less evidence in favour of treating each adjective as having a subject. Therefore, this analysis suffers from the same disadvantage as the XCOMP approach, in requiring two lexical definitions for each adjective or noun. Apart from this, it is structurally quite distinct from both the XCOMP and the PREDLINK approaches in being monostratal. Overall, as Dalrymple et al. (2004) conclude, it is likely that all three approaches are required to account for different constructions in different languages. For more information on copular constructions in LFG, see Dalrymple et al. (2019: 189–197).

4.3.4 The classification of comp

4.3.4.1 Termhood The termhood of sentential complements has not been frequently discussed in the literature. In no small part this is due to the unclear status of the grammatical function comp itself (see Section 4.3.1 above). A number of arguments in favour of treating comp as a non-term gf are given in Dalrymple et al. (2019). If this view is combined with the idea that clausal complements are split between comp and obj (Dalrymple & Lødrup 2000), one can predict that in languages with object agreement, obj-like complements may trigger agreement on the verb while comps may not. This prediction is confirmed in languages like Moksha Mordvin (Mordvinic > Uralic), where, as Belyaev et al. (2017) argue, the verb agrees with obj-like complements (mainly those of factive verbs like ‘know’) but does not agree with comp-like complements (mainly propositional complements of verbs like ‘promise’):

(71) Moksha Mordvin (Mordvinic > Uralic)
učit’əl’-s’ **soda-si-n’ə** / *soda-s’ [**što**
teacher-def.sg[nom] know-npst.3pl.o.3sg.s know-npst.3sg comp
pet’ɛ er’ mejn’ɛ vor’g-əčn’-i urok-stə]
Peter every what.tmpr run.away-ipfv-npst.3sg class-el
‘The teacher **knows** (subj +obj) **that** Peter always misses classes.’

(72) paša **abəščanda-s’** / *abəščanda-z’ə [**što**
Paul[nom] promise-pst.3sg promise-pst.3sg.o.3sg.s comp
il̥’caman’ kud-u]
accompany.npst.1sg.o.3sg.s house-lat
‘Paul **promised** (subj) **that** he would accompany me home.’

4.3.4.2 Semantic restrictedness The status of (x)comp as semantically restricted is less clear. Certainly, sentential complements are semantically diverse: at least factives and non-factives have been distinguished since Kiparsky & Kiparsky (1970), and other distinctions since then have been discussed in the literature, such as between fact, proposition, event (Peterson 1997) and other abstract objects (Asher 1993). However, this is a difference in the semantic type of the argument and its entailments/presuppositions, which is not directly related to semantic roles; it might be more properly compared to the distinction between definite and indefinite NPs — given that definites, like factives, presuppose the existence of their referents, and have other similar properties (see Melvold 1991).

The range of semantic roles that clausal arguments can be associated with is difficult to resolve because these arguments are rather restricted in their distribution. There are very few verbs with two clausal arguments (exceptions being verbs like *prove*, *entail*, etc.), and these all have only subj and comp arguments; I am not aware of any verbs that have two sentential non-subjects (comp, obj or obl). Clausal arguments often cannot have the markings characteristic of NP arguments and hardly ever undergo valency-changing processes (even clausal complements classified as obj can be difficult to passivize). Hence, there is little distributional evidence that could help distinguish between the semantic roles of comp. On a purely speculative basis, one may say that most comps are Themes, some are Stimuli (mental predicates), and some could be classified as Goals (e.g. verbs like *try*). In terms of Dowty (1991), these all fall under the proto-role Patient; thus it is an open question whether these fine-grained distinctions are grammatically relevant. Zaenen & Engdahl (1994) believe that they are not, and that (x)comp is, in fact, semantically restricted, since this gf can only be occupied by clausal arguments. Similarly, Dalrymple & Lødrup (2000), who distinguish between comp and obj (see Section 4.3.1), assume that comp is semantically restricted and that this is what distinguishes comp from obj.

The alternative is simply to avoid definitively classifying comp and xcomp as either semantically restricted or semantically unrestricted. Falk (2001) proposes that comp and xcomp are different from all other gfs in having the positive value for a special feature [c] (for complement). In practical terms, this is equivalent to the position of Zaenen & Engdahl (1994). Another approach is to treat comp as underspecified for being semantically restricted or unrestricted, depending on the context, as in Berman's (2007) analysis of German.

The difficulties in resolving this question only serve to illustrate that comp and xcomp are really apart from all other gfs and require a special analysis – if they are to be distinguished at all, as discussed in detail in Section 4.3.1 above.

4.4 Possessors

The discussion of grammatical functions has so far avoided mentioning possessors. This is because, being nominal dependents, they are not easily comparable to other, clause-level gfs.

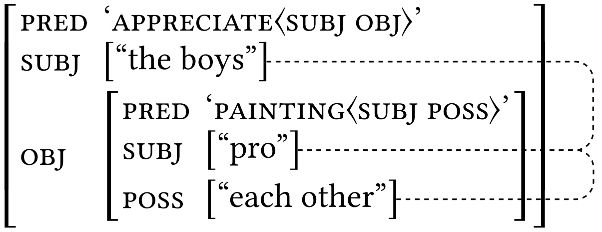
In LFG, possessors are standardly assumed to bear the grammatical function poss. Among clausal gfs, it is most similar to subj in two ways. First, it is the most prominent argument, as, apart from possessors, nouns may only have oblique dependents. Second, it is semantically unrestricted. It is well-known that possessors (in the syntactic sense, i.e. genitive dependents) can have a very wide range of relations to their heads. The semantic non-restrictiveness of possessors is also evident from the fact that in many languages, genitive marks the same arguments in non-finite clauses that are mapped to subj in finite clauses (73).

(73) a. **The enemy** destroyed the city.
b. **the enemy's** destruction of the city

Therefore, some authors propose reducing poss to subj (Sulger 2015). This solution seems too radical, however — at least for some languages. Chisarik & Payne (2003) were the first to introduce a hybrid approach that uses both subj and poss in noun phrases. They analyse English and Hungarian, which both allow two types of possessor expression: English has the "Saxon Genitive" *'s* and *of*-possessors, while Hungarian has nominative and dative possessors. Chisarik and Payne argue that English *'s*-possessors and Hungarian nominative possessors are subjs, while the other two types of possessors are adnoms, which correspond to poss. Laczkó (2004), critical of their analysis of the Hungarian data, also maintains that Hungarian possessors can be either subj or poss, but argues that the gf of the possessor is independent of its marking pattern. Laczkó further develops this analysis of Hungarian in a series of papers, in particular Laczkó (2009, 2017). Laczkó & Rákosi (2019) further argue that in some Hungarian examples such as (74), both subj and poss are present in the f-structure of the nominalization. In this case, the possessor is the reciprocal which triggers 3rd person singular agreement on the nominalized verb, while the subject is the null pronominal coreferent with 'boys' in the main clause (75).

(74) A fiúk$_i$ dijazzák [$_{\text{DP}}$ az egymás$_i$ lefest-és-é-t].
the boys appreciate.3pl the each.other paint-nmlz-poss.3sg-acc
'The boys appreciate the painting of each other.' (Laczkó & Rákosi 2019: 163)

(75)



If poss is a governable gf like subj, all nouns with optional possessors must be assumed to have two variant pred values: with and without a possessor valency, e.g. 'book' and 'book-of⟨poss⟩' (Bresnan 2001, Bresnan et al. 2016: 315 et passim). This seems undesirable, so Dalrymple et al. (2019) propose to treat poss as being ungovernable, like adj, but positioned at the top of the gf hierarchy, like subj. This means that poss is licensed in any f-structure having a pred value, including clausal f-structures; thus, additional care must be taken to ensure that poss is constrained not to appear in inappropriate positions.

5 Overlay and discourse functions

F-structures occupying gf feature values may have additional functions in the clause that link the f-structure to the wider syntactic or discourse context. Following Falk (2001: 59), who took the term from Johnson & Postal (1981), these can be called overlay functions because they must always be connected to arguments or adjuncts by either anaphora or structure sharing (according to Extended Coherence, see Fassi Fehri 1988, Zaenen 1985, Bresnan & Mchombo 1987, Bresnan et al. 2016: 62–63). One overlay function, pivot, serves to capture some of the subject properties of core arguments and has been discussed in Section 4.2.3. Two other important classes of functions are so-called grammaticalized discourse functions, which traditionally included topic and focus but are now increasingly replaced by a single function called dis or udf (discussed in Section 5.1), and functions like q or relpro that are intended to mark elements relativized, questioned, or otherwise selected to serve as input to other syntactic or semantic processes (discussed in Section 5.2).

5.1 topic, focus and dis

Since the earliest work in LFG, "grammatic(al)ized discourse functions" topic and focus have been used at f-structure to represent simultaneously the information structure status of participants and their role in establishing long-distance dependencies such as wh-extraction. It is also often assumed, e.g. in Bresnan (2001) and Bresnan et al. (2016), that subj is unique in being both a grammatical function and a discourse function. This is meant to represent the discourse prominence of subjects and capture some generalizations in the c- to f-structure mapping, but it also means that discourse functions in this understanding are not necessarily overlay functions.[23]

Under this view, f-structure combines morphosyntactic and information-structure features, which is against LFG's tendency for localizing different aspects of language structure at different projections or levels (see Belyaev 2023b [this volume] and Belyaev 2023a [this volume]). This, with other formal and empirical considerations, has caused recent work, notably King & Zaenen (2004) and Dalrymple & Nikolaeva (2011), to promote information structure to a separate projection (see Zaenen 2023 [this volume]), which has removed the need to represent notions such as topic and focus at f-structure. Therefore, many authors feel that only one overlay function is now sufficient for all topicalized, focalized or otherwise displaced material. This function has been variously called UDF for "unbounded dependency function" (Asudeh 2012), OP for "operator" (Alsina 2008), or DIS for "dislocated" (Dalrymple et al. 2019) in the literature.[24]

Regardless of whether DIS or TOPIC / FOCUS are used, these attributes have to be set-valued because there may be multiple dislocated elements in one sentence, whether in the same position, like in (76) from French, where two phrases are right-dislocated (with clitic resumption), or in different positions, as in (77) from English, where *Mary* and *me* are dislocated to the left and right edges of the clause, respectively.

(76) a. French (Romance > Indo-European)

Je	le	lui	ai	donné,	**le livre**,	**à Jean**.
I.CL	it.CL	to.him.CL	have	given	the book	to J.

'I gave it to him, the book, to Jean.'

---

[23] Falk (2006), whose approach was discussed in Section 4.2.3 above, introduces the overlay function PIVOT to account for those subject properties that are associated with syntactic prominence. Therefore, the properties that Bresnan et al. associate with SUBJ as a discourse function can instead be associated with PIVOT in Falk's approach, resolving the ambiguous status of subjects. I am grateful for this observation to an anonymous reviewer.

[24] The treatment of long-distance dependencies in LFG is described in detail in Kaplan 2023 [this volume]; here, I will only discuss issues related to the role overlay functions play in their analysis.

b.

$$\begin{bmatrix}
\text{PRED} & \text{‘GIVE}\langle\text{SUBJ, OBJ, OBJ}_{\text{RECIP}}\rangle\text{’} \\
\text{TENSE} & \text{PAST} \\
\text{DIS} & \left\{ \begin{matrix}
\begin{bmatrix} \text{PRED} & \text{‘BOOK’} \\ \text{DEF} & + \\ \text{PERS} & 3 \\ \text{NUM} & \text{SG} \\ \text{GEND} & \text{M} \end{bmatrix} \\
\begin{bmatrix} \text{PRED} & \text{‘JEAN’} \\ \text{PERS} & 3 \\ \text{NUM} & \text{SG} \\ \text{GEND} & \text{M} \\ \text{PCASE} & \text{A} \end{bmatrix}
\end{matrix} \right\} \\
\text{SUBJ} & \begin{bmatrix} \text{PRED} & \text{‘PRO’} \\ \text{PERS} & 1 \\ \text{NUM} & \text{SG} \end{bmatrix} \\
\text{OBJ} & \begin{bmatrix} \text{PRED} & \text{‘PRO’} \\ \text{PERS} & 3 \\ \text{NUM} & \text{SG} \\ \text{GEND} & \text{M} \\ \text{CASE} & \text{ACC} \end{bmatrix} \\
\text{OBJ}_{\text{RECIP}} & \begin{bmatrix} \text{PRED} & \text{‘PRO’} \\ \text{PERS} & 3 \\ \text{NUM} & \text{SG} \\ \text{GEND} & \text{M} \\ \text{CASE} & \text{DAT} \end{bmatrix}
\end{bmatrix}$$

(77) a. **Mary**, I saw her yesterday, **me**.

b. $$\left[\begin{array}{ll} \textsc{pred} & \text{‘}\textsc{see}\langle\textsc{subj,obj}\rangle\text{’} \\ \textsc{tense} & \textsc{past} \\ \textsc{dis} & \left\{\begin{array}{l} \left[\begin{array}{ll} \textsc{pred} & \text{‘}\textsc{Mary}\text{’} \\ \textsc{pers} & 3 \\ \textsc{num} & \textsc{sg} \end{array}\right] \\ \left[\begin{array}{ll} \textsc{pred} & \text{‘}\textsc{pro}\text{’} \\ \textsc{pers} & 1 \\ \textsc{num} & \textsc{sg} \\ \textsc{case} & \textsc{acc} \end{array}\right] \end{array}\right\} \\ \textsc{subj} & \left[\begin{array}{ll} \textsc{pred} & \text{‘}\textsc{pro}\text{’} \\ \textsc{pers} & 1 \\ \textsc{num} & \textsc{sg} \\ \textsc{case} & \textsc{nom} \end{array}\right] \\ \textsc{obj} & \left[\begin{array}{ll} \textsc{pred} & \text{‘}\textsc{pro}\text{’} \\ \textsc{pers} & 3 \\ \textsc{num} & \textsc{sg} \\ \textsc{case} & \textsc{acc} \end{array}\right] \\ \textsc{adj} & \left\{\left[\textsc{pred}\ \ \text{‘}\textsc{yesterday}\text{’}\right]\right\} \end{array}\right]$$

Notice that the f-structures do not distinguish between two types of dislocation: in the DIS approach, all dislocated elements are members of the same set, while in the TOPIC / FOCUS approach, both would be TOPICs due to their information structure status. Presumably, a distinction at f-structure is not required because the difference between types of dislocation is captured at other levels, such as information structure (i-structure) or prosody (p-structure).

In fact, when so much has been delegated to other levels, it is not clear whether it is really necessary to indicate the dislocated status of a constituent by any f-structure feature. Indeed, in all the analyses of long-distance dependencies that I am aware of, DIS is locally introduced in the rule that defines the dislocated position by the equation $\downarrow \in (\uparrow \textsc{dis})$, and no other rules reference the value of DIS directly. The symbol GF used in paths constraining long-distance dependencies usually includes only non-overlay GFs (Dalrymple et al. 2019: 206), so the dislocation of a phrase from one clause to another does not influence its availability for further extraction. When the dislocated phrase *is* relevant for other processes, such as in relativisation and constituent questions, it occupies the special overlay functions RELPRO and Q. It thus appears that the feature DIS duplicates the information already present at c-structure – that the element is in some dislocated position – and is therefore redundant. This question is discussed in detail in Snijders (2015: section 4.6).

5.2 RELPRO and Q

In some constructions, elements that are dislocated to designated structural positions serve as input to other syntactic or semantic rules and constraints. For example, in relative clauses, the relative pronoun must be linked to the head of the relative phrase, both in syntax (e.g. to ensure agreement in gender and/or number) and in semantics (in order to correctly restrict the reference of the head noun). Similarly, the semantic interpretation of constituent questions must be able to identify the f-structure of the interrogative.

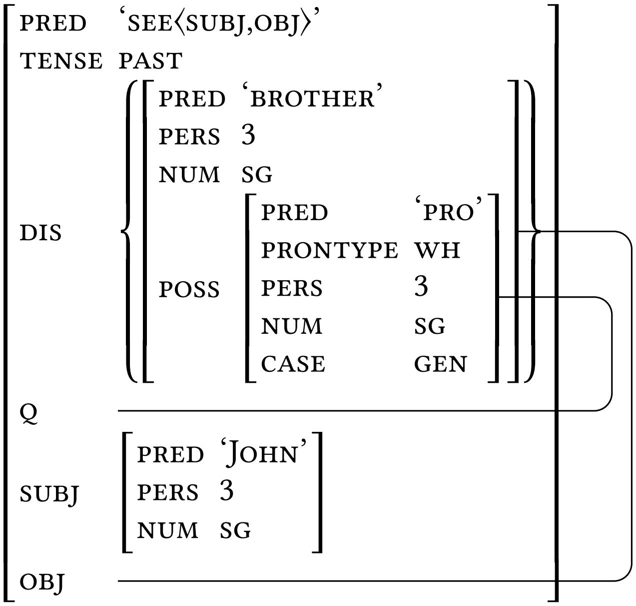
It is not enough to use only DIS in such constructions because DIS is not specific enough. A sentence may have another dislocated element in addition to the relative pronoun or interrogative: for example, in the sentence *John, who saw him?* the f-structures of both *John* and *who* will be elements of DIS, but only *who* must be correctly identified as the question word. The traditional distinction between TOPIC and FOCUS will not help either, because relativization or questioning of a phrase often leads to the extraction of a larger constituent in which it occurs (pied piping), as in the sentence *Whose brother did John see?*, where the dislocated element occupying FOCUS is *whose brother*, but only *whose* is the interrogative element.

For these reasons, LFG analyses of relativisation and constituent questions make use of the additional overlay features RELPRO and Q, respectively, that specifically include the f-structure of the element that is relativized or questioned.[25] For example, the sentence *Whose brother did John see?* will have the f-structure in (78).

---

[25] Similar effects could be achieved by using off-path constraints (see Belyaev 2023a [this volume] on the notion) but this seems to be in essence equivalent to using the overlay functions but results in a more cumbersome analysis (Tracy Holloway King, p. c.). This possibility is explored in Kaplan 2023: Section 5 [this volume].

(78)



In this example, the question word is the possessor *whose*, but English does not allow extraction of just the possessor, so the whole object phrase *whose brother* is dislocated to the left periphery and, consequently, appears in DIS at f-structure. The wh-word itself occupies the value of the special overlay function Q, which represents the element being questioned. For more information on the handling of long-distance dependencies in LFG, see Kaplan 2023 [this volume].

6 Conclusions

In this chapter, I have described the key properties of the LFG view of grammatical functions. An important aspect of LFG is assigning to grammatical functions a central role in grammar, without reducing them to more basic phenomena such as semantic roles, constituent structure position or relative syntactic rank. The inventory of grammatical functions is assumed to be universal, and each grammatical function is supposed to be associated with a distinct pattern of syntactic behaviour. The optimal inventory and the syntactic status of its members are based on three generalizations: (1) the functional hierarchy, which determines constraints on anaphoric binding and semantic role mapping; (2) the classification of grammatical functions into governable vs. ungovernable, semantically restricted vs. unrestricted GFs and terms vs. non-terms, as well as the related cross-classification of GFs in lexical mapping theory; (3) individual properties of specific grammatical functions, primarily subjects. This defines the core five-way distinction between SUBJ, OBJ, OBJ_θ, OBL_θ and ADJ. Four grammatical functions – POSS, COMP, XCOMP and PREDLINK – stand somewhat apart due to being uniquely associated with very specific argument types: nominal possessors, clausal complements and nonverbal predicates. This has resulted in attempts to eliminate PREDLINK and assimilate POSS to SUBJ and (X)COMP to non-clausal other grammatical functions, but there are compelling independent arguments in favour of preserving their distinct status. In addition to these GFs, LFG makes use of so-called overlay functions, which represent positions additionally occupied by GFs that are required for cross-clausal or discourse continuity.

This approach aligns LFG very well with typological and functional approaches to language, where *grammatical relations* are direct counterparts to the LFG *grammatical functions*. In spite of the superficial similarity, however, there is a crucial difference between the two approaches: typology does not generally assume one specific system of grammatical relations to be universal, while LFG is concerned with universality, at least in theory. This focus on universality implies that the LFG notions of grammatical functions are quite removed from their traditional definitions. In particular, there have been interesting developments in the treatment of subjects: Manning (1996) replaces subject and object with more abstract functions PIVOT and CORE that receive an inverse mapping in ergative languages, while Falk (2006) retains the traditional SUBJ as the most prominent argument ($\widehat{\text{GF}}$) while adding the overlay function PIVOT to account for those subjecthood properties that can be associated with other arguments in syntactically non-accusative languages. The distinction between OBJ and OBJ$_\theta$ has also been extended beyond its traditional understanding, with OBJ$_\theta$ being used for unmarked direct objects in differential object marking languages (Dalrymple & Nikolaeva 2011) and for coindexed arguments in polysynthetic languages (see Lander et al. 2021 for a rather radical approach). Finally, the LFG use of a distinct GF (X)COMP for clausal complements is unique in theoretical and typological literature and allows a wide range of intriguing generalizations.

Grammatical functions are a cornerstone of LFG, and their analysis is in line with the general spirit of this framework, which avoids reductionism to the extent of sometimes being overtly redundant in splitting linguistic phenomena into several mechanisms operating at different levels. The framework itself puts no constraint on the relationship betwen these levels; determining to what extent the mapping is regular becomes an empirical question. There is no formal obstacle to eliminating grammatical functions from LFG if it can be demonstrated that they can be reduced to other mechanisms. However, all such attempts to date have been unsuccessful, which demonstrates the viability of the LFG approach to grammatical functions.

Acknowledgments

I am grateful to Mary Dalrymple, Tracy Holloway King, Sylvain Kahane, and two anonymous reviewers for their insightful comments on earlier drafts of this chapter, which have made it much more comprehensive and cohesive. I acknowledge the support of the RSF grant no. 22-18-00528 “Clausal connectives in sentence and discourse: Semantics and grammaticalization paths”.

Abbreviations

Besides the abbreviations from the Leipzig Glossing Conventions, this chapter uses the following abbreviations.

ADD	additive
AOR	aorist
AUG	augmentative (Hakha Lai)
AV	active voice (Tagalog)
BV	benefactive voice (Tagalog)
CL	clitic
CL1	first agreement class (East Caucasian languages)
CL2	second agreement class (East Caucasian languages)
CONN	connective (Hakha Lai)
COMPL	completive
DIM	diminutive
DIR	directive
DV	dative/locative voice (Tagalog)
EL	elative
EMPH	emphatic
FV	final vowel (Kichaga)
HRSY	hearsay evidential (Meskwaki)
INTERJ	interjection
IN	inessive
IO	indirect object
IV	instrumental voice (Tagalog)
LAT	lative
LNK	linker
MAL	malefactive
OV	objective voice (Tagalog)
PCVB	participle-converb (Ashti)
POS	positive
POT	potential
PQP	pluperfect (Moksha Mordvin)
PRET	preterite
SUPER	location above landmark
TMPR	temporal (Moksha Mordvin)

Part II

Grammatical phenomena

Chapter 4

Anaphora

György Rákosi
University of Debrecen

The LFG approach to anaphora explicitly recognizes the substantial amount of variation that we see attested in the grammar of anaphoric elements, and it offers a lexicalist account that captures this diversity. This chapter provides an overview of the major tenets of this approach. We discuss how LFG captures prominence relations between anaphors and antecedents, as well as the inventory of further constraints that determine the size of the binding domain and the search for an antecedent. The chapter includes a brief commentary on logophoric elements and on how the anaphoric dependency itself is represented in LFG accounts, and it concludes with an outlook on other pertinent issues addressed in the LFG literature.

1 Introduction

In the broader sense of the term, anaphora is a referential dependency relation between an ANTECEDENT and an ANAPHORIC ELEMENT, with the latter being dependent on the former for its interpretation. In (1), for example, the embedded subject *he* is in principle free to refer to any available singular discourse participant that matches the gender of the pronoun, but assuming topic continuity between the matrix and the subordinate clauses, the most likely interpretation is that the subordinate subject is anaphorically linked to the matrix subject.[1]

(1) He thought that *he* would catch a train up to London.

(2) My mother, *she* just entered a mysterious decline.

---

[1] Examples (1), (2) and (4) are from the British National Corpus (Davies 2004).

György Rákosi. 2023. Anaphora. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 165–192. Berlin: Language Science Press. DOI: 10.5281/zenodo.10185940

In (2), the anaphoric link between the subject pronoun *she* and the left-dislocated noun phrase *my mother* is obligatory. But this is a property of the construction itself (see Haug 2023 [this volume] on ANAPHORIC AGREEMENT of this sort), since the personal pronoun *she* is not constrained elsewhere to occur in the company of a linguistically expressed antecedent. Personal pronouns can in fact establish reference to discourse participants through a deictic pointing gesture, as happens in (3):

(3) Who did you mean? *Him* or *her* over there?

Thus personal pronouns are born free, even if they often end up bound to antecedents under particular linguistic circumstances.

Personal pronouns are unlike reciprocals or reflexives in this respect, which do normally require the presence of a linguistic antecedent. In the small discourse universe of (4), the subject pronoun *he* refers back to Graham, and the object pronoun *them* to the group of Slater and Sarah. This is a very likely interpretation, but one that is in principle not obligatory. The reciprocal *each other*, however, must be in a strict dependency with an antecedent, which is the object pronoun *them* in (4).

(4) Graham didn't mind Slater knowing about Sara – he had introduced them to *each other*, after all.

Likewise, the object reflexive *themselves* requires the availability of a local antecedent, the subject *these animals* in the case of (5).

(5) These animals protect *themselves* against being eaten by secreting poisonous substances.

Following the accepted practice of generative grammars, I will refer to reflexives and reciprocals as ANAPHORS in this chapter. The term ANAPHORIC ELEMENT is used here as a cover for anaphors and anaphorically interpreted personal pronouns.

An anaphor in this narrow, categorial sense is a referentially dependent type of pronominal expression, which cannot be used deictically and which requires the presence of a linguistically expressed antecedent. The primary aim of this chapter is to give an overview of what anaphoric phenomena have attracted attention in LFG-based research, and what discussions these phenomena have generated. The standard LFG approach to the grammar of anaphors has two major descriptive tenets. First, in line with the lexicalist nature of LFG, the constraints that govern the grammar of anaphoric elements are stated in their lexical entries. Whether these lexical constraints are comprehensive, and thus more or less fully specify the grammar of anaphors, or they are to be supplemented by what Belyaev 2023 [this volume] calls GRAMMAR-WIDE CONSTRAINTS, is an issue where particular approaches may vary. Dalrymple (1993, 2001) and Dalrymple et al. (2019) postulate lexical entries that are rich enough in themselves, while Bresnan (2001) and Bresnan et al. (2016) emphasize the role of pertinent constraints that form part of the inventory of the universal design features of grammar. But this is partly a matter of perspective and emphasis, and in the lexicalist nature of LFG architecture, everything can be stated in the lexicon (evoking redundancy rules or templates where generalisations need to be captured). This chapter takes a comprehensive descriptive approach in presenting pertinent LFG research.

The second major tenet of the LFG approach to anaphora is the recognition that the distinction between anaphors and personal pronouns is not necessarily pronounced: neither empirical reasons, nor general theoretical concerns necessitate an approach in which anaphors and pronouns are considered to be two entirely distinct and discrete categories of grammar. Particular LFG descriptions may make use of a PRONTYPE attribute with values PERSONAL, REFLEXIVE or RECIPROCAL (as well as other pronominal types not relevant for us), but such features tend to play relatively little theoretical role in the actual analysis itself. Therefore, the term ANAPHOR is used here mostly for expository purposes only, with no specific theoretical commitment attached. One reason why the study of anaphoric systems has become a favourite topic of many researchers is exactly their versatile nature, and a major aim of this chapter is to demonstrate how the LFG architecture can be employed to describe this rich landscape adequately.

The structure of this chapter is as follows. In Section 2 and Section 3, I provide an overview of the standard LFG-theoretic approach to the binding of anaphors, discussing first the prominence relations between anaphors and their potential antecedents (Section 2), and then the constraints that determine the binding domain and the search for the antecedent (Section 3). In Section 4, I briefly discuss the LFG approach to discourse-dependent or logophoric elements. In Section 5, I make some comments on anaphor interpretation and on how the anaphoric dependency itself is represented in LFG accounts. Section 6 concludes this chapter.

2 Prominence relations and anaphora

2.1 Syntactic rank

One core property of anaphoric dependencies is that the antecedent needs to be more prominent than the anaphor *at some level of representation*. In Chomskyan generative approaches, the anaphor is required to have a c-commanding antecedent. The relation c-command is defined over hierarchical structures represented as trees, but LFG employs f-structure as the primary locus for capturing generalizations about abstract syntactic relations.[2] Thus, syntactic prominence relations are primarily described in terms of f-structure. This allows us to abstract away from attested variation in the surface coding of anaphoric dependencies in case such variation does not seem to correlate with grammatically relevant differences in how these dependencies are constructed. I illustrate the motivation for the LFG approach with parallel English and Hungarian data involving the reciprocal anaphor.

The triadic predicate *introduce* projects onto a syntactic structure in which the reciprocal anaphor may assume two syntactic functions: it is either the oblique PP argument (6a) or the object (6b), and it is ungrammatical as a subject (6c). The antecedent may either be the object or the subject argument in (6a), but if the reciprocal is the object, then only the subject can antecede it (6c):

(6) a. They$_i$ introduced the children$_k$ to *each other*$_{i/k}$.
b. They$_i$ introduced *each other*$_{i/*k}$ to the children$_k$.
c. **Each other* introduced them to the children.

This observed syntactic asymmetry between the anaphor and the antecedent is described as a difference in syntactic rank as defined by the Functional Hierarchy, which is independently needed in the description of other grammatical phenomena:[3]

(7) a. Functional Hierarchy (Bresnan et al. 2016: 229)

SUBJ > OBJ > OBJ$_\theta$ > OBL$_\theta$ > COMP, XCOMP > ADJ

---

[2] Several definitions of c-command exist; here we simply assume the textbook variety.

[3] This hierarchy has played an important role in LFG, and it has its predecessors and analogues in other frameworks; see, for example, the accessibility hierarchy of Keenan & Comrie (1977), or Pollard & Sag (1992).

b. Syntactic rank (Bresnan et al. 2016: 230)

A locally outranks *B* if *A* and *B* belong to the same f-structure and *A* is more prominent than *B* on the functional hierarchy. *A* outranks *B* if *A* locally outranks some *C* which contains *B*.

An anaphor requires an antecedent which outranks it. Applying (7) to the data in (6), *B* is the anaphor *each other* and *A* is the antecedent, which is either the subject *they* or the object *the children* in (6a), or only the former in (6b). (6c) is out because, among other things, the reciprocal anaphor *each other* is the subject, and since the subject function is at the topmost position of the hierarchy, no outranking antecedent is available in the clause.[4]

The advantages of the f-structure-centered LFG approach to binding are especially apparent if we compare the English data in (6) to their counterparts in other languages, where clausal syntax is different. Hungarian is one such language. In particular, it allows for the pro-drop of subjects (treated as pronoun incorporation in LFG, see Toivonen 2023 [this volume]), and it has a non-configurational VP.[5] Consequently, the Hungarian versions of (6a) may lack an overt subject, and the linear ordering of the constituents is also relatively free within the VP. (8a–8b) represent two discourse neutral configurations, and each has the same ambiguity in terms of antecedent choice that we have seen in the case of the English (6a).

(8) Hungarian

a. Bemutat-ták a gyerekek-et egymás-nak.
introduce-PST.3PL the children-ACC each.other-DAT
'They$_i$ introduced the children$_k$ to each other$_{i/k}$.'

---

[4] This does not necessarily mean that *each other* cannot be a SUBJ, since it can be the subject of a subordinate clause under certain circumstances (see Lebeaux (1983: 724) for pertinent discussion). The following examples are from the British National Corpus (Davies 2004):

(i) We all read what *each other* had written, anyway.

(ii) One wonders how on earth they speak to each other, or if indeed they even know who *each other* is.

(iii) We all know how *each other* plays and that's why things are ticking.

The matrix antecedent outranks *each other* in these cases, too, according to (7), since the matrix SUBJ antecedent locally outranks the COMP that contains the subject anaphor.

[5] See Laczkó 2023 [this volume] and Laczkó 2021 on the non-configurational nature of the Hungarian VP, and on pro-drop phenomena in Hungarian.

b. Bemutat-ták egymás-nak a gyerekek-et.
introduce-PST.3PL each.other-DAT the children-ACC
'They$_i$ introduced the children$_k$ to each other$_{i/k}$.'

Disregarding empirical details that are irrelevant for the purposes of the current discussion (such as the fact that Hungarian employs dative case on the oblique anaphor instead of an adposition), the divergent English and Hungarian c-structures all map onto the same f-structure in (9).[6]

(9) f-structure of (6a) and (8a–8b)

$$

$$

Syntatic rank is a device that is used to describe variation in syntactic prominence as stated at the level of f-structure, and it is primarily at this level where elegant and universally relevant generalisations can be made about anaphoric phenomena. One such generalisation is that an anaphor needs an antecedent that outranks it in the sense of (7).[7]

Syntactic rank captures the most salient aspect of c-command, the arrangement of constituents along a hierarchy. Embedding configurations may create issues which may scope beyond what reference to syntactic rank transparently solves. For example, the potential antecedent cannot be embedded too deeply within the search domain of the anaphor, hence the ungrammaticality of (10).

(10) *The children$_i$'s mother washed themselves$_i$.

---

[6] No INDEX features (PERS and NUM) are specified for the reciprocal anaphor in the f-structure *j* in (9). We provide an overview of the LFG treatment of the feature content of anaphoric elements in Section 5.

[7] Note that the antecedent in (9) locally outranks the anaphor since both are members of the same f-structure *f*. By (7b), this relation need not be local, and it is not always local in the case of other types of anaphors that we discuss in Section 3. See also footnote 4.

(11)
$$

\end{array}\right]
\end{array}\right]
$$

The plural reflexive anaphor *themselves* can only take a plural antecedent. The plural possessor *the children* could in principle act as one, but since it is properly contained within the possessive structure of the subject (f-structure *i* is in f-structure *g*), it cannot license the anaphor and therefore sentence (10) fails. LFG employs the notion of f-command to constrain such scenarios.[8]

(12) F-command (Dalrymple et al. 2019: 238)

f f-commands *g* if and only if *f* does not contain *g*, and all f-structures that contain *f* also contain *g*.

The English reflexive anaphor *themselves* needs an f-commanding antecedent that outranks it. F-structure *g* f-commands f-structure *j* in (11), but since *g* is a singular noun phrase, it does not match the INDEX features of the anaphor (see Section 5). F-structure *i* is plural and could thus be a potential antecedent for the reflexive, but it does not f-command it: one f-structure that contains *i*, namely f-structure *g*, does not contain the f-structure of the anaphor, *j*. Therefore the noun phrase *the children* does not f-command the reflexive anaphor *themselves*, and (10) is ungrammatical.

While f-command is a universal requirement on anaphor licensing, there still are anaphors in some languages that may take non-f-commanding antecedents under certain circumstances. We discuss here two reflexives to illustrate this phenomena. The antecedent of the Icelandic reflexive *sig* or the Mandarin reflexive *ziji*, for example, can be an embedded human possessor under the right discourse conditions. The Icelandic example (13a) describes Sigga's opinion, and the embedded clause, which includes the anaphor, is interpreted in her model of the

---

[8] As Dalrymple et al. (2019: 239) discuss, a more complex definition of f-command is required to cover constructions that involve structure-sharing dependencies. Those concerns are not directly relevant for us now, and (12) suffices for our purposes.

world. The anaphor is thus tied to an antecedent who is a perspective holder, and this saves the configuration even if f-command is not satisfied (and even if the antecedent and the anaphor are not in the same clause). Since the embedded possessor (*Olaf*) is not a perspective holder in the case of (13b), the reflexive is unacceptable there.

(13) Icelandic (Maling 1984: 220–222)

a. Skoðun Siggui er að *sig* vanti hæfileika.
opinion Sigga's is that self.ACC lacks.SBJV talent
'Sigga$_i$'s opinion is that she$_i$ lacks talent.'

b. *Trú Ólafs á guð bjargaði *sér*.
belief Olaf$_i$'s in god saved self.DAT
'Olaf's$_i$ belief in god saved him$_i$.'

As is expected, the possessor cannot be an inanimate noun phrase in examples of this kind, since inanimate entities do not have mental states. Charnavel & Huang (2018) explicitly show that inanimate possessors are degraded in this construction in Mandarin (14b), even if they are claimed to be able to antecede *ziji* elsewhere (see Lam 2021 for a discussion and for further data on *ziji* with an antecedent embedded in the subject). But (14a) is a description of the mental state of the antecedent, Zhangsan, and this is apparently enough to license the anaphor even in the absence of f-command.

(14) Mandarin (a: Tang 1989: 100, b: Charnavel & Huang 2018: 140)

a. Zhangsan de jiaoao hai-le ziji.
Zhangsan DE pride hurt.ASP self
'Zhangsan$_i$'s pride harmed him$_i$.'

b. *Zhe ke shu de guoshi ya wan le ziji.
this CL tree DE fruit press bent ASP self
'The fruits of this tree$_i$ bent it$_i$.'

We discuss the role of point of view in the licensing of certain types of anaphora in Section 4. What the above data in (13) and (14) illustrate is that human or animate possessors in some languages can gain the kind of prominence that allows them to license anaphors even when the f-command relation between antecedent and anaphor is not satisfied.[9]

---

[9] Bresnan et al. (2016: 268) offer an LFG analysis of the Icelandic construction in (13a) that includes the postulation of an f-command relation between the possessor and the embedded reflexive subject. For a recent LFG approach to the Mandarin data, see Lam (2021).

I discuss the LFG approach to domain restrictions on anaphora in Section 3. But before we turn to that, I briefly review anaphoric data where syntactic rank in the sense as we have discussed this notion here, does not seem to be the dominant factor in the search for a prominent antecedent.

2.2 Thematic prominence

Certain anaphors or anaphoric dependencies are constrained by factors that are at least partially independent of syntactic rank. Argument structure relations represent one such factor. If, for example, both the antecedent and the anaphor are oblique arguments of the same predicate, then they are indistinguishable with respect to the Functional Hierarchy in (7a). Dalrymple (1993: 154) discusses the following minimal pair, where the complement of the *to*-PP can antecede the complement of the *about*-PP, but not vice versa (see also Pollard & Sag 1992: 266):

(15) a. Mary talked to John$_i$ about *himself*$_i$.
b. *Mary talked about John$_i$ to *himself*$_i$.

This binding asymmetry can be described with reference to a hierarchy among argument roles, like that of the Thematic Hierarchy of Bresnan & Kanerva (1989) in (17), under the assumption that the *to*-PP bears a type of recipient role in (15), while the *about*-PP is a theme.

(16) Thematic Hierarchy (Bresnan & Kanerva 1989)

AGENT > BENEFACTIVE > RECIPIENT/EXPERIENCER > INSTRUMENT > THEME/PATIENT > LOCATIVE

What rules (15b) out is that the antecedent PP *about John* is less prominent thematically than the anaphoric PP *to himself*. This is because THEME is lower on the hierarchy than RECIPIENT. The Functional Hierarchy, in and of itself, cannot capture this difference, since both PP's are obliques in the f-structure of the sentence.

One potential counterargument to this understanding of the data in (15) is to deny the argumenthood of the *about*-PP. If it is an adjunct, as Reinhart & Reuland (1993: 715) argue, then syntactic rank suffices to explain the ungrammaticality of (15b), since an adjunct PP is less prominent than an oblique on the Functional Hierarchy, and therefore the former cannot antecede the latter. Similar concerns may arise with other predicates that take two PP dependents, since it is often the case that one can find reasons to assume that one of the two PP's is less argument-like than the other.[10]

But reference to the thematic hierarchy may still be necessary elsewhere. Dalrymple (1993: 153) discusses the following Norwegian data set (citing Hellan 1988) as a relevant case. Norwegian ditransitive verbs allow either of their two VP-internal objects to become subjects in the passive construction. (17b) illustrates the version where the recipient is the passive subject, and (17c) has the theme in the same function.

(17) Norwegian (Hellan 1988: 162)

a. Vi overlot Jon pengene.
we gave Jon money
'We gave John the money.'

b. Jon ble overlatt pengene.
Jon was given money
'John was given the money.'

c. Pengene ble overlatt Jon.
money was given Jon
'The money was given to John.'

Norwegian has a dedicated reflexive possessor, *sin*. Interestingly, when the object contains this reflexive, as in (18), then only one of the two potential readings of the passive sentence is acceptable. It is reading (i) below, which includes the malefactive subject argument binding the reflexive in the theme object. We assume that malefactives and benefactives occupy the same position on the Thematic Hierarchy.

(18) Norwegian (Hellan 1988)
Barnet ble fratatt sine foreldre.
child was taken self parents
(i) 'The child was deprived of self's parents.' MALEFACTIVE > THEME
(ii) *'The child was taken away from self's parents.' THEME > MALEFACTIVE

Reading (ii) would have the theme subject binding into the malefactive object, or in other words, a thematically less prominent antecedent binding into a more prominent one. Reference to the Thematic Hierarchy is thus essential here to be able to distinguish between the acceptable and the unacceptable reading of (18).

---

[10] Zaenen & Crouch (2009) argue on the basis of computational efficiency that semantically marked optional PPs are best treated as adjuncts.

2.3 Linear order

Anaphoric relations are sometimes constrained by linear order, inasmuch as the anaphor may be required to have an antecedent that precedes it linearly. Linear order thus represents another dimension of prominence relations relevant in the description of binding phenomena. Facts concerning the linear order of constituents are captured at the level of c-structure in the LFG architecture, and given the f-structure centered nature of LFG, such facts need to be addressed separately.

Consider the following Hungarian data set for the purposes of illustration (É. Kiss 2008). Binding among co-arguments is primarily constrained by the Functional Hierarchy in Hungarian, so the object can bind the oblique argument (19a), but the oblique cannot bind the object (19b).

(19) Hungarian (É. Kiss 2008: 451)
a. Meg-kérdeztem a fiúk-at egymás-ról.
PFV-asked.1SG the boys-ACC each.other-about
'I asked the boys about each other.'
b. *Meg-kérdeztem a fiúk-ról egymás-t.
PFV-asked.1SG the boys-about each.other-ACC
('I asked each other$_i$ about the boys$_i$.')

É. Kiss notes, however, that linear order plays an important role in the case of non-coargument binding: when the antecedent precedes the anaphor embedded in another argument of the verb, then the acceptability of the anaphor improves significantly, even if the antecedent ranks lower on the Functional Hierarchy.

In (20a), the object locally outranks the oblique antecedent, and therefore the reciprocal possessor embedded in the object cannot be bound. But when the oblique antecedent linearly precedes the object, as happens in (20b-20d), then the sentence becomes much less degraded (and in fact, many speakers find these examples fully acceptable).

(20) Hungarian (É. Kiss 2008: 452)
a. *Meg-kérdeztem egymás szülei-t a fiúk-ról.
PFV-asked.1SG each.other parents.POSS-ACC the boys-about
('I asked each other$_i$'s parents about the boys$_i$.')
b. ?A fiúk-ról egymás szülei-t kérdeztem meg.
the boys-about each.other parents.POSS-ACC asked.1SG PFV
'About the boys$_i$, I asked each other$_i$'s parents.'

c. ?A fiúk-ról meg-kérdeztem egymás szülei-t.
the boys-about PFV-asked.1SG each.other parents.POSS-ACC

d. ?Meg-kérdeztem a fiúk-ról egymás szülei-t
PFV-asked.1SG the boys-about each.other parents.POSS-ACC

Thus changes in the linear order save this sort of binding dependency. In other words, both syntactic rank and linear order play a role in constraining non-coargument binding in Hungarian, but the linear order constraint apparently outranks the syntactic rank constraint imposed on the antecedent.[11]

In the LFG literature, Bresnan et al. (2016) provide a comprehensive discussion of the role of linear precedence in conditioning pronominal anaphoric dependencies (see also Belyaev 2023 [this volume]). Mohanan (1982) shows that overt pronouns cannot precede their antecedent in Malayalam, and Kameyama (1985) discusses pertinent Japanese data. In order to be able to capture these and other phenomena sensitive to linear order, LFG relies on the notion of f-precedence, which Kaplan & Zaenen (1989) define as follows:

(21) f f-precedes g ($f <_f g$) if and only if for all $n1 \in \phi^{-1}(f)$ and for all $n2 \in \phi^{-1}(g)$, $n1$ c-precedes $n2$.

The usual flow of information in the correspondence architecture of LFG is from c-structure to f-structure. The relation ϕ^{-1} provides for the inverse correspondence from f-structure to c-structure: it associates f-structures with the c-structures nodes they correspond to. The term $n1 \in \phi^{-1}(f)$ identifies the set of c-structure nodes that correspond to the f-structure f. The definition in (21) thus states that f-structure f f-precedes f-structure g if and only if all the c-structure nodes corresponding to f c-precede all the c-structure nodes corresponding to g. The relation C-PRECEDENCE can be defined as follows:[12]

(22) C-precedence

A c-structure node $n1$ c-precedes a node $n2$ if and only if $n1$ does not dominate $n2$, $n2$ does not dominate $n1$, and the string that $n1$ dominates (or $n1$ if $n1$ is itself a terminal) precedes the string that $n2$ dominates (or $n2$ if $n2$ is itself a terminal).

---

[11] In addition, the antecedent must also f-command the anaphor. This requirement is satisfied in each example in (20).

[12] I thank an anonymous reviewer of this paper and Mary Dalrymple for their help in constructing the definition in (22). By *precede* we simply mean 'be to the left of' in the string.

F-precedence allows us to make reference to linear ordering facts at the level of f-structure, the locus where binding dependencies are primarily constrained in LFG. It relies on the notion of the inverse correspondence from f-structure to c-structure, which is evoked as a somewhat marked feature of the grammatical model. But this only reflects the fact that while conditioning anaphoric dependencies by linear order is an existing pattern in languages, it is not the dominant mode of licensing anaphors.

3 Constraining binding domains

The comprehensive description of a binding relation includes several components, which are stated in terms of f-structural properties in LFG. Anaphors require an antecedent that is available within a particular binding domain. The antecedent and the anaphor need to have matching agreement features, and antecedents are often constrained to be of specific types. For example, some anaphors require a subject antecedent, while others may need an antecedent that is a perspective holder. And, as we have seen in Section 2, the antecedent must be more prominent than the anaphor, which, by default, means that the antecedent f-commands the anaphor as well as outranks it on the Functional Hierarchy. Dalrymple (1993) proposed that these binding constraints are lexically specified on the anaphors, and there is a universally available inventory of them. Dalrymple (2001), Dalrymple et al. (2019), Bresnan (2001), and Bresnan et al. (2016), among others, extend this line of research, which I briefly overview in this section, adding some complementary remarks in Section 4 and Section 5. What lies at the heart of the LFG approach is that the grammatical space that anaphors occupy is too rich to be described in terms of generalizations of the type that classical Principle A represents. Anaphors vary along the parameters summarized above both across languages, and possibly within a single language. This versatility must be captured in any adequate description of anaphoric phenomena.

The core underlying assumption is that anaphors find or search for an antecedent within a specified domain. Inside-out functional uncertainty is used to model this search, since it allows reference to enclosing structures.[13] (23) is the general formula employed in the lexical description of binding dependencies:

---

[13] See Belyaev 2023 [this volume] for an overview discussion of inside-out function application and functional uncertainty, as well as for references to pertinent LFG literature. Strahan (2009, 2011) develops a proposal in which the search is inverted: the antecedent searches for the anaphor using outside-in functional uncertainty.

(23) $((\textsc{gf}^{*}\ \textsc{gf}_{\textsc{pro}} \uparrow)\ \textsc{gf}_{\textsc{ant}})$

$\textsc{gf}_{\textsc{ant}}$ is the grammatical function of the antecedent, and $\textsc{gf}_{\textsc{pro}}$ is the grammatical function of the anaphoric element.[14] The expression $\textsc{gf}^{*}\ \textsc{gf}_{\textsc{pro}} \uparrow$ defines a path from the f-structure of the anaphoric element to an f-structure that contains the antecedent.[15] In terms of a schematic f-structure, (23) describes the following scenario:

(24)
$$ {}_{f}\left[\begin{array}{ll} \textsc{gf}_{\textsc{ant}} & {}_{g}\left[\textsc{antecedent}\right] \\ \ldots\textsc{gf}^{*}\ldots & \left[\begin{array}{ll}\textsc{gf}_{\textsc{pro}} & {}_{j}\left[\textsc{anaphor}\right]\end{array}\right] \end{array}\right] $$

Here $\textsc{gf}^{*}\ \textsc{gf}_{\textsc{pro}} \uparrow$ defines a path from f-structure j to f-structure f, which contains the antecedent (f-structure g).

(23) requires the f-structure of the antecedent to f-command the anaphor (compare 12 and 23). In addition, further prominence relations can be stated in terms of off-path constraints on the f-structure of the antecedent. These include the prominence relations we have surveyed in Section 2: relations defined over the Functional Hierarchy or the Thematic Hierarchy, or linear order constraints. Dalrymple et al. (2019: 516–517) offer a discussion of how such constraints can be implemented, here I simply indicate the availability of this tool by adding a generic prominence template as an off-path constraint, which is meant to represent different types of prominence descriptions as is relevant for the anaphor.

(25) $((\textsc{gf}^{*}\ \textsc{gf}_{\textsc{pro}} \uparrow)\ \underset{@\textsc{prominent}}{\textsc{gf}_{\textsc{ant}}}\ )$

Such an off-path constraint requires the antecedent to be more prominent than the anaphor along one or more of the dimensions discussed here.

Anaphors may also impose further specific requirements on their antecedents. They may require them, for example, to be subjects (see Bresnan et al. 2016 and Dalrymple et al. 2019 for pertinent discussions). The Norwegian reflexive possessor *sin* can only be bound by the subject (26a), but not by the object (26b):

(26) Norwegian (Dalrymple et al. 2019: 510, citing Hellan 1988: 75)

a. Jon ble arrestert i sin kjøkkenhave.
Jon was arrested in self's kitchen.garden
'Jon$_i$ was arrested in his$_i$ kitchen garden.'

---

[14] (23) is in fact applicable to any anaphoric element, be it a reflexive or a reciprocal anaphor proper, or an anaphorically used personal pronoun.

[15] This path may consist of a single attribute only.

b. *Vi arresterte Jon i sin kjøkkenhave.
We arrested Jon in self's kitchen.garden
'We arrested Jon$_i$ in his$_i$ kitchen garden.'

This can be stated simply by constraining the antecedent to be a SUBJ in the (partial) lexical specification of the reflexive possessor *sin*:

(27) $((\text{GF}^{*}\ \text{GF}_{\text{PRO}}\ \uparrow)\ \text{SUBJ})$

The Mandarin Chinese anaphor *ziji* has also been claimed to show subject orientation, and thus (27) is part of its lexical specification (see Lam 2021 for further details):[16]

(28) Mandarin Chinese (Pollard & Xue 1998: 296)
Zhangsan gei-le Lisi yi-zhang ziji de xiangpian.
Zhangsan give-ASP Lisi one-CL self DE picture
'Zhangsan$_i$ gave Lisi$_k$ a picture of himself$_{i/*k}$.'

In contrast, the Norwegian anaphor *ham selv* can only be bound by a non-subject argument, compare (29a) with (29b).

(29) Norwegian (Dalrymple 1993: 29–30)
a. Jeg ga Jon en bok om ham selv.
I gave Jon a book about him self
'I gave Jon$_i$ a book about himself$_i$.'
b. *Jon snakker om ham selv.
Jon talks about him self.
'Jon$_i$ talks about himself$_i$.'

The anti-subject orientation of *ham selv* can be stated as a negative constraint in the lexical entry of this anaphor: the antecedent cannot be a SUBJ.

The final component of the description of anaphoric dependencies, and the one that has received most attention in LFG since the seminal work of Dalrymple (1993), is the delimitation of the binding domain. Four such domains have been found to be relevant in the description of anaphoric binding, which are listed in (30). These domains can be defined with the help of inside-out functional designators and appropriate off-path constraints, which are also added in (30) below (Dalrymple et al. 2019: 507).

---

[16] In addition, *ziji* can also be bound by an antecedent properly contained in the subject, and it is sensitive to logophoricity (see Lam 2021, as well as example (14) above). We discuss logophoricity in Section 4.

(30) a. Coargument Domain: minimal domain defined by a PRED and the grammatical functions it governs

$$(\underset{\neg(\rightarrow\ \mathrm{PRED})}{\mathrm{GF}^*}\ \ \mathrm{GF}_{\mathrm{PRO}}\uparrow)$$

b. Minimal Complete Nucleus: minimal domain with a SUBJ function

$$(\underset{\neg(\rightarrow\ \mathrm{SUBJ})}{\mathrm{GF}^*}\ \ \mathrm{GF}_{\mathrm{PRO}}\uparrow)$$

c. Minimal Finite Domain: minimal domain with a TENSE attribute

$$(\underset{\neg(\rightarrow\ \mathrm{TENSE})}{\mathrm{GF}^*}\ \ \mathrm{GF}_{\mathrm{PRO}}\uparrow)$$

d. Root domain: f-structure of the entire sentence

$$(\mathrm{GF}^*\ \mathrm{GF}_{\mathrm{PRO}}\uparrow)$$

These domain specifications are stated in the lexical entries of anaphors as either POSITIVE or NEGATIVE binding requirements. A positive binding constraint requires the anaphor to be in a binding relation with some entry within the domain described (subject to further constraints, as discussed above), whereas a negative binding constraint states that the anaphor must not be bound to any element within that domain. Positive and negative binding constraints take the following general forms:[17]

(31) a. Positive binding constraint

$$(\uparrow \mathrm{ANTECEDENT})_\sigma = ((\mathrm{GF}^*\ \mathrm{GF}_{\mathrm{PRO}}\uparrow)\ \mathrm{GF}_{\mathrm{ANT}})_\sigma$$

b. Negative binding constraint

$$(\uparrow \mathrm{ANTECEDENT})_\sigma \neq ((\mathrm{GF}^*\ \mathrm{GF}_{\mathrm{PRO}}\uparrow)\ \mathrm{GF}_{\mathrm{ANT}})_\sigma$$

In what follows, we discuss some examples to show how this system of lexical specifications works. Further and more comprehensive discussions can be found in Dalrymple (1993), Dalrymple et al. (2019) and Bresnan (2001).

The Norwegian complex anaphor *seg selv* is described in Hellan (1988) and Dalrymple (1993) as a subject oriented anaphor that requires a co-argument binder. And while Lødrup 2023 [this volume] shows that speakers may also accept object binders in some cases, the co-argument binder requirement seems to be strong. The contrast between the following two examples illustrates this:

---

[17] Identity is stated between the semantic representations of the antecedent and the anaphor. The σ-projection provides the mapping from f-structure to the LFG-type s(emantic)-structure; see Section 5 for more on this.

(32) Norwegian (Dalrymple et al. 2019: 505–506, citing Hellan 1988: 67, 69)

a. Jon fortalte meg om *seg* *selv*.
Jon told me about REFL self.
‘Jon$_i$ talks about himself$_i$.’

b. **Hun* kastet meg fra *seg* *selv*.
she threw me from REFL self.
‘She$_i$ threw me away from self$_i$.’

The difference between the two constructions is that (32b) contains a semantic preposition with a PRED feature, while the oblique PP in (32a) does not.

Consider the f-structure of the grammatical (32a) first. The Coargument Domain constraint (30a) requires a path from f-structure *j* to the f-structure that contains the SUBJ antecedent. Since this is a short path, no PRED feature occurs on the way, and therefore the off-path constraint ¬(→ PRED) is satisfied. (33) is the (simplified) f-structure of (32a):

(33) f-structure of (32a)

$$
{}_f\left[\begin{array}{ll}

\end{array}\right]
$$

---

[18] The PP *fra seg selv* ‘from self’ could alternatively be analyzed as an OBL, but the choice between the ADJ and the OBL analysis is largely orthogonal to our current concerns. See also footnote 10 on this issue.

Here the domain path starts at f-structure k, and to reach the f-structure of the antecedent, we need to pass the PRED feature in j – a move that the off-path constraint $\neg(\rightarrow \text{PRED})$ prohibits. As a result, (32b) is ungrammatical.

The primary Hungarian reflexive, *maga*, is grammatical in non-selected spatial PPs. In fact, it is often the only option in standard Hungarian, and a pronominal PP is unacceptable in the particular case of the Hungarian version of (32b) (Rákosi 2010).

(35) Hungarian

a. János$_i$ el-tolt engem magá-tól$_i$.
János away-pushed.3SG me himself-from
'János$_i$ pushed me away from himself$_i$.'

b. *János$_i$ el-tolt engem (ő$_i$-)től-e$_i$.
János away-pushed.3SG me he-from-3SG
'János$_i$ pushed me away from him$_i$.'

The source marker corresponding to the English preposition *from* is expressed as ablative case morphology in Hungarian (*-tól/-től*). Reflexives behave like lexical nouns in this respect, and they take the ablative case suffix as expected (35a). Personal pronouns, however, trigger agreement morphology on the case marker, and the pronoun itself is usually pro-dropped (35b). But whether this pronoun is overt or is pro-dropped, it cannot have a clause-mate antecedent, resulting in the ungrammaticality of (35b).

(35a) is thus in direct contrast with (32b). The Hungarian reflexive *maga*, unlike Norwegian *seg selv*, is subject to the Minimal Complete Nucleus constraint: it has to be bound within a domain that includes a subject. This is captured in (30b) with the help of the off-path constraint $\neg(\rightarrow \text{SUBJ})$. The f-structure of (35a) is analogous to (34), and using that f-structure for the purposes of illustration, the relevant domain path in Hungarian would take us from the f-structure of the reflexive (k) to f-structure j of the adjunct PP, which is contained within the matrix f-structure f, together with the subject antecedent g. Subject g can serve as the antecedent of the reflexive. Being subject to the Minimal Nucleus Constraint requires this search not to pass a subject antecedent, and it follows that Hungarian *maga* cannot take antecedents that are in another clause.

Interestingly, the Hungarian reciprocal anaphor *egymás* is somewhat freer than the reflexive *maga*, as it can take antecedents from within the Minimal Finite Domain. Compare the following two sentences:

(36) Hungarian (Laczkó & Rákosi 2019: 153)

a. A fiúk látták a lányok-kat lerajzol-ni maguk-at.
the boys saw.3PL the girls-ACC draw-INF themselves-ACC
'The boys$_i$ saw the girls$_k$ draw (a picture of) themselves$_{*i/k}$.'

b. A fiúk látták a lányok-kat lerajzol-ni egymás-t.
the boys saw.3PL the girls-ACC draw-INF each.other-ACC
'The boys$_i$ saw the girls$_k$ draw (a picture of) each other$_{i/k}$.'

The reflexive object of the infinitive can only be co-construed with the infinitival subject (controlled by the matrix object), but it cannot take the matrix subject as its antecedent in (36a). It is thus unlike the reciprocal in (36b), which can.

The Norwegian reflexive *seg selv*, the Hungarian reflexive *maga*, and the Hungarian reciprocal *egymás* are all anaphors, yet the binding constraints that apply to them are different. *Seg selv* needs an antecedent in the Coargument Domain, *maga* takes one from the Minimal Complete Nucleus, and *egymás* may have an antecedent even outside of its own embedding clause as long as the search is confined to the Minimal Finite Domain. In fact, the binding constraints that we have discussed in this section create a relatively large space within which particular lexical types of anaphors may vary, and research in the framework of LFG has shown that this space is indeed occupied by an abundance of anaphoric elements attested cross-linguistically. The list includes such relatively atypical anaphors as the *ìı* pronouns of Yą̧g Dii, which must take long distance antecedents (Dalrymple 2015) within a logophoric domain. We discuss logophoricity and these pronouns in Section 4 below.

4 Logophoricity

Anaphors, especially reflexives, may sometimes appear without a clause- or a sentence-mate antecedent, or even in the complete absence of a linguistically expressed antecedent. The following BNC (Davies 2004) examples contain such reflexives.

(37) a. And suddenly Briant felt better. These people were professionals, like *himself*.

b. I've not done this before and I wanted to try it out with a small group like *yourselves* to see how we go on with it.

c. Our group consisted of Stephen, David, Laura and *myself*, and we were aged twenty-two.

d. Lots of love to Birgitta and *yourself*, and to the boys when you see them.

One hallmark of these types of reflexives is that they are more or less freely exchangeable with personal pronouns. Thus, for example, *himself* in (37a) can be replaced with *him*, and both will refer to Briant in the given context.

Many instances of such types of anaphora have been claimed to be conditioned by discourse factors (see Maling 1984, Sells 1987, Pollard & Sag 1992, Reinhart & Reuland 1993, Culy 1994, and Bresnan et al. 2016, among others). The most prominent of these factors is perspective or viewpoint, in the sense that the (discourse) antecedent of the reflexives is a perspective holder. The reflexive in (37a), for example, occurs in a discourse context in which the feelings of Briant are described, and (37c) projects the speaker's perspective and hence creates a context in which the reflexive *myself* is licensed in the absence of a linguistically expressed antecedent. From a purely syntactic perspective, anaphoric data of this type are often approached as exceptional (see the term EXEMPT ANAPHORA in Pollard & Sag 1992). Pertinent research in LFG has focused on anaphoric elements which, unlike the English reflexive, must take a linguistically expressed antecedent which is a perspective holder. Such anaphoric elements are called LOGOPHORS.[19]

Bresnan et al. (2016) offer an in-depth discussion of logophoricity, including its relation to subjectivity. A logophoric pronoun "refers to one whose speech, thoughts, or feelings are represented in indirect discourse, from that person's own point of view" (Bresnan 2016: 255). They treat the Icelandic reflexive *sig* as a logophoric element (see also Maling 1984, as well as Strahan (2009, 2011)), and Lam (2021) provides a logophoric LFG-analysis of the Mandarin Chinese reflexive *ziji*, as well as of the Cantonese reflexive *jighei* (see also Pollard & Xue 1998 on the nonsyntactic uses of *ziji*). A very intriguing type of a logophoric pronominal is discussed in Dalrymple (2015). The Yą̧g Dii language (Niger-Congo/Adamawa-Ubangi, Cameroon) has a complex pronominal system that includes the *ìı* pronouns. These pronouns are like regular anaphors inasmuch as they cannot be used deictically, and they cannot take discourse antecedents. However, "the antecedent of *ìı* must be the subject of a clause that is at least two clauses distant" (Dalrymple 2015: 1090). In example (38), this pronoun is the subject of the embedded clause S3, and it must be co-construed with the subject of the matrix clause S1.

---

[19] Most of the pertinent research both within and outside of LFG has focused on reflexives, but, as Pollard & Sag (1992) point out, reciprocal anaphors may also be exempt. Szűcs (2019) discusses complex event nominalization data from Hungarian to show that Hungarian reciprocals embedded in such noun phrases may lack a linguistic antecedent and are then licensed as logophors.

(38) Yąg Dii (Dalrymple 2015: 1091)

$_{S1}$[Àkàw	∅	ǫ̀	$_{S2}$[lig	$_{S3}$[bà	ìi	lá	hęn	lálɨ́	páskà
Teacher$_i$	(he$_i$)	say	house	that	he.ìi$_{i/*j}$	eat	thing	eating	Easter

kan	waa	duulí	bìì	vʉ	wʉlɨ́	máa]	bà	dɨ	tɛ́lá?]
with	child	following	his$_i$	PL	there	when,	that.it	is.there	where?

‘$_{S1}$[The teacher$_i$ asks, $_{S2}$[where is the house $_{S3}$[in which he.ìi$_{i/*j}$ will eat the Easter meal with his$_i$ disciples?]]]’

The antecedent subject must be a perspective holder, and the intermediate subject in *S*2 may or may not be coreferential with the pronoun as long as it does not introduce an independent logophoric domain.

Disregarding now details that are irrelevant for our purposes, the binding constraints on this pronoun can be stated as follows:

(39) Binding constraints for *ìı* (Dalrymple 2015: 1117)

$$(\uparrow_\sigma \text{ ANTECEDENT}) = ((\underset{(\rightarrow \text{ LOG})}{\text{GF}_{\text{LOG}}}\ \ \underset{\neg(\rightarrow \text{ LOG})}{\text{GF}^{*}}\ \ \uparrow)\ \text{SUBJ})_\sigma$$

This lexical specification requires the pronoun to take a subject antecedent from an f-structure where a logophoric domain is specified, and the domain path needs to include an intermediate f-structure where no independent logophoric domain is introduced. Formally, the LOG feature appears within the f-structure that corresponds to the logophoric domain:

(40)
$$_{S1}\left[\begin{array}{ll} \text{SUBJ} & \left[\text{LOGOPHORIC ANTECEDENT}\right] \\ \text{GF}_{\text{LOG}} & _{S2}\left[\begin{array}{l} \text{LOG}\ \ + \\ \ \ _{S3}\left[\ldots\text{ÌI}\ldots\right] \end{array}\right] \end{array}\right]$$

Yąg Dii thus has a pronominal system where logophoricity is a grammaticised notion, and it must be employed as an f-structure feature LOG in the determination of the binding domain. In the particular case of the logophor *ìı*, this domain must be unusually large as it must include an extra clause between the clause that hosts the antecedent and the clause that hosts the logophor.

5 On representing referential dependencies

Anaphoric dependencies may be represented via referential indices. These can be used in the f-structures themselves, a practice which I have followed in this chapter. The indices themselves do not form an integral part of the formalism, however; they are mere mnemonics that help visualize the dependency. The machinery that we have introduced in Section 3 allows us to represent such dependencies in a more elegant manner. The notation, in the tradition of Dalrymple (1993), states that the semantic structure of the antecedent and of the anaphoric element are equivalent. The following is an abbreviation for the binding constraints on the basis of Asudeh (2019), where f is the f-structure of the anaphor and f_σ is its semantic structure (see Asudeh 2023 [this volume] for semantic structure in LFG).

(41) $(f\ \textsc{antecedent})_\sigma = f_\sigma$

As Asudeh (2019) argues, this notation has several theoretical advantages over the referential index notation. Firstly and most importantly, it shifts attention to semantic structure, which is the appropriate place to represent referential dependencies.

The postulation of semantic equivalence between anaphor and antecedent abstracts away from the issue that it is often the case that no strict referential identity is required between the two. In (42), for example, the anaphor stands for the image of Kate in the mirror, whereas the antecedent noun phrase refers to the actual individual herself.

(42) Kate saw *herself* in the mirror.

Rákosi (2009) argues that the Hungarian complex anaphor *önmaga* is especially well-suited to contexts of such referential shifts. In fact, it may even take restrictive adjectival or participial modifiers, as in (43) below.

(43) Hungarian

a	tükör-ben	lát-ott	*önmagam*
the	mirror-in	see-PTCP	myself

‘my self/image seen in the mirror’

(43) evokes a context where the speaker feels alienated from his or her own image. To what extent this variation in anaphora interpretation is integral to the study of the grammar of anaphora is partly a matter of perspective (see also Jackendoff 1992 on this issue in general). In any case, if it is, semantic structure is a natural locus to address this issue.

The statement of semantic identity between anaphor and antecedent, in and of itself, does not account for the semantic differences between plural reflexives and reciprocal anaphors, which obviously differ in interpretation. Moreover, reciprocal interpretation is subject to variation from relatively strong (44a) to relatively weak (44b) readings.

(44) a. The students like *each other.*

b. The students followed *each other* into the classroom.

These issues and the overall semantics of reciprocals are discussed at length in Dalrymple et al. (1998) and Haug & Dalrymple (2020). Dalrymple et al. (2018) develop an LFG-based, fine-grained and comprehensive semantic structure representation of anaphoric dependencies within a dynamic semantics framework, which provides a solution to the issues that we have briefly addressed here (see also Dalrymple et al. 2019). What must be stated on the syntactic side, that is, at the level of f-structure, is the requirement that anaphors and antecedents must have matching agreement features. This is achieved in LFG via the INDEX feature set, discussed in detail in Haug 2023 [this volume].[20]

6 Summary

We have seen that LFG differs from other generative frameworks in explicitly recognizing the empirical fact that anaphoric elements are subject to substantial variation both within and across languages, and no single rule or principle of grammar can capture this versatility in itself. Binding relations are complex dependencies with several parameters, all of which can be stated in the lexical entry of anaphors, in line with the lexicalist nature of LFG grammars.

Research within the LFG tradition also addressed other aspects of the grammar of anaphora which we have not focused on. Constraints on coreference relations including pronouns are discussed in Bresnan et al. (2016), whereas Dalrymple et al. (2018) and Dalrymple et al. (2019) provide an in-depth introduction to the semantic composition of anaphora, including discourse anaphoric relations encoded by personal pronouns and other types of pronominals which we have not touched upon in this chapter.

As happens in other frameworks, too, LFG research has focused mostly on the grammar of reflexive anaphors, but reciprocals have also received attention, see especially Hurst (2006, 2010, 2012) and Hurst & Nordlinger (2021). Morphosyntactic variation is in general significant among different types of anaphors, which, given the f-structure centered approach of LFG, is often not the primary focus of investigation. Nevertheless, a number of LFG works address this variation, from the syntactically active bound anaphoric morphemes in Bantu languages

---

[20] Rákosi (2022) argues on the basis of Hungarian data that at least certain types of anaphors may only constrain the INDEX features of their antecedents, but they do not have INDEX features of their own.

(see Bodomo & Che 2023 [this volume]) to the monomorphemic markers of Germanic, Romance and Slavic languages, which may either act as anaphors or as intransitivizers (see, among others, Sells et al. 1987, Alencar & Kelling 2005, Alsina 2023 [this volume], and Hristov 2023 [this volume]). Complex reflexives may have even more complex variants, with interesting syntactic and semantic consequences discussed in Rákosi (2009). Bresnan et al. (2016) give an overview of some issues in typological variation in the morphology of anaphors and its syntactic correlates.

Acknowledgments

I am profoundly grateful to Mary Dalrymple for her editorial help and endless patience. I am also indebted to the three anonymous reviewers, whose comments and suggestions were essential in improving this text. Any remaining errors are mine.

I acknowledge the support of the János Bolyai Research Scholarship of the Hungarian Academy of Sciences, as well as support by the ÚNKP-22-5 New National Excellence Program of the Ministry for Innovation and Technology from the source of the National Research, Development and Innovation Fund.

Abbreviations

Besides the abbreviations from the Leipzig Glossing Conventions, this chapter uses the following abbreviations.

Chapter 5

Agreement

Dag Haug
University of Oslo

This chapter surveys the treatment of agreement in LFG. We show how theories of agreement can be classified by how they use symmetry and feature sharing in their treatments and how LFG usually opts for a symmetric but not feature sharing account. Other topics include the INDEX/CONCORD distinction, how non-f-structure such as linear order and information structure impacts on agreement, long-distance agreement and Wechsler's Agreement Marking Principle.

1 Introduction

Agreement is the linguistic phenomenon whereby a set of features is realized morphologically on two different syntactic tokens, as we see in (1).

(1) The boy loves the girl.

Both the word *boy* and the word *loves* realize a singular number feature.[1] However, this feature is only meaningful on *boy*, where it indicates that that the noun phrase refers to a single boy; *loves* merely agrees, in this case with its subject. Agreement is therefore a directed phenomenon: the *controller* ('boy') has a set of meaningful features and the *target* ('loves') agrees with these.

"Meaningful" must be taken with a grain of salt. We can also have agreement in purely syntactic features such as CASE or in features that are inherent in the controller but do not carry any obvious meaning, such as GENDER. But even in such cases, we observe directionality. Consider (2) from Latin.

---

[1] We are relying here on an inferential, realizational view of morphology whereby *boy* is morphologically singular even if there is no singular morpheme.

Dag Haug. 2023. Agreement. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 193–218. Berlin: Language Science Press. DOI: 10.5281/zenodo.10185942

(2) Latin
rosa spinosa floruit
rose:NOM;F;SG thorny:NOM;F;SG bloomed:PST;3SG
'The thorny rose bloomed.'

The nominative case feature that is realized on *rosa* and *spinosa* is only meaningful on *rosa* because it indicates the grammatical function (subject) of the noun phrase. By contrast the grammatical function (adjunct) of *spinosa* is given by the fact that its case agrees with that of its head, rather than by a specific case feature: if the NP was in object position instead, the case of *rosa* would change because the grammatical function of the noun phrase would change; and the case of the adjective *spinosa* would also change, despite its grammatical function as adjunct remaining the same. Finally, the feminine gender feature in (2) is an inherent, purely formal property of the controller: it does not provide any information about the syntactic function or the meaning of the noun phrase headed by *rosa*, but is a non-variable feature of *rosa* which is part of the information conveyed by the lexeme. By contrast, the adjective *spinosa* inflects for this feature and can assume other gender features, depending on the inherent gender of its controller.

There are three main areas where languages display agreement phenomena. First, there is agreement in predicate-argument structures, where one or more arguments typically act as controllers and the predicate is the target. Second, we observe agreement inside NPs, where typically the head noun controls agreement on targets like determiners, quantifiers, adjectives and other modifiers. Third, we have "anaphoric agreement" between anaphors and antecedents. The latter type of agreement has attracted little attention in LFG work and will consequently largely be ignored here, except that it is relevant as a diachronic source of predicate-argument agreement.

In Section 2, we show how theories of agreement can be classified by how they use symmetry and feature sharing in their treatments. In Section 3 we discuss the INDEX/CONCORD distinction that is drawn in much LFG work on agreement. While agreement is generally treated at f-structure in LFG, Section 4 discusses how linear order and information structure impacts on agreement. Section 5 discusses the diachrony of agreement markers. Section 6 discusses long-distance agreement, a phenomenon which suggests there may be a role for feature sharing in agreement to preserve syntactic locality. Finally, Section 7 discusses Wechsler's Agreement Marking Principle, which is a challenge to symmetric accounts of agreement.

2 Agreement in unification grammars

The basic treatment of agreement in unification-based grammars is very straightforward as we simply need to make sure that the relevant features of the controller and the target unify. This is usually done by specifying functional descriptions that put the features in the same position in the functional structure, namely that of the controller. The specifications of (2) are shown in (3) and yield the f-structure in (4). Only relevant features are shown.

(3) *rosa* (↑ PRED) = 'ROSE'
(↑ NUM) = SG
(↑ CASE) = NOM
(↑ GEND) = FEM
floruit (↑ PRED) = 'BLOOM<SUBJ>'
(↑ SUBJ NUM) = SG
(↑ SUBJ CASE) = NOM
(↑ SUBJ PERS) = 3
spinosa (↑ PRED) = 'THORNY'
((ADJ ∈ ↑) NUM) = SG
((ADJ ∈ ↑) CASE) = NOM
((ADJ ∈ ↑) GEND) = FEM

(4)
$$\begin{bmatrix} \text{PRED} & \text{`BLOOM}\langle\text{SUBJ}\rangle\text{'} \\ \text{SUBJ} & \begin{bmatrix} \text{PRED} & \text{`ROSE'} \\ \text{NUM} & \text{SG} \\ \text{CASE} & \text{NOM} \\ \text{GEND} & \text{FEM} \\ \text{PERS} & 3 \\ \text{ADJ} & \left\{\begin{bmatrix} \text{PRED} & \text{`THORNY'} \end{bmatrix}\right\} \end{bmatrix} \end{bmatrix}$$

In this approach to agreement, there is *symmetry* between the controller and target features in that it does not matter whether a feature value originates from a functional description associated with the controller or the target or both. However, agreement features are *not* shared (in the technical sense of structure sharing in f-structures), but only represented in a single position in the f-structure, that of the controller, reflecting the directedness of agreement. It is this symmetric, yet not feature-sharing approach to agreement that gives the standard LFG analysis its specific flavor, different from analyses that are often found in the derivational tradition starting from Pollock (1989) and in HPSG (Pollard & Sag 1994: chapter 2).

In current derivational approaches, controller features are interpretable and target features are uninterpretable. The Agree mechanism matches uninterpretable features to their interpretable counterparts and deletes them. If uninterpretable features remain, the derivation crashes. Hence all target features must be available on the controller. But in Latin, which is a pro-drop language, this forces us to postulate several null subjects differing only in their interpretable PERS and NUM values, merely to check off the matching uninterpretable features on the verb. The same point is made by Barlow (1988) and Pollard & Sag (1994: 64). Pollard and Sag give the Polish examples in (5), where the verb would be assumed to agree with a null subject.

(5) Polish

kochałem	kochałeś	kochał
I.M loved	you.M loved	he loved
kochałam	kochałaś	kochała
I.F loved	you.F loved	she loved

To maintain an asymmetric view of agreement, we are essentially forced to assume that the examples in (5) involve a multiplicity of phonetically null pronominals, one for each distinct form of the verb.

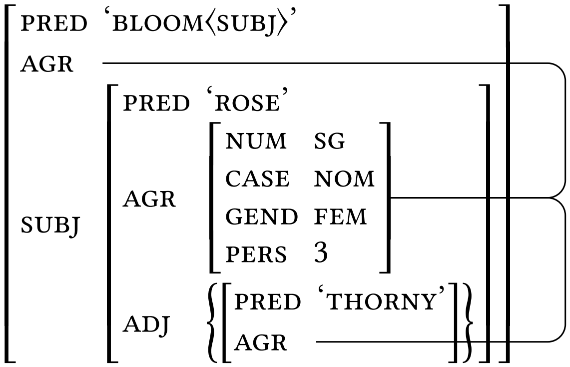
By contrast, on the standard LFG analysis, target features can themselves provide information. Going back to the Latin example from (2), we would get the f-structure in (6) if the subject is pro-dropped to give the simple sentence *floruit* 'It blooms'.

(6)
$$\begin{bmatrix} \text{PRED} & \text{`BLOOM}\langle\text{SUBJ}\rangle\text{'} \\ \text{SUBJ} & \begin{bmatrix} \text{PRED} & \text{`PRO'} \\ \text{NUM} & \text{SG} \\ \text{CASE} & \text{NOM} \\ \text{PERS} & 3 \end{bmatrix} \end{bmatrix}$$

This f-structure arises directly from the f-descriptions of *floruit* in (3) plus an optional description (↑ SUBJ PRED) = 'PRO' associated with the verb. The NUM, CASE and PERS features are specified by the target (the verb) directly, with no need for matching features on the null subject, so that we do not need to multiply covert elements. Few LFG practitioners have therefore adopted an asymmetric mechanism for matching target and controller features, although the LFG framework offers such a mechanism in the form of constraining equations. Nevertheless, we will see in Section 3 that some theories of feature indeterminacy and coordination actually require the use of constraining equations, at least to deal with feature resolution. More substantially, Wechsler (2011) has argued that absence of controller features has grammatical effects. This requires a deeper commitment to asymmetry. We discuss his proposal in Section 7.

While it contrasts with Minimalism in that target and controller features are taken to be symmetric, the standard LFG treatment also differs from an approach that is often seen in HPSG based on structure sharing of the agreement features between the target and the controller. In an LFG setting, we could get such an analysis e.g. by embedding agreement features in a feature AGR to be structure shared between the target and the controller. This would yield the f-structure in (7) instead of (4), if we assume that both predicate-argument agreement and NP-internal agreement involve structure sharing.

(7)



Within the HPSG tradition, Kathol (1999) argues for such an approach. His main argument is that in many cases, target and controller morphology is arguably "the same" (such as the *-a* ending in *ros-a* and *spinos-a*). This is particularly common in noun phrase-internal agreement, but occasionally happens also in predicate-argument agreement, cf. (8).

(8) Swahili (Kathol 1999: ex. 14, originally from Welmers 1973: 171)

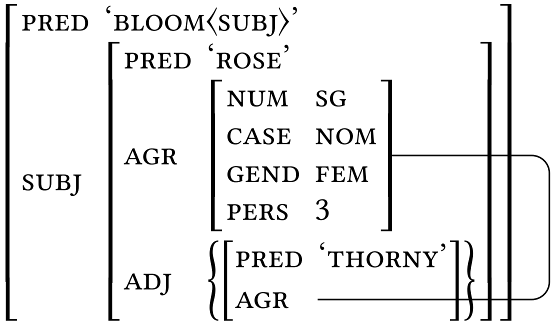
a. **Ki**kapu **ki**kubwa **ki**moja **ki**lianguka.
basket large one fell
'One large basket fell.'

b. **Vi**kapu **vi**kubwa **vi**tatu **vi**lianguka.
baskets large three fell
'Three large baskets fell.'

In such cases, although the morphology is the same, it has to contribute different functional descriptions in the various positions, because the agreement construction is built into the equations. By contrast, if we assume structure sharing, the mapping from morphology to functional descriptions becomes uniform: *-a* in Latin and *ki-* in Swahili always contribute their features to the agr feature structure of the item where they are realized, and agreement will be captured by requiring structure sharing of agr structure in the appropriate configurations.

We can assume that all agreement works in this way, but since morphological identity of target and controller features is much more common in noun phrase-internal agreement, it is possible to assume feature sharing only here and not in predicate-argument agreement. This is illustrated in (9).

(9)



The agr feature bundle is structure shared inside the NP but not between the verb and the NP. This is the option taken in much HPSG work, e.g. Pollard & Sag (1994) and Wechsler & Zlatić (2003). It is natural to connect this difference to the index/concord distinction that we discuss in Section 3: on that view, the agr feature of (9) will be split in two feature bundles, concord (typically relevant for NP-internal agreement) and index (typically between predicates and arguments) and we can assume that only concord agreement involves structure sharing.[2]

Kathol's argument is essentially an architectural argument about how to best capture the morphology-syntax interface. It has not been picked up in the LFG tradition. The most explicit work on the topic, Dalrymple et al. (2019: Chapter 12) assumes the traditional LFG approach and consequently postulates complex so-called m-features (morphological features that are to be mapped to functional descriptions). That is, a first person plural form of the verb is associated with the m-feature in (10).

(10) m-agr:⟨agr(su):{pers:1, num:pl}⟩

The form, then, carries information not just about the features it contributes (first person and plural number) but also *where* it contributes those features (in this

---

[2] Note that Wechsler & Zlatić (2003: 145) say that "subject-verb agreement…is modeled in terms of structure-sharing", although it is clear from Wechsler & Zlatić (2003: 21) that they do not assume the verb bears its own person and number features. I assume that "structure sharing" is used loosely here in the sense of cospecification of features.

case, to the subject). Therefore, there cannot be a uniform representation of *-a* in *ros-a* and *spinos-a* (or *ki-* and *vi-* in 8), since they contribute the same feature to *different* locations. In a structure sharing account we *can* have a uniform representation (of the relevant morphemes or paradigmatic inferences, depending on your view of morphology), where e.g. *-a* is simply associated with nominative, singular, feminine features and the feature sharing that forces agreement stems from the relevant agreement construction. But as (10) shows, we do not *need* structure sharing: we can capture the same facts without it, but at the cost of a (slight) complication of the morphology-syntax interface.

In addition to the architectural issue, the structure sharing approach also makes different empirical predictions in some cases, because the same syntactic position can be simultaneously target and controller for two different agreement processes involving the same feature and hence give rise to so-called long distance agreement. We return to this in Section 6.

To sum up, the standard LFG treatment is symmetric but not feature-sharing: it is based on features contributed by defining equations from (potentially) several sources (the controller and one or more targets) to a single syntactic position. While there has been little pressure to change this except for special constructions, the complexities of agreement phenomena cross-linguistically has led to expansions in many different directions.

3 INDEX, CONCORD and coordination

It is possible for nominal controllers to trigger different values for the same feature on different targets, as in the Serbo-Croatian example (11) from Wechsler & Zlatić (2003: 5).

(11) Serbo-Croatian

Ta	dobra	deca	su	došla.
that:F;SG	good:F;SG	children:(F;SG)	AUX;3PL	come:PRF;PTCP;N;PL

‘Those good children came.’

Here the noun *deca* ‘children’ triggers feminine singular agreement on the determiner and the adjective, but neuter plural agreement on the predicate.[3] Such examples require that we postulate two different bundles of agreement features, generally called INDEX and CONCORD (Pollard & Sag 1994, Kathol 1999, Wechsler

---

[3] Note, though, that the feminine singular and the neuter plural are syncretic in Serbo-Croatian. See Alsina & Arsenijević (2012a,b) and Wechsler & Zlatić (2012) for discussion.

& Zlatić 2003). Both index and concord are syntactic features, modelled at f-structure in LFG, but the intuition is that index features are more closely related to semantics and are the ones that are related to the reference of a noun phrase, typically gender, person and number (but not case). By contrast, concord features are more closely related to morphological class and typically include gender, number and case (but not person). According to Wechsler (2011) this division reflects the historical origin of the morphology on the agreement targets, which typically comes from incorporated pronouns in the case of index agreement, but from nominal classifiers (and other sources) in the case of concord agreement. concord and index are also different in that concord agreement is generally found inside NPs whereas index features are typically relevant to predicate-argument agreement.

Since gender and number are present both in index and concord, they may take different values in those contexts and that is what happens in (11). The f-structure for *ta dobra deca* in this example is shown in (12).

(12)
$$\left[\begin{array}{ll} \textsc{concord} & \left[\begin{array}{ll}\textsc{gend} & \textsc{fem}\\ \textsc{num} & \textsc{sg}\\ \textsc{case} & \textsc{nom}\end{array}\right] \\ \textsc{index} & \left[\begin{array}{ll}\textsc{gend} & \textsc{neut}\\ \textsc{num} & \textsc{pl}\\ \textsc{pers} & 3\end{array}\right]\end{array}\right]$$

It is worth pointing out that although index is in some sense "closer" to the semantics than concord, both are syntactic features, represented at f-structure. In addition to these two kinds of agreement it is necessary to postulate a third, semantic/pragmatic kind of agreement. This is particularly common in pronoun-antecedent agreement. For example, the Serbian/Croatian diminutive noun *devojče* 'girl' may be referred to with a neuter pronoun (reflecting its index gend feature), or with a feminine pronoun, reflecting the meaning of its anteceedent.

Much work in LFG uses representations like (4) as a simplification when the index/concord distinction is not relevant, but actual work on agreement has generally assumed the distinction. However, Alsina & Arsenijević (2012a,b) argued against having two sets of syntactic agreement features. For counterarguments defending the index/concord distinction, see Wechsler & Zlatić (2012) and Hristov (2013).

While some words like *deca* appear to be lexically specified with different index and concord features, another important motivation for the distinction comes from different behaviour in coordinate structures. Consider (13) from Belyaev et al. (2015: 36)

(13) This/*These man and woman are/*is eating sushi.

The coordinate noun phrase in (13) consists of two singular nouns. The determiner must agree in singular number with each of these nouns, whereas the predicate must agree in plural number with the coordination as a whole. This indicates that CONCORD NUM, relevant for NP-internal agreement, is singular, but INDEX NUM, relevant for predicate agreement, is plural.

To derive this CONCORD/INDEX distinction in number, King & Dalrymple (2004) proposed that INDEX features are nondistributive, i.e. they are features not just of the individual conjuncts but also of the conjunction as a whole, based on rules of feature resolution; whereas CONCORD features are distributive, i.e. properties of the individual conjuncts but not of the conjunction as a whole. That is, a conjunction of two singular NPs such as *man and woman* cannot trigger a plural determiner (**These man and woman*) because the determiner agrees in CONCORD. However, it does trigger plural number agreement on the verb (if it is the subject) because the conjunction as a whole has a NUM PL feature in the INDEX, different from the singular feature of the two conjuncts, as shown in (14).

(14)
$$\left[\begin{array}{l} \textsc{index} \begin{bmatrix}\textsc{num} & \textsc{pl}\end{bmatrix} \\ \left\{ \begin{bmatrix} \textsc{pred} & \text{‘}\textsc{woman}\text{’} \\ \textsc{concord} & \begin{bmatrix}\textsc{num} & \textsc{sg}\end{bmatrix} \\ \textsc{index} & \begin{bmatrix}\textsc{num} & \textsc{sg}\end{bmatrix} \end{bmatrix} \begin{bmatrix} \textsc{pred} & \text{‘}\textsc{woman}\text{’} \\ \textsc{concord} & \begin{bmatrix}\textsc{num} & \textsc{sg}\end{bmatrix} \\ \textsc{index} & \begin{bmatrix}\textsc{num} & \textsc{sg}\end{bmatrix} \end{bmatrix} \right\} \end{array}\right]$$

This raises the question of how the features of a coordination are related to those of the conjuncts. The distinction between distributive and nondistributive features was originally introduced by Dalrymple & Kaplan (2000) who used set-valued features to model both indeterminacy and feature resolution in coordination. For example, the PERSON feature is treated in terms of sets over the atomic markers *S* (for “speaker”) and *H* (for “hearer”). In a language like English or Spanish, with no exclusive/inclusive distinction in the first person plural, sets over these atoms are interpreted as in (15).[4]

(15) $\{S, H\}$ first person
$\{H\}$ second person
$\{\}$ third person

On this interpretation, feature resolution corresponds to set union and can be encoded in the phrase structure rule for coordination as in (16).

---

[4] The system of Dalrymple & Kaplan (2000) can also capture the first person exclusive as $\{S\}$ in languages where this is needed.

(16)
$$\text{NP} \longrightarrow \begin{array}{ccc} \text{NP} & \text{CONJ} & \text{NP} \\ \uparrow=\downarrow & & \uparrow=\downarrow \\ (\downarrow \textsc{person}) \subseteq (\uparrow \textsc{person}) & & (\downarrow \textsc{person}) \subseteq (\uparrow \textsc{person}) \end{array}$$

Because the values in (15) are ordered by set inclusion we get a hierarchy effect in resolution, where second and third person resolves to second person, and first and second/third person resolves to first person.

It is worth pointing out that this requires the target features to be stated with a constraining equation as in the sample first person entry in (17).

(17) $(\uparrow \textsc{person}) =_c \{S, H\}$

If the target features were stated constructively, as in the standard approach, a first person verb would be compatible with the coordination of two second person forms, because the first person from would set the PERSON feature to $\{S, H\}$ and each conjunct would simply check that $\{H\}$ is a subset of that. In other words, the set-based approach requires us to give up the symmetric approach to agreement and would therefore run into similar problems with e.g. pro-drop as other asymmetric approaches to agreement, as discussed above.

Alternative accounts of feature resolution that are based on ordinary feature structures rather than sets seem at first sight not to require constraining equations. In particular, Dalrymple et al. (2009) suggests using ordinary LFG features to encode what would be set membership in the analysis of Dalrymple & Kaplan (2000) and to deal with feature indeterminacy that way. Sadler (2011) extends that approach to coordination. For example, in a language like Icelandic, where any coordination of nouns with different genders resolve to neuter gender, the set-based approach would assume values as in (18).

(18) $\{M, F\}$ neuter gender
$\{M\}$ masculine gender
$\{F\}$ feminine gender

This can be translated into standard feature structures by decomposing gender into two features, M and F, as follows.

(19)
a. neuter gender: $\begin{bmatrix} \textsc{m} & - \\ \textsc{f} & - \end{bmatrix}$

b. masculine gender: $\begin{bmatrix} \textsc{m} & + \\ \textsc{f} & - \end{bmatrix}$

c. feminine gender: $\begin{bmatrix} \textsc{m} & - \\ \textsc{f} & + \end{bmatrix}$

The resolution rule will then specify that for each gender feature, if all the conjuncts are +, the set is also assigned +; otherwise the set is assigned −. However, as it turns out, stating this resolution rule explicitly requires the use of constraining equations, namely an implicational constraint.[5] Still, the situation is different from the set-based solution in that the equations on both the target and on the controller conjuncts are constructive. It is only the resolution rule that makes use of constraining equations, suggesting that even in a declarative theory like LFG, feature resolution requires a procedural approach:[6] first, we construct the conjuncts and then we can compute the features of the coordination. On the other hand, the agreement mechanism itself does not require constraining equations, and since the target features are still specified constructively we do not run into problems with pro-drop.

4 Factors outside the f-structure

While agreement is generally determined in terms of f-structure relations, it is widely acknowledged that other factors are also relevant, in particular linear order/c-structure and information structure.

4.1 Linear order

That linear order can be relevant for agreement is shown by so-called single conjunct agreement. (20–21) show some examples from Kuhn & Sadler (2007).

(20) Czech
Na rohožce seděla kočka a pes.
on mat was.sitting:F;SG cat:F;SG and dog:M;SG
'The cat and the dog were sitting on the mat.'

(21) Portuguese
os [mitos e lendas] brasileiras
the:M;PL myth:M;PL and legend:F;PL Brazilian:F;PL
'the Brazilian myths and legends'

In (20), from Czech, the predicate *seděla* agrees only with the closest subject conjunct, *kočka*. In (21), from Portuguese, the determiner agrees with its closest

---

[5] See Dalrymple et al. (2019: 640) for a formalisation of the required resolution rule.

[6] The use of constraining equations in LFG in general has been taken to be a "dynamic residue that resists a purely declarative analysis" (Blackburn & Gardent 1995: 44).

conjunct, the first one, whereas the postposed adjective agrees with the second conjunct, which again is the closest one. Examples such as (21) show that we cannot simply pick out a single distinguished conjunct and make that available for agreement: what is relevant is the distance between the target and the controller.

Kuhn & Sadler (2007) discuss earlier approaches to single conjunct agreement and propose a solution based on dividing features into not only the standard distributive/nondistributive classification, but also to distinguish left-peripheral, right-peripheral and proximity-based features. Dalrymple & Hristov (2010) dispense with the need for dividing features this way and instead provide definitions of new f-structure path descriptions. For example, $f_{(L)}$ is defined as in (22).

(22) $$f_{(L)} \quad \equiv \quad f \qquad \underset{\neg[(\leftarrow \in) \prec_f \rightarrow]}{\in^*}$$

Here, $\in^*$ picks out an arbitrarily embedded member of the set (to account for nested coordination); the Kleene star also allows zero levels of embedding, which would make $f_{(L)}$ refer simply to f. However, in case we pick a set member, it must be the leftmost member of f. This is accomplished by the off-path constraint $\neg[(\leftarrow \in) \prec_f \rightarrow]$, which says that at any point in the path of (potentially nested) coordinations, there must not be other conjuncts $(\leftarrow \in)$ that f-precede $(\prec_f)$ the one we pick $(\rightarrow)$. Hence, if f is not a set, $f_{(L)}$ equals f, but if f *is* a set, $f_{(L)}$ can be either the whole set f or its leftmost member. This allows modelling of optional left conjunct agreement. We can also capture obligatory left conjunct agreement by defining f_L just like $f_{(L)}$ except it can never refer to a set. (So f_L always picks the leftmost member of f.) Similarly we can define f_R and $f_{(R)}$ by reversing the f-precedence relation and finally f_C (closest conjunct) as f_L if $\downarrow$ f-precedes f_L and f_R if f_R f-precedes $\downarrow$. This solution makes it possible to describe (optional or obligatory) single conjunct agreement irrespective of whether the relevant agreement feature(s) are distributive or not; and it does so without altering the LFG formalism.

Consider the f-structure for (21).

(23) $$\begin{bmatrix} \left\{ \begin{bmatrix} \textsc{pred} & \text{‘}\textsc{myth}\text{’} \\ \textsc{concord} & \begin{bmatrix} \textsc{num} & \textsc{pl} \\ \textsc{gend} & \textsc{m} \end{bmatrix} \end{bmatrix} \begin{bmatrix} \textsc{pred} & \text{‘}\textsc{legend}\text{’} \\ \textsc{concord} & \begin{bmatrix} \textsc{num} & \textsc{pl} \\ \textsc{gend} & \textsc{f} \end{bmatrix} \end{bmatrix} \right\} \\ \textsc{adj} \quad \left\{ \begin{bmatrix} \textsc{pred} & \text{‘}\textsc{Brazilian}\text{’} \end{bmatrix} \right\} \end{bmatrix}$$

This f-structure satisfies the following functional description of *brasileiras.*

(24) $((\textsc{adj}\ \uparrow)_C\ \textsc{concord num}) = \textsc{pl}$
$((\textsc{adj}\ \uparrow)_C\ \textsc{concord gend}) = \textsc{f}$

(ADJ ↑) refers in the normal way to the f-structure of the head, and the subscript C then makes sure we select the closest conjunct; if (ADJ ↑) was not a set, the subscript C would simply have no effect.

4.2 Information structure

Besides c-structure/linear order, information structure is also relevant for agreement processes in many languages, as discussed by Dalrymple & Nikolaeva (2011). In their architecture, discourse functions are modelled as features at s-structure and can be accessed from the f-structure through the σ-projection. Dalrymple & Nikolaeva (2011: 123) provide the specification in (25) of the third person singular topical oblique agreement marker in Itelmen.

(25) (↑ OBL PERS) = 3
(↑ OBL NUM) = SG
$((\uparrow \text{OBL})_\sigma$ DF) = TOPIC

More complicated patterns are also possible. Object agreement in Itelmen is only optionally an indicator of the topicality of the object, but it does indicate that there is no oblique topic. This is captured by the description in (26) of the first person singular object agreement marker.

(26) (↑ OBJ PERS) = 1
(↑ OBJ NUM) = SG
$\neg[((\uparrow \text{OBL})_\sigma$ DF) = TOPIC]
$(((\uparrow \text{OBJ})_\sigma$ DF) = TOPIC)

In addition to precedence and information structure role, LFG analyses have shown that agreement can be sensitive to other factors such as adjacency (direct precedence) and various prominence hierarchies based on person and grammatical functions. Broadwell et al. (2011) and Belyaev (2013) analyse such patterns in Kaqchikel and Dargwa respectively and show how they be captured with LFG augmented with Optimality Theory (OT).

5 Diachrony: grammatical and anaphoric agreement

It is a long-standing observation from comparative linguistics (Bopp 1933 [1857]) that agreement markers in predicate-argument structures (i.e. INDEX agreement) arise from incorporated pronouns. That is, we have an evolution from anaphoric agreement with a dislocated noun phrase (*The man, he came*) to grammatical agreement (*The man he-came*). As pointed out by Bresnan & Mchombo (1987), LFG is well placed to capture this development because (unlike what happens in many other formal frameworks), pronouns and agreement markers are very similar, yet also distinct in a way which generates clear predictions about differences between anaphoric and grammatical agreement. In particular, incorporated pronouns always introduce a semantic form (PRED 'PRO'), while agreement markers do not introduce a semantic form or do so only optionally (if the language allows pro-drop). Otherwise, both agreement markers and incorporated pronouns introduce the relevant agreement features. Bresnan & Mchombo (1987) argue that in Chichewa, subject agreement is grammatical and obligatory whereas object agreement is anaphoric and optional. They represent subject markers (SM) and object markers (OM) with the lexical entries in (27).[7]

(27) SM- (↑ SUBJ) = ↓
(↓ INDEX) = α
((↓ PRED) = 'pro')

OM- (↑ OBJ) = ↓
(↓ INDEX) = α
(↓ PRED) = 'pro'

From a diachronic point of view, the subject marker and the object marker reflect different points on a grammaticalization path from pronouns to agreement morphology: the object marker has lost its c-structure independence, but is still in all respects a pronoun at f-structure, contributing its own PRED value. The subject marker has evolved one step further in that the PRED value contribution has become optional. There is a clear connection between the formal representations at the two stages, and the relation between them fits well with the intuitive notion of "bleaching" or "loss of content" in grammaticalization processes.

At the same time, the subtle difference between the two representations, along with some other independent properties of Chichewa, suffice to predict a number of differences between subject and object agreement. First, because the Chichewa sentence structure consists of a subject NP, a head-initial VP and a topic NP (in any order), the NP object must appear directly after the verb (i.e. inside the VP) whenever there is no object marker. When there is an object marker, however, that marker is the actual object, whereas the apparent NP object is an anaphorically linked topic, which can therefore appear anywhere in the clause.

---

[7] We adopt the convention of treating sublexical units such as the subject and object marker as if they were nodes in a syntactic tree, with ↓ designating their own f-structure and ↑ that of the lexical item they attach to, as is done also in the presentation in Bresnan et al. (2016).

Second, because the object marker is a light (i.e. incorporated) anaphoric pronoun, it blocks the use of the independent pronoun in this function, with the effect that the independent object pronoun is reserved for cases of focus and contrastive topics.[8] No such effect is found with the subject marker. Third, objects can be questioned in situ but only when there is no object marker. All these predictions are borne out in Chichewa.

In sum, the LFG framework makes it possible to understand fundamental differences between grammatical agreement with governed functions and anaphoric agreement with discourse functions, while at the same time providing a plausible diachronic pathway from the latter to the former, in line with what we observe in language change. Notice that the analysis relies crucially on treating the subject marker as ambiguous between a true pronoun (with a PRED 'PRO' feature) and an agreement marker (without it). This holds for LFG analyses of pro-drop generally. Toivonen (2000) provides motivation for this kind of "lexical split" analysis by pointing to the case of Finnish possessives, where the agreement marker and the suffixal pronoun differ in other features as well. For more on the LFG analysis of pro-drop, see Toivonen 2023 [this volume].

6 A role for feature sharing? – Agreement domains

In line with the general philosophy of LFG, the formalism itself does not in any way constrain how agreement domains are defined. We could easily write constraints that would enforce purely linear agreement (e.g. agree with closest NP irrespective of grammatical function) or agreement across unbounded domains (e.g. agree with COMP* SUBJ). An advantage of this is that LFG has no problems capturing surprising agreement relations such as those found in Archi, where agreement targets include a mixed bag of a number of first person forms, some adverbial elements, an emphatic particle and one postposition, which all agree with the absolutive element in their clause. (28) shows how the lexical entry for the first person dative pronoun looks according to Sadler (2016), assuming the absolutive argument bears the grammatical function PIV.

---

[8] Though as a reviewer remarks, this blocking effect is not formalized in Bresnan & Mchombo (1987).

(28) *d-ez*
(↑ PRED) = ‘PRO’
(↑ NUM) = SG
(↑ PERS) = 1
(↑ CASE) = DAT
((PATHOUT ↑) PIV GEND) = II
((PATHOUT ↑) PIV NUM) = SG

That is, the first person dative pronoun agrees with a PIV argument that is found by first going up PATHOUT, which is defined as {SUBJ|OBJ|OBL|OBL OBJ}. (29) shows an example where a first person pronoun embedded in PP (OBL OBJ) agrees with the absolutive.

(29) Archi

d-ez	χir	d-e<r>qˤa-r-ši	d-i
II.SG-1SG.DAT	behind	II.SG-<IPFV>go-IPFV-CVB	II.SG-be.PRES

‘She goes after me.’

The first person dative pronoun bears the noun class II (essentially human feminine) marker *d-* because it agrees with the absolutive argument *she* (only expressed through agreement on the verb), irrespective of the gender of the speaker. The equation ((OBL OBJ ↑) PIV GEND) = II captures that. But the use of inside-out functional uncertainties may be problematic in cases where it does not refer uniquely because of structure sharing. More work is needed on this kind of complex agreement paths.

The approach of Sadler (2016) can in principle be extended with paths that cross clausal boundaries (so-called long distance agreement). However, the fact that we *can* write such equations does not mean that we *should*. Locality of grammatical processes remains an important theoretical concern in LFG even if it is not hardwired into the formalism. Haug & Nikitina (2015) argue that several cases of so-called long distance agreement can be given a local treatment if the agreement process is assumed to be structure-sharing. Their main example concerns the so-called “dominant participle” construction in Latin,[9] where a noun and a participle form a non-finite clause which is headed by the participle but bears the agreement features of the noun.

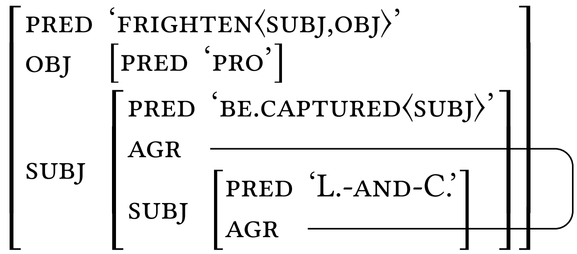
---

[9] Haug & Nikitina (2015) also argue that the same analysis may work for long distance agreement in Tsez, Passamaquoddy and Innu-Aimûn, which has been widely discussed in the generative literature (Branigan & Mackenzie 2002, Bruening 2001, Polinsky & Potsdam 2001).

(30) Latin
ne eum Lentulus et Cethegus … deprehensi
lest him:acc L.:nom;m and C.:nom;m captured:nom;m;pl
terrerent
frighten:impf;subj;3pl
'lest the capture of Lentulus and Cethegus should frighten him' (Sall., Cat 48.4)

According to the analysis in Haug & Nikitina (2015), *Lentulus et Cethegus…deprehensi* ('that Lentulus and Cethegus were captured') is a clause which acts as the subject of the matrix verb *terrerent*. Yet unlike other clausal subjects in Latin, it does not trigger default third person singular agreement on the predicate. Instead, the matrix verb is plural, meaning that it either agrees with the embedded subject *Lentulus et Cethegus*, or the plural feature of the embedded subject has somehow been transferred to the predicate *deprehensi*. *Deprehensi* does bear morphological plural marking, but on the standard, non-feature sharing approach to agreement this feature would only be active in the subject (controller) position. If instead we suppose that features in this kind of agreement are active in both the target and the controller, the target may in turn serve as the controller for another agreement process with the matrix verb as the target. This yields the f-structure in (31).

(31)



Structure sharing agreement between *Lentulus et Cethegus* and *deprehensi* makes the agreement features available in the f-structure which is subj agr relative to the matrix verb, so that there can be normal predicate–subject agreement in the matrix clause. In principle, that agreement could also be structure sharing, but as the apparent long-distance agreement can only be positively demonstrated in participial clauses, Haug & Nikitina (2015) remain agnostic on the matter. However, a similar feature-sharing account of agreement was extended to finite verb agreement by Alsina & Vigo (2014, 2017). Interestingly, their arguments for adopting structure sharing are different: in some cases, such as copular inversion in Catalan and raising constructions in Icelandic, the controller cannot be specified lexically, but is determined by OT constraints over the global f-structure. This, they hold, argues for a view that targets and controllers lexically specify features of their own AGR and then OT constraints decide which AGR structures should be linked to each other. Finally, a feature sharing approach to agreement is also adopted by Sadler (2019) to account for an adjectival construction in Modern Standard Arabic where the target adjective agrees with two distinct controllers.

7 A challenge to symmetry: The Agreement Marking Principle

Wechsler (2011) proposes the principle in (32), called the *Agreement Marking Principle.*

(32) Agreement is driven by a syntactic feature of the controller, if the controller has such a feature. If the controller lacks such a feature, then the target agreement inflection is semantically interpreted as characterizing the controller denotation.

With this principle, Wechsler seeks to explain so-called mixed agreement, i.e. cases where a polite plural pronoun triggers plural agreement on the verb, but singular agreement on some other target, e.g. a predicative adjective as in (33) from French.

(33) French

Vous	êtes	loyal.
you.PL	are.2PL	loyal.M.SG

'You (singular, formal, male) are loyal.'

This pattern follows from the Agreement Marking Principle on the assumption that *vous* bears an INDEX NUM PL feature that is able control INDEX agreement on the verb, but *no* CONCORD NUM feature, which leaves the predicative adjective without an agreement controller, thereby licensing semantic agreement. Moreover, the Agreement Marking Principle gives us an *explanation* of the so-called "polite plural generalization", that there are no languages[10] with the opposite pattern, i.e. where the polite plural pronoun triggers plural agreement on the adjective but allows singular agreement on the verb, or more generally, following Wechsler, on any target that has the PERSON feature. This polite plural generalization follows because pronouns by necessity have INDEX features and any PERSON target must be an INDEX target.

---

[10] See Wechsler (2011: Section 2.1) for the typological data.

Formalizing the Agreement Marking Principle requires use of constraining equations. Wechsler's analysis of the French feminine definite article *la* is given in (34), where $\textbf{female}(\uparrow_\sigma)$ is a simplified representation for the relevant semantic resource that will ensure that the referent is interpreted as female.

(34) *la* $(\uparrow \textsc{gend}) =_c \textsc{f} \vee [\textbf{female}(\uparrow_\sigma) \wedge \neg (\uparrow \textsc{gend})]$

The idea is that when *la* combines with a noun that is lexically specified as feminine gender, such as *sentinelle* 'sentry', the feminine feature is *not* semantically interpreted; but when it combines with a noun that does not have a gender feature, such as *professeur*, it *will* be interpreted semantically. However, this entails a move away from the traditional symmetric approach to agreement in LFG to the asymmetric approach associated with derivational syntax.

As pointed out by Wechsler, the Agreement Marking Principle is not in itself a descriptive generalization, since the presence versus absence of a given agreement feature on the controller NP is not always directly observable, but rather depends upon the grammatical analysis of the NP. However, the radically symmetric nature of the standard LFG analysis allows for cases where there is *no controller* NP at all. This is what we saw in the standard analysis of *floruit* in (6). The lexical entry of the verb on the standard analysis will be as in (35).

(35) *floruit* $(\uparrow \textsc{pred}) = \text{`}\textsc{bloom}<\textsc{subj}>\text{'}$
$(\uparrow \textsc{subj case}) = \textsc{nom}$
$(\uparrow \textsc{subj num}) = \textsc{sg}$
$(\uparrow \textsc{subj pers}) = 3$
$((\uparrow \textsc{subj pred}) = \text{`}\textsc{pro}\text{'})$

On the traditional LFG analysis, which also underlies the diachronic analysis of anaphoric agreement discussed in Section 5, there simply *is* no controller: it is constructed by the target. If we change (35) to interpret the number and person agreement along the lines of the Agreement Marking Principle, we get (36), where $\textbf{\textsc{non-participant}}(\uparrow_\sigma)$ is shorthand for some semantic resource that ensures the subject referent is distinct from the discourse participants (speaker or hearer).

(36) *floruit* $(\uparrow \textsc{pred}) = \text{`}\textsc{bloom}\langle\textsc{subj}\rangle\text{'}$
$(\uparrow \textsc{subj case}) = \textsc{nom}$
$(\uparrow \textsc{subj pers}) =_c 3 \vee [\textbf{\textsc{non-participant}}(\uparrow_\sigma) \wedge \neg (\uparrow \textsc{subj pers})]$
$(\uparrow \textsc{subj num}) =_c \textsc{sg} \vee [\textbf{\textsc{non-participant}}(\uparrow_\sigma) \wedge \neg (\uparrow \textsc{subj num})]$
$((\uparrow \textsc{subj pred}) = \text{`}\textsc{pro}\text{'})$

If we want to maintain the Agreement Marking Principle there are a number of ways we can go. First, we can take (36) at face value and assume that since there is no controller, the agreement features are interpreted semantically. This would yield the prediction that in pro-drop structures, agreement features are always semantically interpreted, which is a strong and quite probably false assumption.[11] Second, we can exploit the fact that the LFG formalism cannot faithfully express the Agreement Marking Principle as formulated in (32). (32) says that agreement in some feature is syntactic, "if the controller has such a feature". However, the LFG formalism offers no way of checking where a feature originates. Constraining equations check whether some feature is present in the minimal solution to the f-description, irrespective of where they originate. Therefore, we can add the constructive equations (↑ SUBJ PERSON) = 3 and (↑ SUBJ NUM) = SG to the optional part of (36). This preserves the formalization of the Agreement Marking Principle, but arguably not its spirit, since the same lexical item provides both target and controller features. Finally, we could envisage a c-structure controller (with the appropriate features) in pro-drop structures, although this seems at odds with all standard assumptions of LFG.

In sum, it is not clear how to best integrate the Agreement Marking Principle in LFG. More generally, symmetry between target and controller features does important work in LFG's traditional theory of agreement and it requires substantial work to alter this fundamental setup.

8 Agreement and semantics

A general question which has not received much attention in the LFG literature concerns how f-structure agreement features relate to the semantic content that they (sometimes) encode. In the standard LFG architecture, levels of linguistic description as found in the projection architecture are related by codescription, where linguistic items simultaneously describe different structures, including syntax and semantics. For example, the lexical entry for a singular noun might look like (37), where $1(x)$ is a cardinality test on the referent.

---

[11] In fact, a reviewer offers a counterexample from Spanish, where second person plural forms can be used for very elevated addressees in a very formal register and crucially the interpretation does not change whether the subject is expressed by means of the pronoun *vos* or is null:

(i) Spanish
(Vos) sois muy bondadoso.
you.PL are.2.PL very kind.M.SG
'You (singular, formal, male) are very kind'

(37) *horse* (↑ PRED) = ‘HORSE’
(↑ INDEX NUM) = SG
(↑ CONCORD NUM) = SG
$\lambda x.horse^{*}(x) \wedge 1(x) : v \multimap r$

This lexical entry simultaneously specifies syntactic singular number (in the form of f-structure features) and semantic singular number (simplified as a cardinality check on x). On the alternative, so-called “description-by-analysis” approach (Halvorsen 1983), semantics is not cospecified together with syntax, but is instead read off the constructed f-structure.

Although codescription is the standard, Andrews (2008) points to two problems for this approach, both having to do with agreement. The first and most obvious problem is that in lexical entries like (37), there is no necessary connection between the syntactic and semantic singular number features: yet outside the limited class of *pluralia tantum* these are closely connected in a way we would predict more clearly if we simply had semantics read the f-structure features. There is to my knowledge no theory of how this connection would work in a codescription approach, but it seems conceivable that the morphology-syntax interface developed in Dalrymple et al. (2019: Chapter 12) could also take care of the interface with semantics and restrict the mappings in a principled way.

The second problem for codescription, according to Andrews (2008), is that it creates the need to decide which of the various lexical entries introducing a given feature-value occurrence is the one that is introducing the semantic constructor. This again relates to the question of symmetry or not between target and controller features. Andrews considers an Italian example with possible pro-drop (38).

(38) Italian

(le	ragazze)	vengono
the.FEM.PL	girls.FEM.PL	come.3PL

‘The girls/they are coming.’

If the subject is present, we presumably want the noun to introduce the plural meaning constructor and the verb not to, but if the subject is omitted, then the verb presumably provides the constructor. However, we already need to make sure that the PRED feature of the subject is instantiated only once, so it is not clear that this is a deep problem, although as Andrews points out, it does open the door to some stipulation.

NP-internal agreement raises more tricky problems. As discussed by Belyaev et al. (2015), there are languages where a plural head noun can take two coordinated singular adjectives as modifiers, as in (39) from Russian.

(39) Russian
krasnyj i belyj flagi
red.SG and white.SG flag.PL
'(the) red and (the) white flags' [2 flags total: one red, one white]

Belyaev et al. (2015) call this pattern "resolving agreement". On their analysis, it has the f-structure in (40).[12] Notice that this treats CONCORD as non-distributive; according to Belyaev et al. (2015) the distributivity of CONCORD is subject to variation across languages, and even across different constructions within particular languages.

(40)
$$\left[\begin{array}{l}
\text{CONCORD}\ \ [\text{NUM}\ \ \text{PL}] \\
\text{INDEX}\ \ [\text{NUM}\ \ \text{PL}] \\
\text{CONJ}\ \ \text{AND} \\
\left\{ \begin{bmatrix} \text{PRED} & \text{`FLAG'} \\ \text{CONCORD} & [\text{NUM}\ \ \text{SG}] \\ \text{ADJ} & \left\{[\text{PRED}\ \ \text{`WHITE'}]\right\} \end{bmatrix} \begin{bmatrix} \text{PRED} & \text{`FLAG'} \\ \text{CONCORD} & [\text{NUM}\ \ \text{SG}] \\ \text{ADJ} & \left\{[\text{PRED}\ \ \text{`RED'}]\right\} \end{bmatrix} \right\}
\end{array}\right]$$

Belyaev et al. (2015) do not offer an explicit semantics in their account, but it is clear that we will have to interpret agreement features from the target (the adjectives) one way or another. Notice that the analysis does not provide an INDEX NUM SG feature on the conjuncts and it would not be trivial to get that. So on a description by analysis approach, we need to interpret the CONCORD NUM SG features of the conjuncts, although CONCORD features are normally understood as meaningless. The (INDEX) NUM PL feature of the whole noun phrase would be superfluous but not harmful, just like in other cases of group formation from two singular nouns.

On a codescription approach, we cannot directly exploit the fact that there are two singular flags in the f-structure in (40). Instead it seems likely that the lexical entry of the singular adjectives themselves will introduce singular number constraints. The special phrase structure rule for resolving agreement might also play a role in constraining when an adjective's number feature is interpreted, to

---

[12] See Belyaev et al. (2015) for the details of how this f-structure arises. In short, the relevant rule for adjective coordination creates two incomplete (PRED-less) NPs, to which each adjective contributes their CONCORD features, including singular number. The PRED feature originating in the noun is distributive and gets copied into each conjunct.

avoid problems of interpreting adjective number features when they agree with e.g. a *plurale tantum*.

We cannot address this issue in further detail here, but we can conclude that in one way or another, the morphological singular feature that occurs on the adjectives in (39) will have to be interpreted. Although details remain unclear, this supports the general symmetric approach to agreement in LFG.

9 Summary

We have seen that the standard treatment of agreement in LFG relies heavily on unification: the controller and the target co-specify a piece of functional structure. There is therefore symmetry between controller and target features, as both contribute grammatical information on an equal footing. On the other hand, the piece of functional structure that is co-specified is usually found only in the syntactic position of the controller (except when feature sharing is assumed), accounting for the directed nature of agreement. To account for certain phenomena in coordination and with special lexical items, it has proven necessary to operate with two such positions (f-structure features), INDEX and CONCORD. While the phenomenon of agreement is thus handled at f-structure, the projection architecture makes it possible to model interactions with other aspects of grammatical structure, notably c-structure and information structure, as has proven necessary for several phenomena.

The symmetric but not feature sharing theory of agreement has proven successful for example in accounting for the diachrony of agreement marking. Nevertheless, there are some constructions that seem to suggest modifications of the basic framework: long distance agreement across clause boundaries can be analyzed as local agreement if we allow structure sharing at least for (some) instances of CONCORD agreement, whereas Wechsler's Agreement Marking Principle suggests that target and controller features are not symmetric. On the other hand, the semantic contribution that target features sometimes make seem to support the traditional, symmetric analysis.

Acknowledgements

I thank Mary Dalrymple and the three reviewers for very helpful feedback on earlier versions of this chapter.

Chapter 6

Case

Miriam Butt
University of Konstanz

This chapter surveys work on case within LFG, beginning with some of the earliest studies in Bresnan (1982). The chapter then moves on to cover the interaction of Mapping Theory with case marking, Optimality Theoretic approaches to case and the ideas articulated by Constructive Case. It closes with an outlook on more recent analyses. While these recent analyses are couched within current LFG and are applicable to a wider range of phenomena, they echo the basic insights of some of the earliest approaches to case in that they essentially take a lexical semantic view of case, but go beyond the lexicon and use LFG's projection architecture to chart the complex interaction between lexical, structural and semantic/pragmatic factors exhibited by case markers crosslinguistically, including core case markers. Examples in this chapter are drawn mainly from Australian, Scandinavian, and South Asian languages.

1 Introduction

In LFG there is no one theory of case and so this chapter goes through a variety of approaches. While the approaches differ formally and focus on a diverse set of phenomena, they are unified by the same underlying sense of how case should be analyzed. Case marking is seen as being closely connected to the identification of grammatical relations (henceforth grammatical functions or GFs), but also to the realization of lexical semantic information, such as experiencer or causer/causee semantics, instruments, goals, locations, etc. Like any piece of morphological or syntactic information, case is seen as contributing to the overall morphosyntactic and semantic analysis of a clause. That is, case marking is taken to provide important information about GF status (e.g., SUBJ vs. OBJ vs. OBJ$_\theta$ or OBL$_\theta$) and about the lexical semantics of the arguments of a predicate. This can go so far as

Miriam Butt. 2023. Case. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 219–266. Berlin: Language Science Press. DOI: 10.5281/zenodo.10185944

taking the form of 'Constructive Case' whereby the case marking is responsible for the 'creation' or introduction of a particular GF into the syntax (Section 4). For example, the ergative might come with the information that a SUBJ must exist in the clause and thus contribute a SUBJ feature to the f-structure analysis.

The chapter begins with a look at the earliest treatments of case in LFG in Section 2, which developed the basic insights informing later work. Case marking is modeled as a combination of syntactic and lexical semantic information and plays a role in the mapping from semantic arguments to GFs. This is discussed in Section 3, with Section 6 laying out the effects of case at the clausal semantic level, i.e. in terms of telicity or partitivity and modality. Case also appears to have pragmatic impact in that it can express information structural meaning and can be governed by information structural concerns.

With the rise of Optimality Theory (Prince & Smolensky 1993), influential work by Aissen as well as Woolford sought to account for Differential Case Marking (DCM) and other distributions of case via an Optimality Theory (OT) approach (Aissen 1999, 2003, Woolford 2001). LFG took an early interest in the possibilities of OT (Bresnan 2000) and as discussed in Section 5, this included experimenting with OT for analyses of case.

Some of the material in this chapter has already been presented in Butt (2006) and Butt (2008), particularly the description of Constructive Case and the mapping between semantic arguments and GFs. However, this contribution provides a deeper look at case in early LFG and at case within approaches inspired by OT. It also updates the discussion with respect to new proposals for mapping/linking and ties the various facets of case marking together in a sketch for an overall comprehensive approach in Section 7. Section 8 summarizes.

2 Early LFG

Some of the earliest LFG work included papers that were specifically devoted to case. This section discusses the contributions by Neidle (1982), Andrews (1982) and Mohanan (1982) on a diverse range of languages, namely Russian, Icelandic and Malayalam, respectively.

2.1 Russian

Neidle (1982) looked at patterns of case agreement in Russian complements and secondary predicates. In essence, Neidle's overall approach to case did not differ much from what would have been standard assumptions at the time in that

Neidle divides case into two broad categories: 1) *structurally predictable* case; 2) *lexically required* case and exceptions. This bipartite distinction still underlies most of the assumptions and theorizing on case in standard GB/Minimalist approaches, e.g., see Butt (2006), Bobaljik & Wurmbrand (2008) for overviews, and is currently framed as an opposition between dependent vs. inherent case, e.g., Baker & Bobaljik (2017).

A special feature of Neidle's approach is the adoption of Jakobson's feature decompositional approach to case (Jakobson 1936). Neidle also briefly touches on the issue of genitive objects in Russian, which are introduced structurally in the presence of negation and more generally when the object is non-quantized. In the latter case, the genitive may be part of a Differential Case Marking (DCM) pattern by which the genitive is used for non-quantized objects and the accusative for quantized objects, e.g., in verbs such as 'demand' (Neidle 1982: 400). Genitive case is sometimes also required by the inherent lexical semantics of the verb (e.g., 'wish').

Neidle does not quite integrate the quantizedness semantics into her account and instead opts for a simple distinction between structural and inherent case. Structural case is assigned via f(unctional)-structure annotations on c(onstituent)-structure rules. For example, the annotations on an object OBJ and an indirect object (termed OBJ2 in early LFG) might look as in (1), where the Jakobsonian-inspired featural decomposition (−, −, +) corresponds to accusative whereas the (+, −, +) corresponds to a dative.

(1)	VP	⟶	V	NP	NP
			↑=↓	(↑ OBJ)=↓	(↑ OBJ2)=↓
				(↓ CASE)=(−, −, +)	(↓ CASE)=(+, −, +)

The structural case assignment is matched up with the functional information gleaned from the morphological case marking on nouns, pronouns, adjectives, etc. That is, if a phrase structure rule as in (1) calls for an accusative object, then whatever noun or pronoun this NP is instantiated by needs to have accusative morphology. Given this approach to structural case, the lexical entries for verbs generally contain no information about case: as shown in (2), verbs specify the type and number of the GFs that are expected (as per basic LFG theory), but do not contain additional information about case.[1]

(2) %vstem V (↑ PRED)='%vstem⟨(↑ SUBJ),(↑ OBJ)⟩'

---

[1] The lexical entry in (2) has been adapted from the original with respect to how a verb stem is represented. The % indicates a variable that can be filled by some value (Crouch et al. 2011). In the lexical entry in (2), this might be the verb 'kill', for example.

On the other hand, a specification for case marking is added to those verbal entries where the case marking patterns are identifiable as being due to the semantics of the verbs (e.g., ‘wish’). This is illustrated in (3), where the case information corresponds to a genitive.[2]

(3) *wish* V (↑ PRED)=‘WISH⟨(↑ SUBJ),(↑ OBJ)⟩’
(↑ OBJ CASE) = (−, +, +)

Effects of the genitive of negation are handled at the c-structural level, with the rule introducing the negation also introducing information that triggers genitive case on the object. The overall approach is thus one in which there is a complex interaction between c-structural, morphological and lexical information. While Neidle’s particular approach in terms of the Jakobsonian-inspired featural decomposition of case was not taken up in LFG, the basic approach to modeling the interplay between lexical semantics, phrase structure and morphological information continues to inform LFG.

2.2 Icelandic

As exemplified by Neidle’s approach, there has never been an assumption within LFG that case should be associated strictly with one GF (or vice versa) or that agreement and case should be inextricably bound up with one another. This is because of the very early recognition within LFG that in addition to non-accusative objects such as those found in Russian: 1) non-nominative subjects also exist in the world’s languages and thus need to be accounted for; 2) agreement does not necessarily track subject status. This was famously established in the early days of LFG with respect to Icelandic (Andrews 1976, Zaenen et al. 1985). In both of the examples in (4) (based on Andrews 1982: 462–463) the dative argument can be shown to be a subject via a battery of subject tests such as reflexivization, control, subject-verb inversion, extraction from complement clauses and subject

---

[2] The explanation of Neidle’s approach here is designed to provide the essence of her ideas, not the particulars. As such the lexical entry is simplified and as part of this simplification, the verb stem has been given in English. The overall analysis Neidle proposes for Russian is complex in its details and the interested reader is referred to the original paper both for more information as to the feature decomposition approach to case and the details of the complex interaction between morphology, c-structure and the lexicon that she maps out. However, as Neidle’s paper is one of the earliest papers on LFG and the theory has developed since, particularly with respect to approaches to morphology, attempting to provide more details as to her approach as part of this chapter (as some reviewers have suggested) would lead us too far afield into a comparison of early vs. current LFG.

ellipsis. The example in (4b) additionally shows that agreement is not an indicator of subjecthood in Icelandic since the third singular verb does not agree with the first person singular subject.

(4) Icelandic

a. Barn-inu batnaði veik-in.
child-DEF.DAT recovered.from.3SG disease-DEF.NOM
'The child recovered from the disease.'

b. Mér er kalt.
I.DAT be.3SG cold
'I am cold.'

Andrews (1982) also discusses instances of non-accusative objects[3] and notes that nominative objects are the rule in dative subject examples as in (4a). These and other considerations lead Andrews to provide a rich and detailed analysis of the case marking patterns in Icelandic as part of a longer paper on Icelandic syntax.

The overall approach to case is similar to that taken by Neidle, though the formalization is quite different. Like Neidle, Andrews (1982) invokes Jakobson on case, but does not adopt a feature decomposition approach. Rather, he builds on Jakobson's idea that the nominative should be analyzed as a default, unmarked (almost non-case) in Indo-European. As a consequence, Andrews develops an account by which nominative is assigned as a default case as part of the syntax (c-structure rules) if no other case has been specified. Accusative is assigned to objects as a default as well, but only in a structure where there is a nominative subject. All other case marking is specified as part of the lexicon.

Andrews specifically notes that the choice of non-default case marking is not arbitrary, but can be tied to semantic generalizations such as experiencer/perception semantics, the semantics of verbs of lacking and wanting, etc. (Andrews 1982: 463). Essentially, non-nominative subjects all seem to mark non-agentivity of one sort or another. However, despite a sense of systematicity underlying the connection between semantics and case marking, Andrews decides that because there is no invariant meaning one can assign to a case, a strategy of encoding non-nominative subject (and non-accusative object) case as part of the lexicon should be followed: "case selection is basically lexical and idiosyncratic, but subject to regularities keyed to the semantics of the matrix verb" (Andrews 1982: 464). As in Neidle's approach, further structurally motivated instances of non-default case marking are allowed. This is exemplified by structural genitives in

---

[3] Also see Svenonius (2002) for a more recent in-depth analysis of non-accusative object marking.

Russian, and in Icelandic non-default case occurs in some instances of passivization. Other case marking that goes beyond the core patterns is dealt with via lexically (or otherwise) stipulated information.

Interestingly, Andrews' basic approach foreshadows the notion of *Dependent Case* (Marantz 2000, Baker 2015). This sees the central problem of case theory as deciding on how to apportion structural case between two core argument participants, with the case marking of one being dependent on the structure of the other. So, if a subject is ergative, there are mechanisms in place which ensure that the object is nominative/absolutive. This is similar (but not identical) to Andrews' treatment of nominative objects in the presence of dative subjects and accusative objects in the presence of nominative subjects.

2.3 Malayalam

A different approach to case is taken by Mohanan (1982). Working on Malayalam, Mohanan entertains an approach pioneered by the Sanskrit grammarian Pāṇini (Böhtlingk 1839–1840) and taken up by Ostler (1979). This holds that the distribution of case can be expressed in terms of generalizations referring directly to thematic/semantic roles. However, Mohanan shows that it is also necessary to assume a structural level at which GFs are encoded in order to be able to properly account for the distribution of case in Malayalam. That is, the level of GFs (f-structure) must mediate between the overt expression of case and the lexical semantics of verbs. In line with Andrews' findings for Icelandic, Mohanan establishes a systematic relationship between lexical semantics and case, but not a one-to-one relationship. In a precursor to Mapping Theory (Section 3), Mohanan proposes the principles in (5).[4]

(5) **Principles of Case Interpretation**

a. Intrepret accusative case as the direct object (OBJ).

b. Interpret dative case as either the indirect object (OBJ2) or the subject (SUBJ).

c. Interpret nominative case as either the subject (SUBJ) or the direct object (OBJ) if the NP is [−animate]; otherwise interpret nominative case as the subject (SUBJ).

There are several things to note about these principles. For one, they assume that case marking plays a central role in the determination of GFs (rather than

---

[4] These have been simplified slightly with respect to the dative for ease of exposition.

constituting features that must be spelled out, checked off or interpreted, as in GB/Minimalist approaches, for instance). For another, the animacy condition in (5c) constitutes an indirect analysis of the DCM phenomenon found in Malayalam whereby animate objects must be marked with the accusative.

The Principles of Case Interpretation are encoded in the grammar via f-structural annotations on c-structure rules which ensure that indirect objects are dative, subjects are either nominative or dative and objects either accusative or nominative. Mohanan is able to capture this space of possibilities elegantly by also working with Jakobson's case features. While the alternation between nominative and accusative objects is taken to be governed by animacy (via well-formedness checking at f-structure), no general principles for the appearance of dative vs. nominative subjects are built into the system. Rather, like Neidle and Andrews, Mohanan steers the licensing of dative subjects via lexical stipulation in the verb's entry, as shown in (6), taken from Mohanan (1982: 545). He classifies both 'sleep' and 'be hungry' as intransitive experiencer verbs. The nominative case on the subject of the verb 'sleep' is taken to follow from the general Principles of Case Interpretation in conjunction with the functional annotations on the c-structure rules. On the other hand, the verb 'be hungry' is lexically stipulated to have a dative subject. The choice of dative vs. nominative subjects is thus steered via the presence or absence of information found in the lexical entries.

(6) a. *uraŋŋ* V (↑ PRED)=‘SLEEP⟨ (↑ SUBJ) ⟩’
EXPERIENCER

b. *wiš̄akk* V (↑ PRED)=‘BE HUNGRY⟨ (↑ SUBJ) ⟩
EXPERIENCER

Mohanan generally assumes that a verb's lexical entry expresses both the thematic roles it takes and the grammatical relations that these correspond to, as shown in (6) and (7). This is in line with early LFG approaches to predicate-argument structure, which assumed a close connection between thematic roles and GFs but did not yet articulate that relationship in any detail (cf. the contributions in Butt & King 2006 [1983]). The articulation of this relationship came with the advent of linking (Section 3).

(7) *t̪inn* V (↑ PRED)=‘EAT⟨(↑ SUBJ), (↑ OBJ) ⟩’
AGENT PATIENT

LFG's work on the linking or *mapping* between thematic roles and GFs in the 1980s and 1990s also entailed a closer look at the lexical semantics of verbs and verb classes, with detailed work such as that by Jackendoff (1990) and Levin (1993) providing inspiration. As such, the conclusions arrrived at by Mohanan that the case patterns in Malayalam are too irregular to be governed by general principles deserve a second look from today's perspective. Consider, for example, the contrasts in (8) and (9), taken from Mohanan (1982: 540–541).[5] Mohanan considers the verbs to "…presumably have the same thematic roles" (Mohanan 1982: 540), namely to all have experiencer arguments. However, the 'became' in (8a) is rather more indicative of an undergoer/patient so this is more likely to be an unaccusative, rather than an experiencer verb. This difference in lexical semantics is likely to govern the difference in subject case so that experiencer semantics is expressed via a dative subject while unaccusatives simply receive a nominative subject by default.

(8) Malayalam

a. awaḷ taḷarn̪n̪u.
she.NOM was tired
'She became tired.'

b. awaḷ-kkə wiš̄an̪n̪u.
she-DAT hungered
'She was hungry.'

Similarly, the contrast between (9a) and (9b) can potentially be explained by (9b) involving a metaphorical location ('happiness came to me'), which lends itself to dative subjects, as argued for by a.o. Landau (2010) and suggested by Localist approaches to case and argument structure, e.g. Gruber (1965), Jackendoff (1990).

(9) Malayalam

a. ñ̄aan san̪t̪oos̩iccu.
I.NOM was happy
'I was happy.'

b. eni-kkə san̪t̪oos̩am wan̪n̪u.
I-DAT happiness came
'I was happy.'

Contrasts such as in (9) are standardly and systematically found in South Asian languages and they thus deserve a better explanation than being relegated to

---

[5] The glosses in these Malayalam examples provide slightly more detail than in the original.

lexical stipulation. The same applies to contrasts as in (10), from Mohanan (1982: 542), where a difference in modality is expressed solely in terms of a difference in case marking on the subject.

(10) Malayalam

a. kuṭṭi aanaye ṇuḷḷ-aṇam.
child.NOM elephant.ACC pinch-MOD
'The child must pinch the elephant.'

b. kuṭṭi-kkə aanaye ṇuḷḷ-aṇam.
child-DAT elephant.ACC pinch-MOD
'The child wants to pinch the elephant.'

Mohanan again resorts to lexical stipulation to model the two different readings (permission vs. promise), but given that these types of contrasts are also widely found in other South Asian languages (Butt & Ahmed Khan 2011, Bhatt et al. 2011), again a more principled analysis is in order (see Section 7).

3 Mapping Theory

Over time, the understanding of case and its relationship with predicate arguments deepened and LFG developed a dedicated *Mapping Theory* to model and explain the systematicity found across a typologically diverse set of languages. A subset of the semantics associated with case has thus by now been covered by this more principled account of the relationship between lexical semantics and GFs. This section briefly charts the development of Mapping Theory from early ideas and formulations to today's standard instantiation, focusing particularly on the role of case. The reader is referred to Findlay et al. 2023 [this volume] for a fuller discussion of Mapping Theory and more recent developments.

3.1 Association Principles with case

It is perhaps no accident that the beginnings of LFG's Mapping Theory were first articulated with respect to Icelandic (Zaenen et al. 1985) — a language with robust case marking that attracted intense linguistic interest in the 1980s because of its demonstrated use of non-nominative subjects (Andrews 1976). Zaenen et al. (1985) present a detailed study of the interaction between Icelandic case and GFs, which bears similarities to the approaches sketched in the previous section. However, the Icelandic Association Principles formulated by Zaenen et al. (1985) in

(11) contrast with Mohanan's principles for Malayalam. Where Mohanan linked case directly to GFs, Zaenen et al. (1985) postulate a complex interrelationship between case, thematic roles and GFs. Another feature of the principles is that they include universal as well as language-specific postulations, as can be seen via a comparison of Icelandic and German, for which Zaenen et al. (1985) provide a comparative analysis.

(11) **Icelandic Association Principles**

1. AGENTS are linked to SUBJ. (Universal)
2. Casemarked THEMES are assigned to the lowest available GF. (Language Specific)
3. If there is only one thematic role, it is assigned to SUBJ; if there are two, they are assigned to SUBJ and OBJ; if there are three, they are assigned to SUBJ, OBJ, 2OBJ.[6] This principle applies after principle 2 and after the assignment of restricted GFs. (Universal)
4. Default Case-Marking: the highest available GF is assigned NOM case, the next highest ACC. (Universal)

(12) **German Association Principles**

1. AGENTS are linked to SUBJ. (Universal)
2. Casemarked THEMATIC ROLES are assigned to 2OBJ. (Language Specific)
3. If there is only one thematic role, it is assigned to SUBJ; if there are two, they are assigned to SUBJ and OBJ; if there are three, they are assigned to SUBJ, OBJ, 2OBJ. This principle applies after principle 2 and after the assignment of restricted GFs. (Universal)
4. Default Case-Marking: the highest available GF is assigned NOM case, the next highest ACC. (Universal)

Like the 1982 approaches of Neidle, Mohanan and Andrews, Zaenen et al. (1985) rely on a mix of universal and structurally determined case assignment (default nominative on subjects and accusative on objects), language-specific rules and lexically stipulated case marking patterns. However, Zaenen et al. (1985) differ significantly from Andrews' approach to Icelandic in that they include thematic roles in the statement of generalizations and associate case as one of several features with a given GF. Andrews, on the other hand, argued for the use of a "composite function" in which GF and case information are welded together to provide

---

[6] This corresponds to OBJ_θ within later LFG approaches.

differentiation among GFs. So for example, one could have a SUBJ DAT vs. a SUBJ ACC or OBJ ACC. These composite functions were licensed by a complex interplay between f-structure annotations and lexical specifications. Over time, Zaenen et al.'s technically simpler but architecturally more complex approach was adopted as the standard way of thinking about Icelandic case marking patterns within LFG.

3.2 Argument structure

We here illustrate Zaenen et al.'s system by way of the example in (13) (Zaenen et al. 1985: 470). The Icelandic verb *óska* 'to wish' is ditransitive, but the goal argument ('her' in 13) is optional.

(13) Icelandic

þú	hefur	óskað	(henni)	þess
you	have	wished	her.DAT	this.GEN

'You have wished this on/for her.'

The genitive and dative on the theme and goal arguments, respectively, are encoded as part of the lexical entry of the verb, as shown in (14). Note that this lexical entry differs from those encountered in the 1982 papers in that Zaenen et al. (1985: 465) "postulate a level of representation at which the valency of a verb is determined and its arguments can be distinguished in terms of thematic roles." The encoding of the number and type of arguments of a verb via a separate level of argument structure was due to a forceful demonstration by Rappaport (2006 [1983]) with respect to derived nominals that argument structure needed to be posited as an independent level of representation.[7]

(14)

óska:	< agent	theme	(goal)>
		[+gen]	[+dat]
a.	SUBJ	2OBJ	OBJ
b.	SUBJ	OBJ	
	[+nom]		

The thematic roles in the verb's argument structure are linked to GFs via the Association Principles in (11). The agent is linked to SUBJ and receives nominative case via the universal principles in 1 and 4. When the goal argument is present, the

---

[7] See Chomsky (1970) for similar conclusions with respect to nominalizations, which led to a general understanding of argument structure as a separate level of representation, currently often realized as vP in Minimalist approaches to syntax.

case marked theme is assigned to the lowest available GF (Principle 2, language-specific), which is the secondary object. That leaves the goal argument to be assigned to the OBJ, since by Principle 3 (universal) if there are three thematic roles, they need to be assigned to SUBJ, OBJ and 2OBJ. In this case SUBJ and 2OBJ have already been assigned, leaving only OBJ.

When the goal argument is not present, the agent is again linked to SUBJ and receives nominative case via the universal principles in 1 and 4. But this time the genitive case marked theme is assigned to OBJ as the lowest available GF, as shown in (14b). The status of OBJ is significant as it is this argument that can be realized as a subject under passivization. The lexically determined case marking is also significant, as these cases tend to be retained in constructions like the passive, as shown in (15) (Zaenen et al. 1985: 471).

(15) Icelandic

a. þess var óskað (*henni)
this.GEN was wished her.DAT
'This was wished.'

b. Henni var óskað þess
her.DAT was wished this.GEN
'She was wished this.'

Today's standard Mapping Theory relates GFs to thematic roles via two abstract linking features, [±*o*](bjective) and [±*r*](estrictive), by which both thematic roles and GFs can be classified (Bresnan & Zaenen 1990, Bresnan 2001, Butt 2006). Additionally, a number of principles govern the association of GFs and thematic roles. These principles were worked out on the basis of a wide range of data, including Bantu, Germanic and Romance. LFG's Mapping Theory can account for a wide range of argument changing operations such as locative inversion, causativization, passives (argument deletion) or applicatives (argument addition), e.g. see Levin (1987), Alsina & Mchombo (1993), Bresnan & Kanerva (1989), Bresnan & Moshi (1990), Alsina & Joshi (1991).

Based on his work with Romance languages (mainly Catalan), Alsina (1996) proposed an alternative version of Mapping Theory and in recent years, Kibort has worked out a revised version, which abstracts away from the use of thematic roles, instead working with abstract argument positions and a complex interplay between syntax and semantics (Kibort 2007, 2013, 2014, Kibort & Maling 2015). This chapter does not delve further into the details of linking as the role of case in most versions of linking has stayed much as it was in Zaenen et al.'s analysis of Icelandic: an extra piece of information that helps determine the mapping between GFs and thematic roles and that needs to be accounted for as part of the mapping between argument structure and GFs. See Butt (2006) and Findlay et al. 2023 [this volume] for overview discussions.

However, we will include a discussion of Schätzle (2018) in Section 6, as she works with Kibort's revised version of linking, and develops an event-based theory of linking for an analysis of the historical rise and spread of dative subjects in Icelandic (yes — again Icelandic!).

3.3 Quirky case

Before moving away from the early LFG approaches to case and linking, this section takes a look at a significant concept that also resulted from the concentrated work on Icelandic: *lexically inherent* or *quirky case*. The data from Icelandic and other languages support a distinction between at least two types of case assignment/licensing. In the papers discussed so far, this was thought of as a distinction between structurally assigned and "lexically inherent" case. The latter also came to be known as "quirky case".

However, the anchoring of case marking information in lexical entries together with the term "quirky" suggests a random lawlessness that must be idiosyncratically stipulated as part of lexical entries. This view on non-default case has become widely accepted within linguistics, but lacks empirical support. As already noted by Andrews (1982) for Icelandic, for example, and confirmed by the data and analyses in Zaenen et al.'s paper, the correlation between thematic role and case marking in Icelandic is actually quite regular in that the "quirky" cases are generally regularly associated with a given thematic role. There seem to be only very few instances of truly idiosyncratic case marking that do not follow from general semantic principles.

Van Valin (1991) explicitly revisited the Zaenen et al. paper and made this point, working out an alternative analysis within Role and Reference Grammar (RRG). Van Valin (1991) takes an event-based approach, working with differences between Vendlerian states, activities, achievements and accomplishments in combination with a macro-role approach to the arguments of a predicate. The paper mainly focuses on dative arguments, whereby dative case is assigned to those arguments which cannot be assigned a macro-role (either actor or undergoer). Dative arguments thus constitute the 'elsewhere' case and do not need to be lexically encoded/stipulated. Van Valin does not explicitly address the other types of non-default case marking.

Although Van Valin frees dative marked arguments from being lexically stipulated, he also essentially works with a bipartite system: case marking which is determined systematically via reference to macro-roles vs. case marking that is idiosyncratic. However, the empirical evidence supports a tripartite, rather than a bipartite approach to case: 1) structural case (e.g., nominative/accusative), 2) semantically conditioned case; 3) idiosyncratic case. Despite the empirical evidence for a tripartite view, this approach constitutes an exception rather than the rule in the literature. Versions of a tripartite view of case marking have been argued for by Donohue (2004) and Woolford (2006), for example. Within LFG this view was first clearly articulated by Butt & King (2004), see Section 7.

4 Constructive case

In this section we turn to a very different type of case marking, namely a phenomenon that has come to be known as *case stacking*, illustrated in (16). Within LFG, Nordlinger (1998, 2000) took on this phenomenon with respect to Australian languages and proposed a strongly lexicalist analysis in which the case markers themselves contribute information about the gfs of a clause.

(16) Martuthunira (Dench 1995: 60)
Ngayu nhawu-lha ngurnu tharnta-a mirtily-marta-a
I.nom saw-pst that.acc euro-acc joey-prop-acc
thara-ngka-marta-a.
pouch-loc-prop-acc
‘I saw the euro with a joey in (its) pouch.’

In (16) the main predicate is ‘see’, which takes a nominative subject (‘I’) and an accusative object, ‘euro’ (a type of kangaroo). The clause also contains two modifying NPs, ‘joey’ (a baby kangaroo) and ‘pouch’. The accusative on these nouns signifies that they modify the obj ‘euro’, the proprietive shows that these are part of a possessive or accompanying relation to another word and the locative on ‘pouch’ signals that this is the location of the joey. The f-structure in (17) shows these dependency relations among the NPs.

(17)
$$\left[\begin{array}{ll}
\text{PRED} & \text{‘SEE}\langle\text{SUBJ,OBJ}\rangle\text{’} \\
\text{SUBJ} & \left[\begin{array}{ll} \text{PRED} & \text{‘PRO’} \\ \text{NUM} & \text{SG} \\ \text{PERS} & 1 \\ \text{CASE} & \text{NOM} \end{array}\right] \\
\text{OBJ} & \left[\begin{array}{ll} \text{PRED} & \text{‘EURO’} \\ \text{PERS} & 3 \\ \text{NUM} & \text{SG} \\ \text{CASE} & \text{ACC} \\ \text{ADJUNCT} & \left\{\left[\begin{array}{ll} \text{PRED} & \text{‘JOEY’} \\ \text{PERS} & 3 \\ \text{NUM} & \text{SG} \\ \text{CASE} & \text{PROP} \\ \text{ADJUNCT} & \left\{\left[\begin{array}{ll} \text{PRED} & \text{‘POUCH’} \\ \text{PERS} & 3 \\ \text{NUM} & \text{SG} \\ \text{CASE} & \text{LOC} \end{array}\right]\right\} \end{array}\right]\right\} \end{array}\right] \\
\text{TENSE} & \text{PST} \\
\text{MOOD} & \text{INDICATIVE}
\end{array}\right]$$

None of this case marking by itself is out of the ordinary. What is special is the ability of languages like Martuthunira to stack cases on top of one another. In a language like Martuthunira that has fairly free word order, this stacked marking of dependents unambiguously indicates which elements belong to which other elements syntactically (see Butt 2000 for some discussion).

The individual case markers could be dealt with straightforwardly by a mix of structural and lexically inherent case, as had been done in the past. However, the case stacking is a different matter. It is not particularly feasible to stipulate all possible case stacking patterns in the lexical entries of the verbs. This kind of “anticipatory” case marking would lead to an unwanted proliferation of disjunctions in the verbal lexicon. Given that Martuthunira has fairly free word order, trying to write rules in the syntax that would anticipate all possible patterns of case stacking would result in an unwieldy and uninsightful treatment of the phenomenon.

Instead, Nordlinger’s solution is to see case morphology as being *constructive* in the sense that a case marker comes with information as to what type of GF it is expecting to mark. Formally, this is accomplished via *inside-out functional* *designation* (Dalrymple 1993, 2001), as illustrated in the (sub)lexical entries for the case markers in (18). The first line in each of the entries is standard: each case marker specifies that the attribute case is assigned a certain value (ergative, accusative, etc.). This ensures that whatever constituent carries the case marker will be analyzed as ergative, or accusative, or locative, etc.

The second line in each entry has the ↑ behind the gf rather than in front of it, signaling inside-out functional designation (Belyaev 2023: Section 3.2.4 [this volume]). This has the effect of adding a constraint on the type of gf the case marker can be associated with. In (18) the effect is that the ergative is constrained to appear within a subj, the accusative within an obj, etc.[8]

(18) a. ergative: (↑ case) = erg
(subj ↑)

b. accusative: (↑ case) = acc
(obj ↑)

c. locative: (↑ case) = loc
(adjunct ↑)

b. proprietive: (↑ case) = prop
(adjunct ↑)

Nordlinger works on the Australian language Wambaya and develops an analysis of the complex interaction between morphology and syntax that characterizes case stacking. Reproducing the entire analysis including an explanation of Wambaya morphosyntax goes far beyond the limited space available in a handbook article: this section therefore stays with the Martuthunira example for purposes of illustrating the general idea behind constructive case.

For the sake of concreteness, this section assumes a view of the morphology-syntax interface in which sublexical items are produced by rules which are analogous to phrase structure rules. This is the approach generally adopted in the ParGram grammar development world (Butt et al. 1999) and as such is useful for a concrete illustration. Note, however, that current LFG literature differs on assumptions as to the morphology-syntax interface. The illustration here adopts the general architecture articulated in Dalrymple (2015).

---

[8] Andrews (1996) also takes on case stacking and also uses LFG's inside-out functionality. However, his focus is on the interaction between morphology and syntax, rather than on case per se.

To begin with, let us consider the partial f-structure resulting from just the information on ‘pouch’ shown in (19). The stacked case marking on this noun not only provides information on the case of the noun (the innermost case morphology), it also “anticipates” the larger structure it will be embedded in. The PREDs of that larger structure will be filled in as part of the overall annotated c-structural analysis, with the partial f-structures corresponding to each of the nouns (and the verb) unifying into the full f-structure in (17).

(19)
$$\left[\begin{array}{ll} \mathrm{OBJ} & \left[\begin{array}{ll} \mathrm{CASE} & \mathrm{ACC} \\ \mathrm{ADJUNCT} & \left\{\left[\begin{array}{ll} \mathrm{CASE} & \mathrm{PROP} \\ \mathrm{ADJUNCT} & \left\{\left[\begin{array}{ll} \mathrm{CASE} & \mathrm{LOC} \\ \mathrm{PRED} & \text{‘POUCH’} \\ \mathrm{NUM} & \mathrm{SG} \\ \mathrm{PERS} & 3 \end{array}\right]\right\} \end{array}\right]\right\} \end{array}\right] \end{array}\right]$$

Recall that the inside-out function designation only serves as a constraint on f-structure. That, is the information found on ‘pouch’ postulates that there should be an OBJ into which it can be embedded. This condition will only be fulfilled if such an OBJ ends up being introduced somewhere so the actual introduction of the OBJ thus needs to come from some other part of the syntax or lexicon.

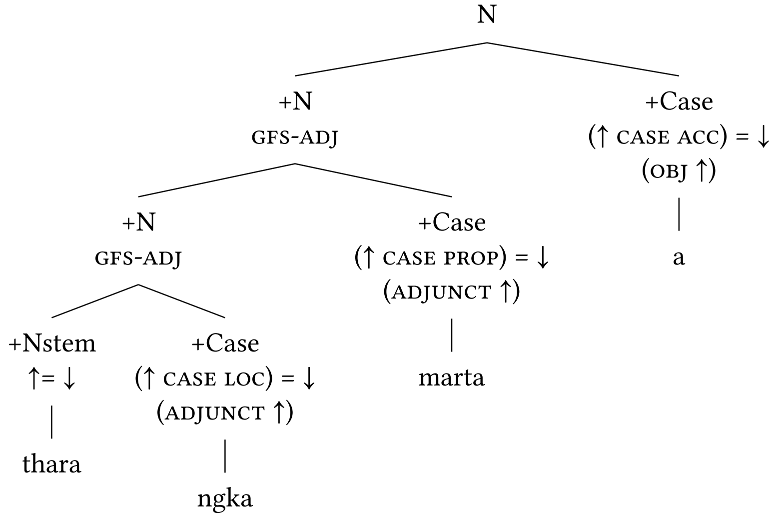
For purposes of illustration, let us assume a (simplified) phrase structure rule for clauses as in (20), which reflects the tendency in Australian languages for a (finite) verb to be in second position and models the general free word order for Australian languages. We can thus have one GF or an adjunct introduced by the XP before the verb and any GF or adjuncts after the verb. Note that “GFS-ADJ” is a template that is expandable as in (21). Similarly, XPs could be expanded to a number of different phrase structure categories, including NPs.

(20)
$$\begin{array}{lllll} \mathrm{S} & \longrightarrow & \mathrm{XP} & \mathrm{V} & \mathrm{XP}^{*} \\ & & @\mathrm{GFS\text{-}ADJ} & \uparrow=\downarrow & @\mathrm{GFS\text{-}ADJ} \end{array}$$

(21)
$$\begin{array}{l} \mathrm{GF\text{-}ADJS} = \{\, (\uparrow \mathrm{SUBJ}) = \downarrow \mid (\uparrow \mathrm{OBJ}) = \downarrow \mid (\uparrow \mathrm{OBL}_{\theta}) = \downarrow \\ \qquad\qquad \mid (\uparrow \mathrm{OBJ}_{\theta}) = \downarrow \mid \downarrow \in (\uparrow \mathrm{ADJUNCT})\} \end{array}$$

Since most of the action takes place in the morphological component in Marthuthunira, let us take a look at a possible sublexical structure (for a discussion of sublexical structure and sublexical rules, see Belyaev 2023: 2.2 [this volume]). In (22) the N expands into a set of sublexical categories, marked with a + for ease of exposition. In our example, we have a noun stem that can combine with a case marker, yielding a sublexical N (+N). This can combine with further case markers, as shown in (22), finally yielding an N.[9]

(22)



The inside-out functional designation on *ngka*, for example, requires that this be part of an ADJUNCT. This is only a constraint and as such does not "construct" the ADJUNCT per se. However, taken together with the space of possibilties licensed by the functional annotations on the mother +N node, the inside-out designation has the effect of selecting exactly the ADJUNCT among the space of possibilities provided by the expansion of GFS-ADJ in (21) and thus, in effect, serving to "construct" this GF by way of the sublexical specification on the case marker.

The same formal effect is found with the accusative marker — here the governing GF is constrained to be an OBJ and this causes the OBJ option to be selected from the set of possibilities in (21), but this time they are selected from the functional annotations on the XP in rule (20), which is instantiated by an NP and expands into the N in (22).

Overall, taking together the functional annotations in the phrase structural and the sublexical space within the N leads us to the f-structure in (19). This partial f-structure can then be unified straightforwardly with information coming from other parts of the clause via the standard unification mechanism in LFG. For example, the unification of (19) with the partial f-structure corresponding to the word *mirtily-marta-a* 'joey-PROP-ACC' shown in (23) results in the unified f-structure in (24). This unification takes place with respect to the information com-

---

[9] Of course, the possible space of combinations in the morphological component must be constrained and this can be done quite simply by writing suitable sublexical rules, but describing all the details here would take us too far afield.

ing from the other words in the clause as well, resulting in the final f-structural analysis in (17).

(23)
$$\left[\begin{array}{ll} \text{OBJ} & \left[\begin{array}{ll} \text{CASE} & \text{ACC} \\ \text{ADJUNCT} & \left\{ \left[\begin{array}{ll} \text{CASE} & \text{PROP} \\ \text{PRED} & \text{`JOEY'} \\ \text{NUM} & \text{SG} \\ \text{PERS} & 3 \end{array} \right] \right\} \end{array} \right] \end{array} \right]$$

(24)
$$\left[\begin{array}{ll} \text{OBJ} & \left[\begin{array}{ll} \text{CASE} & \text{ACC} \\ \text{ADJUNCT} & \left\{ \left[\begin{array}{ll} \text{CASE} & \text{PROP} \\ \text{PRED} & \text{`JOEY'} \\ \text{NUM} & \text{SG} \\ \text{PERS} & 3 \\ \text{ADJUNCT} & \left\{ \left[ \begin{array}{ll} \text{CASE} & \text{LOC} \\ \text{PRED} & \text{`POUCH'} \\ \text{NUM} & \text{SG} \\ \text{PERS} & 3 \end{array} \right] \right\} \end{array} \right] \right\} \end{array} \right] \end{array} \right]$$

Nordlinger's constructive case idea thus establishes case marking as carrying important information for the overall clausal analysis and invests case markers with (sub)lexically contributed information. Because the GF specifications on the case markers clearly signal which parts of the clause belong together, effects of free word order are accounted for automatically. For example, the discontinuous constituents, as illustrated in the Wambaya example in (25), can be treated very naturally. As sketched above for Martuthunira, each word in the clause produces a partial f-structure. These partial f-structures are then unified with others to produce the overall analysis, with the particular position in the clause or adjacency not mattering for the f-structural analysis. What matters is the compatibility of the information coming from the various bits and pieces of the clause, which means that discontinunous constituents which are each marked as ergative will end up being unifed under the same GF at f-structure, in this case the ergative subject.

(25) Wambaya (Nordlinger 1998: 96)

galalarrinyi-ni	gini-ng-a	dawu	bugayini-ni
dog.I-ERG	3SG.M.A-1.O-NFUT	bite	big.I-ERG

'The big dog bit me.'

Butt & King (1991, 2004) take a similarly constructive approach to case in addressing the case marking and free word order patterns of Urdu and they combine this with a theory of linking. This is discussed in Section 7. Before moving on to this and some further aspects governing the distribution of case from an LFG perspective, we however first delve into the insights offered by an adoption of Optimality Theory into LFG.

5 Optimality-Theoretic approaches

Optimality Theory (OT) was originally formulated with respect to phonological phenomena (Prince & Smolensky 1993, Kager 1999), but quickly found its way into syntactic work (Grimshaw 1997) and analyses of case patterns (Legendre et al. 2000). OT assumes an architecture by which several input candidates are generated by a given grammar. These input candidates are subject to a series of ranked constraints and result in just one of the candidates being picked as the most "optimal", i.e. as the resulting surface string. This version of OT is essentially focused on production, but a *bidirectional* version of OT, which could take both the production and the comprehension perspective into account, has been formulated as well (Blutner 2000, Dekker & von Rooy 2000). Constraints are assumed to be universally applicable across all languages, but the rankings of the constraints may differ, giving rise to language-particular patterns (see Kuhn 2023 [this volume] for an overview).

Bresnan (2000) introduced a version of OT that is compatible with LFG, arguing for the merits of this approach. Within OT-LFG, the input to an evaluation by OT constraints is assumed to be f-structure and c-structure pairings and the task of the OT constraints is to pick out the most optimal pairing. Work on case within OT-LFG has generally built on Bresnan's blueprint as well as the notions introduced by bidirectional OT.

5.1 Harmonic Alignment and DCM

OT-LFG work on case also made crucial use of the ideas in Aissen's seminal OT papers (Aissen 1999, 2003), in which she proposes a series of typologically motivated "Harmonic Alignment Scales" to account for DCM. For example, Aissen works with Silverstein's famous person and animacy hierarchy with respect to split ergativity (Silverstein 1976). She distills his and other insights found in the literature into three *universal prominence scales* shown in (27). These scales are applied to DCM, for example, with respect to differential subject marking of the type illustrated in (26) for Punjabi. In Punjabi third person subjects, but not first or second person subjects, may be overtly marked with ergative case.

(26) Punjabi

a. mɛ̃ bɑkra vec^{h}-i-a
PRON.1.SG.F/M goat.M.SG.NOM sell-PST-M.SG
'I (male or female) sold the goat.'

b. o=ne bɑkra vec^{h}-i-a
PRON.3.SG.F/M=ERG goat.M.SG.NOM sell-PST-M.SG
'He/She sold the goat.'

(27) Thematic Role Scale: Agent > Patient
Relational Scale: Subject > Non-subject
Person Scale: Local Person (1st&2nd) > 3rd Person

The three separate preference scales interact across languages. Within OT this interaction is modeled via the concept of *Harmonic Alignment* (Prince & Smolensky 1993), by which each element of a scale is associated with an element of another scale, going from right to left. The Harmonic Alignment of just the Relational and the Person scale in (27) is shown in the second column in (28) (Aissen 1999: 681). The third column in (28) shows the OT constraints derived from the Harmonic Alignment of the two scales. The constraints are arrrived at by interpreting the ranked elements in the Harmonic Alignment as situations which should be avoided, whereby lower ranked elements are the ones to be avoided more strongly than a higher ranked element. So in column 2 the 'x ≻ y' means 'x is less marked/more harmonic than y', and in column 3 the 'x ≫ y' means that the x constraint is ranked higher, i.e., is stronger, than the y constraint.

(28)

Scales	Harmonic Alignment	Constraint Alignment
Local > 3 Su > Non-Su	Su/Local ≻ Su/3 Non-Su/3 ≻ Non-Su/Local	*Su/3 ≫ *Su/Local *Non-Su/Local ≫ *Non-Su/3

Constraints within OT are understood to interact with a notion of markedness, with constraints conspiring to work towards unmarked situations and against marked situations. The Harmonic Aligment scales above state that 1st and 2nd person subjects are less marked than 3rd person subjects and that 3rd person non-subjects are less marked than 1st or 2nd person non-subjects (as per typological observations). Under the assumption that overt case is used to flag those NPs which are marked in some way, these scales and the constraints derived from them correctly predict that ergative case is more likely to occur on 3rd person subjects (the more marked situation), rather than on 1st person subjects. And this is indeed what is observed in Punjabi (26) and crosslinguistically.

Aissen derives another set of constraints targeting the realization of case on objects, and these are provided in (29). She uses these constraints to provide an analysis of well-known Differential Object Marking (DOM) phenomena, such as the definiteness and specificity effects discussed for Turkish by Enç (1991); see also Butt (2006) for an overview discussion.

(29) Relational Scale: Subject > Non-subject
Animacy Scale: Human > Animate > Inanimate
Definiteness Scale: Pronoun > Proper Name > Definite > Indefinite Specific > Nonspecific

Again, these relational scales are based on crosslinguistic observations. We have already seen animacy playing a role in Malayalam case assignment (Section 2). This feature, along with others, also plays a role in Indo-Aryan case marking, as illustrated via the specificity alternation (see 31 for an example).

5.2 OT-LFG and case

Working broadly within OT-LFG, Deo & Sharma (2006) take on the interaction between verb agreement and “core” case marking (ergative, accusative and nominative) on subjects and objects in a range of Indo-Aryan languages. The patterns are complex, but Deo and Sharma identify a set of generally applicable constraints whose variable ranking accounts for the patterns they find across Indo-Aryan and with respect to dialectal variation. In this, they build on Aissen’s work, which is geared mostly towards accounting for the overt morphological realization of case, and combine this with arguments and proposals by Woolford (2001), who focuses more on the abstract realization of case.

Asudeh (2001) contributes to discussions on OT and case by taking on the question of how optionality should be dealt with within OT. This is an interesting problem as OT assumes there should be exactly one optimal candidate, not two or more. Asudeh focuses on data from Marathi as compiled by Joshi (1993), who shows that certain verb classes (mostly involving datives) allow for variable linking. In (30), for example, either one of the arguments could be linked to SUBJ, and the other is then linked to OBJ.

(30) Marathi
sumaa-laa ek pustak milaale
Suma-DAT one book.NOM got
‘Suma got a book.’

In order to account for this type of undisputed optionality in linking possibilities in Marathi, Asudeh makes use of the stochastic version of OT (Boersma 2000), which allows for the ranking of constraints on a continuous rather than a discrete scale and thus provides a way of allowing for optionality. Building on Joshi's original analysis, Asudeh works with Proto-Roles (see Section 6) to steer case assignment and takes up bidirectional OT in the discussion of OT approaches to optionality and, by extension, ambiguity.

Lee (2001a,b) focuses on word order freezing problems in two languages that otherwise allow fairly free scrambling of major constituents: Hindi and Korean. For example, in Hindi subjects and objects can in principle occur in any order, as illustrated by (31), in which the object is overtly marked as accusative, expressing specificity on the object.

(31) Hindi

a. pɑtt^{h}ɑr botɑl=ko toḍ-e-g-a
stone.NOM bottle=ACC break.3.SG-FUT-M.SG
'The stone will break the (particular) bottle.'

b. botɑl=ko pɑtt^{h}ɑr toḍ-e-g-a
bottle=ACC stone.NOM break.3.SG-FUT-M.SG
'The stone will break the (particular) bottle.'

However, when both arguments have the same case marking the clause-initial argument must be interpreted as the subject, as illustrated in (32). This situation occurs when the object is also nominative (and thus non-specific in this Hindi DOM phenomenon) and if all else is equal, e.g., both arguments are equally non-animate as in (32).

(32) Hindi

a. pɑtt^{h}ɑr botɑl toḍ-e-g-a
stone.NOM bottle.NOM break.3.SG-FUT-M.SG
'The stone will break a/the bottle.'

b. botɑl pɑtt^{h}ɑr toḍ-e-g-a
bottle.NOM stone.NOM break.3.SG-FUT-M.SG
'The bottle will break a/the stone.'

Lee works with notions of markedness in conjunction with bidirectional OT constraints to model phenomena such as these. The idea is that constraints from both the production and the comprehension side conspire together to allow for only clause-initial subjects in situations like (32) and that this working together of constraints makes visible the fact that unmarked word order in Hindi and Korean is SOV ("emergence of the unmarked").

Word order in Hindi and Korean has been shown to be associated with information structural effects and Lee's work accordingly includes a larger treatment of word order in terms of information structure. Lee proposes OT constraints which model the interaction of case marking, word order and discourse functions (e.g., topic and focus).

Like Lee, Dalrymple & Nikolaeva (2011) identify information structure as playing a central role in case marking phenomena. Unlike Lee, Dalrymple & Nikolaeva (2011) see the notion of topicality being directly linked to case marking and the innovation of case marking. Dalrymple & Nikolaeva (2011) take on DOM in a large swathe of languages and argue that the OT approaches to case pioneered by Aissen do not go deep enough and that information structural concerns must be taken to play a central role. They develop an alternative LFG analysis which uses LFG's projection architecture to model a complex interaction between c-structure, f-structure, i(nformation)-structure and semantic interpretation. The semantic component is modeled via glue semantics, see Asudeh 2023 [this volume]. Dalrymple & Nikolaeva (2011) analyze a large variety of DOM in very different languages from this clausal semantic perspective on case. In more recent work, Donohue (2020) analyzes the case marking system of Fore, a Papuan language, by building on OT-LFG, Aissen's prominence scales and the bidirectional OT approach to case pioneered by Lee (2001a,b). The account focuses on instances of word order freezing and, more generally, on the strategies for case disambiguation found in Fore.

6 Clausal vs. lexical perspectives

LFG's original approach to linking, argument alternations and valency changing relations such as passives, applicatives or causatives was formulated to apply entirely within the lexicon, in keeping with LFG's primarily lexical perspective on syntax, cf. Findlay et al. 2023 [this volume] and Section 3 of this chapter. Mohanan (1994), Butt (1995) and Alsina (1996) established that this lexical version of linking could not account for argument structure phenemona found with syntactically formed complex predicates. As a consequence, linking within LFG is no longer confined to apply within the lexicon.

In addition to this basic insight into the domain of linking, there is another dimension to the lexical vs. clausal divide which is relevant for an understanding of case. Case is classically understood as marking the relationship between a head and its dependents (Blake 2001). This relationship can be expressed entirely lexically. But, as we have already seen, case expresses much more than specifying how a dependent is related to a head/predicate. Section 5 on OT showed that case regularly marks degrees of agentivity, animacy and referentiality across a wide range of languages. Dalrymple & Nikolaeva (2011) furthermore conclusively demonstrate that information structure plays a large role in the development and structure of case systems, and we saw in the examples from Malayalam in (10) that case can be used to express modality. These semantic reflexes of case marking necessarily need to be taken into account, with Dalrymple & Nikolaeva (2011) rightly criticizing the existing OT accounts for being inherently too limited to provide a full account of the empirically attested patterns.

One underlying reason for this limitation is that while the OT accounts make reference to semantic concepts, they are primarily concerned with accounting for a structural relationship between the two core arguments of a clause (generally the SUBJ and OBJ) and the alternations found in case marking on these two core arguments. An approach to case which allows for the systematic expression of semantic dimensions in conjunction with structural considerations has been articulated clearly by Butt & King (2003, 2004) and has been recently extended in Schätzle (2018) and Beck & Butt (2024). As discussed in Section 7, this approach is quite complex and builds on a number of important semantic insights and formal ingredients. These are presented as part of this section.

6.1 Proto-roles

Classic LFG's Mapping Theory works with thematic roles such as *agent, patient, goal*, etc. The use of such thematic role labels has repeatedly been shown to be problematic, with Grimshaw (1990) advocating for an approach that separates out arguments slots from semantic content and Dowty (1991) instead proposing to see predicate arguments as a collection of semantic entailments from which prototypical Agent vs. Patient roles can be defined. Van Valin (1991) and Van Valin & LaPolla (1997) propose a similar approach whereby the Macro-Roles Actor vs. Undergoer are defined on the basis of event-based properties (e.g., activities vs. results).

Taking these observations and proposals on board, Kibort has formulated a new version of LFG's Mapping Theory in a series of papers (Kibort 2007, 2013, 2014, Kibort & Maling 2015). This revised version adopts Grimshaw's idea of separating out argument slots from semantic content, but does not incorporate a notion of Proto-Roles. However, the idea of Proto-Roles has been adopted within

LFG in a variety of other work, e.g., Alsina (1996), Asudeh (2001) and perhaps most significantly, by Zaenen (1993).

Zaenen shows how Dowty's collection of Proto-Agent vs. Proto-Patient semantic entailments as shown in (33) can be mapped onto LFG's existing Mapping Theory, which uses the features [$\pm o, r$] to relate GFs and thematic roles (see Findlay et al. 2023 [this volume]). Zaenen's principles are shown in (34). These principles interact with other principles of LFG's Mapping Theory to ensure that [$-o$] marked participants are realized either as SUBJ or an OBL, [$+o$] marked participants are linked to an OBJ or an OBJ_θ, etc.

(33) **Proto-Role Entailments**

Proto-Agent Properties

a. volitional involvement in the event or state
(Ex.: Kim in *Kim is ignoring Sandy.*)

b. sentience (and/or perception)
(Ex.: Kim in *Kim sees/fears Sandy.*)

c. causing an event or change of state in another participant
(Ex.: loneliness in *Loneliness causes unhappiness.*)

d. movement (relative to the position of another participant)
(Ex.: tumbleweed in *The tumbleweed passed the rock.*)

e. (exists independently of the event named by the verb)
(Ex.: Kim in *Kim needs a new car.*)

Proto-Patient Properties

a. undergoes change of state
(Ex.: cake in *Kim baked a cake.*, error in *Kim erased the error.*)

b. incremental theme
(Ex.: apple in *Kim ate the apple.*)

c. causally affected by another participant
(Ex.: Sandy in *Kim kicked Sandy.*)

d. stationary relative to movement of another participant
(Ex.: rock in *The tumbleweed passed the rock.*)

e. (does not exist independently of the event, or not at all)
(Ex.: house in *Kim built a house.*)

(34) **Association of Features with Participants** (Zaenen 1993:150,152)

1. If a participant has more patient properties than agent properties, it is marked [$-r$].

2. If a participant has more agent properties than patient properties it is marked [−*o*].
3. If a participant has an equal number of properties, it is marked [−*r*].
4. If a participant has neither agent nor patient properties, it is marked [−*o*].

Neither Kibort nor Zaenen deals with case marking per se. Zaenen applies her formalism to Dutch, which does not exhibit case. Kibort works with Slavic languages and Icelandic, which do have case, but she treats case as a piece of information which informs the linking, rather than as a phenomenon that needs to be explained. In contrast, Schätzle (2018) explicitly works on case and combines Kibort's revised linking theory with Zaenen's integration of Proto-Roles for her analysis of the diachronic trajectory of Icelandic dative subjects, see Section 7.

6.2 Clausal semantics

The idea of Proto-Roles can in principle be applied within the lexicon to refer to the lexical semantics of the predicate. However, properties such as undergoing a change of state, being an incremental theme or attaining an endpoint along a path have by now been firmly established as resulting out of an interaction of the semantics of the Proto-Patient argument with the semantics of the event described by the verb (e.g., Krifka 1992, Verkuyl 1993). The quantizedness of the Proto-Patient argument has been shown to be crucial in determining the telicity of an event; more recently the effect is referred to in terms of scalarity (Hay et al. 1999, Kennedy & Levin 2008). The DCM alternation in (35) provides a representative example of this phenomenon in Finnish (also recall the Russian genitive alternation with respect to quantizedness discussed by Neidle, Section 2) When 'bear' is accusative, it definitely undergoes a change of state (dies) and the entire event is telic. In contrast, when one wishes to express that the intended endpoint of the action was not achieved, 'bear' appears in the partitive.

(35) Finnish

a. Ammu-i-n karhu-n
shoot-PST-1SG bear-ACC
'I shot the/a bear.' (Kiparsky 1998: 267)

b. Ammu-i-n karhu-a
shoot-PST-1SG bear-PART
'I shot at the/a bear (bear is not dead).' (Kiparsky 1998: 267)

Ramchand (1997) discusses the Finnish data along with Scottish Gaelic alternations as in (36) and (37). She analyzes the differences in terms of boundedness. The alternation in (36) is essentially parallel to the Finnish example in (35). The alternation in (37) presents an interestingly different situation, but one that can also be analyzed in terms of boundedness: it expresses the difference between wanting something (unbounded) and getting it (bounded).

(36) Scottish Gaelic

a. tha Calum air na craobhan a ghearradh
be.PRS Calum ASP the trees.DIR OAGR cut.VN
'Calum has cut the trees.'

b. tha Calum a' ghearradh nan craobhan
be.prs Calum ASP cut.VN the trees.GEN
'Calum is cutting the trees (no tree has necessarily been cut yet).'

(37) Scottish Gaelic

a. tha mi air am ball iarraidh
be.prs I ASP the ball.DIR want.VN
'I have acquired the ball.'

b. tha mi ag iarraidh a'bhuill
be.prs I ASP want.VN the ball.GEN
'I want the ball.'

Ramchand (2008) extends and refines her analysis so that events are seen as being built up out of a tripartite structure consisting of an init(iation) subevent, a proc(ess) subevent and a res(ult) subevent. This tripartite structure contrasts with the more common bipartite approach found in the majority of event-based approaches to linking. For example, Jackendoff (1990) assumes a basic CAUSE-BECOME (init-res) relationship and makes provisions for activity verbs (proc), but does not combine all three subevent types into one tripartite template (see Levin & Rappaport Hovav 2005 for an overview), Ramchand demonstrates that her system works for a number of varied phenomena across languages and it has been adopted within LFG by Schätzle (2018) and Beck & Butt (2024), as discussed in the next section.

7 A comprehensive theory

This section first introduces an overall framework for case as developed by Butt and King in various papers (Section 7.1) and then goes on to look at the relationship between case and the theory of linking developed by Schätzle (2018) and Beck & Butt (2024) in Section 7.2.

7.1 Types of case

Butt & King (2003, 2004) develop a theory of case that allows for four basic types: 1) structural case; 2) default case; 3) semantic case; 4) idiosyncratic case. This categorization differs significantly from other theories of case and is explained in some detail via examples in the next subsections. Notably, Butt and King's notion of semantic case is often conflated with idiosyncratic case in other theories and referred to as just one category of quirky/inherent case. Butt and King, on the other hand, argue that the two types need to be separated out for an effective understanding of case systems. Butt and King also define structural case as being that type of case which is only due to purely structural factors. The most common type of case marking in their system is that of semantic case, which exhibits a mix of systematic semantic and structural factors. Crucially, Butt and King center their analysis around an explanation of case alternations (including DCM) and consequently dub their theory *Differential Case Theory* or DCT. Butt and King illustrate their analyses mainly with respect to Urdu, but also include data from Georgian.

7.1.1 Semantic case: Mix of structure and semantics

Urdu has a complex system of case marking. Most of the case marking involves a mixture of structural and semantic factors as illustrated by the core examples in (38) and (39). Overt case marking generally takes the form of case clitics (see Butt & Ahmed Khan (2011) for a history of the development of case marking in Urdu) and the absence of any case marking is glossed as nominative (Mohanan 1994). The ergative is required with (di)transitive agentive verbs when the verb morphology is perfective, see (38a) vs. (38b). The accusative *ko* and the null nominative engage in DOM, with the accusative expressing specificity (Butt 1993) and generally required on animate objects, see (38a,b) vs. (38c).[10]

---

[10] Agreement in Urdu/Hindi works as follows. The verb will only agree with a nominative (unmarked) argument. If the SUBJ is unmarked, the verb agrees with this (38b), else the verb agrees with OBJ if that is unmarked (38a). If neither the SUBJ or the OBJ is available for agreement, the verb defaults to a masculine singular form, as in (38c). See Mohanan (1994) for a comprehensive discussion and Butt (2014) and references therein for information about verb agreement beyond the simple clause.

(38) Urdu

a. nadya=ne gaṛi cɑla-yi hɛ
Nadya.F.SG=ERG car.F.SG.NOM drive-PFV.F.SG be.PRS.3.SG
'Nadya has driven a car.'

b. nadya gaṛi cɑla-ti hɛ
Nadya.F.SG.NOM car.F.SG.NOM drive-IPFV.F.SG be.PRS.3.SG
'Nadya drives a car.'

c. nadya=ne gaṛi=ko cɑla-ya hɛ
Nadya.F.SG=ERG car.F.SG=ACC drive-PFV.M.SG be.PRS.3.SG
'Nadya has driven the car.'

The Urdu ergative and accusative are structural in that they can only appear on subjects and objects, respectively. However, they are also semantically constrained in that they express object referentiality and animacy (accusative) and subject agentivity. The latter is illustrated by (39) where the presence of the ergative case on an unergative verb yields an 'on purpose' reading that is absent when the subject is nominative.

(39) Urdu

a. ram kʰãs-a
Ram.M.SG.NOM cough-PFV.M.SG
'Ram coughed.' (Tuite et al. 1985: 264)

b. ram=ne kʰãs-a
Ram.M.SG=ERG cough-PFV.M.SG
'Ram coughed (on purpose).' (Tuite et al. 1985: 264)

Most case markers in Urdu exhibit this mix of structural and semantic properties and fall under the category of semantic case in DCT.

Butt and King model semantic case via an essentially lexical semantic approach to case in that they associate the relevant information directly with the case marker, specifying both the GF the case marker is compatible with and any attendant semantic information. This is illustrated for the accusative in (40).

(40) ko (↑ CASE) = acc
(OBJ ↑)
(↑SPECIFICITY) = +

Butt and King's approach uses inside-out functional designation like Nordlinger's Constructive Case approach (Section 4) and bears similarities to that approach in that case markers are taken to contribute to the overall analysis of the clause with information that goes beyond just the statement of what type of case is involved.[11] However, the approach goes beyond Constructive Case in providing a more complete view on the interaction between the lexical semantics of a verb, case semantics and structural case requirements.

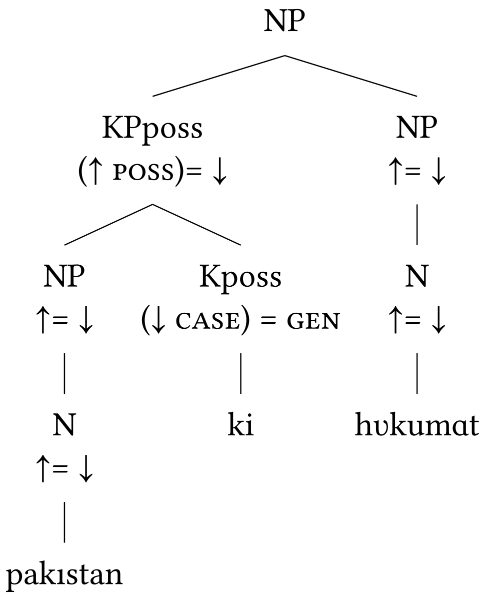
7.1.2 Structural case

Examples of structural case tend to be restricted. In Urdu, an example of a purely structural case is the genitive in NPs, such as in (41), taken from Bögel & Butt (2012).

(41) Urdu
pakıstan=ki hʊkumɑt
Pakistan=GEN.F.SG government.F.SG
'The government of Pakistan'

Genitive within NPs is assigned on purely structural grounds – there are no particular semantics associated with it. As in the early LFG approaches (Section 2) this type of case is therefore assigned only on the basis of c-structure configuration, by means of f-structure annotations on the appropriate c-structure nodes. An example, based on Bögel & Butt (2012), is provided in (42).

(42)



---

[11] Butt & King (2003, 2004) build on initial proposals by Butt & King (1991), foreshadowing Nordlinger's (1998) ideas on Constructive Case.

7.1.3 Reassessment of quirky case

Butt and King's category of semantic case separates out those case marking patterns which are associated with systematic semantic import from truly idiosyncratic case marking that needs to be stipulated (mostly as part of lexical entries). The dative is a prime example for a type of case that is often analyzed as an instance of quirky/inherent/idiosyncratic case despite the fact that it is demonstrably and very systematically associated with a certain semantic import (cf. the discussions in Section 2 and Section 3 above).

In Urdu the dative is also realized by the clitic *ko*. In its function as a dative, the *ko* can appear on indirect goal objects as in (43) and on experiencer subjects, as shown in (44).

(43) Urdu
nadya=ne bɪlli=ko dud di-ya hɛ
Nadya.f=erg cat.f.sg=dat milk.m.nom give-pfv.m.sg be.prs.3.sg
'Nadya has given milk to the cat.'

(44) Urdu
nadya=ko ḍɑr lɑg-a
Nadya.f.sg=dat fear.m.sg.nom be attached-pfv.m.sg
'Nadya was afraid.' (lit. Fear is attached to Nadya.)

The dative alternates systematically with the ergative to express a contrast in agentivity, with the dative signaling reduced agency, generally giving rise to experiencer semantics as in (44) and (45a), but also to deontic modality as in (46a).

(45) Urdu
a. nadya=ko kɑhani yad a-yi
Nadya.f.sg=dat story.f.sg.nom memory come-pfv.f.sg
'Nadya remembered the story.'
b. nadya=ne kɑhani yad k-i
Nadya.f.sg=erg story.f.sg.nom memory do-pfv.f.sg
'Nadya remembered the story (actively).'

(46) Urdu
a. nadya=ko zu ja-na hɛ
Nadya.f.sg=dat zoo.m.sg.obl go-inf.m.sg be.prs.3.sg
'Nadya has/wants to go to the zoo.'

b. nadya=ne zu ja-na hɛ
Nadya.F.SG=ERG zoo.M.SG.OBL go-INF.M.SG be.PRS.3.SG
'Nadya wants to go to the zoo.'

The systematic dative-ergative alternation as well as the tie in to modality indicates that these case patterns are not exclusively due to the lexically specified inherent semantics of a verb, but that the information associated with the case marker is making a significant contribution to the overall semantics of the clause. Generally, the dative marks goal arguments, whether these be recipients (43) or experiencers (44). In a very systematic alternation with the ergative, the dative signals reduced agentivity. The dative and its attendant signaling of reduced agency is pressed into service in the expression of modality in Urdu more generally, see Bhatt et al. (2011) for an overview of modals in Urdu/Hindi. The Urdu dative *ko* is thus also analyzed as an instance of semantic case in DCT.

7.1.4 Idiosyncratic case

Idiosyncratic case is the type of case where no systematic generalizations, either of a structural or of a semantic kind, can be found. This is what distinguishes idiosyncratic case from both semantic and structural case. Instances of idiosyncratic case are typically due to diachronic developments that render the original reason for the case marking opaque, or which result in morphophonological changes that cause the case markers themselves to change and to be reclassified.

An example of truly idiosyncratic marking in Urdu is shown in (47). Recall that Urdu requires the ergative on subjects of agentive transitive perfect verbs. However, while the verb 'bring' in (47) falls into this category, its subject is nominative.

(47) nadya kɪtab la-yi
Nadya.F.SG.NOM book.F.SG.NOM bring-PFV.F.SG
'Nadya brought a book.'

There are no other straightforwardly agentive transitive verbs which behave like this, so this exceptional and idiosyncratic nominative case must be stipulated as part of the lexical entry of *la* 'bring'. Another exceptional verb is *bol* 'speak', which is unergative and should therefore allow for an ergative subject in the perfective, but does not.

7.1.5 Default case

Finally, Butt and King also provide for default case marking. Default case marking occurs when an NP is not already specified for a case feature via some part of the grammar (lexicon, syntax). In languages which require all NPs to be case marked, such NPs receive a default case. In Urdu the default case is the phonologically null nominative, which can only appear on subjects and objects. Default case can be assured via well-formedness statements in the functional annotations on the NP node at c-structure, as shown in (48).

(48)
1. Well-formedness principle: NP: (↑ CASE)
2. Default: (↑ SUBJ CASE)=NOM
3. Default: (↑ OBJ CASE)=NOM

These rules constrain every NP to be associated with a case feature and to make sure that subjects and objects are assigned nominative case in the absence of any other specification. Basically the annotations check if there is a case feature realized. If not, then nominative is assigned by default. This type of if-then realization of functional annotations is slightly more complex than illustrated in (48), which is kept simple for purposes of illustration. A full implementation can be found in the Urdu ParGram grammar (Butt & King 2002, Bögel et al. 2009).

7.2 Event-based linking

The theory in Section 7.1 as to the types of case that must be accounted for does not make reference to linking. However, a theory of linking is clearly also needed as it determines how the event semantics of a verb plays out in terms of syntactic valency and case marking. We saw in Section 6 that an *event-based* approach is necessary for an understanding of DCM patterns (e.g., for telicity or boundedness/scalarity more generally). An event-based approach is also what underlies the generally accepted ideas behind Dowty's Proto-Roles or Van Valin's Macro-Roles, as the prototypical Agent/Patient properties are defined in terms of how the participant is related to the event being described (change of state is being effected, one participant is stationary with respect to another participant, etc.).

Event-based approaches to linking are common (e.g., Jackendoff 1990, Van Valin & LaPolla 1997, Rappaport Hovav & Levin 1998, Croft 2012, see Levin & Rappaport Hovav (2005) for an overview), but are employed within LFG only in a subset of linking approaches. This occurs either indirectly via the incorporation of a notion of Proto-Roles, or explicitly in adaptations of Jackendoff's Lexical-Conceptual Structures, as done by Butt (1995).

Kibort's revised version of Mapping Theory improves on the classic version of mapping within LFG by separating out argument slots from semantic content and formulating new mapping principles that make reference to semantics (Kibort 2014). However, semantic principles are made use of only occasionally and relatively indirectly.

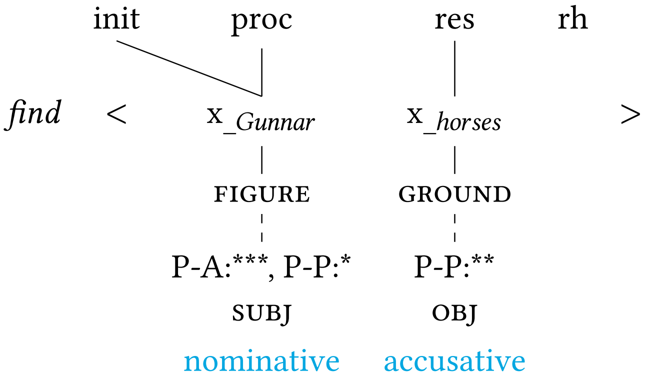
Schätzle (2018) bases herself on Kibort's revised Mapping Theory but brings in semantic information explicitly on several dimensions. Importantly, she adopts Ramchand's (2008) tripartite division of events into three types of subevents: init(iation), proc(ess), res(ult). This event semantic dimension is used to derive Proto-Role properties and these in turn are used to determine the linking between argument slots and GFs. Schätzle also integrates a Figure/Ground dimension. This is intended to do justice to the information-structural effects found with respect to case. However, she does not need the full-fledged representation of information-structure developed by Dalrymple & Nikolaeva (2011), instead adopting the basic Figure/Ground distinction first developed by Talmy (1978).

Schätzle's basic system is illustrated below with respect to the Icelandic example in (49), which is taken from Beck & Butt (2024) and represents a revised version of the original in Schätzle (2018).

(49)	Gunnar	fann	seint	hrossin	um	daginn
	Gunnar.NOM	find.PST.3SG	late	horse.PL.DEF.ACC	during	day.DEF.ACC

'Gunnar found the horses late during the day.'

(IcePaHC, 1400.GUNNAR.NAR-SAG,.281)

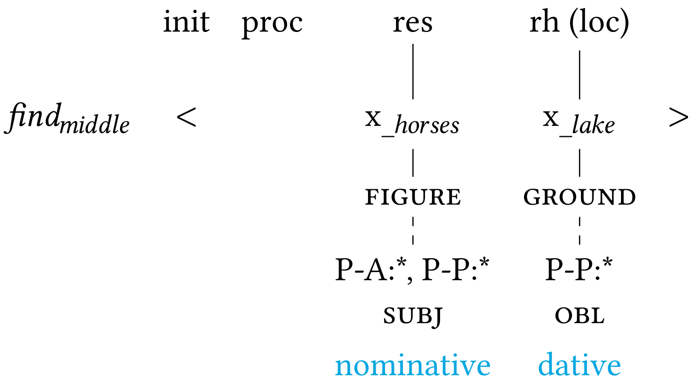


The main predicate here is *finna* 'find', which expresses a dynamic event. The event consists of an initiation of the event, a process during which the event takes place and a result. The initiator of the event is 'Gunnar' so this role is linked to the init subevent. The initiator is also the participant involved in the event as it unfolds, so is also linked to the proc subevent. The 'horses' argument is linked to the result subevent as finding the horses represents the successful culmination of the event. As a sentient initiator that is also the Figure of the clause, Gunnar thus picks up three Proto-Agent (P-A) properties (sentience, init, Figure). As an undergoer of a process, Gunnar receives one Proto-Patient (P-P) property (the occurrence and number of Proto-Role properties is indicated via the number of of '*' on the features P-A and P-P). The 'horses' argument is the Ground and the resultee and as such picks up two Proto-Patient properties and no Proto-Agent properties. The participant with the most Proto-Agent properties is linked to the SUBJ, leaving the horses to be linked to OBJ. The case marking on the SUBJ and OBJ in this case is an instance of default case: the subject is nominative and the object is accusative in the absence of any other specification.

Schätzle (2018) is primarily concerned with investigating the diachronic increase in the occurrence of dative subjects in Icelandic. Using corpus linguistic methodology, she pinpoints the lexicalization of former middles as experiencer verbs as a major reason for the increased use of dative subjects in Icelandic. One of the verbs that has undergone such lexicalization is the verb *finna* 'find', featured in (49). This was reanalyzed as a stative experiencer and raising predicate via middle formation with the middle morpheme *-st* in the history of Icelandic and came to mean 'find, feel, think, seem'.

Schätzle (2018) shows how this process of reanalysis can be understood as a form of locative inversion. There are several steps to this posited diachronic change. First, consider the linking configuration for the middle version of the example in (49), as shown in (50). Under middle formation, *finna* becomes *finna-st*, meaning 'be found, meet', and the initiation subevent is absent for the purposes of linking. The middle predication essentially describes a result, which is that there are found horses.

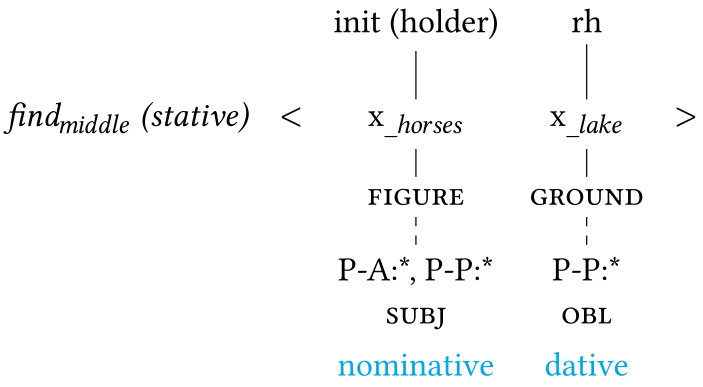
(50) The horses were found at the lake.



Schätzle also adopts Ramchand's (2008) notion of a *rh(eme)*. A rheme serves as a complement slot that modifies the core predication. In (50) this rheme slot is occupied by the locative 'at the lake'. Rhemes are generally not compatible with the Figure role: they provide a Ground argument. So in (50) 'horses' acts as the Figure, picking up one Proto-Agent property. This argument is linked to the result subevent, which yields one Proto-Patient property. The horses thus have more Proto-Agent properties (one) than the lake (none) and so the horses are linked to SUBJ. The rheme is also a locative and this configuration yields a linking to OBL. The SUBJ is nominative per default, and the OBL is marked with the Icelandic spatial dative.

The configuration in (50) in fact very closely resembles that of a straightforwardly stative predication, which is also one possible interpretation of the middle form of 'find'. In this case it means something along the lines of 'be situated/located'. Schätzle posits that in this case the original result participant is interpreted as the holder of a state. The holder of a state is linked to the init subevent in Ramchand's system. As shown in (51), there is no change in the overall linking configuration and the attendent case marking, but there is a change in the interpretation of the event semantics: (51) shows a stative predication rather than the result part of a dynamic event.

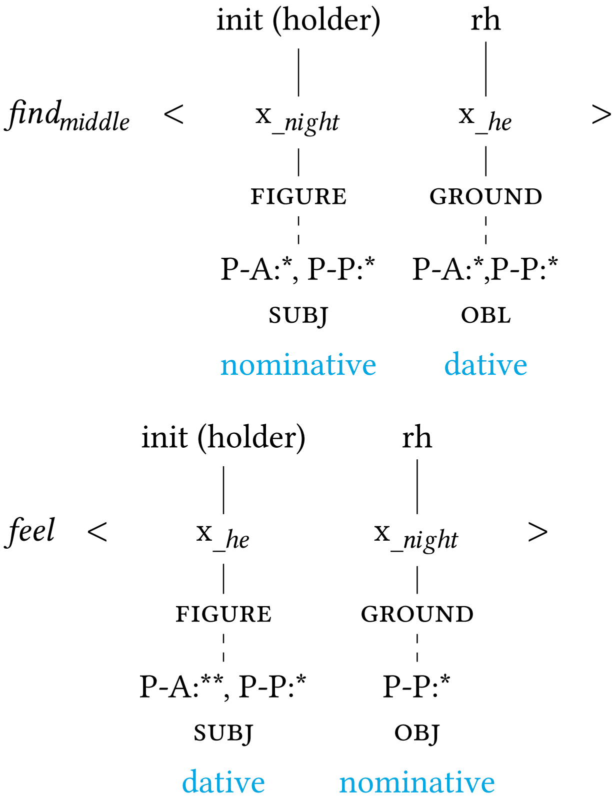
(51) The horses were (located/situated) at the lake.



Schätzle postulates that over time, this type of stative predication via middle formation led to lexicalized experiencer predicates as in (52), where *finna* means 'feel'. These experiencer predicates feature a dative SUBJ synchronically and Schätzle proposes that the dative SUBJ is the result of a flip in the linking relation that occurred when the Ground argument is sentient, as shown in the linking configurations in (52). The first configuration corresponds to a literal locative reading of 'The night was found at him.' and shows the same relations as in

(51), just with a sentient Ground. But this small difference results in an equal distribution of Proto-Role properties across the two event participants. This taken together with a crosslinguistic preference for sentient participants to be interpreted as a Figure rather than as a Ground leads to an unstable linking configuration.

(52) og fannst honum nótt.
and feel.PST.MID.3SG he.DAT night.NOM
‘and he felt the night.’
(IcePaHC, 1861.ORRUSTA.NAR-FIC,.1670)



This unstable linking configuration can be resolved by flipping the Figure/Ground relations and associating the sentient argument with the holder of the state, as shown in the lower linking configuration. With this simple configurational change, the sentient argument now picks up two Proto-Agent properties (Figure and sentience), and one Proto-Patient property as a holder of a state. The other argument receives only one Proto-Patient property as the Ground. The overall effect is that the sentient argument is now linked to SUBJ, the other (non-spatial) argument to OBJ. The originally spatial dative marking is retained on the newly minted SUBJ and feeds into a general pattern of dative marked experiencer subjects in the language.

Beck & Butt (2024) use the same analysis of locative inversion to account for patterns of dative subjects in Indo-Aryan. Their approach also provides an account for the Marathi optional dative subjects discussed by Asudeh (2001) and in Section 5 of this chapter. In Beck and Butt's account the observed optionality is attributed to an unstable linking configuration of the type shown in the upper part of (52). This leads to an optionality that is slowly resolved over time in favor of a dative subject constellation as shown in the lower part of (52). Deo (2003) shows that this is the change that is indeed happening in Marathi, verb class by verb class, verb by verb.

Overall, in this event-based approach to linking, case is matched with certain linking configurations. For example, in Icelandic and Marathi, the holder of a state as in the lower linking configuration in (52) must systematically be associated with a dative and this expresses experiencer semantics.

8 Summary

This chapter has surveyed LFG work on case from some of the earliest LFG papers to some of the most recent developments. The LFG perspective, particularly with respect to Icelandic, was instrumental in establishing a basic division between structural and lexically specified case, where the latter also came to be known as 'quirky' case. Later work put the relationship between predicate arguments and GF on a more systematic footing via the formulation of Mapping Theory. Case was always relevant for Mapping, but not integrated into the theory itself. The event-based linking developed by Schätzle (2018) and Beck & Butt (2024) offers a more natural way of integrating case information, while also building on Kibort's revised Mapping Theory and allowing for an integration of Proto-Role properties. The integration of such Proto-Role properties into accounts of case and linking has been experimented with in a number of ways within LFG over the years, especially in terms of work done within OT-LFG.

Butt and King formulate a theory of case, which distinguishes between four types of case: 1) structural, 2) default, 3) semantically generalizable and 4) idiosyncratic. Their notion of semantic case centrally applies to core arguments of a verb and includes accounts of Differential Case Marking, including modality. Case markers are considered to have their own lexical entries and to be associated with syntactic and semantic information which contributes to the overall syntactic and semantics analysis of the clause. This is in line with Nordlinger's idea of Constructive Case, which can additionally account for case stacking.

This chapter has not included a comparison of LFG with other theories. In terms of linking, LFG employs a distinct version, but the essence of, and the insights behind, linking have very much in common with other theories of the interface between lexical semantics and syntax. The same is true for the OT-LFG approaches to case, which build directly on mainstream OT insights and proposals. However, as far as I am aware, the idea of Constructive Case and the four-way distinction between different types of case is unique to LFG.

Abbreviations

Besides the abbreviations from the Leipzig Glossing Conventions, this chapter uses the following abbreviations.

A	agent	O	object
ASP	aspectual marker	OAGR	object agreement
DIR	directional	PART	partitive
I	class I	PRON	pronoun
MID	middle	PROP	proprietive
MOD	modal	VN	verbal noun

Chapter 7

Complex predicates

Avery D. Andrews
The Australian National University

This chapter surveys LFG work on a somewhat diverse collection of constructions often called complex predicate constructions, which can be broadly characterized by saying that the number of superficially apparent predicates is arguably different from that of actual predicates, either because two apparent predicates can be argued to have combined into one, or one apparent predicate with an affix is actually two predicates. Some of these constructions are also called Reanalysis, Restructuring, Clause Union or Light Verb Constructions, others are often called Serial Verb Constructions. Here we discuss the main analyses of these that have appeared in LFG, giving an overview of the sorts of criteria and analyses that have appeared in the LFG literature.

1 Introduction

The term COMPLEX PREDICATE has been widely and rather loosely applied to a variety of constructions where for some reason it appears that two predicates that might be regarded as independent are behaving as one. This happens in multiple ways, with the result that the term has been applied to constructions which are perhaps not very closely related. The major cases appear to be:

(1) a. Two apparent predicates which appear to be syntactically and morphologically autonomous, but are nonetheless closely integrated semantically. Such constructions were called ‘composite predicates’ in the non-LFG analysis of Cattell (1984), but ‘complex predicates’ in the LFG analyses of Ishikawa (1985) and Matsumoto (1996). One component, the syntactically higher one, is a verb, often called a ‘Light Verb’. The other can be of various categories; Cattell studied

Avery D. Andrews. 2023. Complex predicates. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 267–308. Berlin: Language Science Press. DOI: 10.5281/zenodo.10185946

verb-noun complex predicates in English, Ishikawa investigated a few verb-verb complex predicates in Japanese, and Matsumoto investigated both types of complex predicates in Japanese.

b. Two or more apparent predicates that are integrated semantically, and syntactically to a greater degree than in (1a) or (1c), but still morphologically distinct, in particular, the light verb is still a distinct stem rather than an affix. Examples include Noun+Verb combinations in Hindi (Mohanan 1994), and combinations of noun and other hard-to-categorize items with verbs in Jaminjung (Schultze-Berndt 2000).

c. Items that appear to be distinct morphological and syntactic words, but show deeper signs of integration, such as sharing a single argument structure. This is often called Restructuring, Reanalysis, or Clause Union, and is exemplified by a variety of constructions including especially causatives in Romance (Alsina 1996, 1997, Andrews & Manning 1999, Andrews 2018b, Manning 1992, 1996b), and also Urdu (Butt 1995, 1997, Lowe 2016).

d. Two or more items that are integrated morphologically (for example, one is a stem, the other like an affix), but have a considerable degree of semantic and syntactic autonomy (for example, causatives in Japanese (Ishikawa 1985) and Bantu (Alsina 1997)).

e. Serial Verb Constructions (SVCs), where two or more Vs or VPs occur together with some kind of sharing or combination of argument structure (for example, Tariana as described by Aikhenvald 2003 and analysed in LFG by Andrews & Manning 1999, Dagaare and Akan as described and analysed by Bodomo 1996, 1997, and Barayin as described and analysed by Lovestrand 2018).

These divisions cross-classify extensively with the semantic/conceptual categories expressed by the constructions:

(2) a. Desiderative, modal, potential and other concepts, shading in an unclear manner into auxiliaries expressing tense, aspect and mood (in the LFG literature, discussed in connection with Restructuring and SVCs).

b. Causative, applicative and other valence change (restructuring, SVCs and morphology).

c. Associated motion (restructuring, SVCs, and morphology).[1]
d. Alternatives to a mono-lexical predicate (SVCs and light verb constructions).

In the following sections, I will consider in turn the construction types of (1), with some discussion of the semantic categories they express, and especially the criteria that have been applied to distinguish the supposed complex predicate constructions from similar ones, such as control constructions.

2 Composite predicates

This term was used in the non-LFG analysis of Cattell (1984) to refer to combinations such as *take a walk* or *have a look*, which appear to involve both a main verb and an apparent full NP object, these semantically interpreted together as at least roughly equivalent to a single lexical verb, in many cases. I am not aware of any attempt to reanalyse Catell's English data in LFG, but similar expressions in Japanese were treated at length (Matsumoto 1996), who however called them 'complex predicates'. He also looked at a variety of verb+verb constructions, such as benefactive *morau*, which had been early called 'complex predicates' by Ishikawa (1985).

Ishikawa and Matsumoto developed similar analyses, the latter considerably more extensive and detailed. In both cases, the constructions were treated as XCOMP constructions, with functional control of a SUBJ, motivated by the possiblities for reflexivization for *zibun*, along with a mechanism for allowing arguments to be expressed either in the higher or the lower structure. Ishikawa (1985: 99–100) proposed a principle of 'Object Function Sharing' whereby the equation $(\uparrow \textsc{obj})=(\uparrow \textsc{xcomp}\ \textsc{obj})$ can be added to lexical entries under various circumstances. Matsumoto observed that the apparent possibility of expressing arguments at either level applied to adjuncts as well as arguments, and was also found with a wide range of XCOMP structures, indeed, all of those in Japanese, and so proposed that the nonconfigurational c-structure rule for S could introduce GF's preceded by any number of XCOMPs, constituting a use of functional uncertainty (Matsumoto 1996: 87):

(3)
$$\begin{array}{llcc} \text{S} & \longrightarrow & \text{NP}^{*} & \{\text{V,A}\} \\ & & (\uparrow \textsc{xcomp}^{*}\ \textsc{gf})=\downarrow & \uparrow=\downarrow \end{array}$$

---

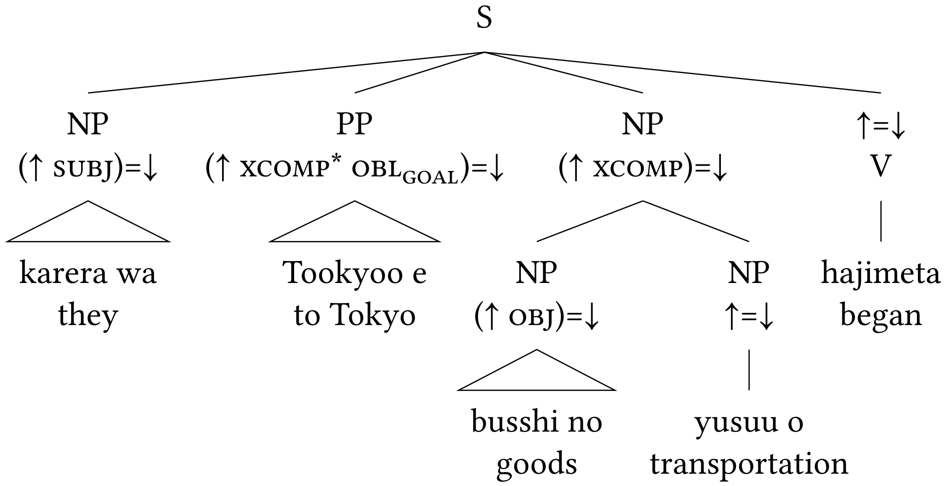
[1] A category that might be unfamiliar to some readers, designating patterns of motion associated with an activity, first identified and named by Koch (1984).

The predicates of these XCOMPs could be verbs, adjectives or verbal nouns, but are all analysed as having verb-like PRED-features taking sentential grammatical relations. But Matsumoto used the resources of LFG to assure that when an argument was expressed in an NP, it was marked with the nominal dependent marker *no* rather than the sentential object marker *o*.

For example, a sample structure is:

(4) Japanese (Matsumoto 1996: 88)

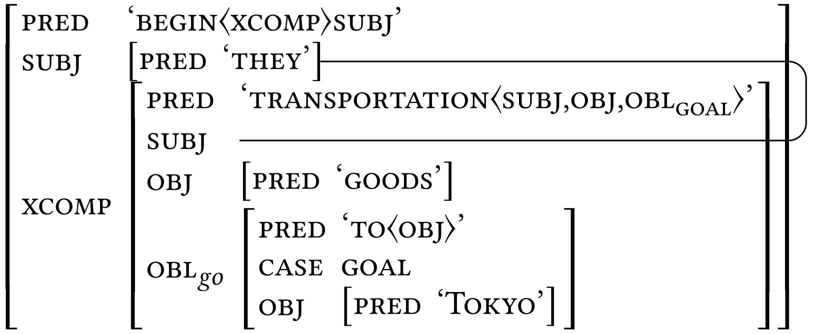
a.



b. karera wa Tookyoo e busshi no yusuu o hajimeta
they TOP Tokyo to goods GEN transportation ACC begin.PST
'They began the transportation of goods to Tokyo.'

The subject is shared between the main clause and the XCOMP by means of functional control, while the directional argument is attributed to the complement clause by means of the functional uncertainty expression, and the object is expressed in the complement clause (with different case-marking conventions in both places, as formalized in LFG by Matsumoto). So the resulting f-structure is:

(5)



Variants of this work for a wide range of structures, including the constructions with NP+*suru* (in which the nominal is marked with the accusative marker *o*; there are also incorporational structures without *o*, to be discussed later), in which the XCOMP-value presumably supplies the meaning, with *suru* being semantically empty, merely transmitting it up to the top sentence level:

(6) Japanese (Matsumoto 1996: 74)
karera wa soko e sono busshi no yusoo o suru
they TOP there GOAL the goods GEN transport ACC do
'They will transport the goods there.'

On this analysis, these structures do not involve any special combination of predicates, so I think it is reasonable to call them 'composite predicates' on the basis of the resemblance that some of them have to the structures investigated by Cattell. But they do have one feature that relates them to the clearer cases of complex predicates, which is the sharing of nonsubject arguments. The word-order characteristics of Japanese (verb final, variable ordering of arguments and adjuncts) allow a reasonably clean treatment of this with the phrase-structure stipulation of (3), which is also very similar to LFG proposals for the intricacies of West Germanic infinitival complements (Zaenen & Kaplan 1995, Kaplan & Zaenen 2003), which are often treated as a kind of complex predicate in the Minimalist literature (for example, Wurmbrand 2017, where complex/restructuring predicates are analysed in terms of certain verbal projections being absent), but not in LFG, where sharing of grammatical attributes is normally required for the term 'complex predicate' to be used.

3 Light verb + coverb structures

The next structures we consider resemble composite predicates in a number of ways, but the apparent complement of the light verb shows signs of syntactic or morphological reduction. Most of the work in LFG has been on Hindi, starting with Mohanan (1994), followed by Mohanan (1997). Occasional later discussions, such as Andrews & Manning (1999: 34–37), consider Wagiman rather than Hindi.

Mohanan considered examples such as:

(7) Hindi
Mohan ko kahaanii yaad aayii
Mohan DAT story.NOM memory.NOM come.PRF
'Mohan remembered the story.'

Here the combination *yaad aayii* functions equivalently to the English inflected verb ‘remembered’. She established a number of facts about these constructions which distinguish them from the composite predicates:

(8) a. The nominal component (here *yaad*) is not head of an NP (cannot be modified by adjectives or coordinated), but an N component of a structure along the lines of $[\mathrm{N}\ \overline{\mathrm{V}}]_{\overline{\mathrm{V}}}$ (the structures are recursive, and contain various other things beyond the V and the N).

b. The V component has some mobility (topicalization but not scrambling); the N does not.

c. The nominal and the verb are jointly responsible for licensing the arguments.

d. Nevertheless, in the most prevalent subtype, the verb can agree with the nominal, so it would appear to bear a grammatical function in f-structure, under traditional assumptions (proposals for a morphological structure might change this).

e. The verbs which participate in this construction also have independent verbal functions.

Concomitant with (8a), there is no reason to believe that there is any expression of arguments by any nominal strategy: the arguments are all expressed as if they were arguments of a simple lexical verb.

Mohanan reconciles these somewhat contradictory phenomena by making use of the fact that LFG deploys multiple levels of representation, including originally c-structure and f-structure, but later extended to include some kind of argument structure (ARG STR) and semantic structure (SEM STR) (the details of what is proposed for these and other additional levels are subject to considerable variation in the literature). In her analysis, ARG STR intervenes between f-structure and SEM STR, and permits a semantically complex combination to function in certain respects as a single-level, monoclausal structure.

The SEM STR of the light verb and the noun fit together in a standard predicate-argument combination, where, for example, in the following example meaning ‘remember’, the upper predicate is a motion verb interpreted metaphorically, while the lower means ‘memory’, the Destination of the upper predicate being identified with the Experiencer of the lower one, which also has an ‘Experienced’ argument:

(9)
$$\begin{bmatrix} \text{REL} & \textit{COME} \\ \text{DEST} & [\,] \\ \text{COME-ER} & \begin{bmatrix} \text{REL} & \textit{MEMORY} \\ \text{EXP-ER} & \\ \text{EXP-ED} & [\,] \end{bmatrix} \end{bmatrix}$$

Mohanan argues from reflexivization phenomena that these form a ‘monoclausal’ pool (Mohanan 1994: 281, 1997: 443–444), but there is a problem with this.

She shows that the complex predicates divide in two types. In the majority type, the light verb agrees in gender with the nominal if the subject is ergative, exactly as would happen if the nominal was an ordinary direct object. Furthermore, a sole argument of this nominal must be in an oblique case, never nominative (lacking any overt case marking) or accusative. In the other type, the verb cannot agree with the nominal, and any sole argument of the nominal is nominative/accusative like an ordinary direct object (Mohanan 1997: 457–469). This indicates that in the first type, there are two levels of f-structure, and the lower level has an effect on the marking of the arguments and perhaps even their grammatical function. It is not clear to me how to integrate the agreement phenomena with the theme of monoclausality (but it is not incompatible with various forms of argument-sharing).

In summary, the first type is similar to the composite predicates as analysed by Matsumoto, but with an apparent difference in reflexivization behavior, while the second seems more like the ones investigated not so much by LFG workers, but more by typologically oriented ones such as Schultze-Berndt (2000) and many others, where there does not appear to be evidence that the non-verbal component (often called a coverb) bears any grammatical function. Neither of these types appear to have attracted much attention in the LFG literature subsequent to the 1990s, a situation that should perhaps be remedied.

4 “Restructuring” complex predicates

These are the constructions that seem to have attracted the most discussion since the 1990s, but without the emergence of a full consensus on how they should be treated. From an LFG perspective, they have the general appearance of control structures, with a subordinate structure that has more apparent syntactic autonomy than the previous type, but the main and subordinate structures also show evidence of being compacted into a single f-structure (monoclausality), with some evidence against an XCOMP analysis. Studies of these structures appear to have begun in the late eighties and early nineties, early full publications being

Butt (1993, 1995) investigating Urdu, and Alsina (1996) investigating Catalan.[2] These closely related approaches were then presented in shorter form in Butt (1997) and Alsina (1997). Also, Manning (1992) developed arguments about the constituent structures of Spanish, while Andrews & Manning (1993, 1999) made proposals about how to handle these constructions in a substantially modified version of LFG. Somewhat later, people began working on similar constructions in Mainland Scandinavian languages; a recent summary is provided by Lødrup (2014a), citing especially earlier LFG work by Niño (1997) and Sells (2004). This work raises a considerable number of interesting questions at the descriptive level, which however do not seem to have attracted a large amount of theoretical attention.

The work on these constructions is distinguished from the earlier work of Ishikawa and Matsumoto on Japanese by the existence of evidence for monoclausality, indicating that in spite of having the superficial appearance of XCOMP structures, they have a single level of f-structure, constituting the LFG version of the 'Clause Union' of Aissen & Perlmutter (1983) or the 'Restructuring' of Rizzi (1978). This however creates a tension with the evidence for hierarchical semantic interpretations matching the c-structure, for which various solutions have been proposed. The Urdu-Hindi[3] and Romance streams contribute somewhat different elements to the picture; we begin with Urdu-Hindi, then look at Romance, and finally make some briefer observations about Mainland Scandinavian. We conclude the section with some theoretical discussion.

4.1 Urdu-Hindi

Butt (1993, 1995, 1997) considered two kinds of complex predicate structures, the 'permissive', which contrasts in interesting ways with an 'instructive' construction that appears to be an ordinary XCOMP structure, and 'aspectual' complex predicates. The former have assumed a prominent position in subsequent discussion, whereas the latter so far appear to have been of more limited interest.

4.1.1 Permissives

Butt's treatment of permissive constructions has made fundamental contributions to the subsequent discussion in at least two ways. First, she showed that there was a distinction between 'complex predicates' (the permissive) and 'complement structures' (the instructive), each appearing with the same two different constituent structures, one where the subordinate verb is head of its own

---

[2] This was a reworking of the Romance language portion of Alsina (1993).

[3] Urdu put first in this combination, since the actual work is largely directed at Urdu, but with high applicability and close relationship to work on Hindi.

VP, another where it forms a complex verb with a light verb. Since both kinds of structures have been argued for in Romance, it is very significant that they can both be found in a single language. Second, she applied a number of tests originally developed by Mohanan (1994) to show that the permissives were monoclausal. These tests involved phenomena of agreement (with objects), control, and anaphora.

The tests involving anaphora are especially important because they refute the possibility of analysing the permissive as an XCOMP in the manner of Ishikawa or Matsumoto. There are two relevant phenomena, bound anaphora with *apnaa*, and obviation with *uskaa*, as illustrated by this selection of examples from Andrews & Manning (1999):

(10) Urdu

a. Anjum$_i$ ne Saddaf$_j$ ko apnaa$_{i/*j}$ xat likʰ-ne
Anjum$_i$ ERG Saddaf$_j$ DAT self's$_{i/*j}$ letter.M.NOM write-INF
di-yaa
give-PRF.M.SG
'Anjum$_i$ let Saddaf$_j$ write her$_{i/*j}$ letter.'

b. Anjum$_i$ ne Saddaf$_j$ ko us-kaa$_{*i/j}$ xat likʰ-ne
Anjum$_i$ ERG Saddaf$_j$ DAT her$_{*i/j}$ letter.M.NOM write-INF
di-yaa
give–PRF.M.SG
'Anjum$_i$ let Saddaf$_j$ write her$_{*i/j}$ letter.'

c. Anjum$_i$ ne Saddaf$_j$ ko apnaa$_{i/j}$ xat likʰ-ne ko
Anjum$_i$ ERG Saddaf$_j$ DAT self's$_{i/j}$ letter.M.NOM write-INF ACC
kah-aa
say–PRF.M.SG
'Anjum$_i$ told Saddaf$_j$ to write her$_{i/j}$ letter.'

d. Anjum$_i$ ne Saddaf$_j$ ko us-kaa$_{i/*j}$ xat likʰ-ne ko
Anjum$_i$ ERG Saddaf$_j$ DAT her$_{i/*j}$ letter.M.NOM write-INF ACC
kah-aa
say-PRF.M.SG
'Anjum$_i$ told Saddaf$_j$ to write her$_{i/*j}$ letter.'

(10a) and (10b) are permissives, and we see in (10a) that the bound pronominal *apnaa* can be anteceded by the overt syntactic subject *Anjum* but not the overt object functioning as the so-called 'causee agent'[4] *Saddaf.* But the facts are reversed

---

[4] The causee agent is the agent of the embedded verb in a causative/permissive construction.

in (10b) with the free pronominal *uskaa*. Here, coreference with the causee agent is good, with the overt subject bad. In both cases, the facts are as they would be in a simple clause. See Butt (2014) for an updated version of this and other arguments for monoclausality, which includes a discussion of the observation by Davison (2013) that the coindexing in (10a) is an oversimplification of the facts: some speakers do accept coreference with either the overt subject or the causee agent. Butt explains this as a consequence of the fact that cross-linguistically, it is often possible for bound pronouns to accept a 'logical subject' (highest-ranked argument of a predicate) as their antecedent, regardless of whether or not this is a syntactic subject. Intra-speaker variation with respect to examples like (10a) is therefore not a critical problem.

Another important property of the permissive is that it seems to have the same c-structure configurations as the instructive. Either the embedded verb and its complements can appear as a VP, which can scramble as a unit to the front of the sentence, but not be interrupted, or, both verbs can appear as a complex verb with the nominal complements able to be scrambled, in which case the two verbs only move as a unit (Butt 1995: 43–47, 1997: 113–115). A selection of examples illustrating VP scrambling and non-interruptibility is (11–12) below, from Andrews & Manning (1999: 23):

(11) Urdu Instructive (Biclausal)

a. Anjum ne **[ciṭṭʰii likʰ-ne]** ko Saddaf ko kah-aa
Anjum ERG letter(NOM) write-INF ACC Saddaf DAT say-PRF.M.SG
'Anjum told Saddaf to write a letter.'

b. Anjum ne kah-aa Saddaf ko **[ciṭṭʰii likʰ-ne]** ko
Anjum ERG say-PRF.M.SG Saddaf DAT letter.NOM write-INF ACC
'Anjum told Saddaf to write a letter.'

c. *Anjum ne kah-aa **ciṭṭʰ ii** Saddaf ko **likʰ-ne** ko

(12) Urdu Permissive (Monoclausal)

a. Anjum ne **[ciṭṭʰii likʰ-ne]** Saddaf ko d-ii
Anjum ERG letter(NOM) write-INF Saddaf DAT give-PRF.F.SG
'Anjum let Saddaf write a letter.'

b. Anjum ne d-ii Saddaf ko **[ciṭṭʰii likʰ-ne]**
Anjum ERG give-PRF.F.SG Saddaf DAT letter(NOM) write-INF
'Anjum let Saddaf write a letter.'

c. *Anjum ne d-ii **ciṭṭʰii** Saddaf ko **likʰ-ne**

The (b) examples are somewhat degraded for pragmatic reasons,[5] while (c) are ungrammatical.

But there are apparent exceptions to non-interruptibility, which arise exactly when the two Vs are adjacent, motivating a surface complex verb construction, similar to the N+V structures investigated by Mohanan:

(13) Urdu
  a. Anjum ne Saddaf ko **likʰ-ne ko kah-aa** ciṭṭʰ ii.
  b. Anjum ne **likʰ-ne ko kah-aa** Saddaf ko ciṭṭʰ ii.

(14) Urdu
  a. Anjum ne Saddaf ko **likʰ-ne d-ii** ciṭṭʰii.
  b. Anjum ne **likʰ-ne d-ii** Saddaf ko ciṭṭʰii.

This is significant for at least two reasons. First, as emphasized by Butt, it corroborates the thesis of LFG that there are (at least) two distinct levels, c-structure and f-structure, with a substantial degree of independence, since each of the two c-structures can occur with both of the f-structures. Second, both of these c-structures have been proposed for the complex predicates of Romance, with, for example. Manning (1992) arguing for a VP complement of complex predicates in Spanish, similarly to Alsina (1996) for Chicheŵa, while Kayne (1975) and subsequent work arguing for a complex verb treatment of causatives in French. Note that the examples in (13) require that it be possible to annotate an NP in the matrix with xcomp obj (Butt 1997: 117, ex (19a)), as also required for the analyses of Japanese by Ishikawa and Matsumoto.

4.1.2 Aspectuals

The permissive complex predicates appear to have the same semantic structure as many complement structures, for example *let* or *allow* in English, with different c- and f-structural packaging, but the semantics of the aspectual complex predicates is harder to explain. They focus on properties of an action such as completion, initiation and volitionality, without giving an impression of taking the main verb as an argument (as is usually the case with the Romance complex predicates considered below). Rather, Butt uses the general framework of Jackendoff (1990) to endow them with a kind of enriched argument structure that combines with that of the main verb.

Some examples are:

---

[5] P.c. from Miriam Butt to Christopher Manning, 1997.

(15) Urdu

a. Anjum ne ciṭṭi likʰ l-ii
Anjum erg note.f.NOM write take-prf.f.sg
'Anjum wrote a note (completely).' (Butt 1995: 93)

b. vo ro paṛ-aa
he.nom cry fall-prf.m.sg
'He fell to weeping (involuntarily).' (Butt 1995: 109)

c. us ne ro ḍaal-aa
he erg cry put-prf.m.sg
'He wept heavily (on purpose).' (Butt 1995: 109)

Butt shows that these pass the tests for monoclausality, but the only one that is really significant is the obligatory agreement with the object as illustrated in (15a),[6] since, if they were xcomps, the complement and matrix subjects would be the same, so the anaphora and control tests would give the same outcomes. She also shows that the c-structures are somewhat different: since the VP structure is unavailable, only the one with a complex verb is possible.

These constructions seem rather different from the intransitive complex predicates in Romance, which from a semantic point of view appear to be syntactic alternatives to ordinary xcomps. Perhaps for this reason, there seems to have been relatively little further work on them, but see Butt (2010).

4.2 Romance

LFG treatments of complex predicates in Romance languages were developed at about the same time and in close communication with the work on Hindi and Urdu, largely by Alex Alsina and Christopher Manning, as presented in Alsina (1993, 1996, 1997), Manning (1992, 1996b), and Andrews & Manning (1993, 1999), building on earlier work mostly in the frameworks of Relational Grammar and Government-Binding Theory.

Although there are many similarities between the Urdu-Hindi permissive complex predicates and the complex predicates of Romance languages, there are significant differences in some of the more empirically striking phenomena. In the Urdu-Hindi permissives, there is clear evidence for two different constituent structures, one a complex verb, the other a VP complement, both also used by the instructive, which is clearly a control structure, bearing the xcomp GF in

---

[6] Although the agent is semantically feminine, it is also ergative, so the verb cannot be agreeing with it.

f-structure. In Romance, however, although there are also xcomps that are morphologically similar to the complex predicates, they have different word-order properties, suggesting a different c-structure. Many verbs can furthermore appear in either construction, with different verbs having different preferences.

The word-order correlations of xcomp vs complex predicate constructions in Romance do not seem to have been much discussed in the LFG literature, but are considered in Sheehan (2016: 982), who illustrates both constructions being possible for perception verbs in French, where the xcomp structure, Exceptional Case Marking (ECM) in the Minimalist Framework, is preferred:

(16) French

a. Jean voir Marie manger le gâteau.
   Jean sees Marie eat.inf the cake
   'Jean sees Marie eating the cake.' (Sheehan (2016: 982, ex. 8b), ECM/xcomp)

b. Jean voit manger le gâteau à Marie.
   Jean sees eat the cake to Mary
   'John sees Mary eating the cake.' (ex 15a, p983; Sheehan (2016: 983, ex. 15a), Restructuring/complex predicate)

The literature agrees that none of the evidence for being a complex predicate construction can appear with the ECM/control structure word order.

Superficially, for the complex predicates, a complex verb structure similar to that of Hindi seems plausible, but, as we will discuss, the LFG literature provides a number of arguments against this. Another difference is that Romance languages have extensive evidence for different orderings of the light verbs producing different interpretations, as well as a considerably richer system of morphological marking of the semantically subordinate verbs by the light verbs. These phenomena create difficulties for a proposal where the f-structure is flat.

The constructions furthermore have a more diverse semantic range that those in Urdu-Hindi, comprising

(17) a. Causative, including extensions including permission, ordering and persuasion
   b. 'Modal' (ability, possibility, desire)
   c. Aspectual (starting and finishing, as well as Perfect and Progressive)
   d. Associated Motion

Another difference is that while in Urdu-Hindi the list of light verbs appears to be limited and closed, in some of the Romance languages it seems to be larger and hazier; for example Solà (2002: 226–228) lists 31 predicates in Catalan excluding the traditional aspectual auxiliaries, which have clitic climbing for arguments, and he indicates that there are more.[7]

The most widely used argument for clause union is the phenomenon of 'clitic climbing', whereby a preverbal clitic appears in front of the light verb rather than next to the verb it is an argument of:

(18) Spanish
Lo quiero ver.
it want.1.SG see.INF
'I want to see it.'

In principle, this argument can be circumvented by allowing the clitics to carry annotations such as '(↑ XCOMP* OBJ)=↓', but there are some issues with this, such as the fact noted originally by Rizzi (1978: 120) that in Italian, the capacity for clitics to climb disappears when the putative XCOMP is preposed by *wh*-movement (and in various other situations):

(19) Italian
a. questi argomenti, dei quali ti verrò a parlare
these arguments of.the which you.DAT come.FUT.1SG to talk.INF
al più presto, …
as soon as possible
'these arguments, about which I will begin to talk as soon as possible, …'
b. *questi argomenti, a parlare dei quali ti verrò
these arguments, to talk.INF of.the which you.DAT come.FUT.1SG
a più presto …'
as soon as possible
'these arguments, about which I will begin to talk as soon as possible, …'

In LFG, this would minimally indicate that there were two possible annotations for these apparent VPs, one allowing (pied-piped) *wh*-movement, the other not. An important characteristic of clitic climbing, discussed by Sheehan (2016) and also by Andrews & Manning (1993) is that it is not in general obligatory, but

---

[7] Note also the relevant observation of García (2009: 185), working in a strongly functionalist approach, that constructions that normally reject indications of being a complex predicate, such as clitic climbing (see below) may accept it under certain pragmatic conditions.

optional, subject to complex preferences and conditions, discussed extensively from a functional perspective by García (2009).

Various further arguments from the literature are reviewed from an LFG perspective in Andrews & Manning (1999: 47–59) of which we will specifically mention one for Catalan from Alsina (1996: 217), which shows that the apparent complement in a restructuring construction does not have a subject, unlike an XCOMP. The argument is that causee agents can't host bare floated quantifiers, although non-overt equi-infinitive subjects can:

(20) Catalan (Alsina, p.c.)

a. Els metges$_i$ ens$_j$ deixen beure una cervesa cadascun$_{i/*j}$.
the doctors us let drink a beer each
'Each of the doctors let us drink a beer.'
*'The doctors let each of us drink a beer.'

b. Els metges$_i$ ens$_j$ han convençut beure una cervesa cadascun$_{i/*j}$.
the doctors us have convinced drink a beer each
'Each of the doctors has convinced us to drink a beer.'
*'The doctors have convinced each of us to drink a beer.'

This is the same kind of argument for clause union as the ones from anaphora for Hindi and Urdu by Mohanan and Butt.

The arguments for clause-union in Romance are similar to those from Urdu-Hindi, but the situation with c-structure is somewhat less clear, in that there is nothing comparable to Butt's argument that both a VP and a complex V structure are available. Rather, both have been argued for, complex Vs mostly in HPSG (Abeillé & Godard 1994, 1996) and VP complements in LFG. Manning (1992, 1996b) presenting arguments drawing heavily on previous work by Kayne and others on French, observes that clitics can climb out of coordinated VPs each with their own causee agent in Spanish as well as French:

(21) a. French
Marie le ferait lire à Jean et dechirer à Paul.
Marie it will.make read.INF to Jean and tear up.INF to Paul
'Marie will make Jean read it and Paul tear it up.'

b. Spanish
Carlos me estaba tratando de topar y de empujar contra María.
Carlos me was trying of bump.INF and of push.INF against Maria
'Carlos was trying to bump into me and push me against Maria.'

He counters proposals to use coordination reduction to explain this away.

Alsina (1997: 226) gives an argument from coordination and provides additional ones from nominalization and from the fact that various elements, such as sentence adverbials set off by comma-pauses, can be inserted between the main and light verbs:

(22) Catalan

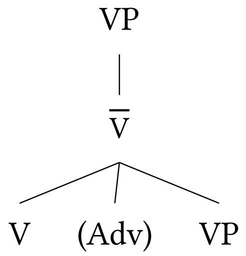
a. La Maria ha fet de debó riure el nen.
the Mary has made truly laugh.INF the boy
‘Mary has truly made the boy laugh.’

b. La Maria ha fet, em penso, riure el nen.
the Mary has made I think laugh.INF the boy
‘Mary has made the boy laugh, I think.’

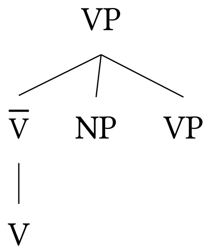
Although it is often possible for certain kinds of particles to be inserted into complex verb structures,[8] this seems to be more than is generally allowed, vindicating the argument.

Although the LFG literature does not have much to say about the c-structure of the complex predicates, I suggest that it is reasonable to propose that they are expansions of an ‘inner VP’, or $\overline{\text{V}}$, to V and VP, as in (23a), whereas the XCOMP/control/ECM constructions are expansions of VP, as in (23b):

(23) a.



b.



The nature of the c-structure difference remains to be fully elucidated.

---

[8] As discussed for Tariana by Aikhenvald (2003) and Jaminjung by Schultze-Berndt (2000).

Although the nature of the constituent structure of Romance complex predicates is not entirely clear, something that is clear is the effect of the c-structure on semantic interpretation. Alsina (1997: 238) provides examples that show the same light verbs appearing in different arrangements in Catalan clause union constructions, and Solà (2002: 239) provides a few more:

(24) Catalan

a. Li acabo de fer llegir la carta.
him.DAT finish.1SG of make.INF read.INF the letter
'I finish making him read the letter.' (Alsina 1997: 238)

b. Li faig acabar de llegir la carta.
him.DAT make.1SG finish.INF of read.INF the letter
'I make him finish reading the letter.' (Alsina 1997: 238)

c. Les pot aver vistes.
them.F.PL can.SG have.INF seen.PST.PTCP.F.PL
'He/She can have seen them.' (Solà 2002: 239)

d. Les ha pogudes veure.
them.F.PL have.3SG been able.PST.PTCP.F.PL see.INF
'He/she has been able to see them.' (Solà 2002: 239)

In Urdu, on the other hand, multiple light verbs occur in an order consistent with semantic interpretation, assuming head-final ordering, but no cases of multiple possible orderings have been produced. The issue of how to control the semantic interpretation in Romance languages is therefore more acute, and there is disagreement about how to do it, as we discuss below.

A final characteristic of Romance is a substantially greater variety of subordinate verb forms. There are three inflectional categories, infinitive, active (present) participle, and passive (past) participle, the latter occurring in both agreeing and non-agreeing forms, with the further problem of specifying the verb-markers as such *a* 'to/at', *de* 'of' and others, mostly historically prepositions. This means that the question of how the marking of the subordinate verb is to be accomplished is more acute. However, the theoretical treatment is not as troublesome as the semantics, as we shall see.

4.3 Mainland Scandinavian

The most striking feature of the Scandinavian constructions is that their most obvious evidence for monoclausality is apparent verbal feature agreement between the light verb and its semantic complement, as illustrated in these examples from Norwegian:

(25) Norwegian (Lødrup 2014a: 4)

a. Forsøk å les!
try.IMP to read.IMP
'Try to read!'

b. Det har jeg glemt å fortalt.
that have.PRS I forget.PTCP to tell.PTCP
'I forgot to say that.'

c. Jeg prøvde å leste det lure smilet hennes.
I try.PST to read.PST the sly grin.DEF her
'I tried to read her sly grin.'

The inflectional agreement in the above examples is optional, most common with imperative forms (25a), less common with participles (25b), and possible for only some speakers with the finite past (25c).

The most-discussed evidence for reanalysis is 'long passives', which are arguably produced by morphological features associated with passive voice being shared across the two levels, as analysed by Lødrup (2014b). An example is:

(26) Norwegian (Lødrup 2014b: 388)
at vaskemaskin-en må huskes å slås på
that washing machine-the must remember.INF.PASS 'to' turn.INF.PASS on
'that you must remember to turn on the washing machine'

While the tense-mood features of (25) appear to percolate down from the upper to the lower verb, the voice feature of (26) percolates in the opposite direction, in a manner somewhat reminiscent of the analysis of auxiliary selection in Italian in Andrews & Manning (1999: 56–60).[9] This suggests that this is a complex predicate structure where both verbs are associated with the same f-structure. Lødrup discusses further verbal constructions similar to these that do not appear to be complex predicate constructions; space precludes discussing them here. Similar phenomena appear to be found in Swedish and Danish, but have not been reported for Icelandic.

---

[9] Due to Manning, according to my recollections.

4.4 Theoretical approaches

A central conclusion from the data of these languages is that the apparent multiple levels of c-structure correspond to one level of f-structure. For example, according to both Butt's and Alsina's analyses, the f-structure of (24a) would be:

(27)
$$\begin{bmatrix}
\text{SUBJ} & \begin{bmatrix}\text{PRED} & \text{`PRO'}\\ \text{PERS} & 1\\ \text{NUM} & \text{SG}\end{bmatrix}\\
\text{PRED} & \text{`FINISH-MAKE-READ'}\\
\text{OBJ} & \begin{bmatrix}\text{SPEC} & \text{DEF}\\ \text{GEND} & \text{FEM}\\ \text{NUM} & \text{SG}\\ \text{PRED} & \text{`LETTER'}\end{bmatrix}\\
\text{OBJ}_{\theta} & \begin{bmatrix}\text{CASE} & \text{DAT}\\ \text{NUM} & \text{SG}\\ \text{PERS} & 3\end{bmatrix}
\end{bmatrix}$$

There are three problems that arise:

(28) a. The morphological marking

b. The combination of multiple PRED-values into one

c. The effect of arrangement on semantic interpretation

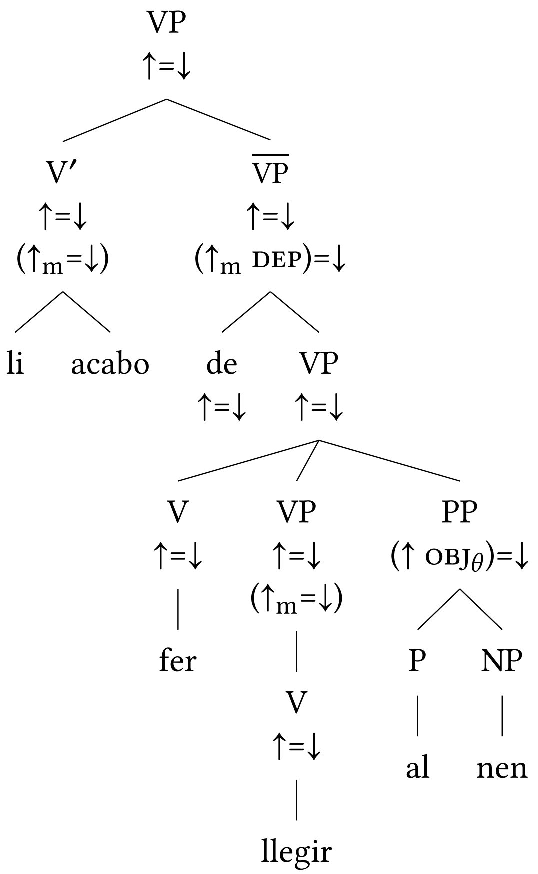
(28a) is the easiest to deal with, because, as discussed in Butt et al. (1999) it can be managed by proposing a morphological projection (m-structure), that comes directly off c-structure, where the relevant featural information can be stored. The m-structure attributes normally proposed are VMARK with values DE, A, etc, for the apparently prepositional marking, and VFORM for the inflectional categories, with values FIN, INF, PRS.PTCP and PST.PTCP. The relevant parts of the lexical entries for the light verbs in (24) will then be:

(29) a. *acabo*: $(\uparrow_{m}\ \text{DEP VMARK}) = \text{DE}$, $(\uparrow_{m}\ \text{DEP VFORM}) = \text{INF}$, $(\uparrow_{m}\ \text{VFORM}) = \text{FIN}$

b. *fer*: $\neg(\uparrow_{m}\ \text{DEP VMARK})$, $(\uparrow_{m}\ \text{DEP VFORM}) = \text{INF}$, $(\uparrow_{m}\ \text{VFORM}) = \text{INF}$

The c-structure will annotate all of the VPs with $\uparrow=\downarrow$ for f-structure, but will assign to them a DEP-value in m-structure:

(30)



The forms can then be managed, and this solution will clearly also work for Hindi.

There is however a potential problem, which is that it was later argued by Frank & Zaenen (2002) that m-structure ought to come off f-structure rather than c-structure directly. With this change, form-determination becomes more complicated. Their solution, which involves rather complex stipulation, works for French auxiliaries, but as discussed by Andrews (2018b), it does not seem very plausible for the richer system of light verbs found in some of the other Romance languages such as Catalan. But we will not pursue this further here, and consider instead the next problem.

This is that if both the main verbs and the light verbs are construed as having PRED-features, the f-structure annotations will produce a PRED-value clash. Within mainstream LFG there have been three proposed solutions. The first was proposed in an earlier form by Alsina (1996: 189), and then in a later, more formal form by Alsina (1997: 235–237). Although it was criticized extensively by Andrews & Manning (1999: 28–34), I think it can be further revised to reduce the force of some of their criticisms.

The core of Alsina's proposal is the idea that light verbs have an empty argument position into which the pred-value of their semantic complement is substituted. A schematic illustration is:

(31) 'cause⟨[P-A] [P-P] P*⟨...[ ]...⟩⟩'

'[P-A]' and '[P-P]' represent the proto-agent and proto-patient roles of Dowty (1991), 'P*' the unspecified predicate that is to be plugged in, and the underbar the fact that in the 'direct causative' construction, the patient of the causative verb is to be identified with some argument of the caused verb. Given (32a) as the subordinate verb to be plugged in, a possible result is (32b):

(32) a. 'read⟨[P-A] [P-P]⟩'
b. 'cause⟨[P-A] [P-P] read⟨[P-A] [P-P]⟩⟩'

Alsina does not present this in an attribute-value notation where the usual methods for unification in LFG apply, but this is clearly a triviality. In what follows, it will be useful to assume that the empty predicate slot in the light verb is the value of an attribute such as parg, in order to formalize the construction of a complex predicate such as (32b) in a more conventional notation.

The next component is the idea that the '↑=↓' annotation on the VP complement of a light verb is either interpreted in a special way (Alsina 1996) or replaced by something a bit different (Alsina 1997). We take the second approach. Here, these VPs are annotated with the novel annotation $\uparrow_H{=}\downarrow$, which is interpreted as follows. The two most important provisions are that the pred-values are not shared between the levels, which can be accomplished with the LFG device of 'restriction', and second, the pred-value of the VP is plugged into to parg-value of the light verb's pred. This can be formalized as follows:

(33) $\uparrow_H{=}\downarrow \quad = \quad \uparrow\backslash_{\text{PRED}} = \downarrow\backslash_{\text{PRED}}$
$(\uparrow \text{PRED PARG}) = (\downarrow \text{PRED})$

This treatment is close to that proposed later for Urdu by Butt & King (2006), the difference being that they also propose a different approach to argument structure and linking.

Alsina's treatment as exposited is a bit less clear than it could have been, because he attaches $\uparrow_H$ to both the light V and its semantic complement VP, which isn't necessary, as noticed implicitly by Butt & King (2006: 241). Manipulating argument-structure in c-structure rules might seem somewhat odd, but these constructions are difficult and seem to resist fully conventional treatments.

The final ingredient is a linking theory. Alsina's and Butt's analyses both require a linking theory that will apply to assembled syntactic structures rather than individual lexical entries. This is a substantial change from the original conception of Lexical Mapping Theory, which was supposed to apply to items listed in the lexicon. Alsina's and Butt's approaches differ in detail, but the basic idea is that the argument structure positions are assigned grammatical relations in accordance with prominence hierarchies, so that the most prominent will be expressed as SUBJ unless the verb is passive, in which case it is expressed as an oblique. The linking theories for complex predicates, including that of Andrews & Manning (1999) furthermore remained somewhat informal until recently, with the proposals of Lowe (2016) to use glue semantics, and Andrews (2018b) to use the 'Kibort-Findlay Mapping Theory' as developed in Asudeh et al. (2014) and Findlay (2016). We will however not pursue linking theory here, but rather review some follow-up proposals to the original analyses.

Andrews & Manning (1999) proposed to reanalyze the material in a way that was in some respects not so different from the original analyses, but set within a rather substantial reorganization of LFG. Rather than there being the two central levels of c-structure and f-structure, it was proposed that all attributes are in the first instance assigned to c-structure, nodes, and then differentially shared by annotations stated in terms of classes of attributes that share in different ways, some more aggressively than others. The bar-features of $\overline{\mathrm{N}}$ theory, for example, would be shared between mother and daughter in only certain coordinate structure and modificational configurations. category features more widely (between N (=N^0) and NP (=N^2), for example). Clause union complex predicates would then have sharing of the grammatical functions SUBJ, OBJ and OBJ_θ and others (which were called the ρ-projection) between the upper and lower VPs, while XCOMPs would not. The morphological features would however not be shared, effectively including in the analysis a kind of morphological projection, of the original kind, coming off of c-structure, rather than f-structure.

This approach reflects a difference in philosophy from Alsina's: he proposes that light verbs and the predicates of their semantic complements combine in a fundamentally different way from ordinary complementation, producing a genuine 'complex predicate', from which follow the peculiarities of linking and the evidence for clause union. Andrews and Manning did not share this intuition. In their account, the light verb constructions appear in very similar configurations to those of the complement structures, the main difference being that the former share grammatical relations while the latter do not,[10] but have their se-

---

[10] The VP complements of the light verbs are introduced as values of an attribute ARG, which might in principle be the same as XCOMP, as long as the latter is not in the ρ projection. This issue is not discussed in the text. In the earlier version of this approach presented in Andrews & Manning (1993), ARG had to be a different attribute than XCOMP.

mantic complements introduced by a different attribute, ARG, that is on a different projection than the f-structural attribute XCOMP, but the mode of semantic composition is fundamentally the same.

This could be defended on the basis that there do not appear to be major semantic differences between the structures where ARG is motivated versus the ones without clitic climbing that call for XCOMP. By contrast, many of the complex predicates investigated by Butt and Mohanan really do seem to involve closer combination between the light verb and the heavy verb, as indicated by Butt's introduction of aspects of Jackendoff's conceptual structures. This leads to a further issue, the treatment of auxiliaries. Butt (2010) argues strongly that auxiliaries are not light verbs, on the basis of having different general behavior and historical trajectories. But in Romance languages, they tend to show the typical behavior of the light verbs, including clitic climbing, and the capacity to condition the form of their apparent complements, and the non-auxiliary light verbs seem to have the semantics of ordinary complement structures in other languages. Catalan *voler*, for example, with restructuring, seems to have essentially the same meaning as English *want*, which does not show clear evidence of restructuring from the perspective of LFG.[11] By contrast, the Urdu light verb contrast between *paṛ* 'fall' and *ḍaal* 'put' signifies contrast between accidental and volitional action, respectively (Butt 1995: 108–109), in a way that is not well captured by the usual kind of semantic composition proposed for complements.

There are three further analyses to consider, Butt and King's 2006 analysis of Urdu, Lowe's (2016) rather different analysis of the same language, and Andrews' (2018b) analysis of Romance. Butt and King's treatment is very similar to the modified version of Alsina's analysis proposed here, but differs in one important respect: it does not use linking theory, but rather uses restriction to prevent the SUBJ and OBJ_{GOAL} (grammatical function of the causee agent) from being shared between the two levels, but uses an equation to identify their value (Butt & King 2006: 241, ex. 8). This might generalize to Romance, but faces a problem in both Romance and Hindi (also, presumably, Urdu), which is that it does not explain the evidence (from anaphora in Urdu, and subject-oriented adverbs in Catalan) that the causee agent is not a subject. In a sentence such as (10a), for example, the subject-bound anaphor *apnaa* is sitting in a clause nucleus whose SUBJ-value is *Saddaf ko*, so it is not clear why it cannot be bound by it, even though the

---

[11] However Grano (2015) argues within Minimalism that English *want* does have restructuring (and similarly for even more superficially biclausal constructions in Modern Greek). But his arguments are based mainly on the inability of various modifiers to appear, as can be explained by the absence of certain functional projections (or perhaps semantic operators), rather than shared f-structures, which is the basis for clause-union in LFG.

f-structure in which this happens is not actually part of the f-structure of the matrix S, due to the operation of restriction.

The 1999 analysis of Andrews and Manning and the 2006 analysis of Butt and King lack a feature that is relatively typical for LFG, which is that the f-structure of a c-structure constituent contains the f-structures of all of that constituent's subconstituents. We might call this property 'monotonicity of f-structure (with respect to c-structure)'. When this property is discarded, analyses involving functional uncertainty can fail in ways that are difficult to predict, which might provide a reason for preferring other kinds of analyses if they are available. A further, related point is that 'forgetting' much of the abstract structure of subconstituents is an essential characteristic of HPSG with its head-feature constraint. It is plausibly a good idea to develop LFG in ways that are clearly distinct from HPSG. The next two analyses retain f-structure monotonicity.

The second one is that of Lowe (2016) of Urdu, which neither uses restriction nor proposes any changes to the LFG framework, but makes use of two different ideas. The first is to treat the light verbs as not having PRED-features, but introducing grammatical features such as [PERMISSIVE +]. This is workable for Urdu-Hindi, because the inventory of light verbs is clearly closed, and they are semantically bleached, but less plausible for Romance, because the inventory is larger, and, as we have previously discussed, not so sharply delimited, and many of the verbs have considerable lexical content, as discussed in the previously mentioned Solà (2002). On the other hand, given glue semantics, it is not clear exactly what the PRED-features are accomplishing, so this might not really be a problem. Given that there is no problem of conflicting PRED-features, a rather clever glue semantics trick is used to get the right interpretation, which cannot be explained properly in the limited space available here. Given the use of a morphological projection or similar device, the analysis solves all problems except for the dependence on the c-structure for scopal interpretation in Romance. In particular, since the causee agent NP is in no way at any level a value of SUBJ, there is no problem with either the phenomena of anaphora in Urdu-Hindi or the floating quantifiers in Catalan. Lowe (2016) also provides an extremely thorough discussion and critique of all previous analyses of complex predicates in LFG.

The final analysis, that of Andrews (2018b), solves the problem of hierarchical interpretation without using a distinct morphological projection, but also obeys f-structure monotonicity. It has significant similarities to the analyses of both Andrews & Manning (1999) and Butt & King (2006). It require some modification to the LFG framework, although a considerably less extensive one than Andrews and Manning's approach. The basic idea is to apply the concept of 'distributive attribute' and 'hybrid object' from Dalrymple & Kaplan (2000) to sets with a single member, so that a complex predicate structure is taken to be a hybrid object with the semantic complement as a set-member:

(34)
$$\left[\begin{array}{l} \textsc{pred}\ \text{`}\textsc{let}\text{'} \\ \ldots \\ \left\{\left[\begin{array}{l}\textsc{pred}\ \text{`}\textsc{write}\text{'}\\ \ldots\end{array}\right]\right\} \end{array}\right]$$

This provides appropriate places to locate the morphologically required features, without requiring a new projection, and also a structure to determine the semantic interpretation, at the cost of requiring a certain amount of stipulation to distinguish the features that need to be shared versus those that cannot be. The Kibort-Findlay Mapping Theory is used to get appropriate interpretation of the arguments of the verb without having to treat the causee agent as a SUBJ-value.

5 Morphologically integrated complex predicates

These are constructions which might be analysed as derivational morphology, but for various reasons have invited analysis as morphologically compacted versions of the previous constructions. The two main examples are Ishikawa (1985) for Japanese, and Alsina (1997) for Chicheŵa, extending their analyses for the previously discussed complex predicate constructions (in the authors' terminology) to the current ones.

5.1 Ishikawa and Matsumoto on Japanese

To analyse Japanese *-(s)ase-* causatives,[12] Ishikawa uses the technique from earlier LFG work such as Simpson (1983) of allowing word-level phrase-structure rules to introduce stems or affixes with a grammatical function. For example, the verb stem *aruk-ase* in example (35a) below is given the tree structure (35b):

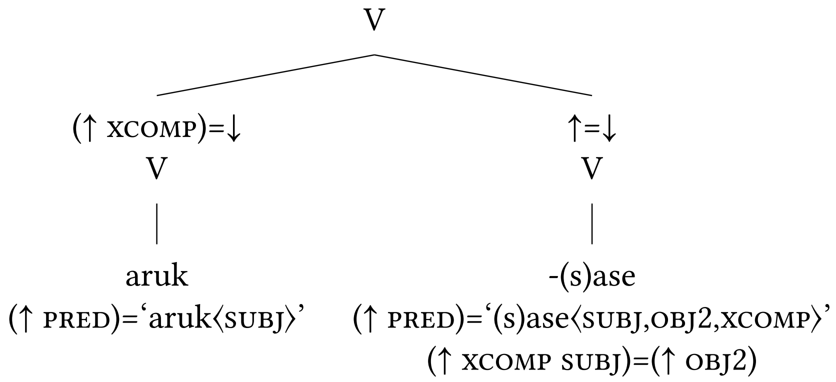
(35) Japanese (Ishikawa 1985: 98)

a. John ga Mari ni/o aruk-ase-ta
John NOM Mary DAT/ACC walk-cause-PST
'John caused Mary to walk.'

---

[12] The initial *s* appears after stems ending in a vowel, but is absent after a consonant.

b.



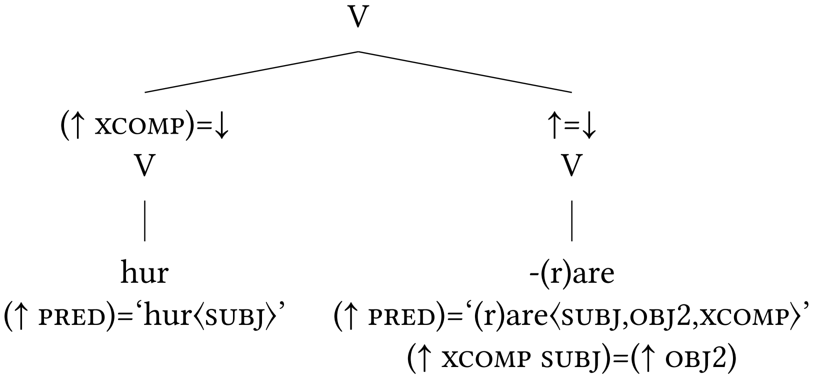
The difference between dative and accusative on the causee agent is semantically significant, treated as whether the grammatical function is iobj2 (currently designated as obj$_{\theta}$) for the dative or obj for the accusative.

Ishikawa extends this analysis to the ‘indirect’ or ‘adversative’ passive, in which the subject is characterized as suffering the effect of the action (Kuno 1973: 303):

(36) Japanese (Ishikawa 1985: 106)
John ga ame ni hur-are-ta
John nom rain dat fall-pass-dat
‘John suffered from rain falling.’

The annotated c-structure for this is:

(37)



There has been a dispute as to whether the adversative passive must always add a new argument, or can be similar in appearance to the regular passive, but expressing adversity to the overt (promoted) subject. Kuno says no, while Ishikawa (1985: 114–124) says yes, although the arguments are complex, and depend on too many details of Japanese for further discussion here.

Matsumoto (1996) provides a similar analysis, but implemented somewhat differently, for causatives, and also certain desideratives. For the latter, he argues that desideratives which take the desired event object as an accusative have a biclausal structure, while the ones where this object is nominative are monoclausal:

(38) Japanese (Matsumoto 1996: 103)

a. boku wa hon o yomi-tai
I TOP book ACC read-want
'I want to read the book.'

b. boku wa hon ga yomi-tai
I TOP book NOM read-want
'I want to read the book.'

The argument that Matsumoto makes is complex, and depends on the possibilities for passivization. One point is that the desiderative forms an adjective rather than a verb, and adjectives as such cannot be passivized. However there is a way out: adjectives of subjective state can be verbalized by adding the suffix *-gar*, meaning 'to show signs of being in the state'. These derived verbs are natural with non-first person subjects, which the original adjectives are not. Although these derived verbs take accusative objects, there is a difference in passivization: the ones whose base forms reject *ga*-marked objects are also the ones that are acceptable in the passive. These are the ones where the subject in some sense wants to 'have' the object:

(39) Japanese (Matsumoto 1996: 107)

a. boku wa sono hon o/ga yomi-tai
I TOP the book ACC/NOM read-want
'I want to read the book.'

b. boku wa kare o/*ga machi-tai
I TOP him ACC/NOM wait-want
'I want to wait for him.'

It is the verbal forms derived from the desideratives that accept *ga* on their patients that can be passivized:

(40) Japanese

a. sono hon wa minna ni yomi-ta-gar-arete-iru
the book TOP all DAT read-want-VBLZ-PASS-ASP
'The book is in such a state that everybody wants to read it.'

b. *kare wa minna ni machi-ta-gar-arete-iru
He top all dat wait-want-vblz-pass-asp
'He is in such a state that everybody wants to wait for him.'

'Long passives' are possible in some but not all of the languages with the complex predicate constructions discussed in the previous section (present in Italian and Catalan, but not in Spanish), but the contrast between these examples does indicate that there are two different constructions. Matsumoto also discusses differences in adjunct interpretation and verbal anaphora to justify the proposed distinction between biclausal and monoclausal.

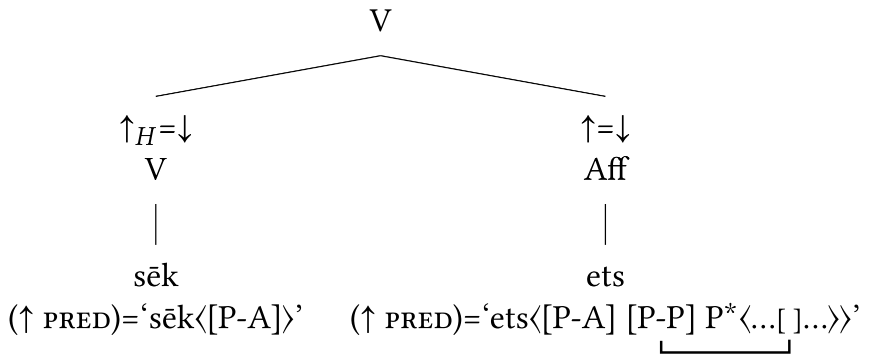
Unfortunately, there does not appear to have been much follow-up to compare Ishikawa's and Matsumoto's analyses with the later ones of Bantu and Hindi-Urdu, to which we turn next.

5.2 Alsina on Bantu, and similar constructions

Alsina (1997) presents an analysis of causatives in Chicheŵa, based on the same account of argument structure and predicate-composition as presented in Alsina (1996). The difference from the treatment of Catalan is in the c-structure: in both cases, the c-structures are monoclausal, but in Chicheŵa, the causative element is treated as an affix to the Caused verb stem, rather than an independent morphological stem, as in Catalan. Alsina provides convincing evidence for this difference.

The c-structures are identical to those proposed by Ishikawa and Matsumoto for Japanese, but the annotations are different: they are the same as they would be for Catalan (assuming my claim that we only need the special annotation for the semantic complement, not the head, and adjusting the lexical entries to fit Alsina's linking theory):

(41)



The analysis actually works a bit better for this construction than the Romance one, because we do not have to worry about conditioning the subordinate verb form, and the problem of different orderings having different semantic interpretations does not arise.

This form of analysis has been extended more widely to other ‘valence change’ constructions, including reciprocals in Chicheŵa (Alsina 1997), passives and antipassives in a variety of languages (Manning 1994, 1996a), and causatives and applicatives in Australian languages (Austin 2005). Complex-predicate-based analyses of morphologically based valence change do not however appear to have been much pursued in recent years. The most recent LFG analysis of passives is, for example, within the Kibort-Findlay Mapping Theory (Findlay 2016), and does not use a complex predicate analysis.

Typology seems to provide some warrant for questioning these analyses. Passive constructions (or, more precisely, constructions in various languages that are often called ‘passive’) do often involve auxiliary verbs in what might plausibly be complex predicate constructions, but those normally called antipassives are to the best of my knowledge always morphological, and apparent complement structures that are actually complex predicates seem likewise to be nonexistent for reflexives and reciprocals. Another intriguing asymmetry arises with causatives and applicatives. As discussed by Austin (2005), it is not unusual for morphological causatives and applicatives to use the same formative.

Austin analyses these in various Australian languages as having the applicative/causative morpheme introduce a light verb AFFECT, with the difference between causative and applicative senses being based on different patterns of argument identification. Sample causative and applicative combinations are (Austin 2005: 32–33):

(42) a. Causative:
AFFECT < Ext Arg Int Arg PRED < Arg >>
+vol −vol −vol
e.g. ‘The man turned the child.’

b. Applicative:
AFFECT < Ext Arg Int Arg PRED < Ext Arg Goal/Loc >>
+vol −vol +vol −vol
e.g. ‘The man laughed at the child.’

In the causative, the agentive argument of the AFFECT predicate is identified with the unaccusative argument of the embedded predicate, while in the applicative, the agentive arguments of the two predicates are identified, and also the second argument of AFFECT and a locative/directional argument of the embedded verb.

This captures the idea that applicatives of such verbs often express a meaning to the effect that the locative/directional is affected by the action.

There is however perhaps a typological issue with the analysis: the causative is often expressed by constructions that look like and often seem to actually be complement constructions, but this is not the case for applicatives, whose sense is however sometimes expressed by serial verb constructions, as we consider in the next section. This typological difference suggests a fundamental structural one, but there is also evidence for a relationship, in that the same formative is sometimes used for both. What I suggest is that the AFFECT concept is common to both, with argument sharing as proposed by Austin, but that the structural relations are different. We can partially express them using the 'Natural Semantic Metalanguage' (NSM) approach of Anna Wierzbicka and her colleagues (Wierzbicka 2006, Goddard 2011), which can be regarded as being a technique for expressing meanings in simple terms that are found to be highly translatable.[13] In the case of causatives, the sense is:[14]

(43) X does something to Y
Because of this, <Caused Event>

In the case of applicatives, there does not seem to be any caused event distinct from what X does to Y, rather what X does *constitutes* X doing something to Y. For this I suggest the following:

(44) <Applied event, performed by X involving Y>
This is X doing something to Y.

This is not of course anywhere near a full explanation of the differences between the constructions, but it is perhaps a start. In particular, it seems plausible that the identity relationship expressed in (44) is not something that is normally expressed by complement structures.

Neither these contemporary analyses of morphological causatives and valence change operations, nor the earlier ones by Ishikawa and Matsumoto, in which they are morphologically expressed XCOMP structures, have received much discussion in recent years.

---

[13] Andrews (2016) is an attempt to express the basic ideas of NSM in a form that might make some sense to people trained in formal semantics.

[14] NSM accounts (called 'explications') of the causative tend to include 'after this' after 'because of this', but I suggest that this is better treated as an inference licensed by a law that effects come after their causes (at least in the local timeline of an individual, ignoring scenarios from science fiction).

6 Serial Verb Constructions

Our last type is SERIAL VERB CONSTRUCTIONS (SVCs). Perhaps the first issue that arises with these is the rather controversial one of defining them. I will here roughly follow Aikhenvald (2006b) in defining them as structures where:

(45) a. There is some evidence of at least partial clause union.
     b. There is no explicit marking of subordination or coordination.

(45a) is an indication that SVCs are complex predicates or at least control structures, while (45b) has no clear status in a formal syntactic analysis of these constructions, but is plausibly very important for their functional characteristics and tendencies in diachronic development, since they do not provide much in the way of overt cues as to what their syntactic structure is.

SVCs have not received much attention in the LFG literature, the main exceptions being the treatment of Tariana in Andrews & Manning (1999),[15] the treatment of Dagaare and Akan (with observations about other languages) in Bodomo (1997), and the recent analysis of Barayin in Lovestrand (2018). In this section, I will consider these three languages, and then take a brief look at Misumalpan causatives, treated as complex predicates by Andrews & Manning (1999), but argued to be something different in Andrews (2018a).

6.1 Tariana

Tariana SVCs[16] consist of a sequence of verbs inflected identically for person, with some further grammatical markers appearing once, in a number of positions. A fundamental division in these constructions is between the 'symmetric' SVCs, which look and act like coordinated verbs (but without any overt coordinator), and the 'asymmetric' ones, which are diverse, but many of them are semantically similar to Romance complex predicate structures, and have some capacity to occur embedded in each other. Andrews & Manning (1999) took this as a basis for analysing the two with similar feature-structures, but differing in the c-structures. A particularly striking piece of evidence for the monoclausality of these constructions is the phenomenon of 'concordant dependent inflection', whereby the caused verb shows subject agreement with the causer, presumably on the basis that this is the subject of the entire construction, rather than the causee agent, its own agent. This is illustrated in the following example:

---

[15] With an update to the framework of Andrews (2018b) in Andrews (2018a).

[16] For a descriptive account see Aikhenvald (2003, 2006a).

(46) Tariana (elicited, Aikhenvald p.c.)
nu-na=tha nu-ra nu-sata dineiru
1SG-want=FRUSTR 1SG-order 1SG-ask money
'I want to order (him) to ask for money.'
(Modal on causative)

In the Andrews and Manning analysis, the light verb shares both the f-projection and the a-projection (roughly equivalent to f-structure and argument structure) with the c-structure mother, while its semantic complement shares only the f-structure, and is introduced into the a-structure as the value of an attribute ARG. In the later version of Andrews (2018a), the light verb has ↑=↓, while the main verb is introduced as a set member.

The various other kinds of analyses we considered would work for Tariana as well as they do for their original subject material, and there would be no need to involve a morphological projection to control the government of the forms of the semantic complement verbs by the light verbs.

6.2 Dagaare and Akan

Most Tariana SVCs can be treated as either syntactically coordinate structures (symmetric SVCs) or as an expression of Romance-type restructuring predicates (asymmetric SVCs), with a different technique of morphological expression. But Dagaare and Akan, two major languages of Ghana discussed by Bodomo (1996, 1997), have additional SVC constructions that do not submit to such analyses, and require something different. These are also considerably more similar than Tariana SVCs to the constructions commonly called SVCs in many other languages.

Bodomo (1997: 80–84) discusses a number of types. One of their characteristics is that in some of the cases, such as action-causation, no plausible suspect for being the 'light verb' can be identified:[17]

(47) Dagaare
a. Benefactive:
o da tong la toma ko ma
3SG PST work(V) FACT work(M) give me
'S/he worked for me.'
b. Action-Causation ('Causative'):
o da daa ma la lɔɔ
3SG PST push me FACT cause-fall
'S/he pushed me down.'

---

[17] *la* is the 'Factive' particle in Dagaare, marking positive affirmations (Bodomo 1997: 65–69).

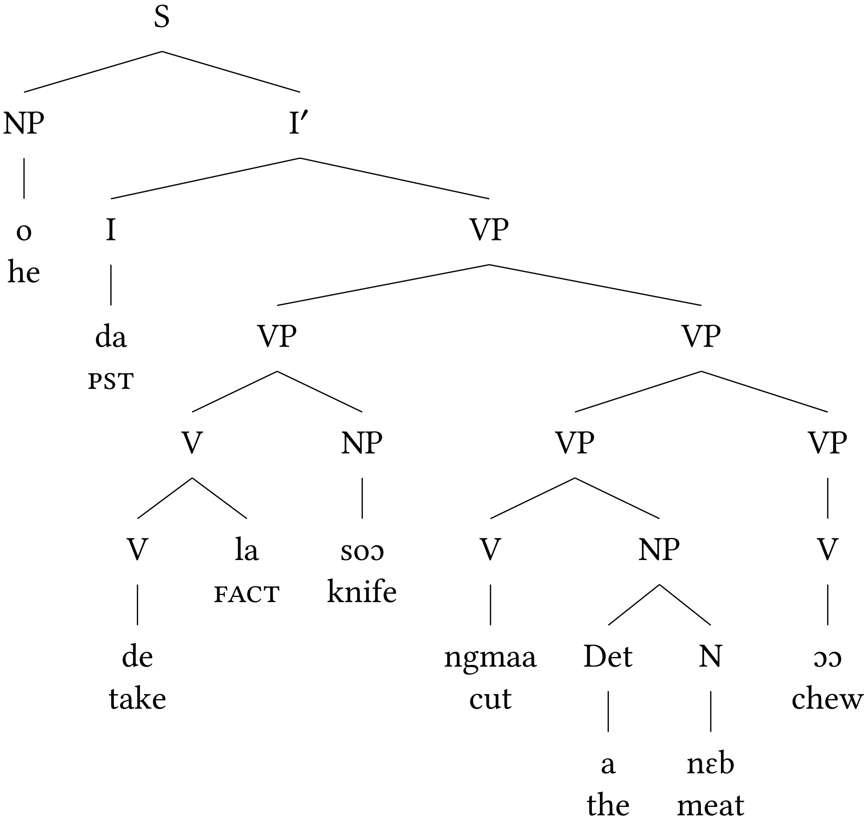
c. Inceptive *take* serialization:
o de la gan ko ma
3sg take fact book give me
‘S/he gave me a book.’

d. Instrumental *take* serialization:
o da de la sɔɔ ngmaa a nɛb ɔɔ
3sg pst take fact knife cut def meat chew
‘S/he cut the meat with a knife and ate it.’

e. Deictic (Directional/Associated Motion)
o da zo wa-ɛ la
3sg pst run come.prf fact
‘S/he ran here/S/he came by running.’

At the level of c-structure, Bodomo proposes flat binary VP structures without specifying what would happen in examples such as (47d) above that might involve nesting, as I suggest below:

(48)



My proposed account is that the upper pair of VP’s constitute instrumental serialization, while the pair embedded under the rightmost member of the upper are a collocation (a type not listed in (47) meaning ‘eat’). Bodomo is however not clear about this, and a flat structure of three VPs sitting under one would be consistent with the text.

For the f-structure analysis, he follows Alsina, with the modification that since it is frequently impossible to regard one of the verbs as light and another as heavy, the two PRED-values are integrated into a ‘PREDCHAIN’ value in a manner that can be formalized in various ways (no specific one is chosen).

The semantics is treated with a ‘cell theory’ that is part of the ‘Sign Model’ of Hellan & Dimitrova-Vulchanova (1996), which does not appear to have ever been published, but seems broadly compatible with many recent ideas about the aspectual constitution of verb meanings. Events have a variety of properties, including an obligatory Core component, and optional Initiation and Termination components. Although there is no published account of the entire theory, the approach seems broadly consistent with that taken by Butt, and could plausibly be implemented by unification, or in the Davidsonian Event semantics used in the Kibort-Findlay Mapping theory (Asudeh et al. 2014, Findlay 2016).

In the causation-action construction, for example, the first verb specifies a ‘action’ component (what is done), the second a ‘causation’ component (what happens because of what is done). If we take the general approach to complex predicates proposed in Andrews (2018b), we could have a VP expanding to two VPs, each producing an element of a set, with a ‘syncategoremantic’ meaning constructor (one introduced by the c-structure rules) setting these up as the action and causation subevents of the main event:

(49)
$$\begin{array}{lccc} \text{VP} & \longrightarrow & \text{VP} & \text{VP} \\ & & \downarrow\in\uparrow & \downarrow\in\uparrow \\ & & \downarrow=\%F & \downarrow=\%G \end{array}$$

$$\lambda e.\exists e_1(\mathit{Action}(e,e_1)) \wedge \exists e_2(\mathit{Result}(e,e_2)) :$$
$$((\%F_\sigma\ \textsc{ev}) \multimap \%F_\sigma) \multimap ((\%G_\sigma\ \textsc{ev}) \multimap \%G_\sigma) \multimap (\uparrow_\sigma\ \textsc{ev}) \multimap \uparrow_\sigma$$

This takes two predicates over events, and creates a single predicate that is true of an event if it contains action and result subevents. This is only an initial suggestion of how a worked out analysis might proceed, but I think it demonstrates that Bodomo’s work provides an excellent basis to start out from.

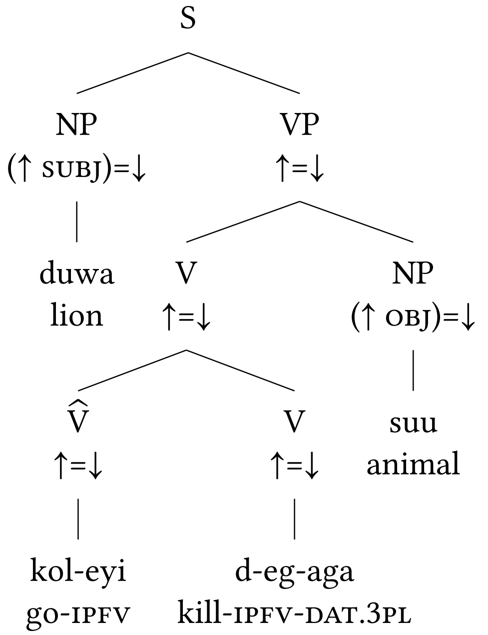
6.3 Barayin

Barayin SVCs are analysed in considerable detail by Lovestrand (2018), using a combination of a very carefully worked out major revision of the LFG version of X-bar theory from Bresnan et al. (2016), and a development of the ‘connected s-structure' (semantic structures) pioneered in Asudeh et al. (2014) and Findlay (2016). The latter allows serial verbs to make various contributions to meaning, sufficient for the range of these structures in Barayin, without needing to build apparent complement structures as appears to happen in Romance, and, to a lesser extent, Tariana.

The apparent syntactic form of the constructions is argued to be a 'nonprojecting word' (Toivonen 2001) left-adjoined to the V, a typical example being:

(50) Barayin

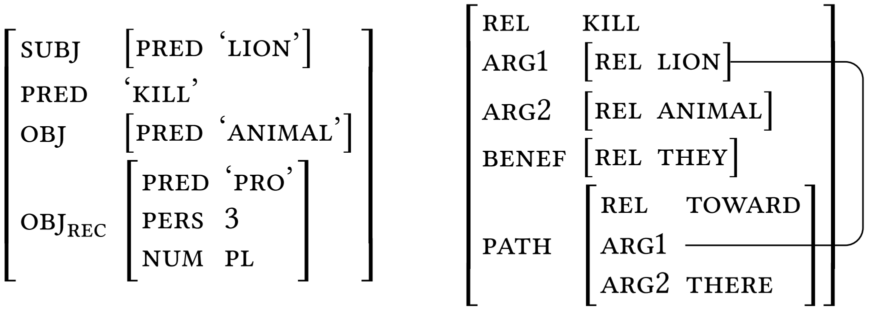
a.



b. duwa kol-eyi d-eg-aga suu
lion go-IPFV kill-IPFV-DAT.3PL animal
'The lion went and killed an animal for them.'

The f- and s-structures of this example would be (not explicitly provided by Lovestrand, but evident from other examples and the annotations for SV *kol-o* (Lovestrand 2018: 221):

(51)



In the semantics of the SV (first member of the SVC construction), there is also a not-fully-formalized provision that the motion along the path can either be simultaneous with or previous to the action of the main verb.

The potential problem of pred-clash is averted by the proposal that the SVs have no pred-feature, which is workable because there are only a limited number of SVs, producing the following kinds of constructions, each discussed by Lovestrand:

(52)
  a. Deictic (Associated Motion with deictic motion verbs such as *kol-o* 'go' as in the examples above).
  b. Manner (*gor-o* 'run' or another manner of motion verb).
  c. Stand (*juk-o* 'stand', incohative or indicating change in the narrative).
  d. Take (*pid-o* 'take', indicating the agent grasping the patient).

Even if the inventory of possible SVs turned out to be at least somewhat open, that fact that there does not appear to be any recursion in the construction means that the extra pred could be managed somehow, perhaps by a variant of the 'EP' proposal of Lovestrand (2020). A further unique and interesting feature of this analysis is that it has been fully implemented in the XLE system. The use of the connected s-structures has significant resemblances to both Butt's use of Jackendoff's Lexical-Conceptual Structures, and Bodomo's use of the unfinished Cell Theory. This is clearly a promising area for future work.

6.4 Misumalpan

The last case I will consider is some so-called serial verb constructions in the Misumalpan languages Miskitu and Sumu, presented as a kind of complex predicate in Andrews & Manning (1999). The constructions at issue have the form of consecutive clauses, expressing a chain of events, but they are interpreted in a range of ways similar to more standard SVC structures with no marking of the verbs (Salamanca 1988). This range of interpretations can be said to justify considering them as SVC constructions regardless of whether we consider their marking pattern to be in accord with (45) or not.

A fairly typical example is:

(53) Misumalpan (Hale 1991: 26, Andrews & Manning 1999: 93)
witin ai pruk-an kahw-ras
he me hit-obv.actual.3 fall-neg
'He hit me and I did not fall down.' (Consecutive Reading)
'He didn't knock me down.' (Causative SVC reading)

The suffix *-an* above is the 'obviative actual', obviative indicating that the subject of the clause whose verb has the marking is different from that of the next, 'actual' being a tense. In the consecutive reading, the clauses indicate different events that apply in sequence, and the negative affix applies to the second event. In the causative SVC reading, the first clause is the event that causes the second to happen, and the negative affix applies to the entire, complex event.

Andrews & Manning (1999) analyse these constructions as involving a rather unusual pattern of attribute sharing, while Andrews (2018a) argues that no unusual syntactic structures are required, and that the interpretations can be obtained by the use of glue semantics.

7 Conclusion

LFG analyses of complex predicates have been concerned primarily with the symmetrical sharing of attributes between different levels, and with the issues of combining the argument structures of multiple verbs into a single one that is associated with one set of grammatical relations. A remaining challenge is a theme that is more dominant in Minimalist analyses, which is the involvement of 'reduced projections', where some of the verbs do not appear to have all of the functional projections that an independent main verb would have (Grano 2015, Wurmbrand 2017). Negation, for example, is frequently impossible for the lower component of a complex predicate (as in Romance), but this is not the case in Urdu (Butt 1995: 49). There is clearly more to be done in this area, perhaps by an elaboration of functional projections in c-structure, of types in glue semantics, or a combination of both.

Acknowledgements

I would like to acknowledge the three reviewers for many very helpful comments and suggested references.

Chapter 8

Coordination

Agnieszka Patejuk
Polish Academy of Sciences and University of Oxford

Coordination is a rich and complex topic. To avoid repeating what has been written in many excellent textbooks and reference guides, this chapter takes a non-standard approach. It starts by presenting the very basics of coordination in LFG, it provides pointers to agreement phenomena related to coordination, and then it proceeds to discuss selected less well-known coordination phenomena and their treatment in LFG, including: non-constituent coordination, coordination of unlike categories, coordination of unlike grammatical functions and coordination involving ellipsis.

1 Introduction

This section starts by introducing two key concepts of coordination in LFG: sets and hybrid objects. Next, it briefly introduces distributivity, a key concept of coordination, on the basis of feature resolution (for non-distributive attributes) and dependent sharing (for grammatical functions, which belong to distributive attributes). Finally, it presents single conjunct agreement as an alternative to resolved agreement (under feature resolution).

Over time, different conventions have been used in f-structures. To avoid potential confusion, the f-structures presented in this chapter have been normalized: as a result, while f-structures in this chapter consistently use the same conventions, they may look different than in original papers. Furthermore, to save space, some f-structures have been simplified by removing attributes which are not relevant in a given context (such as SPEC, for instance).

The following convention is used in c-structure rules in this chapter: if a category on the right-hand side has no annotation, it is assumed to have the (co-)head annotation (↓=↑).

Agnieszka Patejuk. 2023. Coordination. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 309–374. Berlin: Language Science Press. DOI: 10.5281/zenodo.10185948

Except for (189), all examples used in this chapter are either English or Polish.

1.1 Coordination basics: sets and hybrid objects

A basic LFG coordination rule is given in (1), where XP is a variable over categories: every instance of XP in (1) must be replaced by the same category (for example NP).

(1) $$\begin{array}{lllll} \text{XP} & \longrightarrow & \text{XP} & \text{Conj} & \text{XP} \\ & & \downarrow\in\uparrow & & \downarrow\in\uparrow \end{array}$$

While the rule in (1) can only join two conjuncts, its slightly modified version in (2) can join more than two conjuncts: XP^{+} corresponds to one or more occurrences of XP.[1] Furthermore, the rule in (2) includes an optional preconjunction (such as both in *both... and...* or either in *either... or...*):[2]

(2) $$\begin{array}{llllll} \text{XP} & \longrightarrow & \text{(PreConj)} & \text{XP}^{+} & \text{Conj} & \text{XP} \\ & & & \downarrow\in\uparrow & & \downarrow\in\uparrow \end{array}$$

While there are various patterns of coordination (one conjunction, as many conjunctions as conjuncts, one fewer conjunction than the number of conjuncts, etc.), the basic annotations are the same: any (pre)conjunctions are co-heads (↓=↑, omitted above following the convention that lack of annotation is equivalent to having ↓=↑ annotation), while conjuncts are members of the set (↓∈↑) corresponding to the coordinate structure.

Let us consider structures created by these rules, using the simplified lexical entries below:

(3)			
	John	N	(↑ pred)=‘John’
	Mary	N	(↑ pred)=‘Mary’
	and	Conj	(↑ conj)=and
	both	PreConj	(↑ preconj)=both (↑ conj)$=_c$ and

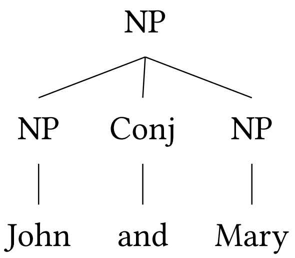
The structures in (4)–(5) can be generated by both rules in (1) and (2), while the structures with the preconjunction in (6)–(7) can only be generated by the rule in (2).

---

[1] Punctuation between non-final conjuncts is ignored in (2).

[2] While (2) overgenerates (*both... and...* can only be used with two conjuncts), some speakers can use *either... or...* with more than two conjuncts (e.g. *either X, Y or Z*).

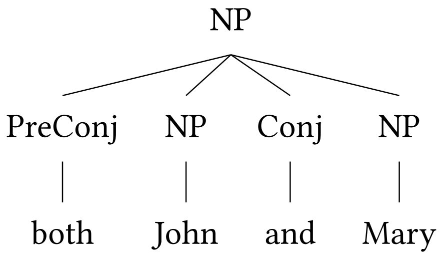
(4)



(5)

$$\left[\begin{array}{ll}\multicolumn{2}{l}{\left\{\left[\textsc{pred}\ \text{‘}\textsc{John}\text{’}\right], \left[\textsc{pred}\ \text{‘}\textsc{Mary}\text{’}\right]\right\}} \\ \textsc{conj} & \textsc{and}\end{array}\right]$$

(6)



(7)

$$\left[\begin{array}{ll}\multicolumn{2}{l}{\left\{\left[\textsc{pred}\ \text{‘}\textsc{John}\text{’}\right], \left[\textsc{pred}\ \text{‘}\textsc{Mary}\text{’}\right]\right\}} \\ \textsc{preconj} & \textsc{both} \\ \textsc{conj} & \textsc{and}\end{array}\right]$$

The f-structures representing coordination are hybrid objects. This is because they contain two types of objects: a set containing the individual conjuncts (sets are represented using curly brackets; set elements may be typeset horizontally or vertically) as well as attributes pertaining to the coordinate structure as a whole (these include the attributes CONJ and PRECONJ[3] representing the conjunction and the preconjunction, respectively).

1.2 Non-distributivity and feature resolution

As mentioned above, the lexical entries in (3) are simplified. The importance of hybrid objects is clearer when more features are represented in the f-structure, so let us extend the lexical entries in (8) by adding the NUM(ber) feature (while still ignoring other features):

(8) *John* N (↑ PRED)=‘JOHN’
(↑ NUM)=SG
Mary N (↑ PRED)=‘MARY’
(↑ NUM)=SG

---

[3] Some works use different attribute names, for instance COORD-FORM and PRECOORD-FORM.

As shown in (9),[4] even though both conjuncts are singular, the coordinate subject as a whole is plural – as a consequence, the verb requires plural agreement:

(9) [[John] and [Mary]] sing/*sings.

(10) *sing* V $(\uparrow \textsc{pred})=\text{‘}\textsc{sing}\langle(\uparrow \textsc{subj})\rangle\text{’}$
$(\uparrow \textsc{subj num}) =_c \textsc{pl}$
sings V $(\uparrow \textsc{pred})=\text{‘}\textsc{sing}\langle(\uparrow \textsc{subj})\rangle\text{’}$
$(\uparrow \textsc{subj num}) =_c \textsc{sg}$

(11) shows how this is reflected in the f-structure: while individual conjuncts are singular (their value of NUM is SG), the entire coordination is plural (its NUM is PL):

(11)
$$\left[\begin{array}{l} \left\{ \begin{bmatrix} \textsc{pred} & \text{‘John’} \\ \textsc{num} & \textsc{sg} \end{bmatrix}, \begin{bmatrix} \textsc{pred} & \text{‘Mary’} \\ \textsc{num} & \textsc{sg} \end{bmatrix} \right\} \\ \textsc{num} \quad \textsc{pl} \\ \textsc{conj} \quad \textsc{and} \end{array}\right]$$

To obtain such a representation, the equation (↑ NUM)=PL must be placed somewhere in the grammar. While normally it would be part of more complex feature resolution rules for number,[5] it is put below in the simplified rule handling NP coordination, see (12).

(12)
$$\begin{array}{llllll} \text{NP} & \longrightarrow & \text{(PreConj)} & \text{NP}^{+} & \text{Conj} & \text{NP} \\ & & & \downarrow\in\uparrow & \downarrow=\uparrow & \downarrow\in\uparrow \\ & & & & (\uparrow \textsc{num})=\textsc{pl} & \end{array}$$

The prerequisite for this equation to work as desired is that the NUM attribute must be non-distributive. This means that such an equation does not distribute to individual conjuncts (which would clash with (↑ NUM)=SG in their lexical entries), but instead it applies to the topmost f-structure corresponding to the entire coordinate phrase, see (11).

Apart from NUM(ber), some typical non-distributive attributes (or features) include GEND(er) and PERS(on). As mentioned above for NUM(ber), such non-distributive attributes are subject to feature resolution: rules specifying which value of these attributes is appropriate for the entire coordinate phrase, given the values of these attributes of particular conjuncts. Feature resolution rules are different for various attributes and may differ across languages. See Haug 2023 [this volume] for more discussion and references.

---

[4] Square brackets in examples indicate the boundaries of coordination and individual conjuncts.

[5] Such rules should consider the type of the conjunction (*and* vs. *or*). Even with *and*, it is not always the case that the number should be plural: *my doctor and best friend* can refer to one or two individuals.

1.3 Distributivity and dependent sharing

The rules in (1)–(2) can also be used to join categories other than NPs. For instance, (13) involves coordination of two sentences, while (14) involves two instances of coordination, at two different levels: NP coordination (*John and Mary*) described above (with the more specialised rule in (12)), and coordination of verbal phrases (*sing and walk*).

(13) [[John sings] and [Mary walks]].

(14) [[John] and [Mary]] [[sing] and [walk]].

In (14) the coordinated nominal subject (*John and Mary*, see its partial f-structure in (11)) is a shared dependent of the coordinated verbal phrases (*sing and walk*, see (15)).

(15)
$$\left[\begin{array}{l}\left\{\left[\textsc{pred}\ \text{`}\textsc{sing}\langle\textsc{subj}\rangle\text{'}\right],\left[\textsc{pred}\ \text{`}\textsc{walk}\langle\textsc{subj}\rangle\text{'}\right]\right\}\\ \textsc{conj}\ \ \textsc{and}\end{array}\right]$$

Since grammatical functions are distributive, no special rules are required to handle examples with a shared dependent such as (14). The equation ($\uparrow$ subj)=$\downarrow$ assigning the subj grammatical function to the NP in (16) distributes to each element of the set corresponding to the VP.[6] As a result, (11) becomes the subject of both conjuncts in (15), yielding (17) which involves structure sharing, indicated using boxed indices ($\boxed{1}$).

(16)
$$\begin{array}{llcc}\text{S} & \longrightarrow & \text{NP} & \text{VP}\\ & & (\uparrow \textsc{subj}){=}\downarrow & \end{array}$$

(17)
$$\left[\begin{array}{l}\left\{\left[\begin{array}{ll}\textsc{pred} & \text{`}\textsc{sing}\langle\boxed{1}\rangle\text{'}\\ \textsc{subj}\ \boxed{1} & \left[\begin{array}{l}\left\{\left[\begin{array}{ll}\textsc{pred}&\text{`John'}\\ \textsc{num}&\textsc{sg}\end{array}\right],\left[\begin{array}{ll}\textsc{pred}&\text{`Mary'}\\ \textsc{num}&\textsc{sg}\end{array}\right]\right\}\\ \textsc{num}\ \ \textsc{pl}\\ \textsc{conj}\ \ \textsc{and}\end{array}\right]\end{array}\right],\left[\begin{array}{ll}\textsc{pred}&\text{`}\textsc{walk}\langle\boxed{1}\rangle\text{'}\\ \textsc{subj}&\boxed{1}\end{array}\right]\right\}\\ \textsc{conj}\ \ \textsc{and}\end{array}\right]$$

---

[6] Most recent analyses would use IP instead of S and I′ instead of VP. However, since these distinctions are not the main focus of this chapter, the rules and c-structures from the literature are not normalised.

1.4 Single conjunct agreement

Single conjunct agreement (SCA) is an alternative agreement strategy available under coordination in some languages. Instead of agreeing with the entire coordinate phrase under feature resolution, under SCA the agreement target (for example: the verb) agrees with one of the conjuncts of its agreement controller (for verbs, typically the subject), usually the closest conjunct – this is known as closest conjunct agreement (CCA). Though furthest conjunct agreement (FCA) is also attested, it is rather rare (compared to CCA).

(18) is a Polish example showing resolved agreement (*szli* 'walked' is plural masculine) as opposed to agreement with the closest conjunct (*szła* 'walked' is singular and feminine):

(18) Polish
Szli/szła [[Marysia] i [Janek]].
walked.3.pl.m1/3.sg.f Marysia.sg.f and Janek.sg.m1
'Janek and Marysia walked.'

See Haug 2023 [this volume] for more discussion of SCA and references.

2 Non-constitutent coordination

When discussing coordination, typically what is discussed is coordination of constituents (typically of the same category and corresponding to the same grammatical function). Kaplan & Maxwell (1988) is the first published LFG analysis of such coordination.

Maxwell & Manning (1996) is a seminal LFG work discussing non-constituent coordination (NCC) where conjuncts do not correspond to constituents. Instead, each conjunct corresponds to a sequence of constituents (or possibly their parts), with no strict requirement of parallelism between conjuncts. Maxwell & Manning (1996: 1) provide the following "grab-bag of other cases of coordination commonly negatively classified as non-constituent coordination" which are outside of the scope of Kaplan & Maxwell (1988), labelling (19) as "conjunction reduction" (CR), (20) as "Right-Node Raising" (RNR), (21) as "Gapping", (22) as "Ellipsis" and (23) as "non-symmetric coordination":

(19) Bill gave [[the girls spades] and [the boys recorders]].
(Maxwell & Manning 1996: (2a))

(20) [[Bill likes], and [Joe is thought to like]] cigars from Cuba.
(Maxwell & Manning 1996: (2b))

(21) [[Bill gave a rhino to Fred], and [Sue a camera to Marjorie]]. (Maxwell & Manning 1996: (2c))

(22) [[Bill likes big cars], and [Sally does too]]. (Maxwell & Manning 1996: (2d))

(23) Bill [[went] and [took the test]]. (Maxwell & Manning 1996: (2e))

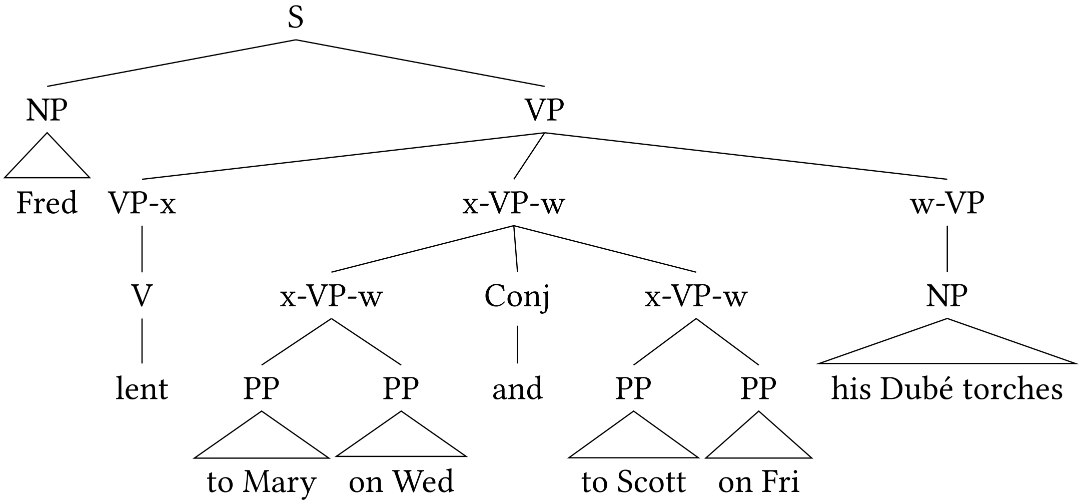
In order to account for instances of CR and RNR, Maxwell & Manning (1996: 3) propose to extend the analysis of coordination by allowing "the coordination of partial expansions of c-structure rules", namely partial expansions of VP rules (such as (26) discussed below), pointing out that this solution makes it possible to "maintain the simple and classic rule for coordination that only identical things are allowed to coordinate".[7]

2.1 Basics of the Maxwell & Manning (1996) analysis

Let us consider (24), where the NCC (*to Mary on Wednesday and to Scott on Friday*)[8] is surrounded by shared material: the subject (*Fred*) and the main verb (*lent*) on the left and the object on the right (*his Dubé torches*). (25) is the tree corresponding to (24).

(24) Fred lent [[to Mary on Wednesday] and [to Scott on Friday]] his Dubé torches.

(25)



(Maxwell & Manning 1996: (15))

---

[7] It can also be used to reanalyse unlike category coordination as same category coordination, see Section 3.1.

[8] *Wednesday* and *Friday* are abbreviated in trees and f-structures to *Wed* and *Fri*, respectively.

The following modified rules can be read off the tree in (25):[9]

(26) VP ⟶ VP-x x-VP-w w-VP

(27) VP-x ⟶ V

(28) x-VP-w ⟶ x-VP-w Conj x-VP-w

(29) x-VP-w ⟶ PP PP

(30) w-VP ⟶ NP

However, the rules above are not complete because f-descriptions are missing. While the rule in (31) could normally be used, in order to handle the NCC in (24), the rules in (28)–(30) must be annotated with f-descriptions as shown in (32)–(34):

(31)
$$\begin{array}{cccccc} \text{VP} & \longrightarrow & \text{V} & \text{PP} & \text{PP}^* & \text{NP} \\ & & & (\uparrow \textsc{obl}){=}\downarrow & \downarrow{\in}(\uparrow \textsc{adj}) & (\uparrow \textsc{obj}){=}\downarrow \end{array}$$

(32)
$$\begin{array}{ccccc} \text{x-VP-w} & \longrightarrow & \text{x-VP-w} & \text{Conj} & \text{x-VP-w} \\ & & \downarrow{\in}\uparrow & & \downarrow{\in}\uparrow \end{array}$$

(33)
$$\begin{array}{cccc} \text{x-VP-w} & \longrightarrow & \text{PP} & \text{PP} \\ & & (\uparrow \textsc{obl}){=}\downarrow & \downarrow{\in}(\uparrow \textsc{adj}) \end{array}$$

(34)
$$\begin{array}{ccc} \text{w-VP} & \longrightarrow & \text{NP} \\ & & (\uparrow \textsc{obj}){=}\downarrow \end{array}$$

There is an important difference between “standard” rules such as (31) and modified rules aimed at handling NCC. While in (31) subsequent dependents have appropriate grammatical function annotations ((↑ OBL)=↓ for the oblique PP, ↓∈(↑ ADJ) for the modifier PP and (↑ OBJ)=↓ for the NP object), the corresponding NCC partial categories in (26), x-VP-w and w-VP, have no annotation, which is interpreted by default as the co-head annotation (↓=↑). As a consequence, the annotations assigning appropriate grammatical functions are instead equivalently placed in (33) (for x-VP-w which rewrites to an oblique PP followed by a modifier PP) and in (34) (for w-VP which rewrites to an NP object). Thanks to the different placement of f-descriptions,[10] such modified rules can account for NCC, unlike the “standard” VP rule in (31).

---

[9] While Maxwell & Manning (1996) use “and” in their rules, it was replaced with “Conj” for consistency.

[10] Moving f-descriptions in this way is crucial in some analyses of other phenomena, including coordination of different grammatical functions (Section 4) and gapping (Section 5.3).

To better understand the analysis of Maxwell & Manning (1996), let us consider its procedural intuition by inspecting partial f-structures created by these rules.

Each conjunct of NCC builds its partial f-structure using the rule in (33): (35) corresponds to the first conjunct (*to Mary on Wednesday*), (36) to the second (*to Scott on Friday*).

(35)
$$\left[\begin{array}{ll} \textsc{obl} & \left[\textsc{pred}\ \text{`}\textsc{Mary}\text{'}\right] \\ \textsc{adj} & \left\{\left[\begin{array}{ll}\textsc{pred} & \text{`}\textsc{on}\langle\boxed{4}\rangle\text{'} \\ \textsc{obj} & \boxed{4}\left[\textsc{pred}\ \text{`}\textsc{Wed}\text{'}\right]\end{array}\right]\right\}\end{array}\right]$$

(36)
$$\left[\begin{array}{ll} \textsc{obl} & \left[\textsc{pred}\ \text{`}\textsc{Scott}\text{'}\right] \\ \textsc{adj} & \left\{\left[\begin{array}{ll}\textsc{pred} & \text{`}\textsc{on}\langle\boxed{6}\rangle\text{'} \\ \textsc{obj} & \boxed{6}\left[\textsc{pred}\ \text{`}\textsc{Fri}\text{'}\right]\end{array}\right]\right\}\end{array}\right]$$

Next, (35) and (36) are added as set elements using the coordination rule in (32).[11]

(37)
$$\left[\begin{array}{l} \left\{\left[\begin{array}{ll} \textsc{obl} & \left[\textsc{pred}\ \text{`}\textsc{Mary}\text{'}\right] \\ \textsc{adj} & \left\{\left[\begin{array}{ll}\textsc{pred} & \text{`}\textsc{on}\langle\boxed{4}\rangle\text{'} \\ \textsc{obj} & \boxed{4}\left[\textsc{pred}\ \text{`}\textsc{Wed}\text{'}\right]\end{array}\right]\right\}\end{array}\right], \left[\begin{array}{ll} \textsc{obl} & \left[\textsc{pred}\ \text{`}\textsc{Scott}\text{'}\right] \\ \textsc{adj} & \left\{\left[\begin{array}{ll}\textsc{pred} & \text{`}\textsc{on}\langle\boxed{6}\rangle\text{'} \\ \textsc{obj} & \boxed{6}\left[\textsc{pred}\ \text{`}\textsc{Fri}\text{'}\right]\end{array}\right]\right\}\end{array}\right]\right\} \\ \textsc{conj}\quad \textsc{and} \end{array}\right]$$

Next, the VP rule in (26) unifies the partial f-structures of 3 co-heads: (38) corresponds to VP-x; (37) is the set corresponding to NCC in x-VP-w; (39) is created by the w-VP rule in (34). As mentioned in Section 1.3 when discussing (14), grammatical functions are distributive; so is PRED. Note that being a distributive feature is consistent with being an instantiated feature: when PRED is distributed, it is uniquely instantiated in each conjunct.[12] As a result, (38) and (39) distribute over (37), yielding the f-structure in (40).

(38)
$$\left[\textsc{pred}\ \text{`}\textsc{lend}\langle\textsc{subj},\textsc{obj},\textsc{obl}\rangle\text{'}\right]$$

(39)
$$\left[\textsc{obj}\ \left[\textsc{pred}\ \text{`}\textsc{Dubé torches}\text{'}\right]\right]$$

(40)
$$\left[\begin{array}{l} \left\{\left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{lend}\langle\textsc{subj},\boxed{2},\boxed{3}\rangle\text{'} \\ \textsc{obj} & \boxed{2}\left[\textsc{pred}\ \text{`}\textsc{Dubé torches}\text{'}\right] \\ \textsc{obl} & \boxed{3}\left[\textsc{pred}\ \text{`}\textsc{Mary}\text{'}\right] \\ \textsc{adj} & \left\{\left[\begin{array}{ll}\textsc{pred} & \text{`}\textsc{on}\langle\boxed{4}\rangle\text{'} \\ \textsc{obj} & \boxed{4}\left[\textsc{pred}\ \text{`}\textsc{Wed}\text{'}\right]\end{array}\right]\right\}\end{array}\right], \left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{lend}\langle\textsc{subj},\boxed{2},\boxed{5}\rangle\text{'} \\ \textsc{obj} & \boxed{2} \\ \textsc{obl} & \boxed{5}\left[\textsc{pred}\ \text{`}\textsc{Scott}\text{'}\right] \\ \textsc{adj} & \left\{\left[\begin{array}{ll}\textsc{pred} & \text{`}\textsc{on}\langle\boxed{6}\rangle\text{'} \\ \textsc{obj} & \boxed{6}\left[\textsc{pred}\ \text{`}\textsc{Fri}\text{'}\right]\end{array}\right]\right\}\end{array}\right]\right\} \\ \textsc{conj}\quad \textsc{and} \end{array}\right]$$

---

[11] Coordination of partial expansions such as in (32) is handled by the general coordination rule in (1).

[12] This makes it possible to account for multiclausal coordination phenomena such as NCC, coordination of different grammatical functions (Section 4.4), SGF (Section 5.1) and gapping (Section 5.3).

One element is missing in (40): the shared subject (*Fred*), see the tree in (25). Assuming a rule for S such as in (16), the annotation (↑ SUBJ)=↓ distributes the NP subject over the partial f-structure in (40), yielding the complete f-structure in (41).

(41)
$$\left[\begin{array}{l} \left\{ \left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{lend}\langle\boxed{1},\boxed{2},\boxed{3}\rangle\text{'} \\ \textsc{subj} & \boxed{1}\left[\textsc{pred}\ \text{`Fred'}\right] \\ \textsc{obj} & \boxed{2}\left[\textsc{pred}\ \text{`Dubé torches'}\right] \\ \textsc{obl} & \boxed{3}\left[\textsc{pred}\ \text{`Mary'}\right] \\ \textsc{adj} & \left\{\left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{on}\langle\boxed{4}\rangle\text{'} \\ \textsc{obj} & \boxed{4}\left[\textsc{pred}\ \text{`Wed'}\right] \end{array}\right]\right\} \end{array}\right], \left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{lend}\langle\boxed{1},\boxed{2},\boxed{5}\rangle\text{'} \\ \textsc{subj} & \boxed{1} \\ \textsc{obj} & \boxed{2} \\ \textsc{obl} & \boxed{5}\left[\textsc{pred}\ \text{`Scott'}\right] \\ \textsc{adj} & \left\{\left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{on}\langle\boxed{6}\rangle\text{'} \\ \textsc{obj} & \boxed{6}\left[\textsc{pred}\ \text{`Fri'}\right] \end{array}\right]\right\} \end{array}\right] \right\} \\ \textsc{conj}\quad \textsc{and} \end{array}\right]$$

An important thing to note about the Maxwell & Manning (1996) analysis of NCC is that it creates multiclausal structures.[13] This means that it is equivalent to a coordination of two VPs, with two instances of a given verb – it is clear in (41), where the set corresponding to coordination contains two clauses with different instantiations of LEND as the main verb.

2.2 Interaction with verbal coordination

(42) demonstrates an interesting issue arising when NCC (*to Mary on Wednesday and to Sue on Friday*) co-occurs with verbal coordination, which is also represented as a set:

(42) John [[gave a book] or [lent a record]] [[to Mary on Wednesday] and [to Sue on Friday]]. (Maxwell & Manning 1996: (43))

Strictly speaking, (42) is more complex than necessary to show the issue at hand:[14] *[[gave a book] or [lent a record]]* is another instance of NCC, which means that more complex c-structure rules are needed to handle this example. (43) is the "standard" VP rule which is split into partial VP rules in (44)–(48) in order to handle NCC in (42).

(43)
$$\begin{array}{llllll} \text{VP} & \longrightarrow & \text{V} & \text{NP} & \text{PP} & \text{PP*} \\ & & & (\uparrow \textsc{obj}){=}\downarrow & (\uparrow \textsc{obl}){=}\downarrow & \downarrow{\in}(\uparrow \textsc{adj}) \end{array}$$

---

[13] Multiclausal structures also arise under gapping (Section 5.3), in some instances of coordination of different grammatical functions (Section 4.4) and when unlike category coordination is reanalysed as NCC (Section 3.1).

[14] The same issue arises in a modified version of (24) with simple coordination of verbs (*gave or lent*):

(i) Fred [[gave] or [lent]] [[to Mary on Wednesday] and [to Scott on Friday]] his Dubé torches.

(44) $\text{VP} \longrightarrow \text{VP-x} \quad \text{x-VP}$

(45) $$\text{VP-x} \longrightarrow \underset{\downarrow\in\uparrow}{\text{VP-x}} \quad \text{Conj} \quad \underset{\downarrow\in\uparrow}{\text{VP-x}}$$

(46) $$\text{VP-x} \longrightarrow \text{V} \quad \underset{(\uparrow \textsc{obj})=\downarrow}{\text{NP}}$$

(47) $$\text{x-VP} \longrightarrow \underset{\downarrow\in\uparrow}{\text{x-VP}} \quad \text{Conj} \quad \underset{\downarrow\in\uparrow}{\text{x-VP}}$$

(48) $$\text{x-VP} \longrightarrow \underset{(\uparrow \textsc{obl})=\downarrow}{\text{PP}} \quad \underset{\downarrow\in(\uparrow \textsc{adj})}{\text{PP}^*}$$

The procedural intuition of the analysis of (42) involves unifying two partial f-structures in the VP rule in (44), both of which happen to be sets: (49) corresponds to VP-x (*gave a book or lent a record*) built using the rules in (45)–(46), while (50) corresponds to x-VP (*to Mary on Wednesday and to Sue on Friday*) built using (47)–(48).

(49) $$\left[\begin{array}{l} \left\{ \begin{bmatrix} \textsc{pred} & \text{‘}\textsc{give}\langle\textsc{subj},\boxed{2},\textsc{obl}\rangle\text{’} \\ \textsc{obj} & \boxed{2}\begin{bmatrix}\textsc{pred} & \text{‘}\textsc{book}\text{’}\end{bmatrix} \end{bmatrix}, \begin{bmatrix} \textsc{pred} & \text{‘}\textsc{lend}\langle\textsc{subj},\boxed{3},\textsc{obl}\rangle\text{’} \\ \textsc{obj} & \boxed{3}\begin{bmatrix}\textsc{pred} & \text{‘}\textsc{record}\text{’}\end{bmatrix} \end{bmatrix} \right\} \\ \textsc{conj} \quad \textsc{or} \end{array}\right]$$

(50) $$\left[\begin{array}{l} \left\{ \begin{bmatrix} \textsc{obl} & \begin{bmatrix}\textsc{pred} & \text{‘Mary’}\end{bmatrix} \\ \textsc{adj} & \left\{ \begin{bmatrix} \textsc{pred} & \text{‘}\textsc{on}\langle\boxed{4}\rangle\text{’} \\ \textsc{obj} & \boxed{4}\begin{bmatrix}\textsc{pred} & \text{‘Wed’}\end{bmatrix} \end{bmatrix} \right\} \end{bmatrix}, \begin{bmatrix} \textsc{obl} & \begin{bmatrix}\textsc{pred} & \text{‘Sue’}\end{bmatrix} \\ \textsc{adj} & \left\{ \begin{bmatrix} \textsc{pred} & \text{‘}\textsc{on}\langle\boxed{5}\rangle\text{’} \\ \textsc{obj} & \boxed{5}\begin{bmatrix}\textsc{pred} & \text{‘Fri’}\end{bmatrix} \end{bmatrix} \right\} \end{bmatrix} \right\} \\ \textsc{conj} \quad \textsc{and} \end{array}\right]$$

As discussed in Section 2.1, when a set is unified with a non-set f-structure, the non-set f-structure is distributed over the set. Maxwell & Manning (1996) discuss the issue of unifying two sets[15] on the basis of example (42), where the first set contains elements labelled as f_1 (*gave a book*) and f_2 (*lent a record*), see the f-structure in (49), while the second set contains f_3 (*to Mary on Wednesday*) and f_4 (*to Sue on Friday*), see (50).

Maxwell & Manning (1996) point out that a possible but undesired result of unifying (49) and (50) is set union, yielding an f-structure containing a set with 4 elements. This is schematically shown in (51), while the corresponding partial f-structure is given in (52).

(51) $\uparrow\{f_1,f_2,f_3,f_4\}$

---

[15] The issue of unifying two sets also surfaces in other coordination phenomena, including multi-clausal coordination of different grammatical functions (Section 4.4) and gapping (Section 5.3).

(52)
$$\left[\begin{array}{l}\left\{\begin{array}{l}\left[\begin{array}{ll}\textsc{pred} & \text{`}\textsc{give}\langle\textsc{subj},\boxed{2},\textsc{obl}\rangle\text{'}\\ \textsc{obj} & \boxed{2}\left[\textsc{pred}\ \text{`}\textsc{book}\text{'}\right]\end{array}\right], \left[\begin{array}{ll}\textsc{pred} & \text{`}\textsc{lend}\langle\textsc{subj},\boxed{3},\textsc{obl}\rangle\text{'}\\ \textsc{obj} & \boxed{3}\left[\textsc{pred}\ \text{`}\textsc{record}\text{'}\right]\end{array}\right],\\ \left[\begin{array}{ll}\textsc{obl} & \left[\textsc{pred}\ \text{`Mary'}\right]\\ \textsc{adj} & \left\{\left[\begin{array}{ll}\textsc{pred} & \text{`}\textsc{on}\langle\boxed{4}\rangle\text{'}\\ \textsc{obj} & \boxed{4}\left[\textsc{pred}\ \text{`Wed'}\right]\end{array}\right]\right\}\end{array}\right], \left[\begin{array}{ll}\textsc{obl} & \left[\textsc{pred}\ \text{`Sue'}\right]\\ \textsc{adj} & \left\{\left[\begin{array}{ll}\textsc{pred} & \text{`}\textsc{on}\langle\boxed{5}\rangle\text{'}\\ \textsc{obj} & \boxed{5}\left[\textsc{pred}\ \text{`Fri'}\right]\end{array}\right]\right\}\end{array}\right]\end{array}\right\}\\ \textsc{conj}\quad \textsc{or}\neq\textsc{and}\end{array}\right]$$

(52) is ill-formed for three reasons.[16] First, it is incomplete: f_1 and f_2 have a missing OBL(ique) argument. Secondly, it is incoherent: f_3 and f_4 have no PRED subcategorising for their OBL arguments. Finally, it is inconsistent due to conflicting values of the CONJ attribute: f_1 and f_2 are conjoined with *or* (($\uparrow$ CONJ)=OR), while f_3 and f_4 are conjoined with *and* (($\uparrow$ CONJ)=AND). Unifying these f-descriptions results in a clash ($\neq$), see (52).

Maxwell & Manning (1996) explain that the desired result is to distribute one set over the other, which yields a set containing 2 elements, each of which also contains 2 elements. There are two ways in which this can be done.

The result of distributing the first set (containing f_1, f_2) over the second (containing f_3, f_4) is schematically shown in (53). This yields the partial f-structure in (54), where the top-level conjunction is AND (it joins f_3 and f_4), while the conjunction in embedded sets is OR (it joins f_1 and f_2). The sentence in (55) provides a natural language intuition of the f-structure in (54) (with the subject added in brackets, since its contribution is not present in (54)).

(53) $\uparrow\{f_3\{f_1',f_2'\},f_4\{f_1'',f_2''\}\}$

(54)
$$\left[\begin{array}{l}\left\{\begin{array}{l}\left[\begin{array}{l}\left\{\left[\begin{array}{ll}\textsc{pred} & \text{`}\textsc{give}\langle\textsc{subj},\boxed{2},\boxed{3}\rangle\text{'}\\ \textsc{obj} & \boxed{2}\left[\textsc{pred}\ \text{`}\textsc{book}\text{'}\right]\\ \textsc{obl} & \boxed{3}\left[\textsc{pred}\ \text{`Mary'}\right]\\ \textsc{adj} & \left\{\boxed{4}\left[\begin{array}{ll}\textsc{pred} & \text{`}\textsc{on}\langle\boxed{5}\rangle\text{'}\\ \textsc{obj} & \boxed{5}\left[\textsc{pred}\ \text{`Wed'}\right]\end{array}\right]\right\}\end{array}\right], \left[\begin{array}{ll}\textsc{pred} & \text{`}\textsc{lend}\langle\textsc{subj},\boxed{9},\boxed{3}\rangle\text{'}\\ \textsc{obj} & \boxed{9}\left[\textsc{pred}\ \text{`}\textsc{record}\text{'}\right]\\ \textsc{obl} & \boxed{3}\\ \textsc{adj} & \left\{\boxed{4}\right\}\end{array}\right]\right\}\\ \textsc{conj}\quad\textsc{or}\end{array}\right],\\ \left[\begin{array}{l}\left\{\left[\begin{array}{ll}\textsc{pred} & \text{`}\textsc{give}\langle\textsc{subj},\boxed{2},\boxed{6}\rangle\text{'}\\ \textsc{obj} & \boxed{2}\\ \textsc{obl} & \boxed{6}\left[\textsc{pred}\ \text{`Sue'}\right]\\ \textsc{adj} & \left\{\boxed{7}\left[\begin{array}{ll}\textsc{pred} & \text{`}\textsc{on}\langle\boxed{8}\rangle\text{'}\\ \textsc{obj} & \boxed{8}\left[\textsc{pred}\ \text{`Fri'}\right]\end{array}\right]\right\}\end{array}\right], \left[\begin{array}{ll}\textsc{pred} & \text{`}\textsc{lend}\langle\textsc{subj},\boxed{9},\boxed{6}\rangle\text{'}\\ \textsc{obj} & \boxed{9}\\ \textsc{obl} & \boxed{6}\\ \textsc{adj} & \left\{\boxed{7}\right\}\end{array}\right]\right\}\\ \textsc{conj}\quad\textsc{or}\end{array}\right]\end{array}\right\}\\ \textsc{conj}\quad\textsc{and}\end{array}\right]$$

---

[16] These problems persist after the f-structure of the subject (*John*) is distributed over all set elements.

(55) (John) [[gave a book or lent a record] to Mary on Wednesday] and [[gave a book or lent a record] to Sue on Friday].

By contrast, (56) schematically shows the opposite situation, where the second set (containing f_3, f_4) is distributed over the first set (containing f_1, f_2). This yields the partial f-structure in (57), where the top-level conjunction is OR (it joins f_1 and f_2), while the conjunction in embedded sets is AND (it joins f_3 and f_4). (58) provides the natural language intuition of (57).

(56) $\uparrow\{f_1\{f_3',f_4'\},f_2\{f_3'',f_4''\}\}$

(57)
$$\left[\begin{array}{l}
\left\{\begin{array}{l}
\left[\begin{array}{l}
\left\{
\left[\begin{array}{ll}
\textsc{pred} & \text{`}\textsc{give}\langle\textsc{subj},\boxed{2},\boxed{3}\rangle\text{'}\\
\textsc{obj} & \boxed{2}\left[\textsc{pred}\ \text{`}\textsc{book}\text{'}\right]\\
\textsc{obl} & \boxed{3}\left[\textsc{pred}\ \text{`}\textsc{Mary}\text{'}\right]\\
\textsc{adj} & \left\{\boxed{4}\left[\begin{array}{ll}\textsc{pred} & \text{`}\textsc{on}\langle\boxed{5}\rangle\text{'}\\ \textsc{obj} & \boxed{5}\left[\textsc{pred}\ \text{`}\textsc{Wed}\text{'}\right]\end{array}\right]\right\}
\end{array}\right],
\left[\begin{array}{ll}

\textsc{adj} & \left\{\boxed{7}\left[\begin{array}{ll}\textsc{pred} & \text{`}\textsc{on}\langle\boxed{8}\rangle\text{'}\\ \textsc{obj} & \boxed{8}\left[\textsc{pred}\ \text{`}\textsc{Fri}\text{'}\right]\end{array}\right]\right\}
\end{array}\right]
\right\}\\
\textsc{conj}\ \ \textsc{and}
\end{array}\right],\\
\left[\begin{array}{l}
\left\{
\left[\begin{array}{ll}
\textsc{pred} & \text{`}\textsc{lend}\langle\textsc{subj},\boxed{9},\boxed{3}\rangle\text{'}\\
\textsc{obj} & \boxed{9}\left[\textsc{pred}\ \text{`}\textsc{record}\text{'}\right]\\
\textsc{obl} & \boxed{3}\\
\textsc{adj} & \left\{\boxed{4}\right\}
\end{array}\right],
\left[\begin{array}{ll}
\textsc{pred} & \text{`}\textsc{lend}\langle\textsc{subj},\boxed{9},\boxed{6}\rangle\text{'}\\
\textsc{obj} & \boxed{9}\\
\textsc{obl} & \boxed{6}\\
\textsc{adj} & \left\{\boxed{7}\right\}
\end{array}\right]
\right\}\\
\textsc{conj}\ \ \textsc{and}
\end{array}\right]
\end{array}\right\}\\
\textsc{conj}\ \ \textsc{or}
\end{array}\right]$$

(58) (John) [gave a book [to Mary on Wednesday and to Sue on Friday]] or [lent a record [to Mary on Wednesday and to Sue on Friday]].

As shown above, due to the fact that there are two ways of distributing one set over the other, (42) has two possible interpretations, depending on whether the scope of disjunction is narrow ((53)–(54)) or wide ((56)–(57)). While this may not be immediately obvious, there is a significant difference in truth conditions between these two interpretations.

In (54) where disjunction has narrow scope, each woman (Mary, Sue) is given a book or lent a record, while in (57) where disjunction has wide scope, both women (Mary and Sue) are given a book or lent a record. This is why (57) could be referred to as the symmetric reading – if Mary is given a book, Sue is also given a book (and vice versa); the same applies to being lent a record. By contrast, (54) does not require such symmetry: this reading is true when Mary (but not Sue) is given a book and Sue (but not Mary) is lent a record (or the other way round). While (54) is true in all situations when (57) is true, the opposite does not hold: there are scenarios when (54) is true but (57) is not.

While the grammar produces both solutions discussed above for (42), there are different views on which of these is more natural. As reported in Maxwell & Manning (1996: 13): “Blevins (1994) argues that the wide scope reading for the disjunction is the most natural interpretation, but we tend to think the opposite”.

3 Coordination of unlike categories

While it has been claimed that coordination can only join identical categories (Chomsky (1957: 36), Williams (1981); more recently Bruening & Al Khalaf (2020)), many works have challenged such claims, showing that there is no such requirement (Peterson (1981), Sag et al. (1985), Bayer (1996); more recently Patejuk & Przepiórkowski (2023)).

When discussing unlike category coordination, the following examples are often used:

(59) Pat is [[a Republican] and [proud of it]]. (Sag et al. 1985: 117, (2b))

(60) Pat is [either [stupid] or [a liar]]. (Sag et al. 1985: 117, (2a))

(61) Pat has become [[a banker] and [very conservative]]. (Sag et al. 1985: 118, (3a))

(62) I consider John [[stupid] and [a fool]]. (Peterson 1981: (35))

(63) I consider that [[a rude remark] and [in very bad taste]]. (Sag et al. 1985: 118, (3b))

(64) We walked [[slowly] and [with great care]]. (Sag et al. 1985: 140, (57))

Except (64), which is an example of coordination of modifiers, all examples above involve predicative complements. Modifiers and predicative complements are the two most popular example types discussed in the literature on unlike category coordination.

There are also examples where unlike category coordination corresponds to a non-predicative argument. As discussed in Patejuk & Przepiórkowski (2023) on the basis of examples below, some predicates require an argument defined in terms of semantics rather than syntactic categories: expressing location (RESIDE), manner (TREAT), duration (LAST) etc. Such phrases may also act as modifiers: (64) is an example of a manner modifier.

(65) [[That place] and [behind these shops]] are where many families reside.

(66) Do you treat the four museums [[individually] or [as a collective]]?

(67) Immunity may last [[10 years] or [longer]]

There are also non-predicative arguments which are not defined semantically. (68) is a famous example often used in the context of unlike category coordination.

(68) You can depend on [[my assistant] and [that he will be on time]]. (Sag et al. 1985: 165, (124b))

However, (68) is controversial/problematic because it involves a subcategorisation violation. While the conjunct closer to the head obeys its subcategorisation requirements, (69), the other conjunct does not, see (70) – neither as a complement of the preposition ON, nor as a direct complement of the verb:

(69) You can depend on my assistant.

(70) *You can depend (on) that he will be on time.

Normally each conjunct is expected to satisfy the subcategorisation requirements of the verb it depends on – this is the case in two other famous examples from Sag et al. (1985):

(71) Pat remembered [[the appointment] and [that it was important to be on time]]. (Sag et al. 1985: 165, (123a))

(72) [[That Himmler appointed Heydrich] and [the implications thereof]] frightened many observers. (Sag et al. 1985: 165, (123b))

The rest of this section focuses on examples which satisfy this constraint, so it will not cover subcategorisation violations such as (68).

3.1 Unlike category coordination or ellipsis

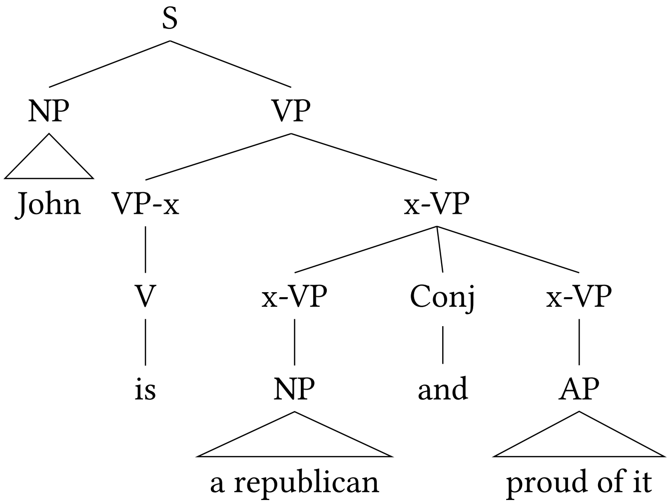
One way to approach the phenomenon of unlike category coordination is to assume that ellipsis is involved, so that what is coordinated are not unlike categories, but larger categories of the same type: for instance two (or more) categories such as S, CP or VP – with ellipsis of the verb in one of the conjuncts (typically the second).

Maxwell & Manning (1996: 3) point out that the solution they propose for non-constituent coordination (NCC, discussed in Section 2) could be used to avoid unlike category coordination in examples such as *John is a republican and proud of it* by "coordinating partial VPs rather than attempting to coordinate an NP and an AP", see the structures in (73)–(74).[17]

---

[17] The contribution of *of it* is consistently omitted in the following f-structures.

(73)



(Maxwell & Manning 1996: (14))

(74)

$$\left[\begin{array}{l}\left\{\left[\begin{array}{ll}\textsc{pred} & \text{‘}\textsc{be}\langle\boxed{2}\rangle\boxed{1}\text{’}\\ \textsc{subj}\ \boxed{1} & \left[\textsc{pred}\ \text{‘}\textsc{John}\text{’}\right]\\ \textsc{xcomp}\ \boxed{2} & \left[\begin{array}{ll}\textsc{pred} & \text{‘}\textsc{republican}\langle\boxed{1}\rangle\text{’}\\ \textsc{subj} & \boxed{1}\end{array}\right]\end{array}\right], \left[\begin{array}{ll}\textsc{pred} & \text{‘}\textsc{be}\langle\boxed{3}\rangle\boxed{1}\text{’}\\ \textsc{subj} & \boxed{1}\\ \textsc{xcomp}\ \boxed{3} & \left[\begin{array}{ll}\textsc{pred} & \text{‘}\textsc{proud}\langle\boxed{1}\rangle\text{’}\\ \textsc{subj} & \boxed{1}\end{array}\right]\end{array}\right]\right\}\\ \textsc{conj}\quad \textsc{and}\end{array}\right]$$

As explained in Section 2, such an analysis produces multiclausal f-structures, as shown in (74).

While reanalysing unlike category coordination as same category coordination of larger categories seems to be a possibility in some cases, there are situations where it has undesired consequences such as having a different reading. As observed in Dalrymple (2017), examples with modifiers such as *simultaneously* and *alternately* have different readings depending on whether unlike category coordination is involved (see the bracketings in (75) and (77)), or an “ellipsis-based”[18] analysis is involved (compare (76) and (78), respectively):

(75) Fred is simultaneously [[a professor] and [ashamed of his work]]. (Dalrymple 2017: (16a))

(76) Fred [[is simultaneously a professor] and [~~is simultaneously~~ ashamed of his work]]. (Dalrymple 2017: (16b))

(77) Fred is alternately [[in a good mood] and [suicidal]]. (Dalrymple 2017: (17a))

(78) Fred [[is alternately in a good mood] and [~~is alternately~~ suicidal]]. (Dalrymple 2017: (17b))

---

[18] This includes the NCC reanalysis proposed by Maxwell & Manning (1996).

In the case of *John is a republican and proud of it*, the truth conditions are the same no matter whether this string is analysed as coordination of unlike categories (giving rise to a monoclausal structure where the predicative complement corresponds to unlike category coordination of an NP and an AP, see (79)) or as same category coordination of VPs, as in (74), which is equivalent to multiclausal *John [[is a republican] and [~~is~~ proud of it]].*

(79)
$$\left[\begin{array}{ll} \textsc{pred} & \text{‘}\textsc{be}\langle\boxed{2}\rangle\boxed{1}\text{’} \\ \textsc{subj}\ \boxed{1} & \left[\textsc{pred}\ \text{‘}\textsc{John}\text{’}\right] \\ \textsc{xcomp}\ \boxed{2} & \left[\begin{array}{l} \left\{\left[\begin{array}{ll} \textsc{pred} & \text{‘}\textsc{republican}\langle\boxed{1}\rangle\text{’} \\ \textsc{subj} & \boxed{1} \end{array}\right], \left[\begin{array}{ll} \textsc{pred} & \text{‘}\textsc{proud}\langle\boxed{1}\rangle\text{’} \\ \textsc{subj} & \boxed{1} \end{array}\right]\right\} \\ \textsc{conj}\quad \textsc{and} \end{array}\right] \end{array}\right]$$

However, there is a clear difference when negation is involved. Consider the string *John is not a republican and proud of it.* Under the NCC reanalysis of unlike category coordination proposed in Maxwell & Manning (1996), this sentence involves a coordination of two negated VPs – this corresponds to (80) which involves a conjunction of two negated predicates, schematically shown in (81).

(80) John [[is not a republican] and [~~is not~~ proud of it]].

(81) $[\neg A \wedge \neg B]$

By contrast, under the analysis where genuine coordination of unlike categories is involved, as in (82), the semantics, schematically shown in (83), involves a negation of a conjunction – under De Morgan's laws, this is equivalent to a disjunction of negations.

(82) John is not [[a republican] and [proud of it]].

(83) $\neg[A \wedge B] \equiv [\neg A \vee \neg B]$

As a consequence, the two analyses of the string *John is not a republican and proud of it* have different meanings. Under the NCC analysis in (80), it can only mean (it has only one reading where it is true): John is not a republican, he is not proud of it ($[\neg A \wedge \neg B]$). Apart from this reading, the following two readings are also available under the unlike category coordination analysis in (82): John is a republican, he is not proud of it ($[A \wedge \neg B]$); John is not a republican, he is proud of it ($[\neg A \wedge B]$). Even though these two are possible readings of this string, they are not available under the NCC analysis.

An analogous issue arises in examples with modifiers such as (64). When negation is present (*We did not walk slowly and with great care*), different analyses also have different meanings. While NCC in (84) has the meaning in (81) which has only one reading (he did not walk slowly, he did not walk with great care), unlike category coordination in (85) has the meaning in (83) where two more readings are possible (he walked slowly, he did not walk with great care; he did not walk slowly, he walked with great care).

(84) We [[did not walk slowly] and [~~did not walk~~ with great care]].

(85) We did not walk [[slowly] and [with great care]].

As shown above, while some examples of unlike category coordination can be reanalysed as conjunction reduction without undesired side-effects (such as distorted, bad semantics), it is not the case that all instances of unlike category coordination can be reanalysed as conjunction reduction (using the analysis designed for NCC). Let us therefore proceed to the discussion of how genuine unlike category coordination can be handled in LFG.

3.2 Categories and c-structure labels

Once the false assumption that coordination can only join elements corresponding to the same category is rejected, the following question immediately arises: when unlike categories are coordinated, what is the category of the coordinate phrase as a whole? Over time, there have been various answers to this question – these are discussed below.

Peterson (2004) proposed that the category of unlike category coordination is the same as the category of the first conjunct, as in the rule in (86):[19]

(86) $\text{X} \longrightarrow \underset{\downarrow\in\uparrow}{\text{X}} \quad \text{Conj} \quad \underset{\downarrow\in\uparrow}{\text{X}}$ (Peterson 2004: (20))

As pointed out in Dalrymple (2017: 38): “This analysis makes the incorrect prediction that the distribution of an unlike category coordination structure matches the distribution of the category of the first conjunct.”[20]

While Peterson (2004) makes unlike category coordination endocentric in the sense that the topmost category is the same as one of the conjuncts, Patejuk

---

[19] While Peterson (2004) uses the C category for the conjunction, it was replaced with Conj in (86) for the sake of consistency as well as to avoid potential confusion (C is typically used for complementisers).

[20] As noted in Bruening & Al Khalaf (2020), Peterson (2004) focuses on cases where the coordinate phrase follows the selector, so the first conjunct is closest to the selector. However, there are cases where coordination precedes the selector (see (72)), so the first conjunct would be farthest from the selector (rather than closest). While this issue can be resolved by assuming that it is the conjunct closest to the selector that corresponds to the topmost category, the point made in Dalrymple (2017) would still hold.

(2015) proposed to use a special category for unlike category coordination (XP or UP), making it exocentric: the rule in (87) uses YP and ZP as variables for different categories.

(87) $$\begin{array}{lllll} \text{XP} & \longrightarrow & \text{YP} & \text{Conj} & \text{ZP} \\ & & \downarrow\in\uparrow & & \downarrow\in\uparrow \end{array}$$ (Patejuk 2015: (4.8))

This proposal is complemented by the use of the distributive CAT attribute in f-structure, making it possible to impose category constraints at this level of representation – rather than using CAT predicate (see Section 3.5.1) and c-structure labels. Under the analysis of Patejuk (2015), the f-structure in (88) corresponds to *John is a republican and proud (of it).*

(88) $$\left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{be}\langle\boxed{2}\rangle\boxed{1}\text{'} \\ \textsc{subj}\ \boxed{1} & \left[\textsc{pred}\ \text{`John'}\right] \\ \textsc{xcomp}\ \boxed{2} & \left[\begin{array}{l} \left\{ \left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{republican}\langle\boxed{1}\rangle\text{'} \\ \textsc{subj} & \boxed{1} \\ \textsc{cat} & \textsc{n} \end{array}\right], \left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{proud}\langle\boxed{1}\rangle\text{'} \\ \textsc{subj} & \boxed{1} \\ \textsc{cat} & \textsc{adj} \end{array}\right] \right\} \\ \textsc{conj}\quad \textsc{and} \end{array}\right] \end{array}\right]$$

According to Dalrymple (2017: 38): "the proposal does not allow the possibility of imposing the category requirements that were shown to be necessary […], since on this view all unlike category coordinations have the same category. It also makes it difficult to enforce category-function correlations and to control the distribution of phrases of different categories, since there is no relation between the category of the unlike category coordination structure and the categories of the conjuncts." This criticism only holds as far as c-structure is concerned (so when the CAT predicate is used, which operates on c-structure labels; see Section 3.5.1). Under the proposal of Patejuk (2015), the categorial constraints discussed in Dalrymple (2017) are imposed at the level of f-structure using the CAT attribute. As shown in (88), conjuncts corresponding to the XCOMP grammatical function have different categories: the value of CAT is N for the noun *republican* and ADJ for the adjective *proud*.

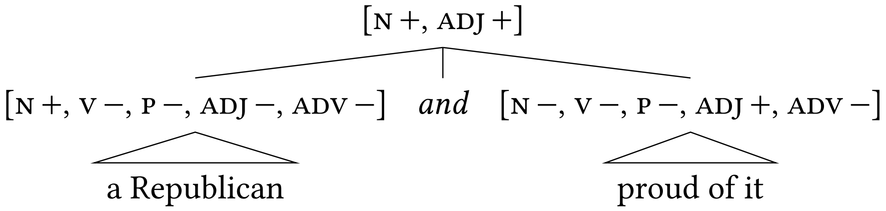
Dalrymple (2017) offers a novel, feature-based solution for choosing the c-structure label of unlike category coordination. While it is conceptually similar to the proposal of Sag et al. (1985), it does not involve controversial feature decomposition (see Bayer (1996) for an extensive critique) as features directly correspond to basic syntactic categories, see (89):

(89) (Dalrymple 2017: (43))

Abbreviation	Feature matrix
N	[N +, V −, P −, ADJ −, ADV −]
V	[N −, V +, P −, ADJ −, ADV −]
P	[N −, V −, P +, ADJ −, ADV −]
Adj	[N −, V −, P −, ADJ +, ADV −]
Adv	[N −, V −, P −, ADJ −, ADV +]

These feature matrices correspond to lexical categories. The category of a coordinate phrase is resolved in a different way (Dalrymple 2017: 48): “the category of a coordinate phrase has the value + for a category feature if there is some conjunct with the value + for that feature”. This makes it possible to provide a simple, elegant account of unlike category coordination: the c-structure in (90) corresponds to *a Republican and proud of it*, where the label of unlike category coordination is [N +, ADJ +].

(90)



(Przepiórkowski & Patejuk 2021: (5))

However, as noted in Przepiórkowski & Patejuk (2021: 208, fn. 4), under such an analysis of coordination, same category coordination has a different category than its conjuncts. For instance, in the case of NP coordination, while the category of all NP conjuncts is [N +, V −, P −, ADJ −, ADV −], the category of the coordinate NP is [N +].

Also, Dalrymple (2017) does not discuss how functional categories such as CP (complementizer phrase) or InfP (infinitival phrase) would be distinguished under this account, which is relevant for unlike category coordination (such as CP and NP, CP and PP, etc.).

Przepiórkowski & Patejuk (2021) offer an alternative solution to the problem of the category of coordination of unlike categories. The analysis proposed in Dalrymple (2017) is limited to categories, while some instances of unlike category coordination require additional constraints, such as appropriate case, complementizer or preposition form (see Section 3.5.2). As a consequence, in order to account for unlike category coordination, it is not enough to state categorial constraints using the built-in CAT predicate (see Section 3.5.1). Przepiórkowski & Patejuk (2021) propose to remove c-structure labels altogether (which is formally equivalent to having just one label) and instead use CAT attribute in f-structure for imposing categorial restrictions (as in Patejuk (2015)). As an example, Przepiórkowski & Patejuk (2021) propose the rule in (91) as a replacement for the rule in (92):

(91) $$\bullet \quad \longrightarrow \quad \begin{array}{c}\bullet\\ (\downarrow \text{\textsc{cat}}) =_c \text{P}\\ \uparrow=\downarrow\end{array} \quad \begin{array}{c}\bullet\\ (\downarrow\text{\textsc{cat}}) \in_c \{\text{P},\text{N}\}\\ (\uparrow \text{\textsc{obj}})=\downarrow\end{array}$$

(Przepiórkowski & Patejuk 2021: (35))

(92) $$\text{P}' \quad \longrightarrow \quad \begin{array}{c}\text{P}\\ \uparrow=\downarrow\end{array} \quad \begin{array}{c}\{\text{NP}|\text{PP}\}\\ (\uparrow \text{\textsc{obj}})=\downarrow\end{array}$$

(Przepiórkowski & Patejuk 2021: (32))

Under this proposal, as in Patejuk (2015), all constraints (related to categories and other features such as case, complementizer or preposition form, etc.) are imposed in f-structure.[21] However, unlike in Patejuk (2015), there is no need for arbitrary c-structure labels for unlike category coordination (such as XP or UP), which was criticised in Dalrymple (2017).

Summing up, this subsection presented different approaches to the problem of choosing the topmost category corresponding to coordination of unlike categories.

3.3 Categories and grammatical functions

Since imposing constraints in f-descriptions relies on grammatical functions to identify the element to be constrained, there is the key question of which grammatical function is appropriate when coordinating unlike categories.

Answering this question can be non-trivial, partially because the choice of the appropriate grammatical function can be controversial even outside of coordination. While LFG considers grammatical functions as primitives of the theory, independent of the position in the c-structure and/or the c-structure category, there have been some discussions and controversy concerning certain grammatical functions. See Belyaev 2023 [this volume] for discussion and references.

Probably the least controversial (though not uncontroversial) grammatical functions include the subj(ect) and the obj(ect). Still, there are different definitions of obj: some (e.g. Patejuk (2015)) choose to define it as the grammatical function which changes to subj when undergoing passivisation, while others (e.g. Börjars & Vincent (2008)) do not consider this as a necessary characteristic.

---

[21] While Patejuk (2015) uses complex off-path constraints to formalise disjunctive constraints, Przepiórkowski & Patejuk (2021) propose to reuse the local variable notation, which results in simpler and more readable constraints – see the discussion in Section 3.5.2.

There has been a lot of debate about complement clauses. Dalrymple & Lødrup (2000) argue that different grammatical functions may be appropriate for complement clauses in different languages, considering obj(ect) and comp ((non-object) closed clausal complement) and proposing criteria for distinguishing these. By contrast, Alsina et al. (2005) argue for getting rid of comp and using obl(ique) instead for non-object complement clauses (among other argument types). Furthermore, Alsina et al. (2005) suggest that it should also be possible to get rid of xcomp (open clausal complement).

On the basis of data from Polish and English, Patejuk & Przepiórkowski (2014a) argue that using xcomp for open (controlled) clausal complements can be problematic, because it is possible to coordinate infinitival phrases (open, controlled) with non-predicative nominals which are closed (do not require control):

(93) Polish
Chcę [[pić] i [papierosa]].
want drink.inf and cigarette.acc
'I want to drink and a cigarette.' (Patejuk & Przepiórkowski 2014a: (1))

(94) My uncle said to hell with that and taught me [[karate], and [to fire weapons]]. (Patejuk & Przepiórkowski 2014a: (27))

Patejuk & Przepiórkowski (2014a) argue that such examples provide independent motivation to get rid of the xcomp: while it would be suitable for the controlled infinitival conjunct (its subject is structure-shared with the matrix subject), it is not suitable for the nominal conjunct which is not controlled and does not have a subject.

Patejuk & Przepiórkowski (2014a) propose an analysis in terms of unlike category coordination, choosing obj as the grammatical function corresponding to coordination in (93).[22] An important novel feature of this analysis is making it possible to establish control into selected conjuncts. This is achieved using the controller attribute (see Section 3.5.2 for detailed discussion), as shown in (95)[23] which corresponds to (93).

(95)
$$\left[\begin{array}{ll}
\text{PRED} & \text{`WANT}\langle\boxed{1},\boxed{2}\rangle\text{'}\\
\text{SUBJ} & \boxed{1}\left[\text{PRED `I'}\right]\\
\text{OBJ} & \boxed{2}\left[\begin{array}{l}\left\{\left[\begin{array}{ll}\text{PRED} & \text{`DRINK}\langle\boxed{1}\rangle\text{'}\\ \text{SUBJ} & \boxed{1}\\ \text{CONTROLLER} & \boxed{1}\end{array}\right], \left[\begin{array}{ll}\text{PRED} & \text{`CIGARETTE'}\\ \text{CASE} & \text{ACC}\\ \text{CONTROLLER} & \boxed{1}\end{array}\right]\right\}\\ \text{CONJ}\quad\text{AND}\end{array}\right]
\end{array}\right]$$

(Patejuk & Przepiórkowski 2014a: (26))

---

[22] If the ability to be passivised is a defining feature of obj, this argument should be an obl in Polish.

[23] The conj attribute was added to this f-structure.

Building on the proposals of Alsina et al. (2005) and Patejuk & Przepiórkowski (2014a), Patejuk & Przepiórkowski (2016) reexamine the repertoire of grammatical functions in LFG, providing additional arguments for getting rid of COMP and XCOMP. They show that it is possible to coordinate categories that would normally correspond to open and closed complements (which again leads to the issue of control into selected conjuncts).

While Patejuk & Przepiórkowski (2016) focus on the discussion of arguments, an analogous observation can be made with respect to adjuncts, where a similar distinction is often made, splitting adjuncts into closed, not controlled (ADJ) and open, controlled (XADJ). In the Polish examples in (96)–(98), the first conjunct would normally be classified as closed (ADJ), while the second conjunct would be open (XADJ). To account for such coordination, a common grammatical function should be identified for such dependents:[24]

(96) Polish
Wychodziliśmy [[szybko] i [unikając spojrzeń innych]].
left.1.PL.M1 quickly and avoiding gazes others
'We were leaving quickly and avoiding peoples' gazes.'

(97) Polish
Przyjechaliśmy do Kotoru [[dosyć późno] i [głodni jak wilki]]…
returned.1.PL.M1 to Kotor pretty late and hungry.NOM.PL.M1 like wolves
'We returned to Kotor pretty late and hungry as wolves…' (Google)

(98) Polish
Gdy [[niechętnie] i [zażenowany]] wchodził za Nirą…
when reluctantly and embarrassed.NOM.SG.M1 entered.3.SG.M1 after Nira
'When, reluctantly and hungry, he entered following Nira…' (NKJP)[25]

This observation is consistent with the general proposal of Patejuk & Przepiórkowski (2016: 549), who conclude that the repertoire of grammatical functions in LFG could be limited to just three: SUBJ(ect), OBJ(ect) (defined as the item that can

---

[24] In Polish, the verb agrees with its subject (which may be implicit, as in (96)–(98)), while predicative adjectives agree with their controller (which may also be implicit, as in (97)–(98)).

[25] NKJP is the National Corpus of Polish (Przepiórkowski et al. (2011, 2012); http://nkjp.pl).

undergo passivisation) and OBL(ique) which serves as the elsewhere grammatical function: "All other dependents, including adjuncts, may be called OBLiques, as in Alsina (1996)." Control into selected conjuncts of OBLiques would be handled in the same way as in (95).

Kaplan (2017) proposes that examples such as (99), analysed as unlike category coordination in Patejuk & Przepiórkowski (2016), see the f-structure in (100), could instead be analysed as non-constituent coordination (NCC, Maxwell & Manning (1996); see Section 2 and Section 3.1), compare the f-structure in (101).[26]

(99) The majority want [[peace] and [to live a comfortable life]].
(Patejuk & Przepiórkowski 2016: (9))

(100)
$$\left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{want}\langle\boxed{1},\boxed{2}\rangle\text{'} \\ \textsc{subj} & \boxed{1}\left[\textsc{pred}\ \text{`}\textsc{majority}\text{'}\right] \\ \textsc{obj} & \boxed{2}\left[\begin{array}{l} \left\{ \left[\begin{array}{ll}\textsc{pred} & \text{`}\textsc{peace}\text{'}\\ \textsc{controller} & \boxed{1}\end{array}\right], \left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{live}\langle\boxed{1},\boxed{3}\rangle\text{'}\\ \textsc{subj} & \boxed{1}\\ \textsc{obj} & \boxed{3}\left[\textsc{pred}\ \text{`}\textsc{life}\text{'}\right]\\ \textsc{controller} & \boxed{1}\end{array}\right]\right\} \\ \textsc{conj}\quad \textsc{and}\end{array}\right]\end{array}\right]$$

(101)
$$\left[\begin{array}{l} \left\{ \left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{want}\langle\boxed{1},\boxed{2}\rangle\text{'} \\ \textsc{subj} & \boxed{1}\left[\textsc{pred}\ \text{`}\textsc{majority}\text{'}\right] \\ \textsc{obj} & \boxed{2}\left[\textsc{pred}\ \text{`}\textsc{peace}\text{'}\right]\end{array}\right], \left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{want}\langle\boxed{1},\boxed{3}\rangle\text{'} \\ \textsc{subj} & \boxed{1} \\ \textsc{xcomp} & \boxed{3}\left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{live}\langle\boxed{1},\boxed{4}\rangle\text{'}\\ \textsc{subj} & \boxed{1}\\ \textsc{obj} & \boxed{4}\left[\textsc{pred}\ \text{`}\textsc{life}\text{'}\right]\end{array}\right]\end{array}\right]\right\} \\ \textsc{conj}\quad \textsc{and}\end{array}\right]$$

(Kaplan 2017: (29))

While (100) involves one instance of the predicate WANT with a coordinate object, the NCC strategy in (101) involves coordination of identical larger categories (VPs), which results in a multiclausal analysis: there are two instances of the predicate WANT, each with a different non-coordinate complement (OBJ vs. XCOMP).

Kaplan (2017: 138) explains that normally the lexical entry in (102) cannot give rise to the f-structure in (101) because "Disjunction in LFG normally has wide scope. Thus either the OBJ frame or the XCOMP frame would be distributed to both elements of the coordination set, and in each case one of the elements will fail the completeness/coherence tests."

(102) *want* (↑ PRED)='WANT⟨SUBJ,OBJ⟩' (Kaplan 2017: (24))
∨ [(↑ PRED)='WANT⟨SUBJ,XCOMP⟩'
(↑ XCOMP SUBJ)=(↑ SUBJ)]

---

[26] The contribution of *comfortable* is ignored in (100)–(101).

Kaplan (2017) offers two solutions to this problem. The first is to use the lexical entry in (103) which uses functional uncertainty for grammatical functions (obj or xcomp) plus an off-path constraint attached to xcomp establishing the subject control relation:

(103) *want* (↑ pred)=‘want⟨subj,{obj | $\underset{(\rightarrow\ \text{subj})=(\leftarrow\ \text{subj})}{\text{xcomp}}$ }⟩’

(Kaplan 2017: (28))

There are two potential challenges for (103): it uses functional uncertainty constructively (disjunction over grammatical functions in pred) and it uses off-path constraints constructively (introducing a defining control equation). However, as mentioned in Patejuk & Przepiórkowski (2014a), while off-path constraints are non-constructive in XLE (Crouch et al. 2011), the native platform for implementing LFG grammars, this does not need to be the case in theoretical analyses (they point out that drafts of the following works allow constructive off-path constraints: Bresnan et al. (2016), Dalrymple et al. (2019)).

The second solution proposed by Kaplan (2017: 138, fn. 9) is to introduce a new built-in template, distrib (see the discussion of (134) in Section 3.5.2), which makes it possible to “declare the disjunctive entry for *want* [(102)] as a narrow-scope distributive property”.

Both solutions proposed in Kaplan (2017) make it possible to reanalyse simple cases of unlike category coordination as NCC (building on Maxwell & Manning (1996)), though without the requirement of strict identity of grammatical functions (due to the possibility of using different lexical entries for different conjuncts). However, these solutions suffer from the same problems as NCC: they cannot handle more complex cases of unlikes (involving negation or modifiers, see the discussion in Section 3.1). There are no such issues with the analysis assuming unlike category coordination.

3.4 Coordinating predicative complements with participles

In early LFG work (Bresnan 1982, Kaplan & Bresnan 1982) the auxiliary be is analysed as a raising verb. The f-structure in (104)[27] corresponds to the sentence *The elephant was worshipped by the child*, which involves passive voice: be is the main verb (having a pred attribute, with be as its value), taking a raised subject and a verbal complement (vcomp) corresponding to the passive lexical verb.

---

[27] Two errors in the original f-structure (Joan Bresnan, pc) were corrected in (104) by adding: the non-semantic subj in the pred of be; structure-sharing of the subj of be and the subj of worship.

(104)
$$\begin{bmatrix} \textsc{pred} & \text{‘}\textsc{be}\langle\boxed{2}\rangle\boxed{1}\text{’} \\ \textsc{subj} & \boxed{1}\begin{bmatrix}\textsc{pred} & \text{‘}\textsc{elephant}\text{’}\end{bmatrix} \\ \textsc{vcomp} & \boxed{2}\begin{bmatrix} \textsc{pred} & \text{‘}\textsc{worship}\langle\boxed{1},\boxed{3}\rangle\text{’} \\ \textsc{subj} & \boxed{1} \\ \textsc{obl}_{\textsc{ag}} & \boxed{3}\begin{bmatrix}\textsc{pred} & \text{‘}\textsc{child}\text{’}\end{bmatrix} \end{bmatrix} \\ \textsc{tense} & \textsc{past} \end{bmatrix}$$

(Bresnan 1982: Figure 1.4b)

The early LFG analysis of progressive constructions is very similar. Kaplan & Bresnan (1982) analyse the sentence *A girl is handing the baby a toy* using the lexical entries for the present participle *handing* and the auxiliary *is* in (105)–(106).[28] These would give rise to the (simplified) f-structure in (107) where the auxiliary is the main verb (note that its PRED value is PROG, unlike in the passive (104)), taking a raised subject and a verbal complement (VCOMP) corresponding to the lexical verb.

(105) *handing* V $(\uparrow \textsc{pred})=\text{‘}\textsc{hand}\langle(\uparrow \textsc{subj})(\uparrow \textsc{obj}2)(\uparrow \textsc{obj})\rangle\text{’}$
$(\uparrow \textsc{participle})=\textsc{present}$

(Kaplan & Bresnan 1982: (65))

(106) *is* V $(\uparrow \textsc{pred})=\text{‘}\textsc{prog}\langle(\uparrow \textsc{vcomp})\rangle(\uparrow \textsc{subj})\text{’}$
$(\uparrow \textsc{vcomp participle})=_c \textsc{present}$
$(\uparrow \textsc{vcomp subj})=(\uparrow \textsc{subj})$
$(\uparrow \textsc{subj num})=\textsc{sg}$

(Kaplan & Bresnan 1982: (70))

(107)
$$\begin{bmatrix} \textsc{pred} & \text{‘}\textsc{prog}\langle\boxed{2}\rangle\boxed{1}\text{’} \\ \textsc{subj} & \boxed{1}\begin{bmatrix}\textsc{pred} & \text{‘}\textsc{girl}\text{’}\end{bmatrix} \\ \textsc{vcomp} & \boxed{2}\begin{bmatrix} \textsc{pred} & \text{‘}\textsc{hand}\langle\boxed{1},\boxed{3},\boxed{4}\rangle\text{’} \\ \textsc{subj} & \boxed{1} \\ \textsc{obj} & \boxed{3}\begin{bmatrix}\textsc{pred} & \text{‘}\textsc{baby}\text{’}\end{bmatrix} \\ \textsc{obj}2 & \boxed{4}\begin{bmatrix}\textsc{pred} & \text{‘}\textsc{toy}\text{’}\end{bmatrix} \\ \textsc{participle} & \textsc{present} \end{bmatrix} \end{bmatrix}$$

Later, the standard LFG analysis of passive/progressive constructions has been to treat the lexical verb as the main verb, while the auxiliary only contributes a bundle of features (such as agreement features, tense, aspect, etc.) – it does not have its own PRED attribute. This results in a “flat” analysis (without embedding) of such constructions: (108) is the flat, monoclausal counterpart of (104), while (109) corresponds to (107).[29]

---

[28] The PRED value in the lexical entry in (106) has been modified to include a non-semantic SUBJ.

[29] Instead of OBJ2 used in early works for the secondary object, as in (107), (109) uses $\textsc{obj}_\theta$.

(108)
$$\begin{bmatrix} \textsc{pred} & \text{`}\textsc{worship}\langle\boxed{1},\boxed{2}\rangle\text{'} \\ \textsc{subj} & \boxed{1}\begin{bmatrix}\textsc{pred} & \text{`}\textsc{elephant}\text{'}\end{bmatrix} \\ \textsc{obl}_{\textsc{ag}} & \boxed{2}\begin{bmatrix}\textsc{pred} & \text{`}\textsc{child}\text{'}\end{bmatrix} \\ \textsc{tense} & \textsc{past} \\ \textsc{passive} & + \end{bmatrix}$$

(109)
$$\begin{bmatrix} \textsc{pred} & \text{`}\textsc{hand}\langle\boxed{1},\boxed{2},\boxed{3}\rangle\text{'} \\ \textsc{subj} & \boxed{1}\begin{bmatrix}\textsc{pred} & \text{`}\textsc{girl}\text{'}\end{bmatrix} \\ \textsc{obj} & \boxed{2}\begin{bmatrix}\textsc{pred} & \text{`}\textsc{baby}\text{'}\end{bmatrix} \\ \textsc{obj}_{\theta} & \boxed{3}\begin{bmatrix}\textsc{pred} & \text{`}\textsc{toy}\text{'}\end{bmatrix} \\ \textsc{tense} & \textsc{present} \\ \textsc{aspect} & \textsc{prog} \end{bmatrix}$$

With predicative complements, the copula has been analysed over time as a raising verb – taking a subject and a predicative complement: open (XCOMP)[30] or closed (PREDLINK), depending on the analysis. There have also been analyses where the predicative item is the main predicate, while the copula only contributes certain features (having no PRED). See Dalrymple et al. (2004) for a comprehensive discussion of all the possibilities.

There is an interesting interaction between unlike category coordination and constructions with an auxiliary (such as passive/progressive constructions). As discussed in Peterson (1981, 2004), it is possible to coordinate a predicative complement with a present/passive participle, see (110)–(115). In order to avoid having to analyse such examples as an instance of ellipsis (conjunction reduction resulting in a multiclausal structure),[31] it is necessary to adopt a uniform analysis of the linking word (as the main verb or not).

In English, many examples of unlike category coordination of a predicative complement and a present participle are discussed in Peterson (1981). Using examples such as (112), among others, Peterson (1981) argues that these are not instances of ellipsis (conjunction reduction) but genuine coordination of unlike categories:

(110) The children were [[happy] and [smiling]]. (Peterson 1981: (9))

(111) John is [[awake] and [asking for you]]. (Peterson 1981: (10))

---

[30] While XCOMP is category neutral, in early LFG (Bresnan 1982, Kaplan & Bresnan 1982) different grammatical functions were used for different categories: ACOMP for adjectives, NCOMP for nouns, etc.

[31] This is also the case under the proposal of Kaplan (2017) to introduce the DISTRIB template, making it possible to treat disjunctive lexical entries as narrow-scope distributive properties (see (134) in Section 3.5.2).

(112) He was [both [happy] and [smiling]]. (Peterson 1981: (27))

Peterson (2004) provides more examples, including one with a passive participle, (114):

(113) Bill could be [[a plumber] and [making a fortune]]. (Peterson 2004: (8c))

(114) I imagined John [[a convicted felon] and [imprisoned for life]]. (Peterson 2004: (8g))

(115) The children are [[awake] and [asking for you]]. (Peterson 2004: (45))

Peterson (2004) provides the f-structure in (116) as the representation of (115):

(116)

$$\left[\begin{array}{ll}
\text{PRED} & \text{‘BE}\langle\boxed{2}\rangle\boxed{1}\text{’}\\
\text{SUBJ}\ \boxed{1} & \left[\text{PRED}\ \ \text{‘CHILDREN’}\right]\\
\text{XCOMP}\ \boxed{2} & \left[\begin{array}{l}\left\{\left[\begin{array}{ll}\text{PRED} & \text{‘AWAKE}\langle\boxed{1}\rangle\text{’}\\ \text{SUBJ} & \boxed{1}\end{array}\right], \left[\begin{array}{ll}\text{PRED} & \text{‘ASK}\langle\boxed{1},\boxed{3}\rangle\text{’}\\ \text{SUBJ} & \boxed{1}\\ \text{OBL}_{\text{GOAL}} & \boxed{3}\left[\text{PRED}\ \ \text{‘YOU’}\right]\end{array}\right]\right\}\\ \text{CONJ}\ \ \ \text{AND}\end{array}\right]\\
\text{TENSE} & \text{PRES}
\end{array}\right]$$

(Peterson 2004: (47))

While Peterson (2004) does not discuss the possibility of using the NCC analysis of Maxwell & Manning (1996) for unlike category coordination, it seems clear that he would not want to adopt it, because it results in a multiclausal f-structure representation, equivalent to VP-level coordination – an elliptical analysis that Peterson (2004) explicitly argues against.

Patejuk & Przepiórkowski (2014b) discuss similar data from Polish, focusing on the coordination of adjectives and passive participles such as in (117), where the first conjunct (*zrobiony* ‘made’) is a passive participle, the second (*bezpieczny* ‘safe’) is an adjective and the third (*zarejestrowany* ‘registered’) is a passive participle with a *by*-phrase:

(117) Polish

Nasz	pas	jest	[[dobrze	zrobiony],	[bezpieczny]
our	runway.NOM.SG.M3	is	well	made.NOM.SG.M3	safe.NOM.SG.M3

i	[zarejestrowany	przez	Urząd	Lotnictwa	Cywilnego]].
and	registered.NOM.SG.M3	by	Office.ACC	Aviation.GEN	Civil.GEN

‘Our runway is well made, safe and registered by the Civil Aviation Office.’ (Patejuk & Przepiórkowski 2014b: (1))

Using Polish negation data as independent evidence, Patejuk & Przepiórkowski (2014b) argue for a unified treatment of BYĆ 'be' as a raising verb taking a complement which can be an adjective, a passive participle, or a coordination of these – as in (117), which they analyse as (118). As a result, as in Peterson (2004), passive and predicative constructions use the embedded representation (as opposed to the flat representation using co-heads).

(118)

$$\begin{bmatrix}
\text{PRED} & \text{`BE}\langle\boxed{2}\rangle\boxed{1}\text{'} \\
\text{SUBJ}\ \boxed{1} & \begin{bmatrix}\text{PRED} & \text{`RUNWAY'}\end{bmatrix} \\
\text{XCOMP}\ \boxed{2} & \begin{bmatrix} \left\{\left(\begin{bmatrix} \text{PRED} & \text{`MAKE}\langle\boxed{1}\rangle \\ \text{SUBJ} & \boxed{1} \\ \text{ADJ} & \left\{\begin{bmatrix}\text{PRED} & \text{`WELL'}\end{bmatrix}\right\} \\ \text{PASSIVE} & + \end{bmatrix}, \begin{bmatrix} \text{PRED} & \text{`SAFE}\langle\boxed{1}\rangle\text{'} \\ \text{SUBJ} & \boxed{1} \end{bmatrix}, \begin{bmatrix} \text{PRED} & \text{`REGISTER}\langle\boxed{1},\boxed{3}\rangle \\ \text{SUBJ} & \boxed{1} \\ \text{OBL}_{\text{AG}} & \boxed{3}\begin{bmatrix}\text{PRED} & \text{`CAO'}\end{bmatrix} \\ \text{PASSIVE} & + \end{bmatrix} \right)\right\} \\ \text{CONJ}\quad \text{AND} \end{bmatrix}
\end{bmatrix}$$

(Patejuk & Przepiórkowski 2014b: (53))

3.5 Disjunctive constraints

The main remaining question related to unlike category coordination is how to impose disjunctive constraints (such as subcategorisation in examples discussed earlier). Over time, there have been two main approaches to this issue. They may also be used together.

3.5.1 CAT predicate

The first approach focuses on constraints related to c-structure categories, relying on the built-in CAT predicate for imposing such constraints, as defined in (119):

(119) $\text{CAT}(f, C)$ iff $\exists n \in \phi^{-1}(f) : \lambda(n) \in C$

"CAT(f, C) is true if and only if there is some node n that corresponds to f via the inverse ϕ correspondence (ϕ^{-1}) whose label (λ) is in the set of categories C." (Dalrymple (2017: (24)) after Kaplan & Maxwell (1996: 93))

Dalrymple (2017) shows how CAT can be used to account for disjunctive subcategorisation requirements of the verb BECOME: assuming that CAT is distributive, each conjunct must satisfy the constraint imposed by CAT. As a result, (120) ensures that the predicative complement (PREDLINK or XCOMP, depending on the analysis) of BECOME must be an adjectival phrase (AdjP), a nominal phrase (NP), or a coordination of these, as in (121).

(120) CAT(($\uparrow$ PREDLINK), {AdjP, NP}) (Dalrymple 2017: (26))

(121) Fred became [[a professor] and [proud of his work]].
(Dalrymple 2017: (6a))

The CAT predicate is designed specifically for imposing constraints on c-structure categories. However, as discussed earlier, accounting for unlike category coordination may require additional constraints, such as having a certain value of case, preposition or complementiser form, etc., or introducing control equations (see (93)–(94)).

Technically, features such as case, preposition form and complementiser form can be added to c-structure category labels, resulting in complex categories such as NP[case], PP[pform,case] or CP[compform], making it possible to impose extra constraints using the CAT predicate that is normally used only for category labels. However, there are some issues with such a solution. First, it requires copying f-structure information to c-structure, resulting in redundancy. More importantly, such a solution would not be sufficient for more complex phenomena such as structural case assignment to the object in Polish because its value of case depends on the presence or absence of negation on the verb assigning case. Simplifying, in Polish the structural object is accusative without negation, but it is genitive if negation is present. This requires more complex constraints.

Consider again the example in (93) (with the corresponding f-structure in (95)), where the object involves unlike category coordination. While the first conjunct (*pić* ‘drink’) is a controlled infinitival phrase (InfP), the second conjunct (*papierosa* ‘cigarette’) is an NP bearing accusative case (as structural case when there is no sentential negation). The simple CAT constraint in (122) restricts categories corresponding to the object of the verb CHCIEĆ ‘want’ to InfP or NP. The version using complex categories in (123) additionally restricts the case of the NP to accusative or genitive (the two possible values, as above).

(122) CAT((↑ OBJ), {InfP, NP})

(123) CAT((↑ OBJ), {InfP, NP[acc], NP[gen]})

While (122) does not restrict the value of case of the NP object in any way, (123) restricts it to accusative or genitive, but the crucial constraint making the value of case dependent on sentential negation is absent. Even with complex categories, it is not sufficient to use the CAT predicate to express more complex constraints necessary in unlike category coordination (such constraints are discussed in Section 3.5.2).

Dalrymple (2017) offers a novel solution to the issue of the category of unlike category coordination by replacing atomic c-structure labels (such as NP, AdjP, PP) with labels consisting of attribute-value structures (see Section 3.2). However, as discussed in Przepiórkowski & Patejuk (2021), such a solution would also not be able to handle more complex disjunctive subcategorisation requirements needed to account for unlike category coordination.

As an alternative, Przepiórkowski & Patejuk (2021) propose to remove category labels from c-structure and move category information to f-structure (see Section 3.2), so that all necessary constraints can be imposed at one level of representation: f-structure. This is discussed in more detail in Section 3.5.2.

3.5.2 F-structure constraints

The second type of disjunctive constraints is related to f-structure. In order to account for unlike category coordination, where each conjunct may satisfy a different set of constraints, such disjunctive constraints must be interpreted distributively, so that the disjunction is evaluated separately for each conjunct.

Consider (124): the object of UNDERSTAND involves unlike category coordination – its first conjunct is an NP, while the second conjunct is a CP with the complementizer THAT:

(124) I understand [[those concerns] and [that they are sincerely held]].
(Patejuk & Przepiórkowski 2023: (39))

Intuitively, the constraint in (125) should be appropriate to account for (124):

(125) $[(\uparrow \textsc{obj case}) =_c \textsc{acc} \vee (\uparrow \textsc{obj comp-form}) =_c \textsc{that}]$

However, as observed in Przepiórkowski & Patejuk (2012) when discussing structural case assignment to Polish subjects which also involves disjunction,[32] while the intended effect of such a disjunctive constraint is for it to be evaluated independently for each conjunct, so that different conjuncts may have different specifications, the actual effect is exactly the opposite: the disjunctive constraint is evaluated once (one disjunct is chosen) and the result is distributed to all conjuncts – as a consequence, all conjuncts must have the same specification. The following formulae from Patejuk (2015) formalise this contrast:

(126) a. $\forall x \in (\uparrow \textsc{gf})[A(x) \vee B(x)]$ (intended)

b. $\forall x \in (\uparrow \textsc{gf})\, A(x) \vee \forall x \in (\uparrow \textsc{gf})\, B(x)$ (actual)

---

[32] In Polish the subject requiring structural case can be – simplifying – nominative or, if it is a non-agreeing numeral, accusative, or a coordination of these. Apart from this, some predicates may take verbal subjects (InfP or CP) which may be coordinated with NPs bearing structural case.

The "liberal" solution offered in Przepiórkowski & Patejuk (2012: 485) is to "understand (non-)distributivity not as a property of features, but as a property of statements". This involves making statements distributive by default – non-distributive statements must be marked explicitly (with "@"). As Przepiórkowski & Patejuk (2012: 485) point out, "An interesting consequence of this proposal is that a given feature may behave distributively in some ways and non-distributively in others.", providing CASE as an example: while it is a non-distributive attribute in Polish, an additional distributive statement is used to ensure that each of the conjuncts bears an appropriate value of case.

The second solution described[33] in Przepiórkowski & Patejuk (2012: 486) is called "conservative" as it does not require any modifications to the LFG theory: it relies on the existing mechanism of off-path constraints. A distributive attribute (typically PRED, as below) is used as an anchor, so that the disjunctive constraint is distributed to each conjunct and evaluated independently: (127) is the off-path counterpart of (125), achieving its intended effect. This solution is presented in more detail in Patejuk & Przepiórkowski (2012a).

(127) $(\uparrow \textsc{obj}\ \underset{[(\leftarrow \textsc{case}) =_c \textsc{acc}\ \vee\ (\leftarrow \textsc{comp-form}) =_c \textsc{that}]}{\textsc{pred}})$

Note that (127) uses constraining equations. While "plain" (not off-path) constraints can be defining (=, introducing an attribute-value pair) or constraining ($=_c$, checking if a given attribute-value pair is present), there are different formal views on off-path constraints. Some works assume these are non-constructive, which means that off-path constraints can only be constraining, so it is not possible to have defining off-path constraints – this is consistent with how off-path constraints work in XLE.[34] However, some theoretical works assume that off-path constraints can be constructive (see the discussion of (103) in Section 3.3), making it is possible to use these for introducing new attribute-value pairs.

This issue (whether off-path constraints can be constructive or not) is of significant importance in the context of unlike category coordination, since some constraints are typically defining – this includes control equations in examples such as (93), where one of the conjuncts requires control. As explained in Patejuk & Przepiórkowski (2014a), the control equation in (128)[35] would produce an ill-formed, incoherent f-structure because the non-infinitival conjunct does not take a subject. The disjunctive constraint in (129), aiming to address this issue, would

---

[33] As explained in Przepiórkowski & Patejuk (2012), this solution is the idea of Mary Dalrymple.

[34] https://ling.sprachwiss.uni-konstanz.de/pages/xle/doc/notations.html#N4.1.5b

[35] As mentioned in footnote 22, OBL may be more appropriate than OBJ for the coordinate phrase in (93).

also not work – as explained above, instead of being distributed as in (126a), it would be interpreted as in (126b): depending on which disjunct is chosen, one of the conjuncts would not satisfy the chosen constraint. (130) is the off-path version of (129) – whether it would have the intended effect depends on whether off-path constraints can be constructive.

(128) $(\uparrow \textsc{subj})=(\uparrow \textsc{obj subj})$

(129) $[(\uparrow \textsc{obj cat})=_c \textsc{inf} \ \wedge\ (\uparrow \textsc{subj})=(\uparrow \textsc{obj subj})] \ \vee\ (\uparrow \textsc{obj cat})\neq \textsc{inf}$

(130)
$$(\uparrow \textsc{obj} \underset{\begin{array}{c}[(\leftarrow \textsc{cat})=_c \textsc{inf} \ \wedge\ (\leftarrow \textsc{subj})=((\textsc{obj} \leftarrow)\ \textsc{subj})]\\ \vee \\ (\leftarrow \textsc{cat})\neq \textsc{inf}\end{array}}{\textsc{pred}})$$

To avoid the potential issue with (130) (since off-path constraints are non-constructive in XLE, this is a real issue for implemented grammars), Patejuk & Przepiórkowski (2014a) describe an alternative solution, again due to Mary Dalrymple: the idea is to use a dedicated attribute, CONTROLLER, to host the controller.

Let us consider again the example in (93), where the complement of CHCIEĆ ‘want’ consists of an infinitival phrase controlled by the subject and a noun phrase bearing structural case. Under this alternative proposal, instead of (128), the lexical entry of CHCIEĆ introduces the modified control equation in (131). As a consequence, the subject of CHCIEĆ is structure-shared with the CONTROLLER attribute of its OBJ complement. This does not trigger the coherence violation in the NP conjunct that is caused by (128).

(131) $(\uparrow \textsc{subj})=(\uparrow \textsc{obj controller})$

In the absence of (128) the InfP conjunct would be incomplete (its SUBJ needs to be filled), so the constraint in (132) is used instead to satisfy completeness. When used inside the InfP, (132) structure-shares the value of its CONTROLLER attribute with its SUBJ, providing the InfP complement of CHCIEĆ with a subject.

(132) $(\downarrow \textsc{controller})=(\downarrow \textsc{subj})$

Together, (131) and (132) make it possible to satisfy completeness by providing the InfP with a controller for its subject without violating coherence in non-infinitival conjuncts in examples such as (93).[36] This solution can also be used for unlike modifiers in (96)–(98).

---

[36] The CONTROLLER attribute could also be used to host the controller of predicative complements, providing an alternative solution to the problem of predicative complements that have a subject of their own such as gerunds or CPs (Dalrymple et al. 2004). While standard open complement (XCOMP(-PRED)) analyses result in incoherence (two different values of SUBJ – one internal vs. one resulting from control), there would be no such problem when control is established via CONTROLLER.

It is worth noting that the CONTROLLER attribute introduced by (131) is represented in each conjunct, no matter whether a given conjunct requires control (as the infinitival conjunct in (93)) or not (as the nominal conjunct in (93)). CONTROLLER would be present even if there is no conjunct requiring control. If this is considered an issue, the restriction operator (\) can be used to remove the CONTROLLER attribute where is not necessary.

As mentioned above, the complement of CHCIEĆ 'want' may be an NP taking structural case (accusative or genitive, depending on the presence of sentential negation) or a controlled InfP. This is formalised in (133) using off-path constraints (non-constructive):

(133)
$$(\uparrow \text{OBJ} \quad \underset{\begin{array}{c} [(\leftarrow \text{CAT}) =_c \text{INF} \ \wedge \ (\leftarrow \text{SUBJ}) =_c ((\text{OBJ} \leftarrow)\ \text{SUBJ})] \\ \vee \\ [(\leftarrow \text{CAT}) =_c \text{N} \ \wedge \\ [[\neg((\text{OBJ} \leftarrow)\ \text{NEG}) \ \wedge \ (\leftarrow \text{CASE}) =_c \text{ACC}] \ \vee \\ [((\text{OBJ} \leftarrow)\ \text{NEG}) =_c + \ \wedge \ (\leftarrow \text{CASE}) =_c \text{GEN}]]] \end{array}}{\text{PRED}} \quad)$$

While off-path constraints make it possible to impose disjunctive constraints under coordination, the resulting constraints are rather complex and hard to read. If off-path constraints are non-constructive (as in XLE), this limitation forces a special way of imposing constraints (defining constraints must be used elsewhere, as shown above).

Alternative solutions include the "liberal" solution of Przepiórkowski & Patejuk (2012) discussed above (making distributivity a property of statements, so that statements are distributive by default, while non-distributive statements must be marked as such).

Kaplan (2017: 133–4, fn. 6) offers another alternative, proposing to formalise the idea of the "liberal" solution of Przepiórkowski & Patejuk (2012) by introducing DISTRIB, "an explicit operator declaring that an arbitrary description P is a distributive property when it is applied to an f-structure f that happens to be a set":

(134) $\text{DISTRIB}(f, v, P)$

Kaplan (2017: 134) adds: "In any invocation (perhaps notated as a built-in template call) f will be a designator (e.g. ↑) and P will be a formula with a variable v that is bound in the scope of P to either the non-set designated by f or to each of its elements in turn."

(135) is the DISTRIB template call corresponding to the off-path constraint in (127), while (136) is the counterpart of (133). (136) is compatible with the CONTROLLER-based approach to establishing control relations shown in (131)–(132).

(135) @distrib((↑ obj), %o, [(%o case)=$_c$ acc ∨ (%o comp-form)=$_c$ that])

(136) @distrib((↑ obj), %o,
[(%o cat)=$_c$ inf ∧ (↑ subj)=$_c$(%o subj)] ∨ [(%o cat)=$_c$ n ∧
[[¬(↑ neg) ∧ (%o case)=$_c$ acc] ∨ [(↑ neg) ∧ (%o case)=$_c$ gen]]])

However, since constraints imposed using distrib can be constructive, (137) can be used instead. It introduces a standard defining control equation ((↑ subj)=(%o subj) instead of (↑ subj)=$_c$(%o subj)), so there is no need to use the controller attribute.

(137) @distrib((↑ obj), %o,
[(%o cat)=$_c$ inf ∧ (↑ subj)=(%o subj)] ∨ [(%o cat)=$_c$ n ∧
[[¬(↑ neg) ∧ (%o case)=$_c$ acc] ∨ [(↑ neg) ∧ (%o case)=$_c$ gen]]])

The last alternative solution, proposed by Przepiórkowski & Patejuk (2021), is to reuse the formal device of local names (local variables) as a way of stating distributive properties – (138) is the counterpart of (127), while (139) corresponds to (133).

(138) (↑ obj)=%o ∧
[(%o case)=$_c$ acc ∨ (%o comp-form)=$_c$ that]

(139) (↑ obj)=%o ∧
[(%o cat)=$_c$ inf ∧ (↑ subj)=$_c$(%o subj)] ∨ [(%o cat)=$_c$ n ∧
[[¬(↑ neg) ∧ (%o case)=$_c$ acc] ∨ [(↑ neg) ∧ (%o case)=$_c$ gen]]]

As in the case of distrib proposed by Kaplan (2017), constraints imposed in this way can also be constructive, so – as in (137) – it is possible to use (139) with a defining control equation in order to avoid using the controller attribute to establish control.

While the "liberal" solution of Przepiórkowski & Patejuk (2012) makes statements (including disjunctive constraints) distributive (as in (126a); non-distributive properties need to be marked explicitly), the solutions proposed by Kaplan (2017) and Przepiórkowski & Patejuk (2021) are both "conservative" in the sense that statements are non-distributive (see (126b)) unless they are stated using the distrib template or local names, respectively.

4 Coordination of unlike grammatical functions

Coordination can be even more unlike than when unlike categories are involved: in some languages it is possible to coordinate unlike grammatical functions under some circumstances. This is very robust in Slavic, Romanian and Hungarian, but it is also possible, to a lesser extent, in other languages, including English. This phenomenon has been discussed in the literature under different names, including: "lexico-semantic coordination" (Sannikov 1979, 1980, Mel'čuk 1988), "hybrid coordination" (Chaves & Paperno 2007) and "heterofunctional coordination" (Przepiórkowski 2022). While this type of coordination is sometimes referred to as "wh-coordination" (Bîlbîie & Gazdik 2012) when the discussion is restricted to interrogative items (as in (140)),[37] there are many more possible types of conjuncts, corresponding to different types of quantifiers: the universal quantifier in (141), the existential quantifier (indefinite pronouns in (142), free choice pronouns in (143)), *n*-words in (144) (existential quantifier in scope of negation), etc. The basic generalisation is that this variety of coordination joins elements which belong to the same (restricted) semantic type, but they correspond to different grammatical functions.

(140) Polish
[[Kogo] i [komu]] przedstawił?
who.ACC and who.DAT introduced
'Who did he introduce to whom?' (Kallas 1993: 121, (241))

(141) Polish
Obiecać można [[wszystko] i [wszystkim]].
promise may everything.ACC and everyone.DAT
'One may promise everything to everyone.' (NKJP)

(142) Polish
[[Ktoś], [gdzieś] i [coś]] mocno pokiełbasił.
someone.NOM somewhere and something.ACC really messed up
'Someone really messed something up somewhere.' (NKJP)

(143) Polish
czy [[komukolwiek], [kiedykolwiek] i [do czegokolwiek]]
PRT anybody.DAT anytime and for anything
przydał się poradnik
come in handy guide
'Has a(ny) guide ever come in handy to anybody for anything?' (NKJP)

(144) Polish
[[nikogo] i [nic]] nie może tłumaczyć.
nobody.GEN and nothing.NOM NEG can excuse
'Nothing can excuse anybody.' (NKJP)

---

[37] All examples used in this section are in Polish. Except for (148), all examples are from Patejuk (2015). Some glosses and translations have been modified.

4.1 Is this really coordination?

When discussing coordination of different grammatical functions, a fundamental question arises: is this really coordination? For instance, in Polish the word *i* can be a conjunction, but it can also be an interjection or a particle. So perhaps the word that seems to be a conjunction in this construction is not a conjunction (but some other element) and such examples do not involve coordination. Patejuk & Przepiórkowski (2012b), Patejuk (2015), Patejuk & Przepiórkowski (2019) present a range of arguments showing that coordination of different grammatical functions is a genuine instance of coordination.

As Patejuk & Przepiórkowski (2019: 28) point out: "in all languages which allow for joining different grammatical functions the joining element has the same form as a conjunction". As shown below, different conjunctions may be used.

There are examples with unambiguous conjunctions, such as *oraz* in (145).

(145) Polish

[[kto]	oraz	[kiedy]]	miałby	płacić	za	postawiony	budynek
who.NOM	and	when	should	pay	for	erected	building

'Who and when would be supposed to pay for the erected building?' (NKJP)

There are examples such as (146) where other interpretations exist, but these are not appropriate in the given context. Apart from the conjunction, the only alternative interpretation of *lub* is as the imperative form of the verb LUBIĆ 'like', clearly not suitable in (146).

(146) Polish

Mile	widziane	odpowiedzi	merytoryczne,	bez	przypuszczeń
welcome		responses	substantive	without	speculating

[[kto]	lub	[czego]]	będzie	w	Wikipedii	szukał.
who.NOM	or	what.GEN	AUX	in	Wikipedia	seek

'Welcome are substantive responses, without speculating who will seek what in Wikipedia.' (NKJP)

Some conjunctions have special requirements – for instance, *ani* 'neither/nor' belongs to *n*-words, so it needs negation to be licenced. As shown in (147), removing negation results in ungrammaticality, which is consistent with the behaviour of the conjunction *ani*.

(147) Polish
Nigdy nie wyjeżdżałyśmy na wakacje, bo *(nie) miałyśmy [[z
never NEG leave for holidays because NEG had with
kim] ani [za co]]…
who.INS nor for what.ACC
‘We would never go on holiday because there was nobody we could go with and there was no money to go.’ (Joanna Bator, *Ciemno, prawie noc*, 119)

Some examples, apart from a conjunction, also include a preconjunction, as in (148).

(148) Polish
…kiedy wyjawisz [nie tylko [kto], ale i [dlaczego]] otrzymał
when disclose not only who.NOM but and why received
awans.
promotion
‘…when you explain not only who, but also why got promoted.’
(Patejuk & Przepiórkowski 2019: (9))

Finally, it is possible to coordinate more than two items – see (142) and (143).

Summing up, there is substantial evidence showing that different grammatical functions are joined with a conjunction and the construction in question is a variety of coordination.

4.2 How to represent such coordination?

Having established that coordination of different grammatical functions is indeed an instance of coordination, the next question is how it should be represented.

Patejuk & Przepiórkowski (2012b) offer an analysis with two possible representations: monoclausal (involving one clause, where all conjuncts are dependents of the same clause) or multiclausal (involving more than one clause, where conjuncts are dependents of different clauses; this is equivalent to clause-level coordination with ellipsis). It may be the case that the two different representations are needed in the same language, as in Polish.

Patejuk (2015) provides a critical review of various diagnostics/arguments for determining the right representation for coordination of different grammatical functions. While there are cases when it is necessary to adopt the multiclausal representation (for instance, when the conjuncts cannot belong to the same clause, see Section 4.4), it is hard to rule out the multiclausal representation elsewhere, unless it is assumed that ellipsis only operates under identity. Without this assumption, it is difficult to argue against arbitrary ellipsis mechanisms (which may be arbitrarily powerful). Due to this, it seems reasonable to assume that unless there are good reasons to adopt the multiclausal analysis, the monoclausal analysis should be preferred by default as the more economical representation.

The analysis presented below is the one proposed in Patejuk (2015) (which is an improved version of Patejuk & Przepiórkowski (2012b)). (149) is the topmost rule corresponding to the coordination of different grammatical functions; the two disjuncts on the right-hand side correspond to two different representations discussed in detail later: XPlxm_{type} is monoclausal (Section 4.3),[38] while XPlxb_{type} is bi/multiclausal (Section 4.4).

(149) $$\text{anyLEXSEM} \longrightarrow \left\{ \begin{array}{c|c} \text{XPlxm}_{type} & \text{XPlxb}_{type} \\ \downarrow\in(\uparrow \text{UDF}) & \end{array} \right\}$$

The category anyLEXSEM is mostly intended to be used as the initial[39] dependent of S (or CP): (150) is a modified version of (16). Since conjuncts inside anyLEXSEM have appropriate annotations (including GF), anyLEXSEM has no annotation (equivalent to ↓=↑).

(150) S ⟶ anyLEXSEM VP

4.3 Monoclausal

The monoclausal representation is appropriate for coordination of different grammatical functions when all conjuncts can be dependents of the same clause. This has been the case in all examples so far. However, conjuncts do not have to be dependents of the same head. There are examples where they depend on different heads, as in (144) and below:

(151) Polish

[[Skąd]	i	[jakie]]	otrzymujemy	informacje?
whence	and	what.ACC	receive	information.ACC

‘What information and from where do we receive?’ (NKJP)

---

[38] UDF (unbounded dependency function, Asudeh (2011)) is a discourse function used instead of TOPIC/FOCUS so as to avoid representing information structure concepts in f-structure.

[39] Examples such as (147) show that such coordination can also be used non-initially.

(152) Polish
[[Jakie] i [kto]] może ponieść konsekwencje?
what.ACC and who.NOM can bear consequences.ACC
'Who can suffer what consequences?' (Google)

(153) Polish
[[Ile] i [czego]] znaleźli?
how much.ACC and what.GEN found
'How much, and (of) what, did they find?' (NKJP)

In (144) the first conjunct (*nikogo* 'nobody') is the object of the infinitival complement (*tłumaczyć* 'excuse'), while the second conjunct (*nic* 'nothing') is the subject of the main verb (*może* 'can'). In (151) the first conjunct (*skąd* 'from where') is a modifier of the verb (*otrzymujemy* 'get'), while the second conjunct (*jakie* 'what') is a modifier of the verb's object (*informacje* 'information'). (152) is similar to (144) and (151): the first conjunct (*jakie* 'what') is a modifier of the object (*konsekwencje* 'consequences') of the infinitival complement (*ponieść* 'suffer'), while the second conjunct (*kto* 'who') is the subject of the main verb (*może* 'can'). (153) is different because one conjunct depends on the other:[40] while the first conjunct (*ile* 'how much') is the object of the verb (*znaleźli* 'found'), the second conjunct (*czego* 'what') is the nominal complement of *ile*.[41]

The formalisation of Patejuk (2015) relies on the following components:

(154)
$$\begin{array}{cccccc} \text{XPlxm}_{type} \longrightarrow & \text{XPlxmC}_{type} & [, & \text{XPlxmC}_{type}]^{*} & \text{Conj} & \text{XPlxmC}_{type} \\ & \downarrow\in\uparrow & & \downarrow\in\uparrow & & \downarrow\in\uparrow \end{array}$$

(155)
$$\text{XPlxmC}_{type} \longrightarrow \left\{ \text{XPextr}_{type} \mid \text{XPlxm}_{type} \right\}$$

(156)
$$\begin{array}{ll} \text{XPextr}_{type} \longrightarrow & \text{XP}_{type} \\ & \uparrow=\downarrow \\ & ((\textsc{udf} \in^{*} \uparrow)\ \textsc{xpath}\ \textsc{gf}^{+})=\downarrow \end{array}$$

(157)
$$\text{XP}_{type} \equiv \{\text{NP}|\text{PP}|\text{ADVP}|\text{AP}\}_{type}$$

(158)
$$type \equiv \{\ all \mid any \mid int \mid neg\ \}$$

(159)
$$\textsc{xpath} \equiv \textsc{xcomp}^{*}$$

---

[40] ZNALEŹĆ 'find' cannot take a genitive partitive object, so *czego* cannot be analysed as its object: **Czego znaleźli?*

[41] In Polish, the numeral phrase is headed by the numeral which takes a nominal complement (with agreeing numerals, it has the same case while with non-agreeing numerals it is genitive).

(160) $\textsc{gf} \equiv \{\textsc{subj}|\textsc{obj}|\textsc{obj}_{\theta}|\textsc{obl}|\textsc{adj} \in\}$

All rules in (154)–(157) use the $_{type}$ variable defined in (158) – its value must be the same on both sides of the rule. (154) is the topmost rule corresponding to monoclausal (hence "m" in XPlxm) coordination of different grammatical functions ("lx" in XPlxm stands for "lexico-semantic", the term first used in Sannikov (1979, 1980) to refer to such coordination). XPlxm_{type} rewrites to a sequence of XPlxmC_{type} conjuncts (hence "C" in XPlxmC) – it is only possible to coordinate conjuncts belonging to the same semantic type (listed in (158)). (155) rewrites XPlxmC_{type} to XPextr_{type} (no embedding) or XPlxm_{type}, which makes it possible to embed such coordination. (156) rewrites XPextr_{type} to XP_{type} – the metacategory[42] defined in (157) as a disjunction of categories of the same $_{type}$.

Together with (149)–(150), these produce the following monoclausal f-structure for (151):

(161)
$$\left[\begin{array}{ll}
\textsc{pred} & \text{‘}\textsc{receive}\langle\boxed{1},\boxed{2}\rangle\text{’} \\
\textsc{subj} & \boxed{1}\left[\textsc{pred}\ \ \text{‘}\textsc{pro}\text{’}\right] \\
\textsc{obj} & \boxed{2}\left[\begin{array}{ll}\textsc{pred} & \text{‘}\textsc{information}\text{’}\\ \textsc{case} & \textsc{acc}\\ \textsc{adj} & \left\{\boxed{3}\right\}\end{array}\right]\\
\textsc{adj} & \left\{\boxed{4}\right\}\\
\textsc{udf} & \left\{\left[\begin{array}{l} \left\{ \boxed{4}\left[\begin{array}{ll}\textsc{pred} & \text{‘}\textsc{whence}\text{’}\\ \textsc{type} & \textsc{int}\end{array}\right], \boxed{3}\left[\begin{array}{ll}\textsc{pred} & \text{‘}\textsc{what}\text{’}\\ \textsc{case} & \textsc{acc}\\ \textsc{type} & \textsc{int}\end{array}\right]\right\} \\ \textsc{conj}\ \ \textsc{and}\end{array}\right]\right\}
\end{array}\right]$$

(Patejuk 2015: (5.125))

To see how the monoclausal analysis of Patejuk (2015) works, let us consider its procedural intuition showing how (161) is built using the rules in (149)–(150) and (154)–(160).

(162) and (163) are the partial f-structures built by the words *skąd* and *jakie*, respectively:

(162)
$$\left[\begin{array}{ll}\textsc{pred} & \text{‘}\textsc{whence}\text{’}\\ \textsc{type} & \textsc{int}\end{array}\right]$$

(163)
$$\left[\begin{array}{ll}\textsc{pred} & \text{‘}\textsc{what}\text{’}\\ \textsc{case} & \textsc{acc}\\ \textsc{type} & \textsc{int}\end{array}\right]$$

---

[42] Unlike XPlxm_{type}, XPlxmC_{type} and XPextr_{type}, XP_{type} is a metacategory: ≡ is used instead of ⟶ as the rewrite symbol in the rule defining XP_{type}, so the right-hand side categories in (157) appear in c-structure instead of XP_{type}.

These words are interrogative (their lexical entries specify the value of the TYPE attribute as INT), so they correspond to categories ADVP$_{int}$ and AP$_{int}$, respectively. According to (157), each of these categories is an instance of XP$_{int}$ metacategory. Following (155)–(156), XPextr$_{int}$ rewrites to XP$_{int}$ and XPlxmC$_{int}$ to XPextr$_{int}$, so: XPlxmC$_{int}$ $\longrightarrow$ XPextr$_{int}$ $\longrightarrow$ XP$_{int}$. Next, the rule in (154) adds XPlxmC$_{int}$ conjuncts to a set, building the f-structure in (164), which contains the f-structures in (162) and (163) as set elements. Then the rule in (149) rewrites anyLEXSEM to XPlxm$_{int}$ with $\downarrow\in(\uparrow \textsc{udf})$ annotation. As a result, the f-structure in (164) is added as a member of the UDF set, see (165).

(164)
$$\left[\begin{array}{l} \left\{ \left[\begin{array}{ll}\textsc{pred} & \text{‘}\textsc{whence}\text{’}\\ \textsc{type} & \textsc{int}\end{array}\right], \left[\begin{array}{ll}\textsc{pred} & \text{‘}\textsc{what}\text{’}\\ \textsc{case} & \textsc{acc}\\ \textsc{type} & \textsc{int}\end{array}\right]\right\}\\ \textsc{conj}\ \ \textsc{and}\end{array}\right]$$

(165)
$$\left[\begin{array}{ll} \textsc{obj} & \left[\textsc{adj}\ \left\{\boxed{3}\right\}\right]\\ \textsc{adj} & \left\{\boxed{4}\right\}\\ \textsc{udf} & \left\{\left[\begin{array}{l} \left\{ \boxed{4}\left[\begin{array}{ll}\textsc{pred} & \text{‘}\textsc{whence}\text{’}\\ \textsc{type} & \textsc{int}\end{array}\right], \boxed{3}\left[\begin{array}{ll}\textsc{pred} & \text{‘}\textsc{what}\text{’}\\ \textsc{case} & \textsc{acc}\\ \textsc{type} & \textsc{int}\end{array}\right]\right\}\\ \textsc{conj}\ \ \textsc{and}\end{array}\right]\right\} \end{array}\right]$$

It is now possible to see and explain the effect of the rule in (156), where XP$_{int}$ has two annotations. While $\uparrow=\downarrow$ builds the f-structures in (162)–(163), which are later used to build the coordinate f-structure in (164), $((\textsc{udf} \in^{*} \uparrow)\ \textsc{xpath}\ \textsc{gf}^{+})=\downarrow$ structure-shares the f-structure of each conjunct. $(\textsc{udf} \in^{*} \uparrow)$ is the path to the top-level f-structure containing the UDF attribute, XPATH defined in (159) produces any sequence (including zero) of XCOMPs (making it possible to embed the f-structure inside verb chains), while $\textsc{gf}^{+}$ produces any non-zero sequence of GFs defined in (160). Together, these equations make it possible to structure-share each conjunct inside the UDF set with any grammatical function that can be reached using this path. As a result of this annotation, in (165) the f-structure $\boxed{4}$ corresponding to *skąd* is structure-shared with the element of the ADJ set at the main level (via resolved $((\textsc{udf} \in^{*} \uparrow)\ \textsc{adj} \in)=\downarrow$ annotation, equivalent to $\downarrow \in ((\textsc{udf} \in^{*} \uparrow)\ \textsc{adj}))$, while the f-structure $\boxed{3}$ corresponding to *jakie* is structure-shared with the element of the ADJ set of the OBJ attribute at the main level (via resolved $((\textsc{udf} \in^{*} \uparrow)\ \textsc{obj}\ \textsc{adj} \in)=\downarrow$ annotation, equivalent to $\downarrow \in ((\textsc{udf} \in^{*} \uparrow)\ \textsc{obj}\ \textsc{adj}))$.

Finally, using the rule in (150), the partial f-structure in (165) corresponding to the coordination of different grammatical functions (*skąd i jakie* ‘where from and what’) is unified with the partial f-structure in (166) corresponding to the rest of the sentence (*otrzymujemy informacje* '(we) get information'), yielding the final f-structure in (161) – a monoclausal representation where all conjuncts belong to the same clause (even though they depend on different heads).

(166)
$$\left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{receive}\langle\boxed{1},\boxed{2}\rangle\text{'} \\ \textsc{subj} & \boxed{1}\left[\textsc{pred}\ \ \text{`}\textsc{pro}\text{'}\right] \\ \textsc{obj} & \boxed{2}\left[\begin{array}{ll}\textsc{pred} & \text{`}\textsc{information}\text{'}\\ \textsc{case} & \textsc{acc}\end{array}\right]\end{array}\right]$$

4.4 Multiclausal (including biclausal)

The multiclausal representation, unlike the monoclausal one, is appropriate for instances of coordination of different grammatical functions where conjuncts are dependents of different clauses. Such a representation is suitable when conjuncts cannot be codependents (as in Polish where certain examples would otherwise be ungrammatical). While it may also be preferred for other reasons (as in English and other languages with optional arguments but without pro-drop), this will not be discussed here for reasons of space.

In Polish, there are two cases where the multiclausal analysis of coordination of different grammatical functions is necessary: coordination of the *yes*/*no* interrogative particle CZY with another interrogative item, as in (167), and coordination of relatives, see (168):

(167) Polish
Nie wiadomo było, [[czy] *(i) [kiedy]] wróci.
NEG know was PRT and when returns
'It was not clear whether and when (s)he/it would return.' (NKJP)

(168) Polish
SŁOWA tej księgi pozwalają budować człowieka [[któremu] *(i)
words this book let build man who.DAT and
[z którym]] jest dobrze żyć.
with whom is good live
'Words of this book let one build a man for and with whom it is good to live.' (NKJP)

Patejuk (2015) proposes two representations for multiclausal coordination of different grammatical functions: one involves as many clauses as conjuncts (Section 4.4.1), while the other always involves two clauses (Section 4.4.2). While only the "as many clauses as conjuncts" representation is appropriate for coordination of relatives, coordination of CZY with other interrogative items may be analysed using either representation. The difference is visible with more than two conjuncts, so let us consider an example with three conjuncts:

(169) Polish

[[Czy],	[kiedy]	i	[kto]]	zajmie się	drogami	[...]	nie	wiadomo.
PRT	when	and	who.NOM	take care	roads.INS		NEG	known

'It is not known, whether, who and when will take care of the roads.'

(NKJP)

4.4.1 As many clauses as conjuncts

These rules produce the representation where it is possible to have more than two clauses:

(170)
$$\begin{array}{cccccc} \text{XPlxb}_{rel} & \longrightarrow & \text{XPextrbicl}_{rel} & [,\ \text{XPextrbicl}_{rel}]^{*} & \text{Conj} & \text{XPextrbicl}_{rel} \\ & & \downarrow\in\uparrow & \downarrow\in\uparrow & & \downarrow\in\uparrow \end{array}$$

(171)
$$\begin{array}{cccccc} \text{XPlxb}_{int} & \longrightarrow & \text{PARTbicl}_{int} & [,\ \text{XPextrbicl}_{int}]^{*} & \text{Conj} & \text{XPextrbicl}_{int} \\ & & \downarrow\in\uparrow & \downarrow\in\uparrow & & \downarrow\in\uparrow \end{array}$$

(172)
$$\begin{array}{ccc} \text{PARTbicl}_{type} & \longrightarrow & \text{PART}_{type} \\ & & \uparrow=\downarrow \\ & & @\textsc{prodrop} \end{array}$$

(173)
$$\begin{array}{ccc} \text{XPextrbicl}_{type} & \longrightarrow & \text{XPextr}_{type} \\ & & \downarrow\in(\uparrow \textsc{udf}) \\ & & @\textsc{prodrop} \end{array}$$

(174)
$$\begin{array}{ccl} \textsc{prodrop} & \equiv & ((\uparrow \textsc{subj pred})=\text{`}\textsc{pro}\text{'}) \\ & & ((\uparrow \textsc{obj pred})=\text{`}\textsc{pro}\text{'}) \\ & & \dots \\ & & ((\uparrow \textsc{gf pred})=\text{`}\textsc{pro}\text{'}) \end{array}$$

(170)–(171) are the topmost rules handling bi/multiclausal (hence "b" in XPlxb, while "m" stands for "monoclausal" in XPlxm) coordination of different grammatical functions where XPlxb rewrites to a sequence of conjuncts: relative (XPextrbicl_{rel}) in (170), or interrogative in (171) – with PARTbicl_{int} (the *yes*/*no* interrogative particle CZY) as the first conjunct and XPextrbicl_{int} as the remaining conjuncts. According to (172)–(173), PARTbicl_{type} and XPextrbicl_{type} rewrite to PART_{type} and XPextr_{type}, respectively; both right-hand side categories contain calls to the PRODROP template defined in (174). It contains conjoined optional statements, so each call may optionally introduce various implicit arguments (in case these are not filled locally, which would violate completeness).

Together with (149)–(150) and (156)–(160), rules in (171)–(174) produce the following multiclausal f-structure for (169) (leaving out the contribution of *nie wiadomo*):

(175)
$$\left[\begin{array}{l} \left\{ \left[\begin{array}{ll} \text{PRED} & \text{`TAKE\_CARE}\langle\boxed{1},\boxed{2}\rangle\text{'} \\ \text{SUBJ} & \boxed{1}\left[\text{PRED `PRO'}\right] \\ \text{OBL} & \boxed{2}\left[\text{PRED `ROADS'}\right] \\ \text{CLAUSE-TYPE} & \text{INT} \end{array}\right], \left[\begin{array}{ll} \text{PRED} & \text{`TAKE\_CARE}\langle\boxed{3},\boxed{2}\rangle\text{'} \\ \text{SUBJ} & \boxed{3}\left[\text{PRED `PRO'}\right] \\ \text{OBL} & \boxed{2} \\ \text{ADJ} & \left\{\boxed{4}\right\} \\ \text{UDF} & \left\{\boxed{4}\left[\begin{array}{ll} \text{PRED} & \text{`WHEN'} \\ \text{TYPE} & \text{INT} \end{array}\right]\right\} \end{array}\right], \left[\begin{array}{ll} \text{PRED} & \text{`TAKE\_CARE}\langle\boxed{5},\boxed{2}\rangle\text{'} \\ \text{SUBJ} & \boxed{5} \\ \text{OBL} & \boxed{2} \\ \text{UDF} & \left\{\boxed{5}\left[\begin{array}{ll} \text{PRED} & \text{`WHO'} \\ \text{TYPE} & \text{INT} \end{array}\right]\right\} \end{array}\right] \right\} \\ \text{CONJ} \quad \text{AND} \end{array}\right]$$

(Patejuk 2015: (5.239))

To better understand this multiclausal analysis, let us consider its procedural intuition showing how the f-structure in (175) is built using the rules listed above.

(176)–(178) are the f-structures built by the words *czy* ‘whether’, *kiedy* ‘when’ and *kto* ‘who’ which correspond to categories PART$_{int}$, ADVP$_{int}$ and NP$_{int}$, respectively:

(176)
$$\left[\begin{array}{ll} \text{CLAUSE-TYPE} & \text{INT} \end{array}\right]$$

(177)
$$\left[\begin{array}{ll} \text{PRED} & \text{`WHEN'} \\ \text{TYPE} & \text{INT} \end{array}\right]$$

(178)
$$\left[\begin{array}{ll} \text{PRED} & \text{`WHO'} \\ \text{TYPE} & \text{INT} \end{array}\right]$$

According to (157), ADVP$_{int}$ and NP$_{int}$ are instances of the XP$_{int}$ metacategory. The rule in (173) rewrites XPextrbicl$_{int}$ to XPextr$_{int}$, while (156) rewrites XPextr$_{int}$ to XP$_{int}$ (so: XPextrbicl$_{int}$ $\longrightarrow$ XPextr$_{int}$ $\longrightarrow$ XP$_{int}$). The rule in (172) rewrites PARTbicl$_{int}$ to PART$_{int}$. The f-structures below built by these rules contain the contributions of calls to the PRODROP template as well as structure-sharing via UDF (resulting from the annotation in (156)): (179) corresponds to PARTbicl$_{int}$, while (180)-(181) correspond to XPextrbicl$_{int}$.

(179)
$$\left[\begin{array}{ll} \text{SUBJ} & \left[\text{PRED `PRO'}\right] \\ \text{CLAUSE-TYPE} & \text{INT} \end{array}\right]$$

(180)
$$\left[\begin{array}{ll} \text{SUBJ} & \left[\text{PRED `PRO'}\right] \\ \text{ADJ} & \left\{\boxed{4}\right\} \\ \text{UDF} & \left\{\boxed{4}\left[\begin{array}{ll} \text{PRED} & \text{`WHEN'} \\ \text{TYPE} & \text{INT} \end{array}\right]\right\} \end{array}\right]$$

(181) $$\left[\begin{array}{ll} \textsc{subj} & \boxed{5} \\ \textsc{udf} & \left\{ \boxed{5}\left[\begin{array}{ll} \textsc{pred} & \text{‘}\textsc{who}\text{’} \\ \textsc{type} & \textsc{int} \end{array}\right] \right\} \end{array}\right]$$

(179) consists of (176) (contributed by *czy*, the first conjunct) and an implicit subject introduced by the first optional equation in the PRODROP template defined in (174). (180) consists of (177) (contributed by *kiedy*, the second conjunct) added to the UDF set using (173) as $\boxed{4}$ and structure-shared using (156) as a member of the ADJ set of the main-level f-structure; it also contains an implicit subject introduced by PRODROP. (181) consists of (178) (contributed by *kto*, the third conjunct) added to the UDF set as $\boxed{5}$ and structure-shared with the value of the SUBJ attribute of the main-level f-structure. (181) does not contain any contributions of PRODROP – all statements in (174) are optional.

Using the rule in (171) which handles coordination of interrogative items corresponding to different grammatical functions, the f-structures in (179)–(181) are added to a set, yielding the f-structure in (182) which corresponds to XPlxb_{int}. The rule in (149) rewrites any LEXSEM to XPlxb_{int} without any annotation (so it is interpreted as ↓=↑ by default).

(182) $$\left[\begin{array}{l} \left\{ \left[\begin{array}{ll} \textsc{subj} & \left[\textsc{pred}\ \text{‘}\textsc{pro}\text{’}\right] \\ \textsc{clause-type} & \textsc{int} \end{array}\right], \left[\begin{array}{ll} \textsc{subj} & \left[\textsc{pred}\ \text{‘}\textsc{pro}\text{’}\right] \\ \textsc{adj} & \left\{\boxed{4}\right\} \\ \textsc{udf} & \left\{ \boxed{4}\left[\begin{array}{ll} \textsc{pred} & \text{‘}\textsc{when}\text{’} \\ \textsc{type} & \textsc{int} \end{array}\right] \right\} \end{array}\right], \left[\begin{array}{ll} \textsc{subj} & \boxed{5} \\ \textsc{udf} & \left\{ \boxed{5}\left[\begin{array}{ll} \textsc{pred} & \text{‘}\textsc{who}\text{’} \\ \textsc{type} & \textsc{int} \end{array}\right] \right\} \end{array}\right] \right\} \\ \textsc{conj}\ \ \textsc{and} \end{array}\right]$$

(183) $$\left[\begin{array}{ll} \textsc{pred} & \text{‘}\textsc{take\_care}\langle\textsc{subj},\boxed{2}\rangle\text{’} \\ \textsc{obl} & \boxed{2}\left[\textsc{pred}\ \text{‘}\textsc{roads}\text{’}\right] \end{array}\right]$$

Finally, using the rule in (150), the f-structure in (182) corresponding to the coordination of different grammatical functions (*czy, kiedy i kto* ‘whether, when and who’) is unified with the f-structure in (183) corresponding to the rest of the sentence (*zajmie się drogami* ‘will take care of the roads’), yielding (175) as the final f-structure for (169) – it is a multiclausal representation where each conjunct belongs to a different clause.

While the multiclausal representation presented above is simple (there are as many clauses as conjuncts), it has some shortcomings. Since each clause has its own call to the PRODROP template, this can result in multiple implicit pronouns, as in (175) where the first two clauses have different implicit subjects – even though they look the same, they are distinct entities. While this could be solved by coindexation, such a representation is not economical.

There is another issue related to economy of representation: while the *yes*/*no* interrogative particle CZY cannot be placed in the same clause as other interrogative items (such as *skąd* 'where' or *kto* 'who'), interrogative items other than CZY can be co-dependents, which means these could be placed in the same clause. This observation is the reason for exploring the alternative multiclausal (biclausal) representation discussed in Section 4.4.2 below.

4.4.2 Always two conjuncts

The following rules are used to obtain a biclausal representation of coordination of different grammatical functions – one that always involves two coordinated clauses: the first clause contains PARTbicl$_{int}$, while the second one contains XPextrbicl$_{int}$. If such coordination involves more than two conjuncts, as in (169), the second clause is analysed an instance of monoclausal coordination of different grammatical functions (XPlxm$_{type}$, see Section 4.3) – such cases involve embedded monoclausal coordination in the second conjunct.

(184)
$$\text{XPlxb}_{int} \longrightarrow \underset{\downarrow\in\uparrow}{\text{PARTbicl}_{int}}\quad \text{Conj}\quad \underset{\downarrow\in\uparrow}{\text{XPextrbicl}_{int}}$$

(185)
$$\text{XPextrbicl}_{type} \longrightarrow \left\{ \begin{array}{c|c} \text{XPextr}_{type} & \text{XPlxm}_{type} \\ \downarrow\in(\uparrow \text{ UDF}) & \downarrow\in(\uparrow \text{ UDF}) \\ \text{@PRODROP} & \text{@PRODROP} \end{array} \right\}$$

Together with (149)–(150), (154)–(160), (172) and (174), the rules in (184)–(185) produce the f-structure in (186) for (169). (186) consists of two clauses: the first one contains the *yes*/*no* interrogative particle CZY, while the second clause involves monoclausal coordination of *kiedy* 'when' and *kto* 'who' in the UDF attribute, whose elements are structure-shared with the relevant dependents of this clause (ADJ and SUBJ, respectively).

(186)
$$\left\{ \begin{bmatrix} \text{PRED} & \text{'TAKE\_CARE}\langle\boxed{1},\boxed{2}\rangle\text{'} \\ \text{SUBJ} & \boxed{1}\begin{bmatrix}\text{PRED} & \text{'PRO'}\end{bmatrix} \\ \text{OBL} & \boxed{2}\begin{bmatrix}\text{PRED} & \text{'ROADS'}\end{bmatrix} \\ \text{CLAUSE-TYPE} & \text{INT}\end{bmatrix}, \begin{bmatrix} \text{PRED} & \text{'TAKE\_CARE}\langle\boxed{3},\boxed{2}\rangle\text{'} \\ \text{SUBJ} & \boxed{3} \\ \text{OBL} & \boxed{2} \\ \text{ADJ} & \{\boxed{4}\} \\ \text{UDF} & \left\{\begin{bmatrix} \left\{\boxed{4}\begin{bmatrix}\text{PRED} & \text{'WHEN'}\\ \text{TYPE} & \text{INT}\end{bmatrix}, \boxed{3}\begin{bmatrix}\text{PRED} & \text{'WHO'}\\ \text{TYPE} & \text{INT}\end{bmatrix}\right\} \\ \text{CONJ} \quad \text{AND} \end{bmatrix}\right\} \end{bmatrix} \right\}$$

(Patejuk 2015: (5.244))

The f-structures produced by the words *czy*, *kiedy* and *kto* are the same as in (176)–(178).

While the f-structure corresponding to PARTbicl$_{int}$ is the same as in (179), the f-structure corresponding to XPextrbicl$_{int}$ is different from what is described in Section 4.4.1. According to the rule in (185), XPextrbicl$_{int}$ rewrites to XPextr$_{int}$ or XPlxm$_{int}$. (169) involves three conjuncts: the first one (*czy*) corresponds to PARTbicl$_{int}$, while the remaining two must be analysed as XPlxm$_{int}$ – as monoclausal coordination of different grammatical functions described in Section 4.3. Rules presented there produce the f-structure in (187) for *kiedy i kto*:

(187)
$$\begin{bmatrix} \textsc{subj} & \boxed{3} \\ \textsc{adj} & \left\{\boxed{4}\right\} \\ \textsc{udf} & \left\{\begin{bmatrix} \left\{\boxed{4}\begin{bmatrix}\textsc{pred} & \text{`}\textsc{when}\text{'}\\ \textsc{type} & \textsc{int}\end{bmatrix}, \boxed{3}\begin{bmatrix}\textsc{pred} & \text{`}\textsc{who}\text{'}\\ \textsc{type} & \textsc{int}\end{bmatrix}\right\} \\ \textsc{conj} \quad \textsc{and} \end{bmatrix}\right\} \end{bmatrix}$$

Using the topmost rule for biclausal coordination of different grammatical functions in (184), the f-structures corresponding to PARTbicl$_{int}$ and XPextrbicl$_{int}$, (179) and (187), respectively, are added to a set, producing the f-structure in (188) for *czy, kiedy i kto*.

(188)
$$\left\{ \begin{bmatrix} \textsc{subj} & \boxed{1}\begin{bmatrix}\textsc{pred} & \text{`}\textsc{pro}\text{'}\end{bmatrix} \\ \textsc{clause-type} & \textsc{int} \end{bmatrix}, \begin{bmatrix} \textsc{subj} & \boxed{3} \\ \textsc{adj} & \left\{\boxed{4}\right\} \\ \textsc{udf} & \left\{\begin{bmatrix} \left\{\boxed{4}\begin{bmatrix}\textsc{pred} & \text{`}\textsc{when}\text{'}\\ \textsc{type} & \textsc{int}\end{bmatrix}, \boxed{3}\begin{bmatrix}\textsc{pred} & \text{`}\textsc{who}\text{'}\\ \textsc{type} & \textsc{int}\end{bmatrix}\right\} \\ \textsc{conj} \quad \textsc{and} \end{bmatrix}\right\} \end{bmatrix} \right\}$$

Finally, the f-structure in (188) corresponding to *czy, kiedy i kto* is unified with the f-structure in (183) corresponding to the rest of the sentence (*zajmie się drogami*), yielding the f-structure in (186) as the final representation of (169).

Unlike (175) discussed in Section 4.4.1, the representation in (186) is biclausal: the first clause contains the first conjunct (*czy*), while the second clause contains the remaining conjuncts (second *kiedy* and third *kto*) analysed as monoclausal coordination of different grammatical functions (Section 4.3). As a consequence, (186) uses only one implicit argument (the subject of the first clause), making it a more economic representation of (169) than (175).[43]

---

[43] The place where the conjunction is represented is another difference between (175) and (186). While in (175) it joins the three clauses, in (186) it joins the last two conjuncts inside the UDF set in the second clause. Patejuk (2015: 131) addresses this issue by copying the conjunction from UDF to the clause level.

5 Coordination and ellipsis

This section discusses selected phenomena involving multiclausal structures and ellipsis. In German Subject Gap in Finite/Fronted (SGF) construction and Polish "intertwined" coordination a dependent is shared by clauses headed by different predicates, while gapping involves sharing at least the main predicate.

5.1 SGF: Subject Gap in Finite/Fronted construction

Frank (2002) offers an analysis of the German SGF:

(189) German
[[In den Wald ging der Jäger] und [fing einen Hasen]].
into the forest went the hunter and caught a rabbit
'The hunter went into the forest and caught a rabbit.'
(Frank 2002: (4), from Wunderlich 1988)

As shown in (189), SGF involves coordination of clauses (headed by different verbs) with a shared subject which is placed inside the first clause (rather than to the left or to the right of the coordinated clauses, which would make dependent sharing straightforward).

Examples such as (189) are handled using (190), a dedicated c-structure rule for CP-level coordination which optionally structure-shares the GDF (grammaticalised discourse function) inside the first conjunct so that it is distributed across all conjuncts. While, following Bresnan (2001), GDF is defined in (191) as SUBJ, TOPIC or FOCUS, in German SGF it is further restricted – it must be the subject, as explained in Frank (2002).

(190)
$$\text{CP} \longrightarrow \begin{array}{c}\text{CP}\\ \downarrow\in\uparrow\\ ((\downarrow \textsc{gdf})=(\uparrow \textsc{gdf}))\end{array} \quad \begin{array}{c}\text{Conj}\\ \\ \\ \end{array} \quad \begin{array}{c}\text{CP}\\ \downarrow\in\uparrow\\ \\ \end{array}$$

(191) $\textsc{gdf} \equiv \{\textsc{subj}|\textsc{topic}|\textsc{focus}\}$

The structures below,[44] created using (190), correspond to (189). Even though the NP *der Jäger* belongs exclusively to the first conjunct in the c-structure in (193), the corresponding f-structure fragment, $\boxed{1}$, is structure-shared by both conjuncts in (192).

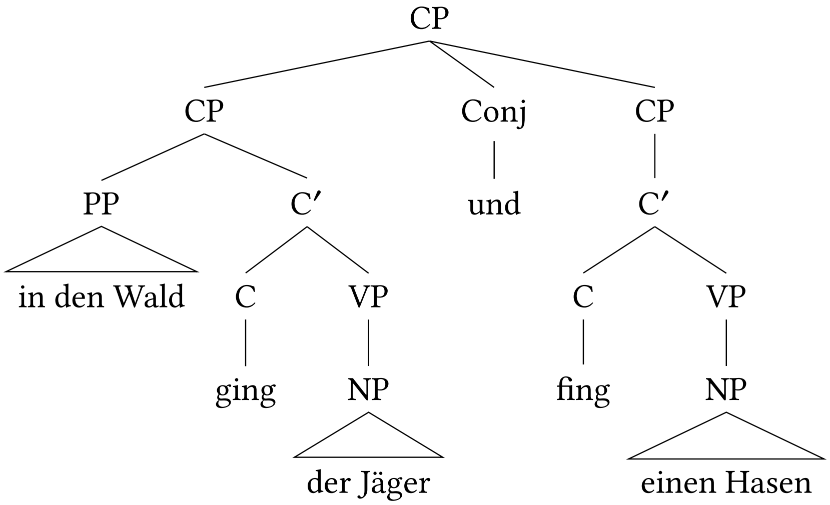
---

[44] (192)-(193) are a modified (normalised/translated) version of Frank (2002: (36)).

(192)

$$\left[\begin{array}{l} \left\{ \left[\begin{array}{ll} \text{PRED} & \text{`GO}\langle\boxed{1},\boxed{2}\rangle\text{'} \\ \text{SUBJ} & \boxed{1}\left[\text{PRED `HUNTER'}\right] \\ \text{OBL} & \boxed{2}\left[\begin{array}{ll} \text{PRED} & \text{`INTO}\langle\boxed{3}\rangle\text{'} \\ \text{OBJ} & \boxed{3}\left[\text{PRED `FOREST'}\right]\end{array}\right] \\ \text{TOPIC} & \boxed{2}\end{array}\right], \left[\begin{array}{ll} \text{PRED} & \text{`CATCH}\langle\boxed{1},\boxed{4}\rangle\text{'} \\ \text{SUBJ} & \boxed{1} \\ \text{OBJ} & \boxed{4}\left[\text{PRED `RABBIT'}\right]\end{array}\right] \right\} \\ \text{CONJ} \quad \text{AND} \end{array}\right]$$

(193)



5.2 Sharing "intertwined" dependents

Discussing coordination data from Polish,[45] Patejuk & Przepiórkowski (2015) offer an analysis of "intertwined" dependents – dependents which are interpreted as shared by all conjuncts, even though they are placed inside the first conjunct, like the subject in German SGF discussed in Section 5.1. However, there are fewer restrictions in Polish – unlike in German, it seems that any dependent may be shared: subject in (194), object in (195) and even particles such as *się*, as in (196) where it is a reciprocal marker (RECP).

(194) Polish
[[Przyjechali żandarmi] i [chodzili od domu do
came.PL.M1 soldier.NOM.PL.M1 and walked.PL.M1 from house to
domu]].
house
'Soldiers came and walked from house to house.' (NKJP)

---

[45] Except for (203)–(204), all examples in Section 5.2 are from Patejuk & Przepiórkowski (2015).

(195) Polish
[[Zakleiła kopertę] i [wepchnęła do torebki]].
sealed.SG.F envelope.ACC and stuffed.SG.F into handbag
'She sealed the envelope and stuffed it into the handbag.' (NKJP)

(196) Polish
[[Całowali się] i [przytulali]]!
kissed.PL.M1 RECP|RECP and hugged.PL.M1
'They were kissing and hugging each other!' (Google)

While (194) and (195) could also be analysed as involving an implicit argument (an instance of pro-drop) in the second conjunct coreferent (via coindexation) with the appropriate argument (subject or object) in the first conjunct, this does not apply to (196). This is because *się* is analysed as a marker: it is not put on the list of arguments (the verbs in (196) only take a subject), so it cannot be analysed as an implicit argument.

As discussed in Patejuk & Przepiórkowski (2015), *się* has many functions in Polish: it can be a reflexive/reciprocal marker, an impersonal marker, or it can be "inherent" – a semantically contentless particle that is required lexically by certain predicates. In (196) the shared *się* has the same function (reciprocal) with respect to both predicates (KISS and HUG) – this is glossed as RECP|RECP where | separates functions. In (197) the shared marker has a different function in each conjunct – as shown in (198), the first conjunct requires inherent *się* (INH), while the second conjunct takes reflexive *się* (REFL):

(197) Polish
[[Śmiali się] i [pukali w głowy]].
laughed.PL.M1 INH|REFL and knocked.PL.M1 in heads
'They were laughing and asking if somebody is nuts.' (literally: 'They were laughing and knocking themselves on their heads.')

(198) Polish
[[Śmiali się] i [pukali się w głowy]].
laughed.PL.M1 INH and knocked.PL.M1 REFL in heads

On the basis of examples such as (197), Patejuk & Przepiórkowski (2015) argue that the SGF analysis would not be appropriate: not only because *się* is not an argument (it is analysed as a marker, so it is not on the list of arguments), but also because it is a weak, unstressed form (as opposed to the pronoun *siebie* 'self'), so it cannot bear discourse functions such as TOPIC or FOCUS. Also, while the SGF analysis involves distributing a designated grammatical function of the first conjunct (the subject) over the entire coordination, Patejuk & Przepiórkowski (2015) show that structure sharing the f-structure contribution corresponding to *się* would not be appropriate in (197), because the first conjunct requires a different type of *się* than the second conjunct, as shown in (198).

In Patejuk & Przepiórkowski (2015), the word *się* introduces two kinds of constraints: (↑ SIE PRESENT) = +, a defining equation marking that this word is present in the f-structure, and a constraining equation ensuring that the type of *się* is specified elsewhere (by the verb, if it is required lexically, or constructionally for impersonal *się*). Verbs that lexically require *się* also introduce two constraints: a constraining equation requiring the presence of this marker, (↑ SIE PRESENT) $=_c$ +, and a defining equation specifying the type of *się*: (↑ SIE REFL) = + for reflexive *się* and (↑ SIE INH) = + for inherent *się*. If one were to adopt an SGF-like analysis by structure-sharing the SIE attribute of the first conjunct with the entire coordination, the result would be incorrect. This is because the SIE attribute contains the contribution of *się* as well as the verb in the first conjunct, so it would not yield an appropriate analysis of (197): the second verb would have multifunctional *się* (inherent and reflexive), instead of having inherent *się* in the first conjunct and reflexive *się* in the second conjunct. In principle, this problem with the SGF-like analysis could be worked around by using the constraint (↓ SIE PRESENT)=(↑ SIE PRESENT) instead of (↓ SIE)=(↑ SIE) when sharing *się*.

However, instead of an SGF-like analysis, Patejuk & Przepiórkowski (2015) propose an alternative solution by introducing a rule handling coordination with "intertwined" dependents, see (199), where such dependents (DEP) are placed in the c-structure at the same level as the conjuncts (IP) and the conjunction (Conj). This way, the f-structure contribution of DEP, possibly disjunctive or underspecified, can be resolved independently for each conjunct, making it possible to account for examples such as (197). The rules in (199)–(200) produce the structures in (201)–(202) corresponding to (197).[46]

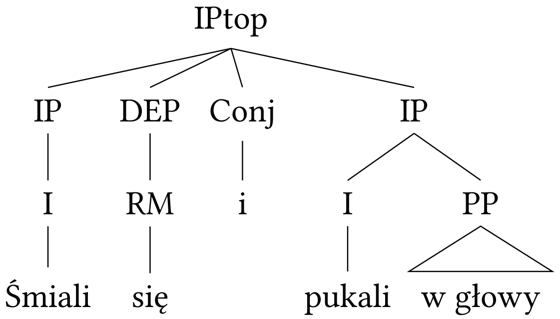
(199)
$$\begin{array}{lccccc} \text{IPtop} & \longrightarrow & \text{IP} & \text{DEP} & \text{Conj} & \text{IP} \\ & & \downarrow\in\uparrow & & & \downarrow\in\uparrow \end{array}$$

(200)
$$\begin{array}{lcccccccc} \text{DEP} & \longrightarrow & \{ & \text{ARG} & | & \text{MOD} & | & \text{RM} & \} \\ & & & (\uparrow \textsc{gf}){=}\downarrow & & \downarrow \in (\uparrow \textsc{adjunct}) & & & \end{array}$$

---

[46] Additional constraints are used to structure-share the implicit subject (see also: (195)–(196)).

(201)



(202)

$$\left[\begin{array}{l} \left\{ \left[\begin{array}{ll} \text{PRED} & \text{`LAUGH}\langle\boxed{1}\rangle\text{'} \\ \text{SUBJ} & \boxed{1}\left[\begin{array}{ll}\text{PRED} & \text{`PRO'}\\ \text{CASE} & \text{NOM}\\ \text{NUM} & \text{PL}\end{array}\right] \\ \text{SIE} & \left[\begin{array}{ll}\text{INH} & +\\ \text{PRESENT} & +\end{array}\right]\end{array}\right], \left[\begin{array}{ll} \text{PRED} & \text{`KNOCK}\langle\boxed{1},\boxed{2}\rangle\text{'} \\ \text{SUBJ} & \boxed{1} \\ \text{OBL} & \boxed{2}\left[\begin{array}{ll}\text{PRED} & \text{`HEAD'}\\ \text{PFORM} & \text{W}\end{array}\right] \\ \text{SIE} & \left[\begin{array}{ll}\text{REFL} & +\\ \text{PRESENT} & +\end{array}\right]\end{array}\right] \right\} \\ \text{CONJ}\quad\text{AND}\end{array}\right]$$

(Patejuk & Przepiórkowski 2015: (64))

The defining equation (↑ SIE PRESENT) = + introduced by *się* is distributed across coordination in (201), together with the constraining equation requiring that the type of *się* is specified ((↑ SIE {REFL|RECP|INH}) $=_c$ +). The latter is resolved independently for each conjunct: the type of *się* is specified by the lexical entry of the verb; it is inherent (INH) in the first conjunct, while in the second it is reflexive (REFL), as shown in (202).

The analysis of Patejuk & Przepiórkowski (2015) could be used for German SGF: while the c-structure would be different, the corresponding f-structure would be the same.

Apart from the analysis of shared *się*, there is one more situation which clearly distinguishes between the effects of the analysis of Patejuk & Przepiórkowski (2015) and an SGF-like analysis: when a shared dependent displays case syncretism that is disambiguated by predicates requiring different values of case, as in the following example:

(203) Polish

[[Marysia	lubi	Janka]],	a	[Zosia	nienawidzi]].
Marysia.NOM	likes	Janek.ACC/GEN	and	Zosia.NOM	hates

‘Marysia likes Janek, while Zosia hates him.’

In this example, the first verb (*lubi* ‘likes’) requires an accusative object (in the absence of sentential negation), while the second verb (*nienawidzi* ‘hates’) requires a genitive object – the form *Janka* is syncretic between accusative and genitive, so it can be used as the object of both predicates, despite their different case requirements.

Except for word order, (203) is analogous to (204) (originally from Dyła (1984)):

(204) Polish
Kogo [[Janek lubi] a [Jerzy nienawidzi]]?
who.ACC/GEN Janek.NOM likes and Jerzy.NOM hates
'Who does Janek like and Jerzy hate?' (Dalrymple et al. 2009: (10))

Dalrymple et al. (2009) offer an analysis of (204) which involves a complex CASE attribute (instead of atomic values used so far for CASE), making it possible to account for case syncretism and feature indeterminacy. The lexical entry of the noun *kogo* (the same applies to *Janka* in (203)) contains a disjunctive specification of case: (↑ CASE {ACC|GEN}) = +, while lexical entries of verbs assign appropriate values of case to their object: (↑ OBJ CASE ACC) = + for *lubi* (when there is no sentential negation) and (↑ OBJ CASE GEN) = + for *nienawidzi*. Under such an analysis, the f-structure in (205) corresponds to (204).[47]

(205)

$$\left[\begin{array}{l} \left\{ \left[\begin{array}{ll} \text{PRED} & \text{`LIKE}\langle\boxed{1},\boxed{2}\rangle\text{'} \\ \text{SUBJ} & \boxed{1}\left[\begin{array}{ll}\text{PRED} & \text{`JANEK'}\\ \text{CASE} & \text{NOM}\end{array}\right] \\ \text{OBJ} & \boxed{2}\left[\begin{array}{ll}\text{PRED} & \text{`WHO'}\\ \text{CASE} & \left[\text{ACC}\ +\right]\end{array}\right]\end{array}\right], \left[\begin{array}{ll} \text{PRED} & \text{`HATE}\langle\boxed{3},\boxed{4}\rangle\text{'} \\ \text{SUBJ} & \boxed{3}\left[\begin{array}{ll}\text{PRED} & \text{`JERZY'}\\ \text{CASE} & \text{NOM}\end{array}\right] \\ \text{OBJ} & \boxed{4}\left[\begin{array}{ll}\text{PRED} & \text{`WHO'}\\ \text{CASE} & \left[\text{GEN}\ +\right]\end{array}\right]\end{array}\right] \right\} \\ \text{CONJ} \quad \text{AND} \end{array}\right]$$

Coming back to (203): under an SGF-like analysis the accusative object of the first conjunct is distributed over the entire coordination, so the object of the first conjunct would be marked for accusative case, while the object of the second conjunct would be marked for accusative and genitive case – this is undesired. By contrast, under the account of Patejuk & Przepiórkowski (2015) case is assigned independently in each conjunct (rather than being copied from the first conjunct), so the f-structure representation of (203) would be analogous to (205): the object of the first conjunct would only be marked for accusative case, while the object of the second conjunct would only bear genitive case.

5.3 Gapping

Gapping is a variety of clause-level coordination where certain elements of the first conjunct (the non-gapped conjunct, the conjunct without a gap) are shared

---

[47] In Dalrymple et al. (2009) NPs lexically specify impossible values of CASE as −. To save space, these attribute-value pairs are omitted in (205). For OBJ these are: NOM −, DAT −, INST −, LOC −, VOC −.

(marked with underline) with the second conjunct (the gapped conjunct, the conjunct with some gap(s)). Minimally the main verb is shared, as in (206), but some of its dependents may also be shared, as in (207) where the direct object (*an apple*) is also shared.

(206) [[Marge gave an apple to Lisa], and [Homer a donut to Bart]]. (Patejuk & Przepiórkowski 2017: (1))

(207) [[Marge gave an apple to Lisa], and [Homer to Bart]]. (Patejuk & Przepiórkowski 2017: (2))

5.3.1 Basics of the Patejuk & Przepiórkowski (2017) analysis

Patejuk & Przepiórkowski (2017) offer an LFG analysis of gapping which relies on two key features: the set-based representation of coordination and distribution. The material in the first conjunct (the verb and all its dependents) is split into two parts: shared and non-shared. The shared material is distributed over the coordination of non-shared material, namely the set which contains non-shared material from the first conjunct and the partial f-structure produced by dependents in the second conjunct.

The analysis relies on the rules shown in (208)–(211). (208) is the main coordination rule for gapping where IP1 is the non-gapped conjunct (defined in (209)),[48] while IP is the gapped conjunct (see (210)).[49] Each dependent (DEP, see its definition in (211)) of the non-gapped conjunct (IP1) may be shared or not. This is achieved using the annotation (↑ (LOCAL))=↓ on DEP in (209), which resolves to one of two possible annotations: ↑=↓ distributes the DEP over the entire coordination (so that it is shared by all conjuncts: non-gapped and gapped), while (↑ LOCAL)=↓ makes it belong to the non-gapped conjunct only (it is not distributed over coordination in gapping). Finally, each dependent (DEP, in IP1 and IP) is assigned appropriate f-structure annotation (including GF) in (211).

(208)
$$\begin{array}{llcccc}
\text{IP} & \longrightarrow & \text{IP1} & [,\ \text{IP}]^{*} & \text{Conj} & \text{IP} \\
 & & \uparrow=\downarrow & \downarrow\in\uparrow & & \downarrow\in\uparrow \\
 & & (\downarrow \textsc{local}) \in \uparrow & & &
\end{array}$$

(209)
$$\begin{array}{llcc}
\text{IP1} & \longrightarrow & \text{DEP}^{*}, & \text{I} \\
 & & (\uparrow (\textsc{local})) = \downarrow &
\end{array}$$

---

[48] IP1 may contain negation: sentential negation is a prefix in Polish (though it may be separated from the verb by whitespace), so it is part of I. However, negation in the gapped conjunct is not a prefix (there is no verb, it is gapped) and it comes as the last element – this is why (210) contains an extra NEG.

[49] The optional NEG (sentential negation) in (210) is required by Polish examples such as (226).

(210) $\text{IP} \longrightarrow [\text{DEP}^{*},\ (\text{I})]\ \ (\text{NEG})$

(211) $$\text{DEP} \equiv \left\{ \begin{array}{c|c|c|c} \text{NP} & \text{PP} & \text{InfP} & \ldots \\ (\uparrow \{\textsc{subj}|\textsc{obj}\}) = \downarrow & (\uparrow \textsc{obl}) = \downarrow & (\uparrow \textsc{xcomp}) = \downarrow & \end{array} \right\}$$

Together, these rules give rise to (212) as the f-structure corresponding to (206).

(212) $$\left[\begin{array}{ll} \multicolumn{2}{l}{\left\{ \boxed{0} \left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{give}\langle\boxed{1},\boxed{2},\boxed{3}\rangle\text{'} \\ \textsc{subj} & \boxed{1}\left[\textsc{pred}\ \text{`Marge'}\right] \\ \textsc{obj} & \boxed{2}\left[\textsc{pred}\ \text{`}\textsc{apple}\text{'}\right] \\ \textsc{obl} & \boxed{3}\left[\textsc{pred}\ \text{`Lisa'}\right] \end{array}\right], \left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{give}\langle\boxed{4},\boxed{5},\boxed{6}\rangle\text{'} \\ \textsc{subj} & \boxed{4}\left[\textsc{pred}\ \text{`Homer'}\right] \\ \textsc{obj} & \boxed{5}\left[\textsc{pred}\ \text{`}\textsc{donut}\text{'}\right] \\ \textsc{obl} & \boxed{6}\left[\textsc{pred}\ \text{`Bart'}\right] \end{array}\right] \right\}} \\ \textsc{conj} & \textsc{and} \\ \textsc{local} & \boxed{0} \end{array}\right]$$

(Patejuk & Przepiórkowski 2017: (19))

What follows is a procedural intuition of this analysis, showing how (212) is constructed.

(213) is the partial f-structure corresponding to the first (non-gapped) conjunct, constructed using the rules in (209) and (211). Using (211), each dependent of the first conjunct is assigned an appropriate GF, as shown in (214)–(216): *Marge* is the SUBJ(ect), *an apple* is the OBJ(ect), *to Lisa* is an OBL(ique). According to (209), the main verb is shared (by default, it has the co-head annotation: ↓=↑), while each of its dependents (DEP) may be shared or not. In (206) the annotation of all dependents resolves to (↑ LOCAL)=↓, so they are not shared. This results in the partial f-structure in (213) corresponding to IP1.

(213) $$\left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{give}\langle\textsc{subj},\textsc{obj},\textsc{obl}\rangle\text{'} \\ \textsc{local} & \boxed{0}\left[\begin{array}{ll} \textsc{subj} & \left[\textsc{pred}\ \text{`Marge'}\right] \\ \textsc{obj} & \left[\textsc{pred}\ \text{`}\textsc{apple}\text{'}\right] \\ \textsc{obl} & \left[\textsc{pred}\ \text{`Lisa'}\right] \end{array}\right] \end{array}\right]$$

(214) $\left[\textsc{subj}\ \left[\textsc{pred}\ \text{`Marge'}\right]\right]$

(215) $\left[\textsc{obj}\ \left[\textsc{pred}\ \text{`}\textsc{apple}\text{'}\right]\right]$

(216) $\left[\textsc{obl}\ \left[\textsc{pred}\ \text{`Lisa'}\right]\right]$

(217) is the partial f-structure corresponding to the second (gapped) conjunct, constructed using the rules in (210) and (211). Using (211), each dependent (DEP) is assigned an appropriate GF, as shown in (218)–(220). According to (210), all dependents (DEP) of the gapped conjunct (IP) have the default co-head annotation, so their partial f-structures are unified, yielding (217) as the partial f-structure corresponding to IP (gapped conjunct).

(217) $$\begin{bmatrix} \textsc{subj} & \begin{bmatrix}\textsc{pred} & \text{‘}\textsc{Homer}\text{’}\end{bmatrix} \\ \textsc{obj} & \begin{bmatrix}\textsc{pred} & \text{‘}\textsc{donut}\text{’}\end{bmatrix} \\ \textsc{obl} & \begin{bmatrix}\textsc{pred} & \text{‘}\textsc{Bart}\text{’}\end{bmatrix} \end{bmatrix}$$

(218) $$\begin{bmatrix} \textsc{subj} & \begin{bmatrix}\textsc{pred} & \text{‘}\textsc{Homer}\text{’}\end{bmatrix} \end{bmatrix}$$

(219) $$\begin{bmatrix} \textsc{obj} & \begin{bmatrix}\textsc{pred} & \text{‘}\textsc{donut}\text{’}\end{bmatrix} \end{bmatrix}$$

(220) $$\begin{bmatrix} \textsc{obl} & \begin{bmatrix}\textsc{pred} & \text{‘}\textsc{Bart}\text{’}\end{bmatrix} \end{bmatrix}$$

The final step is to apply the gapping coordination rule in (208). While it does two things at the same time, this will be presented as two separate steps for the sake of exposition. The first effect of (208) is to produce (221) – the partial f-structure corresponding to the coordination of non-shared material from both conjuncts. As a result of the (↓ LOCAL) ∈ ↑ annotation on the non-gapped conjunct (IP1) in (208), the content of its LOCAL attribute is added to the set (see (213) for the f-structure of the non-gapped conjunct); the standard ↓∈↑ annotation on the gapped conjunct (IP) adds its f-structure (see (217)) to the set.

(221) $$\left[\begin{array}{l} \left\{ \boxed{0}\begin{bmatrix} \textsc{subj} & \begin{bmatrix}\textsc{pred} & \text{‘}\textsc{Marge}\text{’}\end{bmatrix} \\ \textsc{obj} & \begin{bmatrix}\textsc{pred} & \text{‘}\textsc{apple}\text{’}\end{bmatrix} \\ \textsc{obl} & \begin{bmatrix}\textsc{pred} & \text{‘}\textsc{Lisa}\text{’}\end{bmatrix} \end{bmatrix}, \begin{bmatrix} \textsc{subj} & \begin{bmatrix}\textsc{pred} & \text{‘}\textsc{Homer}\text{’}\end{bmatrix} \\ \textsc{obj} & \begin{bmatrix}\textsc{pred} & \text{‘}\textsc{donut}\text{’}\end{bmatrix} \\ \textsc{obl} & \begin{bmatrix}\textsc{pred} & \text{‘}\textsc{Bart}\text{’}\end{bmatrix} \end{bmatrix} \right\} \\ \textsc{conj} \quad \textsc{and} \end{array}\right]$$

The second effect of (208), resulting from the ↓=↑ annotation on IP1, is to distribute the partial f-structure in (213), corresponding to the shared material from the first conjunct,[50] over the f-structure in (221) which corresponds to the coordination of non-shared material from both conjuncts. The result of this operation is (212): the final f-structure for (206).

5.3.2 Distribution under gapping: Interactions with other phenomena

Patejuk & Przepiórkowski (2017) discuss interactions between the proposed analysis of gapping, which relies on distribution, and other phenomena, including subject-verb agreement, case assignment and unlike category coordination.

Unlike in (206)–(207), where the verb form used in the first conjunct (*gave*) would also be appropriate in the second conjunct (if it was present), there are examples where different agreement features would be required in different conjuncts, as in (222) from Polish, see the corresponding f-structure in (223):

---

[50] Apart from the main predicate, this includes the LOCAL attribute – this is the desired result (Section 5.3.2).

(222) Polish

[[Lisa	lubiła	Nelsona],	a	[Nelson	(lubił)	Lisę]].
Lisa.NOM.F	liked.F	Nelson.ACC.M1	and	Nelson.NOM.M1	liked.M1	Lisa.ACC.F

'Lisa liked Nelson and Nelson (liked) Lisa.'

(Patejuk & Przepiórkowski 2017: (28))

(223)

$$\left[\begin{array}{l}
\left\{ \boxed{0} \left[\begin{array}{ll} \text{PRED} & \text{`LIKE}\langle\boxed{1},\boxed{2}\rangle\text{'} \\ \text{SUBJ} & \boxed{1}\left[\begin{array}{ll}\text{PRED} & \text{`LISA'}\\ \text{CASE} & \text{NOM}\\ \text{GEND} & \text{F}\end{array}\right] \\ \text{OBJ} & \boxed{2}\left[\begin{array}{ll}\text{PRED} & \text{`NELSON'}\\ \text{CASE} & \text{ACC}\\ \text{GEND} & \text{M1}\end{array}\right]\end{array}\right], \left[\begin{array}{ll} \text{PRED} & \text{`LIKE}\langle\boxed{3},\boxed{4}\rangle\text{'} \\ \text{SUBJ} & \boxed{3}\left[\begin{array}{ll}\text{PRED} & \text{`NELSON'}\\ \text{CASE} & \text{NOM}\\ \text{GEND} & \text{M1}\end{array}\right] \\ \text{OBJ} & \boxed{4}\left[\begin{array}{ll}\text{PRED} & \text{`LISA'}\\ \text{CASE} & \text{ACC}\\ \text{GEND} & \text{F}\end{array}\right]\end{array}\right]\right\} \\
\text{CONJ} \quad \text{AND} \\
\text{LOCAL} \quad \boxed{0}
\end{array}\right]$$

(Patejuk & Przepiórkowski 2017: (29))

The key feature of the analysis presented above is that it distributes the verb from first conjunct over the entire coordination – as a result, all constraints imposed by the verb are distributed. Assuming a standard account of S-V agreement, where it is handled in the lexical entries of verbs (requiring the subject to satisfy certain agreement constraints, as in (224) where the subject must be singular and feminine), such requirements are distributed to each conjunct, so the subject of each conjunct must satisfy these requirements.

(224) $(\uparrow \text{SUBJ NUM}) =_c \text{SG} \wedge (\uparrow \text{SUBJ GEND}) =_c \text{F}$

This is problematic in (222), where the verb *lubiła* 'liked' in the first conjunct requires a singular feminine subject. While *lubiła* is compatible with *Lisa* in the first conjunct, it is not appropriate for *Nelson* in the second (gapped) conjunct. Though *Nelson* is singular, it is masculine – so it would be compatible with the masculine verb form *lubił*.

Patejuk & Przepiórkowski (2017) offer a solution, presenting it as conceptually similar to single conjunct agreement (see Section 1.4), where, instead of agreeing with the entire subject, the verb may agree with a designated conjunct as the agreement target. The proposed solution accounts for potential mismatches in S-V agreement between the first conjunct (without a gap) and the gapped conjunct using the LOCAL attribute, which contains the non-shared material from the first conjunct. (225) below is a modified version of (224).

(225) $[\%\textsc{s} = (\uparrow \textsc{subj}) \vee \%\textsc{s} = (\uparrow \textsc{local}\ \textsc{subj})] \wedge$
$[(\%\textsc{s}\ \textsc{num}) =_c \textsc{sg} \wedge (\%\textsc{s}\ \textsc{gend}) =_c \textsc{f}]$

While (224) uniformly requires the subject to be singular and feminine, (225) has a disjunctive specification of the agreement target (%s). The constraint in (225) is distributed to all conjuncts, where it is resolved independently. When %s resolves to (↑ subj), (225) has the same effect as (224), requiring the subject of the given conjunct to satisfy these constraints – it is not satisfied in the second conjunct of (222). However, when %s resolves to (↑ local subj) in the second conjunct, the relevant agreement requirements are trivially satisfied, because they are checked against the subj inside the local attribute (see the f-structure in (223)) – instead of the subj attribute of the given conjunct.

The fact that constraints imposed by the verb are distributed to all conjuncts and resolved independently in each conjunct makes it possible to account for independent case assignment in gapping. Consider (226) with the corresponding f-structure in (227).

(226) Polish
[[Lisa lubiła Nelsona], a [Nelson Lisy nie]].
Lisa.nom.f liked.f Nelson.acc.m1 but Nelson.nom.m1 Lisa.gen.f neg
'Lisa liked Nelson, but Nelson didn't like Lisa.'
(Patejuk & Przepiórkowski 2017: (34))

(227)
$$\left[\begin{array}{l}\left\{\boxed{0}\left[\begin{array}{ll}\textsc{pred} & \text{`}\textsc{like}\langle\boxed{1},\boxed{2}\rangle\text{'}\\ \textsc{subj} & \boxed{1}\left[\begin{array}{ll}\textsc{pred} & \text{`}\textsc{Lisa}\text{'}\\ \textsc{case} & \textsc{nom}\\ \textsc{gend} & \textsc{f}\end{array}\right]\\ \textsc{obj} & \boxed{2}\left[\begin{array}{ll}\textsc{pred} & \text{`}\textsc{Nelson}\text{'}\\ \textsc{case} & \textsc{acc}\\ \textsc{gend} & \textsc{m1}\end{array}\right]\end{array}\right], \left[\begin{array}{ll}\textsc{pred} & \text{`}\textsc{like}\langle\boxed{3},\boxed{4}\rangle\text{'}\\ \textsc{subj} & \boxed{3}\left[\begin{array}{ll}\textsc{pred} & \text{`}\textsc{Nelson}\text{'}\\ \textsc{case} & \textsc{nom}\\ \textsc{gend} & \textsc{m1}\end{array}\right]\\ \textsc{obj} & \boxed{4}\left[\begin{array}{ll}\textsc{pred} & \text{`}\textsc{Lisa}\text{'}\\ \textsc{case} & \textsc{gen}\\ \textsc{gend} & \textsc{f}\end{array}\right]\\ \textsc{neg} & +\end{array}\right]\right\}\\ \textsc{conj}\quad \textsc{and}\\ \textsc{local}\quad \boxed{0}\end{array}\right]$$

(Patejuk & Przepiórkowski 2017: (35))

As mentioned earlier (see Section 3.5.1), simplifying, in Polish objects marked for structural case are required to bear accusative case in the absence of sentential negation, while genitive case is required if negation is present. In (226) the object of the first conjunct is accusative due to the lack of negation, while the object of the gapped conjunct is genitive because negation is present there. The relevant disjunctive case constraint is evaluated independently in each conjunct, leading to the f-structure representation in (227).

There is another interesting consequence of the fact that disjunctive constraints imposed by the verb are distributed across coordination under gapping. If a given verb allows for coordination of different categories – for instance, its object may correspond to an NP or a CP, as in (228) – then the object of the first conjunct may be an NP, while the object of the gapped conjunct may be a CP, as in (229), whose f-structure is given in (230).

(228) Polish
Lisa chciała [[książkę] i [żeby ktoś ją
Lisa.NOM wanted book.ACC and that somebody.NOM she.ACC
przytulił]].
hug
'Lisa wanted a book and that somebody hug her.'
(Patejuk & Przepiórkowski 2017: (38))

(229) Polish
[[Lisa chciała książkę], a [Maggie żeby ktoś
Lisa.NOM wanted book.ACC and Maggie.NOM that somebody.NOM
ją przytulił]].
she.ACC hug
'Lisa wanted a book and Maggie wanted that somebody hug her.'
(Patejuk & Przepiórkowski 2017: (39))

(230)

$$\left[\begin{array}{ll} \multicolumn{2}{l}{\left\{ \begin{array}{l} \boxed{0}\left[\begin{array}{ll} \text{PRED} & \text{‘WANT}\langle\boxed{1},\boxed{2}\rangle\text{’} \\ \text{SUBJ} & \boxed{1}\left[\begin{array}{ll}\text{PRED} & \text{‘LISA’}\\ \text{CASE} & \text{NOM}\end{array}\right] \\ \text{OBJ} & \boxed{2}\left[\begin{array}{ll}\text{PRED} & \text{‘BOOK’}\\ \text{CASE} & \text{ACC}\end{array}\right] \end{array}\right], \left[\begin{array}{ll} \text{PRED} & \text{‘WANT}\langle\boxed{3},\boxed{4}\rangle\text{’} \\ \text{SUBJ} & \boxed{3}\left[\begin{array}{ll}\text{PRED} & \text{‘MAGGIE’}\\ \text{CASE} & \text{NOM}\end{array}\right] \\ \text{OBJ} & \boxed{4}\left[\begin{array}{ll} \text{PRED} & \text{‘HUG}\langle\boxed{5},\boxed{6}\rangle\text{’} \\ \text{SUBJ} & \boxed{5}\left[\begin{array}{ll}\text{PRED} & \text{‘SB’}\\ \text{CASE} & \text{NOM}\end{array}\right] \\ \text{OBJ} & \boxed{6}\left[\begin{array}{ll}\text{PRED} & \text{‘SHE’}\\ \text{CASE} & \text{ACC}\end{array}\right] \\ \text{COMP-FORM} & \text{THAT} \end{array}\right] \end{array}\right] \end{array} \right\}} \\ \text{CONJ} & \text{AND} \\ \text{LOCAL} & \boxed{0} \end{array}\right]$$

(Patejuk & Przepiórkowski 2017: (41))

6 Conclusion

On the basis of various phenomena, this chapter discussed the possibilities created by the two key concepts related to coordination in LFG: the set-based representation (conjuncts are elements of a set) and distribution whose effects are important at two levels (attributes vs. properties). The distinction between distributive and non-distributive attributes is crucial not only for phenomena related to agreement (including feature resolution), it also makes it possible to share parts of f-structure (enabling dependent sharing). This chapter also discussed distribution at the level of properties (complex statements), showing that it is necessary to account for disjunctive subcategorisation constraints in coordination, which include not only category, but also features such as CASE, preposition/complementiser form, etc.

Apart from run-of-the-mill coordination, this chapter presented a range of more challenging coordination phenomena, including non-constituent coordination (NCC), coordination of unlike categories, coordination of different grammatical functions (showing the difference between monoclausal and multiclausal representation) and phenomena associated with ellipsis such as German SGF, sharing intertwined dependents and gapping. Selected interactions between these phenomena have also been discussed.

Despite its considerable size, this chapter could only discuss a selection of topics related to coordination. Feature resolution was only mentioned very briefly, on the assumption that it is more closely related to agreement than coordination. A key issue which has not been touched upon here is the semantics of coordination. Dalrymple et al. (2019: Chapter 16) is an excellent chapter devoted to coordination in LFG (with a different selection of phenomena, providing rich references) which extensively covers these two topics. It is remarkable in that it includes semantics as its key component, together with a formalisation in Glue.

Abbreviations

Besides the abbreviations from the Leipzig Glossing Conventions, this chapter uses the following abbreviations.

M1	human masculine (virile) gender
M3	inanimate masculine gender
PRT	particle
INH	inherent

Acknowledgements

I am very grateful to three anonymous reviewers, Mary Dalrymple and Adam Przepiórkowski for valuable feedback that led to many improvements in earlier versions of this chapter.

Chapter 9

Clause structure and configurationality

Avery D. Andrews
The Australian National University

LFG differs strongly from Mainstream Generative Grammar in basing its theory of clause structure on overt surface appearance, as would be input to a parser, rather than the outputs of a derivational process that might produce these structures. This leads to a number of differences, such as a much smaller number of functional projections, and more emphasis on a typology of overt structures, including the inclusion of special provisions for 'non-configurationality'. In this chapter, we examine LFG analyses resulting from this perspective from the beginning of LFG in Bresnan (1982b) through to the theory as presented in Bresnan et al. (2016).

1 Introduction

Because LFG is based on using phrase-structure rules (PS rules, with a substantial involvement of universal principles) to provide a direct description of overt structure, with more abstract levels such as f-structure determined by annotations on these rules, they carry a major burden in describing the organization of clause-structure. In particular, it is not possible to invoke 'movement' mechanisms to get things into their surface positions. Rather, with one plausible minor exception,[1] the PS rules have to put everything in the exact positions where they are found overtly, albeit with the possible help of filtering by other components of the grammar.

Partly for this reason, in LFG. the treatment of clause structure has been from the beginning closely involved with the concept of 'non-configurationality', a term coined by Hale (1981) to refer to situations where linear order does not determine grammatical relations in any clear way, and where, in addition, referring

---

[1] "Second position" items, as discussed below.

Avery D. Andrews. 2023. Clause structure and configurationality. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 375–424. Berlin: Language Science Press. DOI: 10.5281/zenodo.10185952

expressions and other clausal constituents are sometimes discontinuous. Transformational Grammar and its more direct descendants, sometimes called 'Mainstream Generative Grammar', avoided having a problem with this by proposing that underlying clause structures were transformed into overt ones by the application of 'scrambling' rules (in later work, sometimes relegated to the 'phonology'). But when phrase structure rules are to be used for providing a direct characterization of overt structures (with filtering by other components), this is not possible.

Another relevant issue is the position of subjects. If a language appears to have verb phrases that exclude an apparent 'subject' NP argument, then the PS rules have to provide a position for NP external to VP, while if a putative subject is freely intermixed with other arguments, then we probably do not want to have a full-sized VP containing the verb and other arguments, but rather have the verb and the arguments appear directly under S.[2] The theory should then plausibly provide two possibilities along the lines of (a) and (b) below, where (a) puts an NP in front of a VP, while (b) has no VP:[3]

(1) a. S ⟶ NP VP
    b. S ⟶ NP^* V NP^*

A comma could also be included in the first rule to allow the NP to precede or follow the VP, as in Makua (Stucky 1983).

A further general consequence of the archicture is that because many phenomena including agreement, case-marking and anaphora can be largely or entirely described in terms of the more abstract level of f-structure, the sources of evidence for phrase structure are more limited than they are in Mainstream Generative Grammar. We cannot, for example, easily use coreference phenomena to motivate phrase structures in which one object in a double object construction c-commands another, but would need a very extensive (and therefore fragile) argument to show that other levels such as f-structure are not sufficient.

In this chapter, I take a predominantly historical approach to clause structure in LFG, on the basis that a reader might want to engage in literature from any

---

[2] As we shall see, languages sometimes have a smaller verbal phrase containing the verb and certain other material, but not, normally, the object; this is sometimes treated as a VP, and sometimes as a different kind of verbal phrase, often symbolized as $\overline{\text{V}}$.

[3] We don't use the 'ID/LP' notation of Gazdar (1982), first applied to LFG by Falk (1984), to allow the daughters of S to appear an any order in (1b) (S ⟶ NP^*, V) because of the plausibility of interpreting this as a possibly null string of NPs, either before or after one V. There are issues worth looking into further here, but not in this chapter.

time from the early 1980s to the present, and therefore find useful some discussion of what kinds of proposals were being made at different times. I will divide the history of clause structure in LFG into three periods so far, with the possibility of a new one starting now. In the first, from the beginnings of LFG in the early 1980s to the early 1990s, some version of the X-bar theory was assumed, but there was little explicit discussion about exactly what that version was. The 90s constitute a transitional period, in which both the 'extended projections' from Minimalism and ideas from Optimality Theory are taken on. The third period plausibly begins with Bresnan's (2001) theory of structure-function mappings, which can be seen as a consolidation of the work of the transitional period, based on a division between 'endocentric' and 'exocentric' structure, the former obeying the X-bar theory with functional structures, the latter not, along with some principles derived from Optimality Theory, such as Economy of Expression. This approach has persisted with little alteration through Bresnan et al. (2016) to the present. Since it is the result of multiple analyses of different languages by a number of people, I will call it the '2001 Synthesis'. More recently, a fourth period may have begun with Lowe & Lovestrand (2020) and Lovestrand (2022), a thorough revision of the underlying phrase-structure theory making greater use of architectural ideas of LFG rather than simply applying some version of mainstream X-bar theory. However there hasn't yet been substantial work on a variety of clause structures in this new approach.

In this chapter, I consider early LFG in the first section, the transitional period in the second, and the 2001 Synthesis in the third. Then, in the fourth section, I review some of the earlier and transitional systems in light of the 2001 Synthesis, and discuss the revisions that are thereby motivated, and conclude with a speculation about S derived from a modification in the new X-bar framework made in Lovestrand (2022).

2 Early LFG

In early LFG, it was assumed that some version of the X-bar theory was correct, but no attempt was made to seriously formalize or revise the proposals that were standard at the time. Bresnan (1982a: 354-356), which also appeared in the foundational LFG collection Bresnan (1982b), developed a fairly permissive theory of 'structure-function mappings', many provisions of which have persisted until now. This theory constrains how c-structure nodes can be annotated to produce f-structures, and shows the influence of Ken Hale's ideas about 'configurational' vs. 'non-configurational' languages. The other papers in the 1982b collection tended to conform to these ideas without discussing them explicitly.

In these papers, the languages treated as configurational (where grammatical relations are largely coded by phrase-structure position) were English, French, Russian and Icelandic, all of them analysed as SVO, while the one analysed as non-configurational was Malayalam, predominantly verb-final. Most of the SVO languages were analysed with distinct S and VP rules like these:

(2) a. $\begin{array}{llcc} \mathrm{S} & \longrightarrow & \mathrm{NP} & \mathrm{VP} \\ & & (\uparrow \textsc{subj})=\downarrow & \uparrow=\downarrow \end{array}$

b. $\begin{array}{llccc} \mathrm{VP} & \longrightarrow & \mathrm{V} & \mathrm{NP} & \ldots \\ & & \uparrow=\downarrow & (\uparrow \textsc{obj})=\downarrow & \end{array}$

But for Icelandic, Andrews used a flat S rule with subject first (consistent with Bresnan's 1982a: 354/296[4] schema, which he does not however cite or discuss).

From that time to the present, a major concern of LFG authors has been to marshal arguments that c-structure relationships were neither a necessary nor sufficient basis for assigning grammatical relations in the general manner suggested by Chomsky (1965) and persisting through to Chomsky (1981), which appeared in the early days of LFG, and beyond. So considerable attention was paid to arguing for the nonexistence of a VP node in languages that appeared not to have a VP constituent, and a contrastive sketch of configurational English versus non-configurational Warlpiri constitutes the first chapter of the high-level LFG textbook (Bresnan et al. 2016).

In the following two subsections, we consider first Malayalam, and then Warlpiri, the other non-configurational language to which considerable attention was paid in this period; discussion of Warlpiri was included in Bresnan (1982a) and several other chapters in the Bresnan (1982b) collection.[5]

2.1 Malayalam

Non-configurational Malayalam, an essentially verb-final language, was analysed by Mohanan (1982) using the clausal category S, introducing its arguments as an unstructured, possibly empty, string of NPs. It was proposed to have a verb-final S rule, with the NPs introduced by a rule whose first version was (Mohanan 1982: 507):

(3) $\mathrm{S} \longrightarrow \mathrm{NP}^{*} \quad \mathrm{V}$

---

[4] The page before the '/' is for the journal version, the one after for the page in the 1982 volume.

[5] Warlpiri is discussed in Simpson & Bresnan (1983), but the focus of that article is grammatical relations rather than clause structure as such.

Annotations for this version of the rule were not specified. Later (Mohanan 1982: 542–643), a series of annotations are proposed associating specific grammatical functions with cases and other properties such as animacy, for example:

(4) (↑ obj)=↓
(↓ case)=acc
(↓ anim)=+

This is one of the alternative annotations to the NP in rule (3), allowing any NP in the series to have any grammatical function, subject to filtering by other constraints of LFG.

The flatness of the structure given by (3), with its absence of a VP dominating objects, is motivated by several arguments, one of which is the fact that the bearers of the grammatical relations can appear in any order. But the most important one, according to Mohanan (1982: 526-533), is the workings of a clefting phenomenon which allows all and only direct daughters of the S to be clefted, but not subconstituents of anything, such as possessors or objects of prepositions. The construction is effected by suffixing *-aanə* 'is' to the last word of the clefted constituent, and *-ṯə* 'is' to the verb. Some relevant examples are:

(5) Malayalam (Mohanan 1982: 528-529)

a. Kuṭṭi iṉṉale ammakkə anaayey-aaṇə koṭuṯṯa-ṯə.
child yesterday mother.dat elephant-is gave-it
'It was an elephant that the child gave to the mother yesterday.'

b. kuḷaṯṯil wecc-aaṇə jooṇinte kuṭṭi aanaye ṇuḷḷia-ṯə.
pond at-is John.gen child elephant pinched-it
'It was at the pond that John's child pinched the elephant.'

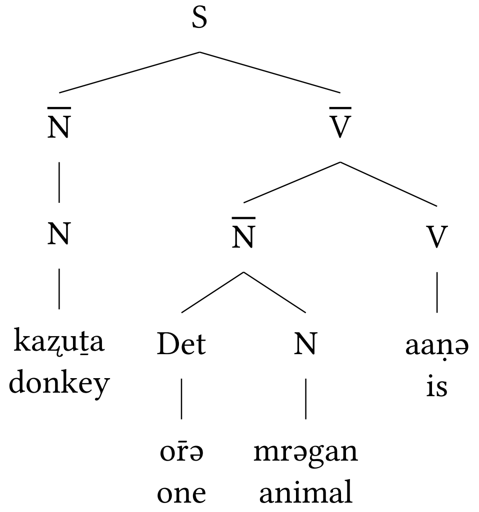
c. *kuḷaṯṯil aaṇə weccə jooṇinte kuṭṭi aanaye ṇuḷḷia-ṯə
pond is at John.gen child elephant pinched-it

In (a), the object is clefted, in (b) the PP, but when we try to cleft the object of the PP (or, not shown, the possessor of the object), the result is bad. The proposed generalization is that you can cleft a direct constituent of S, but not a subconstituent of S, which precludes the existence of a VP sitting on top of the verb and its object.

There are two further significant elaborations in Mohanan's analysis. First, it turns out that Malayalam is not actually strictly verb-final: in main clauses, the verb can be followed by additional NPs, but this normally requires putting a heavy nuclear pitch on the verb, wiping out the word melodies on the following NPs, and lengthening the vowel of the verb, evidently with some kind of contrastive meaning (Mohanan 1982: 511). This is furthermore not possible with certain kinds of subordinate clauses. Mohanan suggests an analysis involving a ‘scrambling rule’, which applies to the S rule, but this is not an option that is available in the LFG formalism, and these NPs need to be introduced in their surface positions, presumably with annotations connecting them to discourse functions (Zaenen 2023 [this volume]).

The second elaboration is that there is a kind of verb phrase, but it contains only the verb and certain additional elements, such as NPs and PPs used to form Copula Constructions and Complex Predicates (Mohanan 1982: 513-534). An example is:

(6)



‘The donkey is an animal.’ (Mohanan 1982: 513–534)

These are plausibly VPs (maximal projections of V, Malayalam having only one phrasal projection layer), which are however very restricted in what kinds of constituents and bearers of grammatical relations they can introduce. On the other hand, some superficially similar complex verbal constituents in other languages do not appear to contain any maximal projections, and so can be analysed as V^0 nodes with adjoined ‘non-projecting’ lexical nodes (Toivonen 2001), also discussed in Belyaev 2023 [this volume]. One example is Complex Predicate constructions in Japanese (Ishikawa 1985, Matsumoto 1996), discussed in Andrews 2023 [this volume], and another is Warlpiri preverbs, considered shortly below.

Another important characteristic of Malayalam and other non-configurational languages is that all or most arguments of verbs can be freely omitted, and understood as if they were represented by pronouns. Mohanan (1982: 544) discusses this briefly, and provides a few examples including:

(7) Malayalam (Mohanan 1982: 544)
Roṭṭi ewiṭe? Kuṭṭi ṯiṉṉu.
bread where? Child ate.
'Where is the bread? The child ate it.'

The LFG treatment of this kind of phenomenon uses lexical rules of 'anaphoric control', developed in Bresnan (1982a), which optionally add a pronominal f-structure specification to the lexical entries of verbs. In the above case, this would be (↑ OBJ PRED)='PRO'. In Malayalam, anaphoric control applies to the grammatical relations SUBJ, OBJ, and OBJ$_\theta$ ('indirect object'; OBJ2 in the original). Anaphoric control is not restricted to non-configurational languages, and is subject to numerous variations in different languages. In English, anaphoric control is predominantly used with subjects of nonfinite verbs, but also applies in some other, more limited, circumstances. For example, an inanimate subject can be omitted but understood as if it refers to something that the group of people being addressed are looking at:

(8) Looks bad! [said by one of a group of people staring at an engine with smoke coming out of it]

The typological range of such constructions and their semantics deserves further investigation in LFG.

2.2 Warlpiri

A more extreme form of non-configurationality was addressed in the comprehensive analysis of Warlpiri provided by Simpson (1983), later published with substantial revisions as Simpson (1991), and also discussed by Nordlinger 2023 [this volume]. Warlpiri differs from Malayalam (and Japanese) in a number of ways:

(9) a. In finite clauses, there is no constraint on NPs coming after the verb.
b. NPs can be discontinuous, with different components appearing separated by other constituents of the clause.
c. There is an 'auxiliary', obeying a complex 'second position' constraint.

All of these phenomena are illustrated in this example:

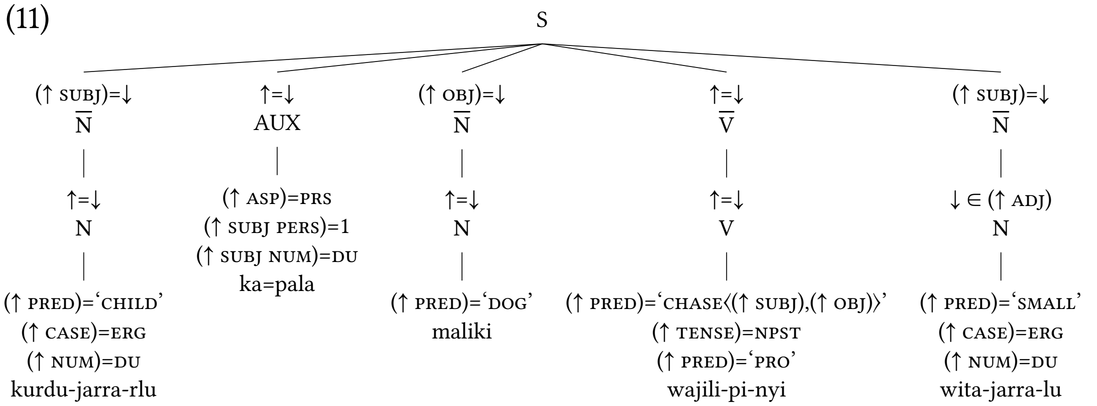
(10) Warlpiri
Kurdu-jarra-rlu ka-pala maliki wajilipi-nyi wita-jarra-rlu.
child-du-erg prs-du dog(abs) chase-npast small-du-erg
'(The) two small children are chasing the dog.'
'(The) two children are chasing the dog and they are small.'

The theoretically most interesting point is (9b).

Hale (1981) described the two nominals 'child' and 'small' in (10) as being interpretable in two ways, one being the 'merged' interpretation, shown in the upper gloss, where the two components are interpreted in the same way as a normal NP in English, and the other being the 'unmerged' interpretation, shown in the lower gloss, in which the second nominal is interpreted as a secondary predicate giving additional information.

To capture the merged interpretation, Simpson proposed that an NP (in her analysis, for Warlpiri, an $\overline{\text{N}}$, the language having no evidence for either a specifier level for lexical projections, or any kind of DP) could expand to an adjunct alone with no head (as well, as of course, to a single head), so that two independently introduced components of an f-structural NP-correspondent could merge, as reflected in the annotations on the tree for example (10):[6]

(11)



(Simpson 1991: 283)

The annotations on the first and last $\overline{\text{N}}$s allow them to unify into a single f-substructure, the value of subj:

---

[6] Note that Simpson assumed a rule or convention that would copy agreement features from the f-structure correspondent of an NP down to those of its adj-members. There is furthermore a problem with the positioning of AUX that we will consider shortly.

(12)
$$\left[\begin{array}{ll}
\textsc{subj} & \left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{child}\text{'} \\ \textsc{adj} & \left\{\left[\begin{array}{ll}\textsc{pred} & \text{`}\textsc{small}\text{'}\\ \textsc{case} & \textsc{erg}\end{array}\right]\right\} \\ \textsc{case} & \textsc{erg}\end{array}\right] \\
\textsc{pred} & \text{`}\textsc{chase}\langle(\uparrow \textsc{subj}),(\uparrow \textsc{obj})\rangle\text{'} \\
\textsc{asp} & \textsc{prs} \\
\textsc{tense} & \textsc{npst} \\
\textsc{obj} & \left[\textsc{pred}\ \text{`}\textsc{dog}\text{'}\right]
\end{array}\right]$$

Similarly to Malayalam, Warlpiri also makes extensive use of anaphoric control, although many arguments not expressed as NPs will receive morphological registration in the AUX constituent, which we will discuss shortly.

There are two further characteristics of Simpson's analysis that interact with each other, and have been important in later developments. The first is that similarly to Malayalam, Simpson analyses Warlpiri as having an inner VP, symbolized as $\overline{\text{V}}$, containing the verb and certain other elements, especially 'preverbs', as discussed in Simpson (1991: 111). However none of these items can contain complex phrasal constituents, and it is therefore probably better to treat them as non-projecting words adjoined to V.

The second additional feature of Warlpiri, already seen in the Warlpiri tree structure (11), is the 'AUX' constituent. This was postulated for Warlpiri[7] in the classic article of Hale (1973: 310), as a constituent containing three kinds of constituents, all optional. First comes a 'complementizer', which has a variety of functions, later called the 'augment' by Laughren (2002). We will follow this usage. Next comes the 'base', which is one of the tense-aspect markers *-ka* 'present imperfective' or *-lpa* 'past imperfective'.[8] Finally come agreement markers, for subject and object. Hale (1973: 312) proposed that if the augment+base sequence was less than two syllables in length, then the auxiliary could not appear in initial position, but only after some other, evidently first, element of the clause.[9]

Simpson (1991: 83) proposes that the underlying position of the AUX is initial, as specified by this rule:

---

[7] AUX as a node-type was widely proposed at that time for the analysis of many other languages, including English, as discussed extensively for example by Akmajian et al. (1979).

[8] Hale treated the future marker *kapi* as a base, but Legate (2008) shows that it is actually an augment.

[9] With the exception that certain items, such as topics set off with a pause, were seen as appearing outside the basic clause structure, allowing the AUX to appear in apparent third position if these items were included.

(13) S $\longrightarrow$ (AUX) α $(\alpha)^*$
$\alpha = \overline{\mathrm{V}}, \overline{\mathrm{N}}$, Particle
(↑ ASPECT) ↔ (↑ TENSE)
Assign (↑ G)=↓ freely
(where G stands for any grammatical function)

The second line tells us that α can be any of three kinds of constituents, while the third adds the information that ASPECT is specified if and only if TENSE is, a move that has the effect of requiring a verb to be present if an AUX is, by mechanisms we will not consider here. Finally, the last two lines allow constituents to be annotated freely as either heads (↑=↓) or arguments bearing any grammatical function, providing a high degree of non-configurationality, including generating multiple $\overline{\mathrm{N}}$ nodes with the (↑ SUBJ)=↓ annotation, allowing NP-splitting.

AUX is then put into second position in most examples by first allowing all AUXs to be classified as enclitics, but obligatorily so for the ones with monosyllabic bases (Simpson 1991: 69). Then the clitics are postposed to a position after the first phonological unit by a rule of sentence-phonology:

(14) Encliticization Rule:
]AUX $[\alpha]$ $[\alpha]^*$ → α+AUX $[\alpha]^*$
(the ']' in front of AUX represents that the AUX has enclitic status)

It is perhaps worth noting that for all examples where AUX appears in second position, the trees are also written with AUX in second position, including the effects of the Encliticization Rule in the diagram. In later work, various aspects of this proposal are questioned and revisions proposed, as we will see later, in Section 3.2 of this chapter.

A final observation I will make about Warlpiri concerns the treatment of discontinuous NPs. The LFG analysis permits an NP to be split into any number of separated components, all of which can contribute to a single f-structure with a nominal PRED-feature, subject to no constraints of any kind. There is considerable work showing that this appears to be false, including Schultze-Berndt & Simard (2012), Schultze-Berndt (2022) and Louagie & Verstraete (2016). Rather, discontinuous NPs appear to be associated with a range of specific discourse functions (and to furthermore be rather rare, probably not more than 1% of NPs), and examples where an NP is split into three or more components at the same level in f-structure (e.g. demonstrative, modifier(s) and head noun) do not appear to be attested in the literature so far. Unfortunately, none of this recent literature discusses Warlpiri, but I am aware of no triply split NPs in Simpson (1983, 1991), Nash (1986) or Laughren (1989),[10] nor in the discussion of discontinuous NPs in Latin and Classical Greek provided by Devine & Stephens (2000). Therefore, the proposition that discontinuous constituents are limited to two components is a proposition worth further investigation.

Similarly to Mohanan, Simpson provides some arguments for a flat structure and no VP, but they are more complex than Mohanan's cleft argument, one involving coreference, another involving nonfinite constructions. These will not be discussed here.

Concluding our discussion of the first period, we find a basic distinction between configurational and non-configurational encoding, the former associated with SVO languages, usually associated with a VP, the latter with verb-final or verb-anywhere languages, often with flat structure. It was usual to assume some kind of X-bar theory, without being very specific about the details. There were however some intimations of later developments, such as Falk's (1984) analysis of the English Auxiliary system, in which, influenced by Jackendoff (1977), he treats auxiliaries as a lexical category M, taking VP as a complement and the subject as a specifier. This can be seen as an early version of the idea of the functional projection IP, with its binary branching auxiliary structure as opposed to the flat ternary structure NP AUX VP proposed for S by Akmajian et al. (1979), which is taken up in the third period, the 2001 Synthesis (Section 4).

3 The transitional period

The characteristics of the transitional period are (a) the introduction of the concept of 'functional categories' from the GB and Minimalist frameworks, a feature which has remained; (b) considerable experimentation with ideas from Optimality Theory, which appears to have fallen off to some degree, although it is still being explored (Kuhn 2023 [this volume]). The dating of the period is difficult, since the use of functional categories could be said to have been anticipated by Falk (1984), while drafts of what I take to be the initiation of the third period, Bresnan (2001), were available to some workers as early as 1996 (Nordlinger 1998: 15). But I will here take it to begin with Kroeger (1993),[11] where the functional categories I and C are adopted from Government-Binding theory, and continue until the publication of Bresnan (2001). Many of the features of what I will in the next

---

[10] Who also provides an example of discontinuous participial VPs, which Simpson (1991) argues are nominalized.

[11] The Stanford PhD thesis upon which the book is based is from 1991.

section call the '2001 Synthesis' are present in the analyses of the transitional period, to the point that some discussions could be put in either section. But here we take an essentially chronological view surveying phenomena that lead to the 2001 Synthesis, presenting the resulting system in Section 4, together with some new analyses as well as possible updates to older ones.

3.1 Kroeger (1993) on Tagalog

Tagalog is a verb-initial language with preverbal discourse positions, and, according to Kroeger, no evidence for a VP, and some evidence against (we will consider a different view below), but evidence for some other predicate phrases, namely, PP, AP and NP. Kroeger analyses these patterns by taking from Chung & McCloskey (1987) the idea of a special category 'S' that can constitute a predication ('small clause') without providing TAM information, and combining this with the notion of a 'functional projection' IP, where the S appears as the complement of I. He also departs from Chung & McCloskey to allow S to expand to a lexical predicate and multiple arguments, rather than only to a subject NP and a predicate phrase.

For clauses with an aspect-marked verb, this verb appears in the I head of the functional projection IP (INFL for Kroeger), while the arguments and adjuncts appear in free order under S, although there are some tendencies (p. 111):

(15)
   a. The 'Actor' (non-nominative Agent marked with *ng*, or *ni* if a proper name) tends to come first.
   b. The 'Nominative' (marked with *ang*, or *si* if a proper name) tends to come after the other arguments.
   c. "Heavier" NP's tend to follow "lighter" NPs.

Kroeger does not actually give a structure for a sentence with multiple NP arguments: the closest is one with a clitic Actor and a focussed adjunct in the specifier of IP. Clitics are however subject to very interesting positional restrictions which in this case put the clitic *ko* after the SPEC of IP, as indicated in this example (Kroeger 1993: 129), where the original tree has INFL rather than just I:[12]

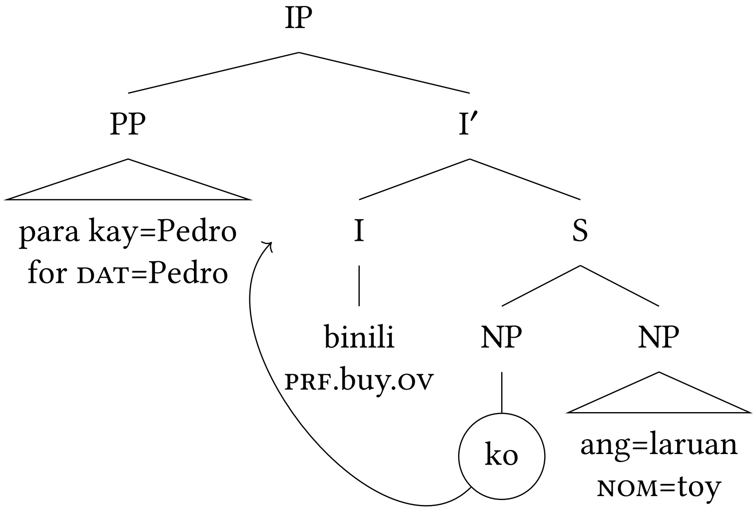
---

[12] The clitic rule, discussed in Kroeger (1993: 119-123), is: "Clitics appear immediately after the first daughter of the smallest maximal projection that contains them" (but there are some apparent exceptions). The 'object-focus' suffix glossed OV indicates that the Patient of the verb is the 'grammatical subject', traditionally called the 'focus' in Philippine linguistics, analysed by Kroeger as the SUBJ grammatical function in his LFG analysis.

(16) Tagalog

a. [Para kay=Pedro] ko binili ang=laruan.
for DAT=Pedro 1SG.GEN PRF.buy.OV NOM=toy
'For Pedro I bought the toy.'

b.

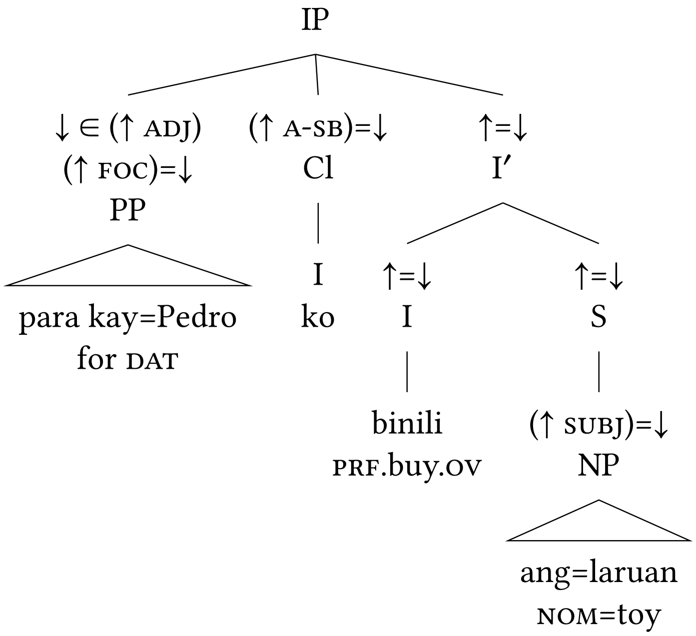


In this tree, the *ko* is ascribed to a position under S where a full NP argument could appear (initial in accord with the ordering tendencies noted above), with the arrow indicating some kind of clitic displacement to after the first constituent of IP. Another thing to note is the use of prime notation rather than bars, so I′ instead of $\bar{\text{I}}$. In this chapter, I will use whichever notation is employed by the original author.

Since functional projections have both the head and the complement annotated with ↑=↓, there is no problem with assembling the f-structure for a c-structure such as (16b). The initial PP is an instance of what Kroeger and much subsequent work has called 'Adjunct Fronting', which applies to the bearers of non-core GFs, that is, adjuncts, oblique arguments and adverbials (Kroeger 1993: 43). We can analyse this by allowing SPEC of IP to receive one of the non-term grammatical functions, together with some sort of focus-like discourse function. I can't find an explicit statement of this in the literature, but it appears to be an implication of the discussion in Kroeger and other sources such as Gerassimova & Sells (2008) that the construction is clause-bounded, since only subjects are said to be extractable from subordinate clauses, and only from ones that are themselves subjects (Kroeger 1993: 210, 215-221).

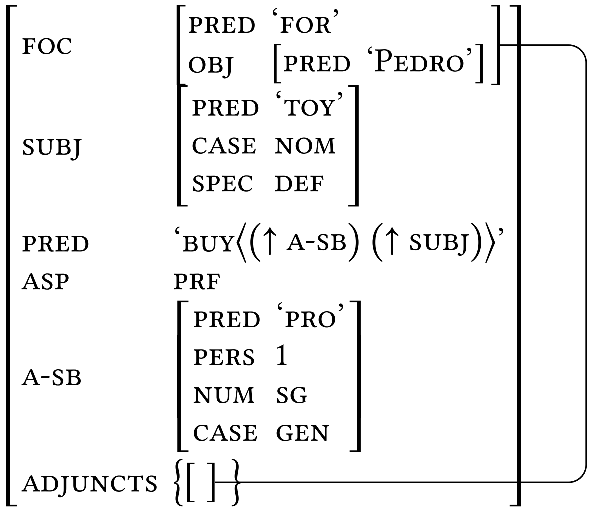
So we can propose an annotated structure like (17) below for the example, with the clitic *ko* placed overtly in its second position, without concern here for what constraints put it there, an issue discussed extensively by Kaufman (2010), but too complex to attempt to provide an updated account of here. We will notate it as ‘A-SB’, for the non-subject Agent in Philippine languages, following the choice of Manning (1996) for the Agent in syntactically ergative languages such as Inuit:

(17)



Given appropriate lexical entries, this will produce the following f-structure:[13]

(18)

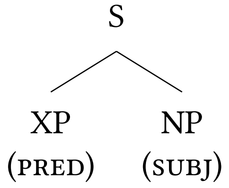


---

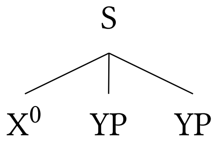
[13] This structure uses the older treatment of discourse functions such as FOCUS as grammatical functions in f-structure, along the lines of Bresnan (2001: 97-98) or Bresnan et al. (2016: 97). Kroeger (1993) does not provide any specific f-structures. For contemporary views, see Zaenen 2023 [this volume].

In addition to verbal clauses, there are clauses with adjectival, nominal and prepositional predicates. Kroeger argues that these show a different pattern, where some phenomena of clitic placement are said to show that the main predicate can either appear on its own as first daughter of S, or as head of a phrase that contains its complements, with the subject final under S in the former case, as indicated by these (somewhat abbreviated) structures (Kroeger 1993: 133):

(19) a.



b.



Unfortunately, Kaufman (2010: 259-260), working within the Minimalist framework, finds that the clitic facts cited by Kroeger[14] do not appear to be representative, in ways that undermine Kroeger's analysis. Since this is of some interest for the history of the subject, I think it is worth considering the examples, in the hope that it will be further investigated in LFG.

What Kroeger says is that with nominal, adjectival and propositional phrasal predicates, a personal pronoun clitic can appear either at the end, or after the predicate word, illustrated here for PP:

(20) Tagalog

a. Galing sa=Maynila siya.
from DAT=Manila 3SG.NOM
'He is from Manila.'

b. Galing siya sa=Maynila.
from 3SG.NOM DAT=Manila
'He is from Manila.'

But with a verbal main predicate, the sentence-final position is impossible:

---

[14] Originally from Schachter & Otanes (1972) and Sityar (1989).

(21) Tagalog

a. ??Hinangkan ng=nanay ako.
prf.kiss.dv gen=mother 1sg.nom
'I was kissed by mother.'

b. Hinangkan ako ng=nanay.
prf.kiss.dv 1sg.nom gen=mother
'I was kissed by mother.'

This is to be explained by:

(22) a. A principle to the effect that the clitics are placed after the first constituent in the domain they apply to, which is the IP.

b. The two constituent structures in (19) are available for nonverbal predicates, but only the flat one of (19b) for verbal predicates.

However, Kaufman finds that there is no significant difference between the clitic final position for verbal and nonverbal predicates: both are pretty bad. He also argues that Kroeger's generalization about where the clitic goes is insufficient, and proposes something different, well beyond the scope of this chapter. This leaves the flat rule (19b) motivated by the evidence, but not (19a), for Tagalog.

Nevertheless, there is motivation for structures of the general form of (22a) elsewhere in the Austronesian language family: Dalrymple and Randriamasimanana use it in their XLE grammar of Malagasy,[15] and Liu (2017) presents an LFG analysis of Squliq Atayal arguing on various grounds for this structure. Finally, Kaufman & Chen (2017) review a rather long tradition of argumentation in Austronesian historical syntax for the position that structures with a clause-initial predicate phrase and a following subject are the original form of the 'Philippine type' of which Tagalog is the most often discussed exemplar.

It is perhaps worth emphasizing that the 'subject' in Philippine languages is not the classic subject of western European languages with its strong association with semantic Agent properties, but rather the 'Pragmatic Peak' of Foley & Van Valin (1984), drawing heavily on earlier work by Paul Schachter and Edward Keenan (Keenan 1976, Schachter 1977), or the 'g-subject' of Manning (1996). These have an association with topic-like pragmatic functions, but not with agentivity. Indeed, the constructions with patient as subject tend to be more common than those with agent, and are closer in form to the proposed diachronic original, as discussed by Kaufman & Chen (2017).

---

[15] http://users.ox.ac.uk/~cpgl0015/pargram/; argumentation is however not provided.

A final point is that above IP, arguably the domain of clitic positioning, there are projections treated by Kroeger as CP, and irrelevant to clitic positioning (resulting in 'third position' phenomena), and this general approach is also adopted by Kaufman (2010).

3.2 Warlpiri: non-configurationality in Australian Languages

Austin & Bresnan (1996) update Simpson's (1983, 1991) analysis of Warlpiri to use the functional projection IP to house the material constituting the auxiliary, and also give an extended treatment of Jiwarli. Two important differences between Warlpiri and Tagalog with respect to I are:

(23) a. In Warlpiri, the verb does not appear in I.[16]
  b. I nodes in Warlpiri that meet a certain condition, to be discussed immediately below, cannot appear initially, at least in a phonologically independent clause.
  c. Most items, including the verb, can appear in front of the auxiliary material (contents of I). This analysis proposes two mechanisms for how this happens: NPs appearing in SPEC of IP, and a prosodic inversion operation for verbs and preverbs.

The nature of condition (b) calls for some discussion.

As mentioned above, earlier work from Hale (1981) to Simpson (1991) proposed that the AUX had to appear in second position if the augment+base was monosyllabic, but Laughren (2002) shows that the bisyllabicity condition is not correct, on the basis that the complementizer *yi-* 'for, since' followed by a null base can appear initially, as long as the entire auxiliary, including agreement markers, is bisyllabic (all the other augments are bisyllabic). This is also the case for the present imperfective base *-ka*, but apparently not for the past imperfective base *-lpa*.[17] So I suggest that the actual condition is a combination of phonology and morphology:

(24) In order for I to be overtly initial in Warlpiri, its contents must:
  a. be at least bisyllabic
  b. be phonologically well-formed as a word (initial *-lp* clusters are not allowed)

---

[16] Legate (2008) proposes in her Mimimalist analysis that the verb can be attracted to I, but in LFG, there is no advantage to be obtained by allowing it to appear there, as we will see below.

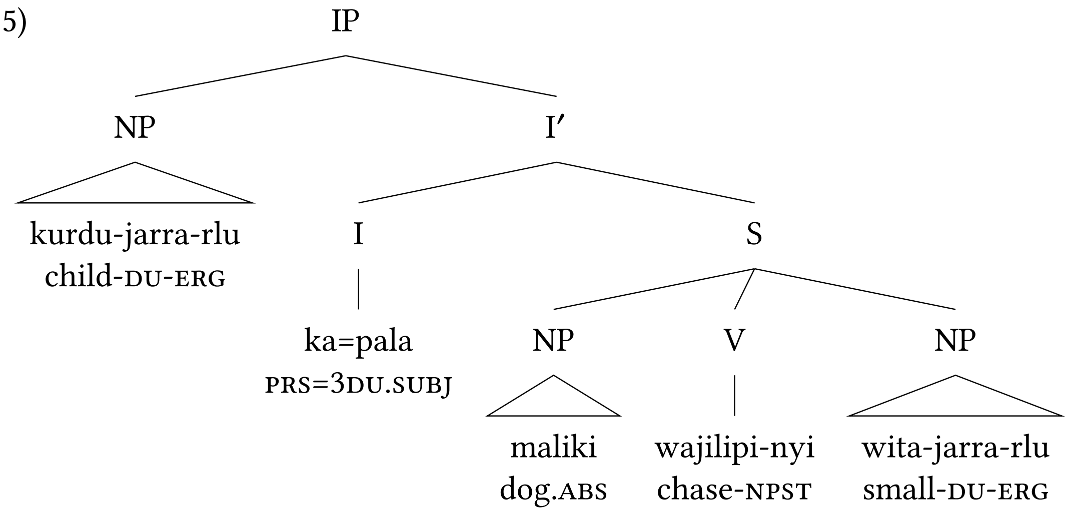
[17] But the existence of possible exceptions is discussed in Laughren (2002: 125, footnote 19).

c. have an overt augment+base (either augment or base is sufficient, as long as something appears).

I will call an auxiliary that meets these conditions ‘heavy’, and one that doesn’t, ‘light’. So our basic generalization is that only heavy auxiliaries can be initial in the sentence.

With this issue considered, we examine the basic sentence structure that Austin & Bresnan (1996) propose for Warlpiri, with an initial NP in the SPEC of IP position, and auxiliary material in the following I:

(25)



This illustrates the first mechanism whereby the auxiliary material can appear in second position, but is not plausible for cases when the verb is in first position, because a lexical category should not be able to occur in SPEC position in Warlpiri (Austin & Bresnan 1996: 226).

To deal with verb-initial sentences, Austin & Bresnan propose the rule of prosodic inversion from Halpern (1995), which moves the contents of I to a position after the verb, or, sometimes, after the initial part of a complex verb. This division of labor permits the inversion rule to apply to a considerably more restricted range of cases than Simpson’s Encliticization, removing the need for it to swap the auxiliary around multiword phrases.

Examples of multiword phrases are modifier+modified nominal constructions with case marking, on either only the last or both elements, and also coordinate NPs (auxiliaries in boldface to make the examples easier to follow):

(26) Warlpiri

a. Kurdu(-ngku) wita-ngku=**ka** maliki wajilipi-nyi
child(-ERG) small-ERG=PRS dog(ABS) chase-NPST
'The small child is chasing the dog.'
(Nash 1986: 159-160, citing Hale (1981))

b. Karnta-ngku manu ngarka-ngku=**pala** kurdu nya-ngu
woman-ERG and man-ERG=3.DU.SUBJ child.(ABS) see-PST
'The man and the woman saw the child.' (Nash 1986: 177)

Since these multi-word NPs can be generated in a position before I, we do not need to have any rule putting the auxiliary after them.

However, sentences with something other than an NP appearing before the auxiliary pose some tricky problems. If all and only the things found in this position were verbs, we could suggest that a V could optionally be adjoined to I, appearing in front of the auxiliary material. But this proposal faces two problems. One is that if the preverb appears in its normal position before the verb, then the auxiliary can appear between them, as long as it doesn't contain an augment (but polysyllabic auxiliaries with base *ka* are fine.):[18]

(27) Warlpiri (Austin & Bresnan 1996: 227)

a. Rambal-luwa-rnu=**rna=rla=jinta** marlu-ku
mistake-shoot-PST=1SG.SUBJ-1SG.DAT-DD kangaroo-DAT

b. Rambalpa=**rna=rla=jinta** luwa-rnu marlu-ku
mistake=1SG.SUBJ-3SG.DAT-DD shoot-PST kangaroo-DAT

'I shot at a kangaroo and failed.'

If the auxiliary intervenes, a preverb whose stem ends in a consonant must end in the stem-extender *-pa*, which it can do anyway. This indicates that one requirement for intervention is that the preverb must be construed as in some sense being an independent word.

Another is that for those 'productive' preverbs that can appear after or before the verb, the auxiliary material seems to almost obligatorily appear after just the verb rather than after the whole verb+preverb combination when the preverb comes second (Simpson 1991: 117):

---

[18] The suffix *-jinta* glossed DD indicates that this is a 'failed effect' construction discussed in Hale (1973: 336), in which the object is marked dative, indicating that the action indicated by the verb did not succeed.

(28) Warlpiri (Nash 1986: 52)
Yani=**rli** wurulypa
go-NPST=12 seclusion
‘Let’s go and hide.’

Nash observes that the ordering *yani-wurulypa=rli* occurs once in a text, but seems much less common than the other possibilities, while Simpson characterizes it as “hardly ever found, and it is usually rejected by speakers”. This is a problem for any analysis which puts V in front of I in c-structure, unless we assume a category other than V to dominate the V+Preverb order.[19]

So the conclusion is that an inversion rule along the lines of Simpson’s encliticization is needed, but applying in a narrower range of cases, more consistent with being a morphological or phonological operation. Austin & Bresnan (1996) assume that it is the ‘prosodic inversion’ of Halpern (1995), which only applies as a last resort. This is supposed to explain why the clitics can’t be inserted into phrasal units as in (27), but there is a problem here in that the structure in which the phrasal NP is sitting in SPEC of IP is different from one where it is initial in S right after I, so it is not clear that a ‘last resort’ restriction can apply in a well-defined manner.[20] A further problem is that it appears to be fine for a heavy auxiliary to appear after the verb (Laughren 2002: 97), so a last resort restriction won’t work.

What I suggest is an inversion rule which can be formulated like this:

(29) I V/Pvb
1 2 ⇒ 2+1
Subject to restrictions that need further investigation.

The category restriction is sufficient to prevent I from being inserted into an NP (a restriction documented at considerable length by Laughren), and another restriction, not formalized here, states that an auxiliary with an augment cannot be inserted into a verb.

A final problem discussed by Laughren (2002) and Legate (2008) concerns evidence that there is more than one functional projection dominating S, in spite of no evidence of two distinct head positions being occupied in the same clause. This is the interaction of topicalization and focus in questions. In (30) below, we see the auxiliary between the topic and a question word:

---

[19] On the other hand, Laughren (2002: 100) provides such an example without comment, but with a heavy auxiliary which could not be inserted into the verb.

[20] And it is furthermore clear that it is in general not impossible for second-position clitics to be inserted into otherwise intact NPs; this is for example rather common with *-que* ‘and’ in Latin.

(30) Warlpiri (Legate 2008: 34)
Kuturu-ju ka=npa=nyanu nyarrpara-wiyi marda-rni?
nullanulla-TOP PRS.IPFV=2SG.NOM=ANAPHOBJ where-first have-NPST
'Where do you have this nullanulla of yours?'

And in (31a-c) below, we see that a potentially interrogative word can be interpreted as either interrogative or indefinite if it appears right after an auxiliary, but only interrogative if before, while (31d) shows that if a potential question word appears further into the clause, after the auxiliary and the verb, it can only be interpreted as indefinite:

(31) Warlpiri
a. Kaji=ka=rna nyarrpara-kurra ya-ni.
NFACTC=PRS.IPFV=1SG where-ALL go-NPST
'I might go somewhere.'/'Where might I go?' (Legate 2008: 17)
b. Nyarrpara-kurra kaji=ka=rna ya-ni.
where-ALL NFACTC=PRS.IPFV=1SG go-NPST
*'I might go somewhere.'/'Where might I go?' (Legate 2008: 17)
c. Nyiya=rlangu kaji=ka=rlu nyina
what-for.example NFACTC=PRS.IPFV=3PL.OBJ be.NPST
wampana-piya-ju.
spectacled.hare.wallaby-like-TOP
'What ones for example might be like this spectacled hare wallaby?' (Legate 2008: 18)
d. Kaji=lpa=ngu wanti-yarla nyiya-rlangu
NFACTC=PST.IPFV=2SG.OBJ fall=IRR what-for.example
milpa-kurra.
eye-ALL
'If something fell into your eyes …'
*'What might have fallen into your eyes?' (Legate 2008: 18)

I tentatively suggest the following analysis. The auxiliary appears in a fixed position, which Austin & Bresnan call I, although C would also work. The interrogative/indefinite pronouns are interpreted as interrogative if they appear 'external to S', indefinite if 'internal'. 'Internal to S' means that they appear inside the lowest S in a stack of S's to which things have been adjoined (and are therefore not themselves adjoined), 'external to S' outside of the lowest in such a stack, so either adjoined to a S or in some higher projection. In Warlpiri, there are two ways in which this can happen: they can appear in Spec of CP, giving rise to

(31b-c) above, or adjoined to S, giving rise to the interrogative interpretation of (31a), where an internal position is also possible, giving rise to the indefinite interpretation. But in the case of (31d), the pronoun can only be internal to S, so only an indefinite interpretation is possible. However, for this to be the case we need a bit more, namely a restriction on adjunction to S, that it can only add a question-focus, which is easy to arrange with appropriate annotations.[21] Finally, in the case of (30), the Spec of CP position is occupied by the topic, so adjunction to S, and consequent position right after the auxiliary, is the only possibility for an interrogative reading (the only one that makes sense in the context).

The essential difference between the present LFG analysis and Legate's is that in the LFG analysis, the auxiliary appears in one position, and interrogatives in two, one on on either side of the auxiliary, while in Legate's, interrogatives appear in one position, while auxiliaries can appear overtly in two. I am aware of no clear theory-independent empirical evidence distinguishing between these possibilities; they are each motivated by what appears to work out best given the resources of the theory.

3.3 Russian

Although Russian has sometimes been presented as non-configurational, King (1995) argues that it is configurational, but with provisions that make the word order considerably more flexible than in English. She provides first a Government and Binding (GB) analysis, and then an LFG one, which leans heavily on the GB analysis for data and associated discussion.

She analyses Russian clauses as having CP, IP and VP layers, with two bar levels in each. The outer level of the VP introduces subjects, and there is one further layer over CP, which is available only in main clauses. This is for 'external topics', which have an initial XP, set off by a pause, with possibly an anaphoric pronoun later in the clause (King 1995: 202):

(32) Russian

a. Gleb, ja ego ne ljublju.
   Gleb, I him not like
   'Gleb, I don't like him.'

---

[21] I do not know what happens if there is more than interrogative word; typologically, there are various possibilities.

b.

Opera,	net	drugogo	vida	musykal’nogo	iskusstva,	kotoryj	privlekal
opera	not	other	type	musical	art	which	attract

by	k	sebe	takoe	vnimanie.
would	to	itself	such	attention.

‘Opera, there is no other kind of musical art which would attract such attention to itself.’

She analyses this with an ‘expression phrase’ rule (Banfield 1982, Rudin 1985) as follows, outside the X-bar system (similarly in her GB analysis):

(33) EP ⟶ XP CP
(↑ E-TOP)=↓ ↑=↓

King (1995: 105) suggests that these external topics do not fall under the X-bar system in Government-Binding theory, and does not attempt to assimilate them to X-bar theory in LFG either, but I suggest that perhaps the rule in (33) could be replaced by ‘Chomsky-adjunction’ to CP,[22] with some kind of further restriction, perhaps essentially semantic, preventing them from occurring in embedded positions (King 1995: 106):

(34) CP ⟶ XP CP
(↑ E-TOP)=↓ ↑=↓

Russian is not a full pro-drop language, so that an NP coreferential with an E-TOP is normally expressed.

In C we find the complementizer *što* and the question-marker *li*, most frequent in embedded questions, while in SPEC of CP we find question words: all question words in multiple wh-questions (King 1995: 215), unlike in English where only one appears. This is illustrated in the following example (King 1995: 216, ↑=↓ annotations omitted):[23]

(35) Russian

a.

kogda	kto	udaril	Boris-a
when	who(NOM)	hit	Boris-ACC

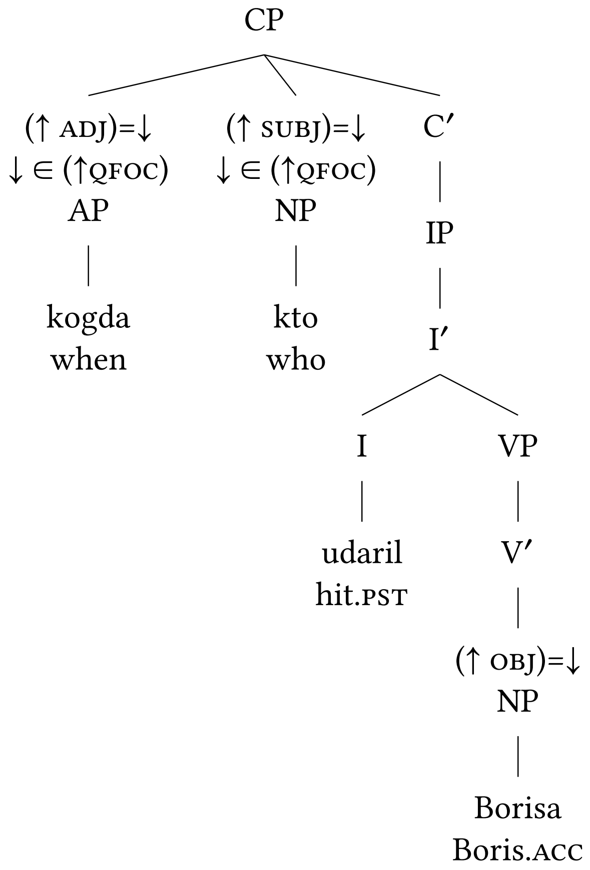
‘Who hit Boris when?’

---

[22] Meaning that it has one CP node as sister, another as mother, with identical feature-composition.

[23] In the tree, the annotation over the first constituent should be ↓ ∈ (↑ ADJUNCTS), but in the structure I give the original.

b.

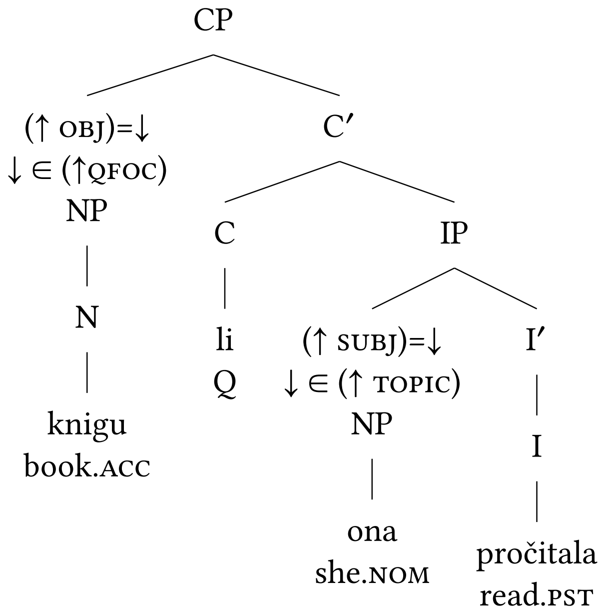


Yes-no questions can be marked either by intonation, or with the marker *li*, which appears in second position, after either an XP or the verb. An XP in front of *li* is interpreted as a focus, with the body of the question presupposed (King 1995: 236–237, King 1994), and items in SPEC of IP are Topics, as indicated by the annotation:

(36) Russian:

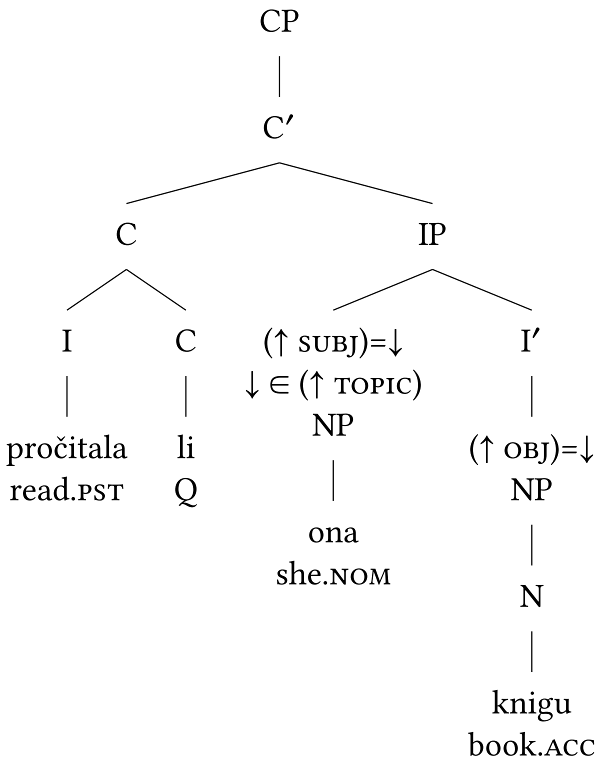
a. Knigu li ona pročitala?
book.ACC Q she.NOM read.PST
'Was it a book that she read?'

b.



If the yes-no question has no focus, then the verb appears before *li*, and King proposes that the verb is adjoined to C:

(37)



This solution avoids the issue of putting a nonmaximal projection in specifier position, and is independently motivated by the absence of the focus-presupposition articulation that appears when there is an XP in the specifier position. Formally, it could also be applied to Warlpiri, but without the additional motivation, insofar as is now known, and the problem of insertion of the auxiliary into combinations of verb and preverb would remain unsolved.

Moving down into IP, what we find here is 'internal topics' normally followed by contrastive foci, but with the possibility of some topics, especially pronouns, to come after the foci. Both contrastive foci and post-focus topics bear grammatical functions in their clause, and therefore do not cooccur with resumptive pronouns. The ordering phenomena are also connected to the issue of 'emotive' vs. 'non-emotive' sentences, an important topic in Russian syntax that does not get much discussion in King's LFG analysis (although more in the GB one). After considering various proposals, including recursive right-branching, King's final proposal is to use the ID/LP rule format (King 1995: 208), previously mentioned in footnote 3, where the '<' symbol in (b) means that the item in front of < must appear before the one after, if both occur in the structure:

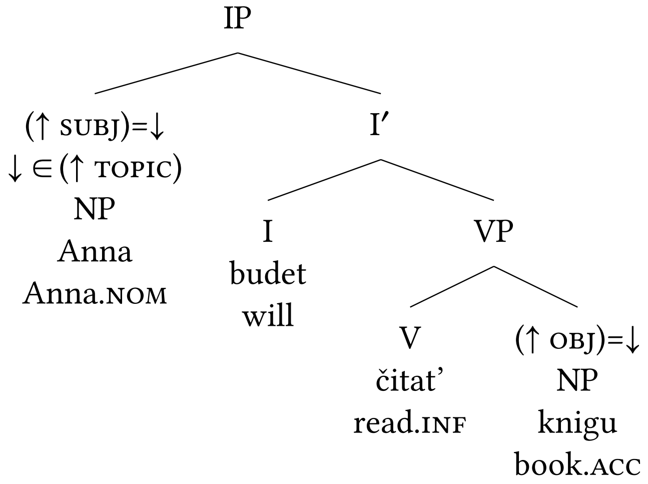
(38) a. $$\begin{array}{llcc} \text{IP} & \longrightarrow & \text{XP}^{*}, & \text{I}' \\ & & (\uparrow \text{GF})=\downarrow & \uparrow=\downarrow \\ & & \downarrow \in (\uparrow \text{DF}) & \end{array}$$

b. TOP < CFOC, XP < I′

A constraint putting the I′ after the XPs has been added, and 'DF' (discourse function) is assumed to comprise ordinary topics (TOP but not ETOP), and contrastive foci (CFOC). This formulation allows for considerable flexibility in word order, even though the language is fundamentally configurational. The big difference between King's IP rule for Russian and Bresnan's for English is that in Russian, any GF that is also topic or focus can appear in Spec of IP, while in English, only subjects can. King (1995: 133) notes that preverbal subjects tend to appear less markedly topicalized than other preverbal items, and discusses some possible reasons for this, including the tendency for arguments to be ordered consistently with the thematic hierarchy, which would put Agentive subjects, the most frequent kind, at the top, and therefore tending to be first.

In I itself appear finite verbs, either main verbs as in example (36), or the future auxiliary *budet* 'be', used to form imperfective futures, with the main verb appearing as head of VP:

(39)



This leads on to the structure of VP.

A somewhat unusual feature of King's analysis is that it introduces subjects not only as SPEC of IP, but also as SPEC of VP, along with other governed GFs that appear in V′ as usual, leading to this rule (King 1995: 209):[24]

(40) a.
$$\text{VP} \longrightarrow \underset{(\uparrow \textsc{subj})=\downarrow}{\text{(XP)}} \quad \underset{\uparrow=\downarrow}{\text{V}'}$$

b.
$$\text{V}' \longrightarrow \underset{\uparrow=\downarrow}{\text{V}} \quad \underset{(\uparrow \textsc{gf})=\downarrow}{\text{XP}^*}$$

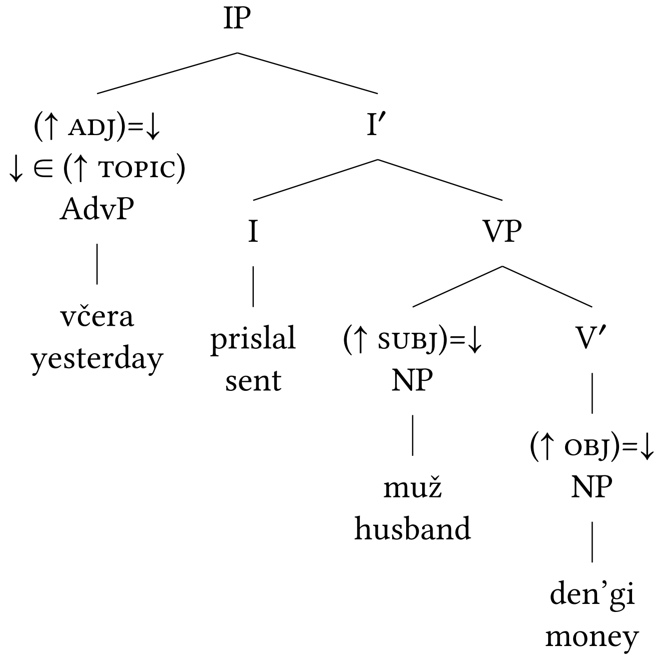
The evidence for this comes from various kinds of sentences where the subject is not also a topic, discussed more in King's GB analysis than in the LFG version.

One kind of example is 'thetic sentences', which assert that something happened, with no NP or other constituent singled out as the topic. The order in such examples is VSX*, as illustrated in the example below, as answer to the question 'what happened yesterday' (King 1995: 101):

---

[24] King omits the Kleene star on the complements in (b), presumably as a typographical error.

(41)



‘Yesterday (my) husband(FOC) sent(FOC) (me) money(FOC).’

The placement of the subject in SPEC of VP rather than SPEC of IP causes it to be interpreted as Focus rather than Topic, leading to a thetic interpretation of the clausal material excluding *včera* ‘yesterday’. We will see later in Section 5.3 that this analysis can be assimilated to that of other languages within the 2001 Synthesis presented in that section, by having the complement of I be (configurational) S rather than VP with internal subject.

3.4 German

German as analysed by Choi (1999)[25] resembles Warlpiri in arguably having only one functional projection,[26] but differs in a number of respects:

(42) a. Verbs can appear in the functional projection (and, often, must), but otherwise appear finally in VP.

b. There is no NP-splitting.

c. There is some evidence for an S node, although this is challenged by the later work of Berman (2003).

---

[25] A revised version of her 1996 Stanford dissertation of the same title.

[26] A possibly confusing factor is that the German problem in Bresnan et al. (2016: 375-379) assumes that the auxiliary *haben* in final position is an occupant of I, but makes no argument for this analysis, which Choi explicitly rejects (Choi 1999: 33). Berman (2003: 31-32), citing Choi, also discusses the lack of evidence for I.

The functional projection in these works is labelled “C′”,[27] and houses complementizers in subordinate clauses, and the topmost (main) verb in matrix clauses. Otherwise, the verb appears clause-finally, and the so-called “auxiliaries” are treated as main verbs taking VP complements. Full clauses consist of an S with an NP VP structure. A sample main clause with the auxiliary *sollte* is:

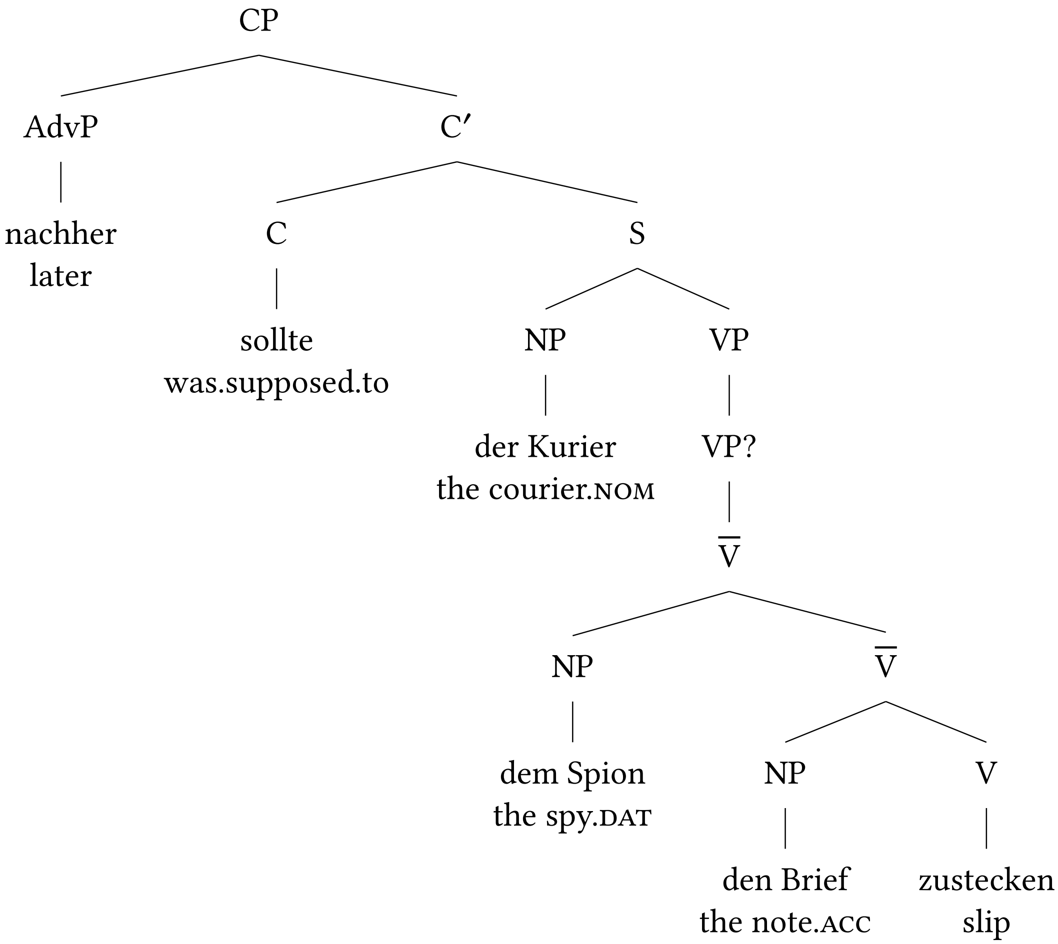
(43) German

a.

Nachher	sollte	der Kurier	dem Spion	den Brief	zustecken.
later	was.supposed.to	the courier.NOM	the spy.DAT	the note.ACC	slip

‘Later, the courier was supposed to slip the letter to the spy.’

b.



---

[27] Presumably because it contains some traditional complementizers, such as *dass* ‘that’, although this choice is essentially arbitrary.

This structure is extrapolated from Choi (1999: 19, ex. 7a) on the basis of later examples such as Choi (1999: 27, ex. 20). The nested $\overline{\text{V}}$ nodes are postulated to introduce the complements of V, a feature of the 2001 Synthesis which appears to be arbitrary, as we will discuss in Section 4.

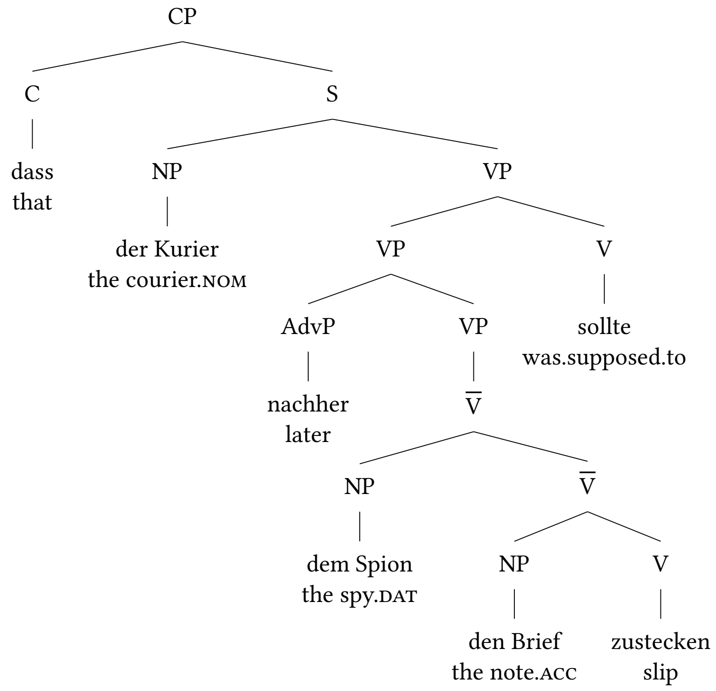
The question-marked VP solely dominated by another VP is motivated by the fact that the verbs traditionally called 'auxiliaries' in German (*sein* 'be', *haben* 'have', *werden* 'become', and the modals such as *sollen* 'should', which also has other meanings) appear syntactically to be plausibly taken to be the complement of the auxiliary *sollen* in C, whose VP appears immediately over the one with the question-marks. On the other hand, LFG for some time has been strongly oriented towards structure minimization principles, and the upper VP, which would be annotated '↑=↓', is not doing anything, and is therefore highly likely to be omitted, and indeed seems to be omitted by Choi in the somewhat later abbreviated structure (17) on p. 26.

A typical subordinate clause structure is:

(44) German (Choi 1999: 27, ex. 20)

a. dass der Kurier nachher dem Spion den Brief zustecken
that the courier.NOM later the spy.DAT the note.ACC slip
sollte
was.supposed.to
'that the courier was supposed to slip the note to the spy later'

b.



Here we see the complementizer occupying C, and the VP complement to the auxiliary *sollte*, at the end.

Although this analysis is in accord with the 2001 Synthesis, to be discussed in the next section, a later analysis by Berman (2003) rejects certain aspects of it, especially the arguments for putting the subject under S, as we will consider in Section 5.4 below.

3.5 Korean

The languages we have seen so far have one or two functional projections over S or equivalent, but Choi (1999) presents Korean as having none: S expands to NP followed by VP. She finds no evidence for I or C, since the functions of these projections are expressed by formatives on the verb, removing the need for any phrase structure positions to house them, and no other kinds of evidence for their existence.

She provides three arguments for VP (Choi 1999: 43–47), of which I will give two. One of them is that there is a contrastive focus-marking particle *nun* which can be attached to either an object NP or the verb to make either the attached-to constituent or the entire VP the focus, but not the entire clause including the subject. Illustrating the two readings for marking on the object, we have:

(45) Korean
Mary-ka chayk-un ilk-nun-ta
Mary-NOM book-TOP read-PRS-DCL
'Mary reads nothing but books.'
(Mary does nothing but read books)
(Choi 1999: 45, example 52; note that Choi glosses the marker as 'TOP' even though its function here is described as contrastive focus.)

Another argument is phonological: syllable-initial obstruents become voiced after a vowel in a phonological phrase, and this happens between an object and the following adverb *caypalli*, but not a subject; here, the segments voiced for this reason are italicized:[28]

(46) Korean
a. Cwuni-*g*a kong-ul *j*aypalli *j*a*b*-a.
Cwuni-NOM ball-ACC quickly catch-PRS
'Cwuni catches balls quickly.'

---

[28] Choi uses underlining to indicate the non-phonemic voicing, rather than different segmental phonetic symbols.

b. Kong-ul Cwuni-ga caypalli *jan*-a.
ball-ACC Cwuni-NOM quickly catch-PRS
'Balls Cwuni catches quickly.'

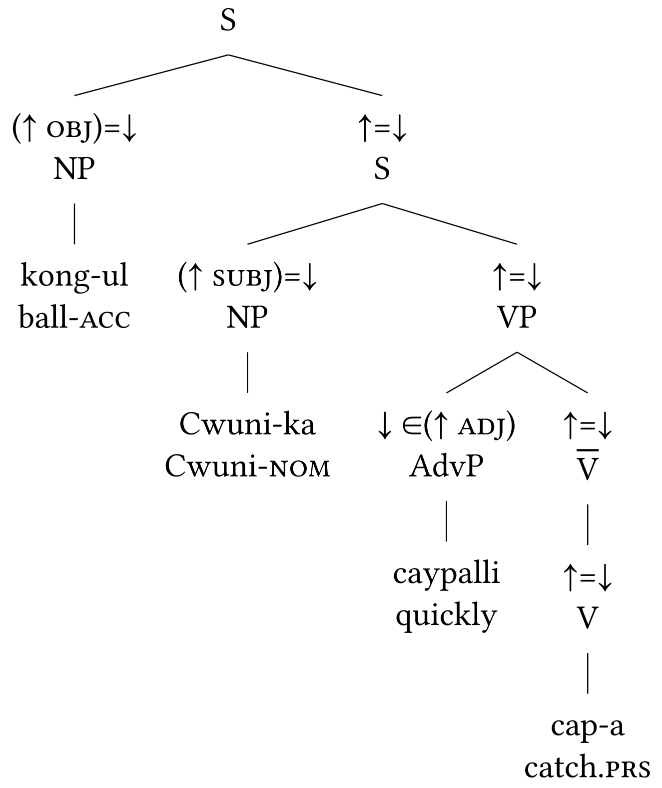
This treatment contrasts with that of Sells (1994), who proposes that Korean has an 'inner VP' (similar to the combinations of verb and preverb in Warlpiri) which can be plausibly analysed as a V^0 with adjoined non-projecting words, but no S vs. VP distinction. Instead, following Fukui (1986), all arguments are attached by phrase structure rules expanding VP to XP and VP, recursively. Sells's argument for the VP seems convincing, but not those for the binary branching structures for the arguments (Sells 1994: 353, fn. 2). Later, in Bresnan (2001), a branching VP like that of Sells was accepted, but with no serious attempt to show that it was superior to the more traditional flat VP assumed by Choi.

Another important characteristic of Choi's phrase structures is the absence of verbal functional projections. She considers an analysis in which tense and the declarative markers are treated as inhabitants of I and C, respectively, and morphologically fused with the verb, but rejects such analyses on the basis of violating the LFG principle that inflected words are inserted under single terminal nodes in the c-structure. One could propose that these projections do exist, but are fused with the verb via lexical sharing, but then there would be the problem of the nonexistence of any evidence for the syntactic autonomy of the two components, of the kind that the mechanism of lexical sharing was devised in order to explain.

As a consequence of the absence of C and I, we cannot use SPEC positions of these projections to house preposed items to provide a treatment of scrambling as found in (46b). Choi does not in fact present any c-structures for scrambled sentences in Korean, but states (Choi 1999: 9) that this is to be the structure for scrambling, and illustrates them for German (Choi 1999: 127, ex. 17a) with left-adjunction to S. This illustrates the principle that LFG does not propose a functional projection if there is no material that can occupy the head of that projection (in any structure; it is allowed for the head position to be unoccupied in some structures).

Furthermore, since there is no IP, we can't use SPEC of IP to house the subject, so Choi proposes S expanding to NP and VP. Therefore, the structure of (46b) is:

(47)



Caypalli is not one of the adverbs listed by Sells as restricted to immediately preverbal position, so we introduce it here as a daughter of VP rather than adjoined to V. The general question of VP versus $\overline{\text{V}}$ is a difficult one, which the new phrase structure theory of Lowe & Lovestrand (2020) might allow us to eliminate and thereby solve, but this is beyond the scope of this chapter.

4 The 2001 synthesis

And now we turn to the system presented in Bresnan (2001), foreshadowed at various points in the preceding discussion, and largely unchanged in its successor (Bresnan et al. 2016), which will be the source of our page reference citations. We have already introduced many elements of this proposal, so it is time to develop it more systematically. The basic ingredients, some of which are present in all of the intermediate stage analyses, are:

(48) a. the 3-level X-bar theory of Chomsky (1970), with one lexical and two phrasal levels, with the option for a language to have only two levels (one lexical and one phrasal), as in Warlpiri;

b. the modified system of category features (for nouns, verbs, etc.) from Jackendoff (1977) and Bresnan (1982a);

c. functional (extended) projections in the version of Grimshaw (2000), in which the extended projections share category features with their complements, which facilitates keeping the number of phrasal projections to 2. These are normally called I (as in Warlpiri), or C (as in German);
d. the existence of a category S, outside of the X-bar system, which can either be non-configurational, as proposed for Tagalog and Warlpiri, or configurational as will be proposed for Welsh and some minor constructions in English;
e. principles of structure-function mapping that limit what kinds of grammatical functions can be introduced in what positions;
f. the claim that phrases in the X-bar system are 'endocentric', while S is 'exocentric'.

A new feature of the 2016 version relative to the 2001 version is the 'non-projecting words' of Toivonen (2001), discussed in Belyaev 2023 [this volume], which have a category feature but are adjoined to another phrase without projecting anything themselves. Another feature of both versions that is not widespread in X-bar theory is the treatment of multiple complements. Bresnan et al. (2016: 127) observe that there are two possible treatments of complements, (49a) below with a nested structure, (49b) with a flat one:

(49) a. X′ ⟶ X′, YP
b. X′ ⟶ X, YP*

(49b) is what the older LFG literature assumed, (49a) what Bresnan (2001) and Bresnan et al. (2016) propose, on the basis of supporting a 'flexible definition of an endocentric complement' (Bresnan 2001: 118, Bresnan et al. 2016: 123).[29] Option (a) constitutes the choice that Choi makes for German in example (43), and works well when the complements can be ordered freely, but it is not clear to me how it is to account for the ordering restrictions in double object constructions, where the OBJ tends to precede an OBJ$_\theta$; the relevant restrictions can be easily stated, either with conventional phrase structure rules as in most early LFG, or with the ID/LP format (briefly mentioned in footnote 3). I suggest this is an issue best left for future investigation.

A further theme that interacts with the X-bar principles is a tendency to reduce the complexity of c-structure to a minimum. Two of the more important conditions are:

---

[29] Bresnan et al. (2016), fn. 50 refers to footnote 41, but that appears to be be irrelevant; the relevant definition appears on the page following fn. 41.

(50) a. A c-structure position is not postulated unless there is a class of items that can fill it.
  b. In any specific structure, all nodes are optional.

(50a) prevents us from postulating a functional projection such as ‘T’ for topic, or ‘E’ for ‘evidential’, unless we can find a class of items that plausibly appear in their head positions, while (50b) allows us to leave out items in specific cases, as will be discussed below.

The optionality of c-structure positions is an aspect of an important more general principle, Economy of Expression (Bresnan et al. 2016: 90):

(51) **Economy of Expression**:
All syntactic phrase structure nodes are optional and are not used unless required by independent principles (completeness, coherence, semantic expressivity).

A consequence of this principle is that the traditional principle of ‘S as the “initial symbol” in a phrase-structure derivation of a sentence’ is abandoned: a ‘sentence’ can phrase-structurally be an S, an IP, or a CP, depending on the language and details of the particular sentence. I suggest that this involves a shift from a traditional ‘syntactic’ notion of sentence-hood to a more ‘semantic one’, since glue semantics (Asudeh 2023 [this volume]) can connect these multiple superficial syntactic structures to a single semantic type. Further reductions in the complexity of c-structure are achieved by the reworking of X-bar theory developed in Lovestrand & Lowe (2017), but these have not yet been applied to a substantial typological variety of clause structures so as to produce results with differently organized overall structure, and therefore will not be discussed here.

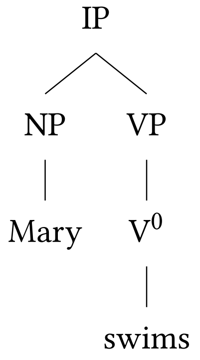
The c-structure principles interact with a set of structure-function mapping principles, which constrain the relationship between the c-structures and the f-structures. The principles (Bresnan et al. 2016: 105-109) assert that:

(52) a. C-structure heads are f-structure heads.
  b. Complements of functional categories are f-structure co-heads.
  c. Specifiers of functional categories are the grammaticalized discourse functions, such as SUBJ, FOC, TOP.
  d. Complements of grammatical categories are the non-discourse argument functions, such as OBJ, OBJ_θ (but not SUBJ).
  e. Constituents adjoined to phrasal constituents are optionally nonargument functions, either adjuncts or nonargument discourse functions.

This principle does not apply to S, whose daughters can bear any grammatical function.

Some simple effects of these principles apply in the structure for ‘Mary swims’:[30]

(53)



(Bresnan et al. 2016: 120)

The NP ‘Mary’ can be a subject because it is external to the VP in SPEC of IP position, while the other nodes will bear the ↑ = ↓ equation and so will correspond to the single f-structure that the NP’s f-structure correspondent is SUBJ of. Turning to Economy, unfilled heads and intermediate level nodes that dominate nothing but their head are eliminated, and the IP, VP, and V nodes will all correspond to the same f-structure.

The CP level appears in complement clauses, where the complementizer is head of C, and in certain other structures such as questions, where we get a CP level with an auxiliary verb filling C, a kind of analysis that is strengthened by the fact that an auxiliary can replace the complementizer *if* in a somewhat archaic/solemn variant of conditional clauses:

(54) Has he called?

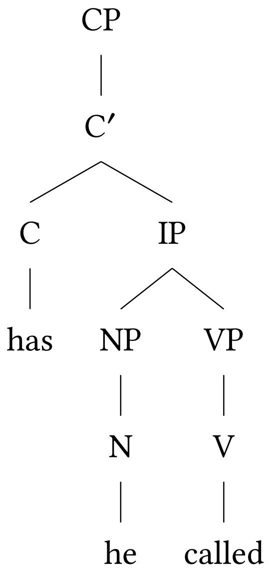
(55) a. If he had called, I would have answered.
b. Had he called, I would have answered.

For (54), given the preceeding, the plausible structure is:

---

[30] The Bresnan (2001) version has S instead of IP, but this is rejected due to the lack of independent evidence for S in English main (indeed, finite and most nonfinite) clauses in English.

(56)



The IP provides the location of the subject, which has no alternative locations in English finite clauses.[31] The conditional clause in (55b) has the same structure, with the preposed auxiliary replacing the overt complementizer that appears in (55a).

In the systematization of Bresnan et al. (2016: 103), the functional projections are distinguished from the lexical ones by having values 1 or 2 for a feature F, whose value is unspecified for lexical projections. This implies that the choice of C or I in the 1 level languages such as Warlpiri and German is arbitrary, with a further consequence that any tendency in two-level languages to express some things in C and others in I is probably functional in origin. It is of course also possible for there to be no verbal functional projections at all, as argued by Choi for Korean, and is plausibly also the case for Malayalam and Japanese.

5 Applications to languages

In this section we consider the application of the 2001 synthesis to various languages, starting with Welsh, and then reviewing some of the previous ones which call for comment. Malayalam and Korean fit without further discussion, and so are omitted here.

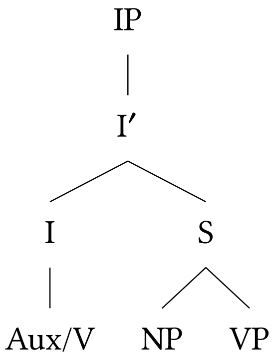
---

[31] But, as we will see shortly, certain nonfinite ‘small clauses’ arguably use S rather than IP. The exact nature of the connection between ‘finiteness’ and IP deserves further investigation.

5.1 Welsh

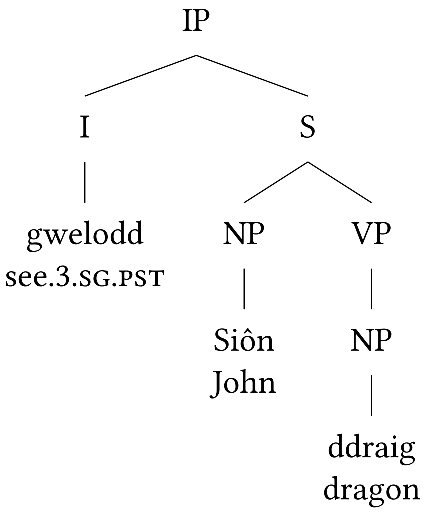
The basic structure for a main clause is:

(57)



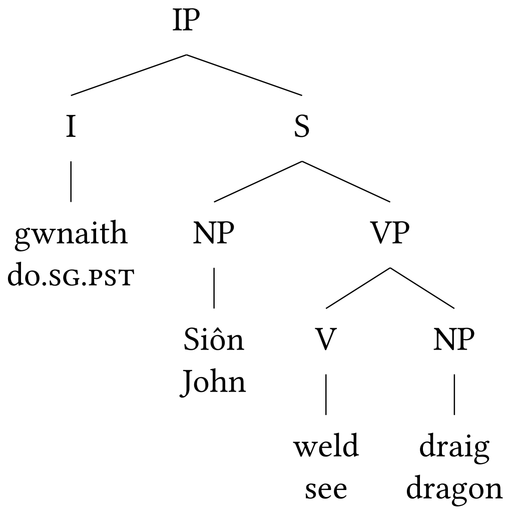
If there is no auxiliary, the finite verb appears at the front of the sentence, in the I position, as shown in (58a) below, very similarly to King's (1995) analysis of Russian. But if there is an auxiliary, the auxiliary appears in I, the verb initially in V of VP, again similarly to Russian, as shown in (58b), but with the VP under S dominating the subject, rather than a two-level VP (Bresnan et al. 2016: 131-133):

(58) a.



'John saw a dragon.'

b.



'John saw a dragon.'

One issue here is how a VP can appear sitting over only an NP in (58a). This goes against the idea that an endocentric category needs to have a head, while the presence of a VP is motivated by the range of things that can appear in the position after the subject, where overt VPs sometimes appear over the same material.

This problem is averted by the 'Extended Head Principle' (Bresnan et al. 2016: 135-137), which in effect says that a phrase can have a 'displaced head', as long as that head appears within a higher phrase having the same f-structure correspondent. The definition of 'extended head' is:

(59) Given a c-structure containing nodes $\mathcal{N}$ and $\mathcal{C}$ and a c- to f-structure correspondence ϕ, $\mathcal{N}$ is an extended head of $\mathcal{C}$ if and only if $\mathcal{N}$ is the minimal node in $\phi^{-1}(\phi(\mathcal{C}))$ that c-commands $\mathcal{C}$ without dominating $\mathcal{C}$. (Bresnan et al. 2016: 136)

and the principle is:

(60) Every (phrasal)[32] lexical category has an extended head

Although we have discussed only I, Welsh also has a functional projection C, containing complementizers as discussed by for example Roberts (2005). Therefore it is a 2-level language like English, but differs from English in that the complement of I is S rather than VP. This is required because in Welsh, the position of the subject is after the auxiliary rather than before it. 'I+S' languages, such as

---

[32] This qualification is absent from the original, but seems to me to make the principle work properly.

for example Tagalog, also often have the property that S can have PP, AP, and NP as well as VP as the predicate phrase, but this does not appear to be the case for Welsh, since it uses a copula in sentences where these play the semantic role of predicate.[33] Welsh also differs from English (and is similar to most other Germanic languages) in that all verbs can appear in I, rather than only a restricted class of 'auxiliaries'.

5.2 More English

As observed above, the fact that English puts the subject in front of I rather than after it indicates that it has VP rather than S as complement of I, an analysis corroborated by the fact that a verb is obligatory in finite clauses (recalling that IP shares category features with its complement, so excludes a non-verbal complement). But nevertheless, as observed by Chung & McCloskey (1987), English does arguably have nonfinite clauses where S expands to NP subject and a predicate phrase, which can be NP, AP, VP or PP. These so-called 'small clauses' are used in English to express a combination of incredulity and often dismay (Akmajian 1984):

(61) a. What?? Him an alcoholic??
b. What?? Her sick with the flu??
c. What?? Him run(ning) a company??
d. What?? That guy in the White House??

Along with nonfiniteness comes accusative case on the subject and no agreement with any verbal element. This is evidence that in English, nominative case on NPs is a marker of finiteness on the clause, somewhat in the manner of the proposals of Pesetsky & Torrego (2007) within the Minimalist program, although an LFG analysis would have quite a different implementation, similar to the treatment of 'modal case' in Tangkic languages, as presented in somewhat different forms by Andrews (1996) and Nordlinger (1998). In these languages, nominative forms would have an equation specifying an appropriate tense feature value for whatever they were subject of.

Another plausible case for S would be gerundive nominalizations with accusative (rather than genitive) subjects, as analysed by Schachter (1976):

---

[33] Bresnan et al. (2016: 130) suggest that Welsh has these as possible predicates under S, but no examples are provided, and Welsh appears in fact to use a copula. See Borsley (2019) for a recent discussion of Welsh copular clauses in the framework of HPSG.

(62) John giving/*give an invited talk might be a good idea

A potential issue with having NP expanding to S here is that the predicate phrase of the S is restricted to being a VP whose verb is marked with *-ing*. But this can be accommodated by including an appropriate constraining equation in the c-structure rule:

(63)
$$\text{NP} \quad \longrightarrow \quad \begin{array}{c} \text{S} \\ \uparrow=\downarrow \\ (\downarrow \textsc{vform}) =_c \textsc{ing} \end{array}$$

The constraining equation will require the predicate of the S to be a verb, as well as a verb marked with *-ing*. Taking this analysis further would require entering the realm of 'mixed category constructions', beyond the scope of this chapter. But there is clearly a question of what causes S to have a rather limited distribution in English, as opposed to other languages such as Welsh or Tagalog.

5.3 Russian revised

Moving on to Russian, King's analysis, discussed in Section 3.3, diverges from the previous analyses we have discussed in this section in using a two-level VP, with the top level introducing a subject. This difference can be easily eliminated by replacing the upper level VP with S, but is there any serious motivation for doing that?

The structure-function mapping principles listed in (52) are not entirely clear on this: (52c) says that specifiers of functional categories are the grammaticalized discourse functions, which suggests no, but grammaticalized discourse functions can also be adjoined (52e), which suggests possibly yes. A general point that suggests that the S analysis is correct is that the question of what should appear in the specifier of VP in many languages, such as English, has always been rather controversial. Fukui (1986) proposes that only functional, not lexical, categories, have specifiers, and this appears to be consistent with what we have seen here. On the other hand, specifier is at least a somewhat plausible place to locate quantity and degree modifiers of nouns and adjectives, but there could be a weaker position that specifiers of lexical categories do not supply arguments to those categories, but serve different functions when they exist at all.

If we accept this reanalysis, a natural concomitant is to place postposed focussed subjects and certain other NPs under S, following the VP:

(64)
$$\text{S} \quad \longrightarrow \quad \begin{array}{c} (\text{XP}) \\ (\uparrow \textsc{subj})=\downarrow \\ \end{array} \quad \begin{array}{c} \text{VP} \\ \uparrow=\downarrow \\ \end{array} \quad \begin{array}{c} \text{XP}^{*} \\ (\uparrow \textsc{gf})=\downarrow \\ (\uparrow \textsc{foc})=\downarrow \end{array}$$

King (1995: 210) put these under V′ in order to treat examples such as:

(65) Russian (King 1995: 209)
Kupila plat'e Inna.
bought dress Inna
'Inna.FOC bought a dress.'

But this actually does run against the structure-function mapping principle (52d). Using S in this way gives us a version of King's analysis that is clearly within the framework of the 2001 Synthesis.

5.4 German again

German, however, presents a problem. Choi's treatment was within the Synthesis, in spite of originating in 1996, but Berman (2003) eroded an important aspect of it, that subjects appear under S. In particular, following Haider (1990, 1995), she concluded that various kinds of presumed subjects were included in VP-preposing, including the rather hard to dismiss unergatives, which cannot be construed as nominative objects, as is possible for some of the other examples:

(66) German (Berman 2003: 36)
Kinder gespielt haben hier noch nie.
children played have here still never
'Children have never played here.'

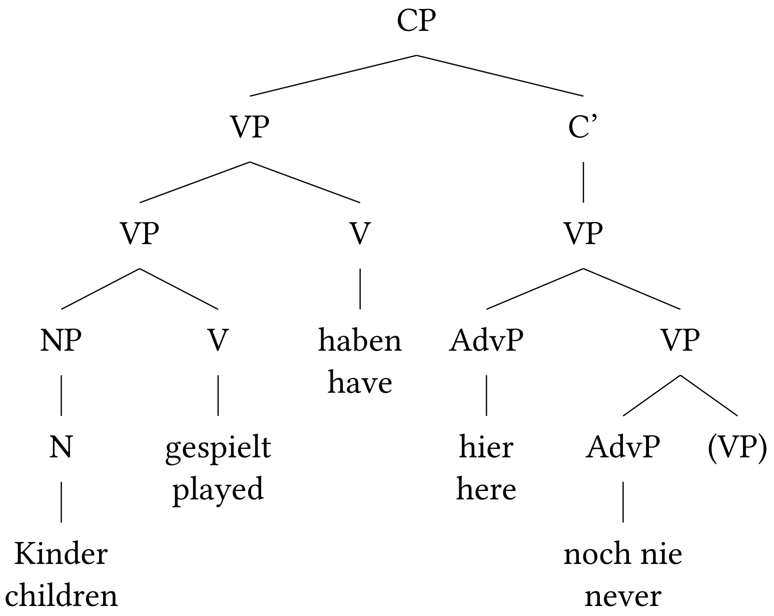
Her solution was to introduce all arguments, including subjects, under VP in nested VPs, her VP not being clearly distinct from Choi's $\overline{\mathrm{V}}$, with a complex verb at the bottom, as discussed in a considerable amount of literature in different frameworks.[34]

Unfortunately, she did not provide an actual tree for this example ((28b) in the text, nor for the similar (28a)), but I suggest:

---

[34] For example Wurmbrand (2017) in Minimalism, Zaenen & Kaplan (1995) in LFG.

(67) German



Where the parenthesized (VP) is an informal notation for the fact that the head of the unparenthesized VP above it is supplied by the Extended Head Principle from the Spec of CP position.

This would seem to call for revision of Choi's structures for German such as (44a), but, on the other hand, the VP-internal subjects appear to be restricted; for example, they must be indefinite. So it is not excluded that there is both an S where most subjects reside, as proposed by Choi, and subjects appearing in the VP, as proposed by Haider. Alternate word orders are also produced by 'scrambling', with strong effects on information structure, as extensively discussed by Choi.

5.5 Final remarks

We can sum up the discussion in the previous subsections into a set of rules for when to posit S as opposed to VP as complement of I and in some other environments.

(68) a. If SPEC of IP has a subject position, and subjects appear there, rather than in the complement of I, then the complement of I is VP or possibly other maximal lexical projections.

b. If subjects appear in the complement rather than in the SPEC of IP, then the complement of I is S.

c. This can happen in two ways: either S is non-configurational, introducing predicates and arguments in variable order (with the possibility of the predicates being ordered at the end or beginning of S), or S is configurational, dominating NP and a predicate phrase (maximal projection).

In this context, we interpret ‘subject’ as the core grammatical function (Bresnan et al. 2016: 97) that is also a discourse (topic) grammatical function (Bresnan et al. 2016: 100). We also of course assume S when there is no evidence for I, as in Korean.

The organization of functional projections, on the other hand, is to be ascertained by the arrangements of elements marked by verbal features with respect to other members of the clause, with a general tendency for there to be more intervening items when the projections precede the main verb position than when they follow, leading to a tendency for verb-final languages to appear to lack verbal functional projections.

It is clear that many of the languages we have considered are due for careful reanalysis, due to unresolved issues and discrepancies between earlier and later versions of LFG, and also taking into account the new phrase structure theory of Lowe & Lovestrand (2020). Of particular interest would be the nature of clitic placement in Tagalog, and the issue of flat versus nested structure in non-configurational languages such as Tagalog and German, where the order of arguments is free, but the predicate is fixed at one end or the other.

A major study of clause structure that we have not tried to work through is Sells (2001) on Swedish, for the reason that this makes heavy use of Optimality Theory in ways that have not become mainstream in LFG. However, word order and clause structure in Scandinavian languages is an extremely complex and interesting area that deserves further investigation.

I will conclude with a speculation about the nature of nonconfigurationality. This is that nonconfigurational S is what ensues diachronically when a language makes such extensive use of discourse-conditioned preposing that the learner gives up trying to analyse it, but instead returns as c-structure something that is essentially a list of fragments, similar to what the XLE system (Forst & King 2023 [this volume]) does when it can’t find a parse. But the syntax does find an f-structure for the c-structure fragment list appearing under S. The idea of non-configurational S as a kind of partial failure of c-structure parsing would be consistent with the revision of the theory of Lowe & Lovestrand (2020) proposed in Lovestrand (2022), whereby non-configurational S has no category feature value.

Chapter 10

Unbounded dependencies

Ronald M. Kaplan
Stanford University

The basic grammatical representations and formal operations of Lexical Functional Grammar are designed to take advantage of the fact that most syntactic dependencies apply to nearby elements of the string, constituent structure, or functional structure. As is well known, languages also exhibit phenomena with syntactic relations that hold over wider and potentially unbounded domains. The earliest LFG approaches to such unbounded dependencies were modeled after the phrase structure solutions of other frameworks. But it is now generally recognized that the functional configurations enshrined in f-structure support the simplest descriptions and explanations of the ways that such dependencies interact with the local organization of clauses and sentences. This chapter surveys many of the theoretical, empirical, and technical issues that have been discussed in the LFG literature and in the linguistic literature more broadly. Modern LFG accounts of unbounded dependencies make use of functional uncertainty with off-path annotations, carefully defined technical devices that integrate well with other aspects of the LFG formalism.

1 Introduction

Grammatical representations and the operations defined on them are designed to take advantage of the fact that most syntactic dependencies (such as agreement, government, and control) are local. Typically, they can be defined on string-adjacent elements or on elements that can be made tree-adjacent with hierarchical structures of modest and definite depth. It is also well known, however, that languages exhibit some phenomena that require the capability to describe syntactic relations that hold over wider domains. With such unbounded dependencies, a grammatical function assigned within an embedded clause is correlated with

Ronald M. Kaplan. 2023. Unbounded dependencies. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 425–481. Berlin: Language Science Press. DOI: 10.5281/zenodo.10185954

a configuration of items that appear elsewhere in the sentence and perhaps far away from the other words and phrases that make up that clause. Constructions with different patterns of unbounded dependencies have posed descriptive and explanatory challenges to most grammatical theories. This is because the correlations can be sensitive in intricate ways not only to internal properties of the clause and properties of the external configuration, but also to syntactic properties of the intervening material.

There is a substantial literature that aims to identify principles that apply broadly, if not universally, to condition the appearance of unbounded dependencies and also to identify the dimensions of variability across constructions and languages. This chapter surveys just some of the major descriptive and theoretical challenges that these dependencies have presented and sketches how they have been, or in some cases might be, addressed with the tools and techniques of Lexical Functional Grammar. Section 2 sets the stage for this discussion with some simple examples of the topicalization construction. These show that a phrase at the front of a sentence is interpreted as an argument of a distant predicate and its syntactic features are governed by that predicate. Kaplan & Bresnan (1982) proposed an LFG account of unbounded dependencies based on the categories and dominance relations of c-structure. Section 3 outlines that original proposal but then summarizes the considerations that led Kaplan & Zaenen (1989) to conclude that these dependencies are better described in functional terms, as instances of "functional uncertainty". Functional uncertainty is a straightforward extension to the notation of functional descriptions and has now become the standard mechanism for characterizing unbounded dependencies in LFG grammars.

English constituent questions (Section 4) are slightly more complicated than topicalizations because of the additional requirement that an interrogative pronoun exists at an uncertain position inside the initial question phrase. In traditional treatments the topicalized and question phrases correspond to the values of distinguished f-structure attributes, TOPIC and FOCUS respectively, that serve as signals for the discourse entailments of these constructions. It has been argued that those entailments properly belong to a separate component of grammar, Information Structure (Zaenen 2023 [this volume]), and this suggests (Section 5) removing such grammaticized discourse functions from f-structure in favor of explicit mappings to i-structure made possible by LFG's Correspondence Architecture.

The English *tough* construction (Section 6) is of interest because its unbounded dependency is introduced by an annotation in a lexical entry rather than a c-structure rule, and also because the shared f-structure element is governed by predicates in two different clauses. This may lead to a connectivity problem wherein a sentence is grammatical even though the two clauses assign incompatible values to some features, CASE in particular. This section outlines several solutions to that problem. Connectivity is also a potential issue for relative clauses, since as in *tough* constructions the relativized NP appears to play a role in two clauses. Relative clauses have the additional complexity, like constituent questions, that an initial topic phrase must contain a relative pronoun at some uncertain position. Relative clauses are discussed in Section 7.

Section 8 covers a collection of constraints that may be layered on top of the basic constructions previously described. For some constructions in some languages the form of a clause may change if a dependency passes through it. Some clauses and some configurations are impervious to unbounded dependencies, forming what are traditionally known as islands. And there are also linear order constraints that seem to tie the functionally-specified unbounded dependencies more closely to the sequence of words in the sentence. The last section discusses possible LFG accounts for parasitic gaps and other multiple gap constructions, a dependency pattern that is unexpected and problematic for almost every grammatical theory.

2 Topicalization: A simple unbounded dependency

Typical examples of unbounded dependencies are topicalization, constituent questions, and relative clauses in English and other languages. What is important in these constructions is that an element in a matrix clause bears a grammatical function governed by the verb in a clause that may be arbitrarily far away in the sentence. This is exemplified by the topicalization in (1).

(1) Mary, John claimed that Bill said that Henry called.

In (1), *Mary* is understood as the object of *called* but it occurs outside the embedded clause that contains that verbal predicate. Hence local functional equations are not able to describe the dependency nor can it be inferred from the local c-structure hierarchy. Without further specification the embedded f-structure will be incomplete. Of course the grammar can include a local functional dependency with a long sequence of attributes to share information between the higher and lower clauses in this particular sentence. But the hallmark of dependencies of this type is that they tend to be unbounded in the sense that the embedding structure can be arbitrarily deep, as the following variant of (1) suggests:

(2) Mary, John claimed that Bill said that Henry expected to call.

There is little morphological marking on the elements of English topicalization. But in other languages it is very clear that the external item must have the markings that go along with the clause-internal grammatical function to which it is assigned. The following German example is an illustration of such a correlation:

(3) German (Berman 2003)
Den Peter glaube ich hat die Maria eingeladen
the.ACC Peter believe I has the Maria invited
'Peter, I think that Maria has invited.'

Here *den Peter* is in the accusative because *einladen* 'invite' takes an accusative object. Case marking is not the only connectivity effect. Reflexivization constraints also register the external element as fulfilling a function in the embedded f-structure, as shown in the following Icelandic example:

(4) Icelandic
Sjálfum sér held ég ekki að Jón geðjist.
Himself think I not that John likes.
'I don't think that John likes himself.'

In Icelandic, elements that are coreferent with the subject of their clause need to take a reflexive form (*sjálfum* in this example) that is distinct from a nonreflexive pronoun (*hann*). This requirement must be satisfied even when the subject is realized outside of the clause.

As a first approximation, the obvious way to handle such interactions is through the kind of structure sharing that is used in LFG descriptions of raising constructions (Vincent 2023 [this volume]). There it is also the case that an f-structure element plays two roles, e.g. subject of a lower clause and object of a higher one. What is different in the case of unbounded dependencies is the fact that the inventory of possible f-structure paths between higher and lower elements cannot in principle be characterized by finite sequences of intermediate functions.

3 LFG formalizations

LFG has two types of syntactic representations and it is not clear *a priori* whether unbounded dependencies should be modeled in the c-structure or in the f-structure.

3.1 Early approach based on c-structure

In Kaplan & Bresnan (1982) unbounded dependencies were modeled via the c-structure spine as in many other frameworks of that period. The representation for sentence (1) is shown in Figure 1.[1]

In this formulation the linkage between the clause-external item and its clause-internal function is specified by the c-structure rules in (5). This analysis depends on the fact that the obj function is assigned to an NP under VP (5c) and that any NP can expand to an empty "trace" node, indicated by e in (5b).

(5) a. $\text{CP} \longrightarrow \underset{\substack{(\uparrow \textsc{topic})=\downarrow \\ \downarrow=\Downarrow}}{\text{NP}} \quad \underset{\uparrow=\downarrow}{\text{C}'}$

b. $\text{NP} \longrightarrow \underset{\uparrow=\Uparrow}{\text{e}}$

c. $\text{VP} \longrightarrow \underset{\uparrow=\downarrow}{\text{V}} \quad \underset{(\uparrow \textsc{obj})=\downarrow}{\text{NP}}$

The double arrows ⇑ and ⇓ are metavariables, like ↑ and ↓, that denote the f-structures corresponding to c-structure nodes in particular configurations. In the annotations on a daughter category in a given rule, ↑ refers to the f-structure corresponding to the mother node, and ↓ refers to the f-structure corresponding to the daughter. In contrast, the double arrows (called "bounded-domination metavariables") match nodes that are separated in the c-structure but are related through a longer dominance path. Thus the NP in front is a sister of a clause that contains the trace node, and the dominance path between the nodes is allowed because it does not contain other nodes that encode so-called island constraints (see Section 8.2). The dotted line in Figure 1 connects the two c-structure nodes with matching double arrows. The c-structure-to-f-structure correspondence then induces the sharing relationship depicted in the f-structure. The topic function

---

[1] The nodes in this c-structure are labeled with modern X′ categories instead of the traditional categories found in earlier LFG papers (e.g. Kaplan & Bresnan 1982, Kaplan & Zaenen 1989). But I depart from common X′ assumptions in showing c-structures that are not cluttered with nodes that are nonbranching, nonmajor, nonlexical, and functionally transparent (annotated with ↑=↓). Other categories (like C′ and VP′) can appear as macro arguments, phantom categories, or metacategories in c-structure grammar specifications (Kaplan & Maxwell 1996, Crouch et al. 2011) and thus can still be used to express generalizations over the context-free rules that describe well-formed c-structures. In that regard they have the same explanatory value as the names and arguments of the f-structure templates discussed by Dalrymple et al. (2004). These reduced c-structures are compatible with Bresnan's (2001) notion of economy and with Lovestrand & Lowe's (2017) theory of minimal phrase structure.

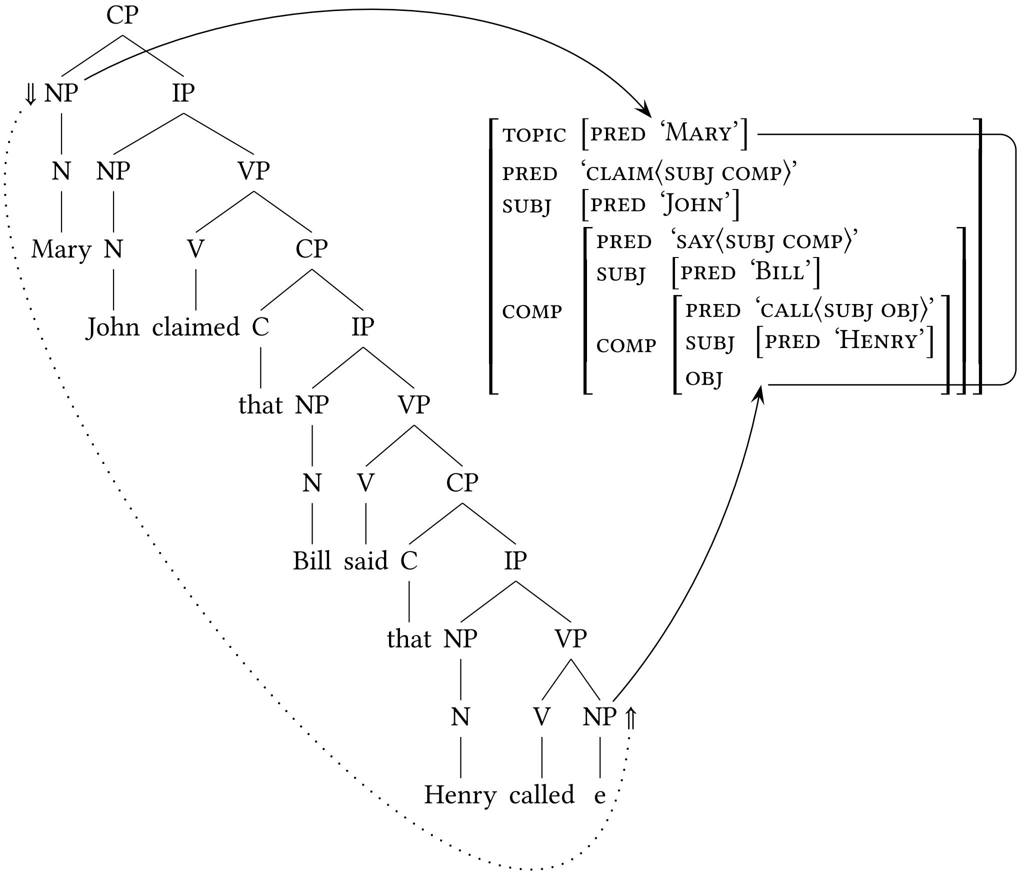

Figure 1: Long-distance relation in c-structure induces f-structure sharing for sentence (1), following Kaplan & Bresnan (1982).

records the special significance of the external constituent as a placeholder for subsequent interpretation by other components of grammar, but it is not here involved in establishing the syntactic connection; Section 5 revisits the grammatical status of the discourse attributes TOPIC and FOCUS.

In this example the nodes that are linked by the double-arrows are both labeled by the same c-structure category NP, but this is not a necessary property of the topicalization construction. Indeed, Kaplan & Bresnan (1982) noted that in some cases instead the nodes are required to have categories that mismatch, as illustrated in (6). Examples (6a-b) show that a CP complement can appear within a clause immediately after *think* but not after *think of*. In contrast, a CP complement in topicalized position is acceptable only when it is linked to the canonical NP position after *of* (6c-d).

(6) a. He didn't think that he might be wrong.

b. * He didn't think of that he might be wrong.

c. * That he might be wrong he didn't think.

d. That he might be wrong he didn't think of.

In the face of examples such as these, Kaplan & Bresnan (1982) embellished their node-linking notation to enable a more intricate relationships of nodes and categories.

It became apparent through subsequent research, however, that constraints on unbounded dependencies are generally more sensitive to functional rather than to c-structure properties. Kaplan & Zaenen (1989) point out that in Icelandic, for example, binding into comps is possible but binding into adjunct clauses is restricted, even when these two types of embeddings have similar c-structures. They consider the following sentences:

(7) Icelandic

a. Jón var að þvo gólfið eftir að María hafði skrifað bréfið.
John was at wash floor.the after that Maria had written letter.the
'John was washing the floor after Maria had written the letter.'

b. þu vonaðist til að hann fengi bíl.
You hoped for that he will.get car
'You hoped that he would get a car.'

They argue that both embedded clauses are introduced with a PP that is the c-structure sister of the main verb, but the f-structures for these sentences are different. In the first example the embedded clause is not an argument of the main verb whereas in the second one it is. This difference correlates with the binding contrast illustrated in (8).

(8) Icelandic

a. *Þessi bréf var Jón að þvo gólfið eftir að María hafði skrifað.
this letter was John at wash floor.the after that Maria had written
'This letter, John was washing the floor after Maria had written.'

b. Hvaða bíl vonaðist þú til að hann fengi.
Which car hoped you for that he will.get
'Which car did you hope that he would get?'

These Icelandic contrasts and the English examples (6) together suggest that the constraints on unbounded dependencies cannot easily be stated in terms of c-structure categories and configurations. In both cases a more natural account can be formulated in terms of functional properties, the difference between arguments and adjuncts, in the Icelandic case, and the restriction against the COMP function with the predicate *think* in the English case.

In general, unbounded dependencies are acceptable only if they assign clause internal functions that satisfy the subcategorization requirements of the embedded predicates. The topicalization example (1) is grammatical because the predicate *call* subcategorizes for the function OBJ; the putative topicalization (9c) is ungrammatical because *arrive* is intransitive.

(9) a. I think Henry will call Mary.
b. * I think Henry will arrive Mary.
c. * Mary I think Henry will arrive.

The fact that subcategorization in LFG is defined at the level of f-structure via the Completeness and Coherence Conditions provided strong motivation for investigating a functional approach to unbounded dependencies.

Additional motivation comes from the fact that unbounded dependencies resemble more local dependencies in the way that they interact with coordinate structures. Sentence (10a) is grammatical because *dedicate* subcategorizes for both an OBJ and an oblique function OBL_θ while (10b) is unacceptable because *bake* does not subcategorize for OBL_θ. Grammatical functions in LFG distribute to all of the conjuncts of a coordination set (Bresnan et al. 1985, Kaplan & Maxwell 1988b, Dalrymple & Kaplan 2000, Patejuk 2023 [this volume]), and thus the coordination (10c) fails Coherence just as in the uncoordinated case. The topicalization (10d) is also ungrammatical, and the simplest explanation is that the within-clause function of the external phrase is distributed in the ordinary way across both predicates.

(10) a. John dedicated a pie to Bill.
b. * John baked a pie to Bill.
c. * John dedicated and baked a pie to Bill.
d. * To Bill, John dedicated and baked a pie.

3.2 Uncertainty of function assignments

Based on these considerations, Kaplan & Zaenen (1989) developed an approach that refers mainly to f-structure notions to characterize the nature of unbounded dependencies. The f-structure sharing induced by the domination metavariables

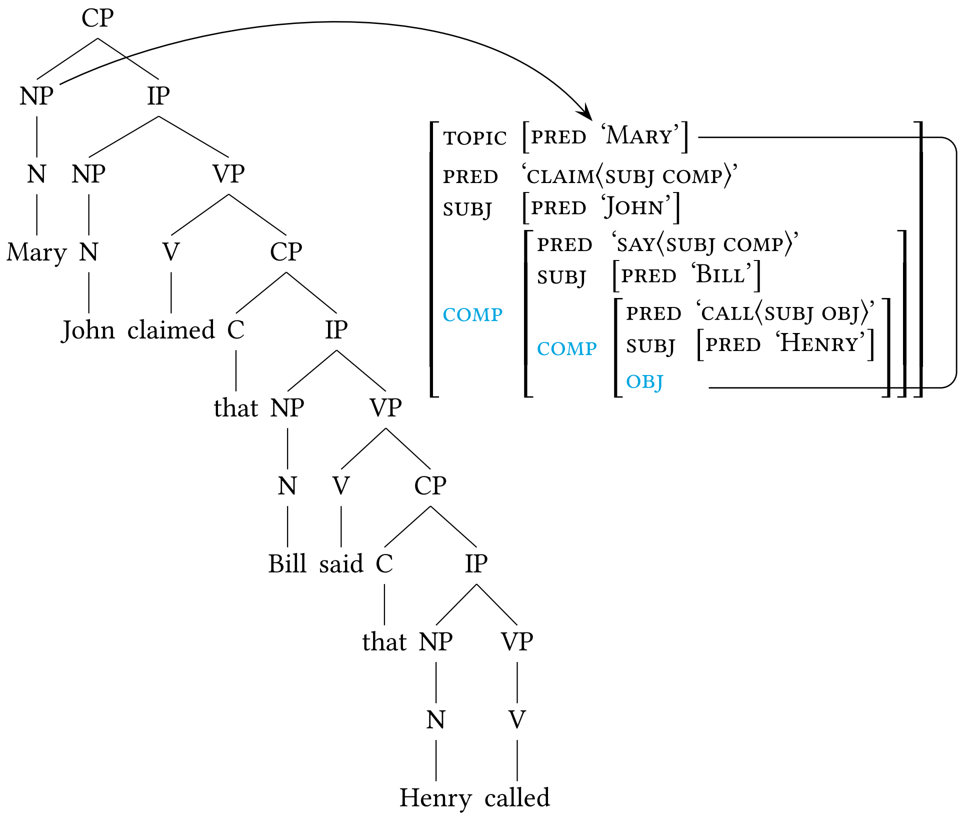

Figure 2: Unbounded relation for sentence (1) defined directly in f-structure via the path of blue attributes (after Kaplan & Zaenen 1989).

for the particular example in Figure 1 can be specified directly by the f-description annotation in the alternative rule (11a). This is true even if a c-structure rule such as (5b) is not used to provide a trace NP. Instead, a traceless c-structure configuration is licensed by the alternative VP rule (11b), independently needed for the analysis of clauses with intransitive verbs.

(11) a. $$\text{CP} \longrightarrow \begin{array}{cc} \text{NP} & \text{C}' \\ (\uparrow \text{TOPIC}) = \downarrow & \uparrow=\downarrow \\ (\uparrow \text{COMP COMP OBJ}) = \downarrow & \end{array}$$

b. $$\text{VP} \longrightarrow \begin{array}{c} \text{V} \\ \uparrow=\downarrow \end{array}$$

The grammatical functions on the longer path in (11a) match the blue attributes in the f-structure in Figure 2 and thus establish the intended link for sentence (1).

For the dependency in sentence (2), however, a longer equation with an additional XCOMP is required, and it is not clear at the position of the topic NP which of the two equations should be chosen to fit the f-structure embeddings of the following clause. In fact, since there is no bound in principle on the depth of an unbounded dependency, there would be infinitely many equations to choose from to account for all possible linkages to the within-clause function of the external NP.

Kaplan & Zaenen (1989) addressed the unbounded uncertainty of the within-clause function assignment by extending the notation and interpretation of LFG's functional descriptions. Kaplan & Bresnan (1982) introduced the basic format and satisfaction condition for function-application expressions of single attributes in (12a) and for notational convenience provided the left-associative extension to a path of attributes in (12b), with (12c) defining the base case of an empty string. Condition (12d) is satisfied by members of a set of f-structure elements, and the later addition (12e) is the foundation for LFG's distributive theory of coordination, as illustrated in (10) above.

(12) Satisfaction conditions for attributes

a. $(f\ a) = v$ iff f is an f-structure, a is an attribute and $\langle a, v\rangle \in f$.

b. $(f\ a\sigma) = v$ iff $a\sigma$ is a string of attributes and $((f\ a)\ \sigma) = v$.

c. $(f\ e) = v$ iff $f = v$ (e denotes the empty string).

Satisfaction conditions for sets

d. $v \in f$ iff f is a set and v belongs to f.

e. $(f\ a) = v$ iff f is a set and
$(g\ a) = v$ for all $g \in f$ if a is a distributive attribute
$\langle a, v\rangle \in f$ if a is a nondistributive attribute.

Kaplan & Zaenen (1989) first generalized from the single-string specification (12b) to sets of attribute strings as in (13a).

(13) Functional uncertainty

a. If Paths is a set of attribute strings,
$(f\ \textsc{Paths}) = v$ iff $((f\ a)\ \mathit{Suff}(a, \textsc{Paths})) = v$, where
$\mathit{Suff}(a, \textsc{Paths}) = \{\sigma \mid a\sigma \in \textsc{Paths}\}$.
(the suffixes of strings in Paths that begin with attribute a)

b. $(f\ \in) = v$ iff $v \in f$ for the special "attribute" $\in$.

The uncertainty about which paths might result in complete and coherent within-clause function assignments is represented under this formulation by the choice between alternative strings in such a path language. A language containing at least the strings comp comp obj and comp comp xcomp obj, for example, would account for both topicalization sentences (1–2). According to (13b), if the special attribute ∈ on a path coincides with a set of f-structures, the path can continue through any one of the set's freely chosen elements.

A finite enumeration of path-strings is in essence only a succinct way of specifying a finite disjunction; it would not yet express the unbounded nature of these dependencies. But Kaplan & Zaenen (1989) went further and allowed path-sets to be regular languages containing possibly an infinite number of strings. Such languages can be specified as regular expressions that appear in the annotations in rules and lexical entries. Rule (14) extends the particular annotation in rule (11) to account not only for examples (1–2) but also for topicalizations with comp embeddings of arbitrary depth.

(14)
$$\text{CP} \longrightarrow \begin{array}{cc} \text{NP} & \text{C}' \\ (\uparrow \textsc{topic}) = \downarrow & \uparrow=\downarrow \\ (\uparrow \textsc{comp}^{*}\ \textsc{obj}) = \downarrow & \end{array}$$

Each of the infinitely many paths in this uncertainty language begins with some number of comps, what Kaplan and Zaenen called the "body", and finally ends in obj (the "bottom"). Rule (15) covers a larger set of English topicalization patterns by relaxing the category of the external phrase and enlarging the set of paths in the uncertainty language.[2]

(15)
$$\text{CP} \longrightarrow \begin{array}{cc} \text{XP} & \text{C}' \\ (\uparrow \textsc{topic}) = \downarrow & \uparrow=\downarrow \\ (\uparrow \textsc{TopicPaths}) = \downarrow & \end{array}$$
$$\text{where } \textsc{TopicPaths} \text{ is } \{\textsc{comp}, \textsc{xcomp}, \textsc{adj}\ (\in)\}^{*}\ [\textsc{gf}-\textsc{comp}]$$

As discussed by Kaplan and Zaenen, CP is a possible realization for the generic XP category in this rule and thus provides the c-structures for the topicalized complements of *think* in (6c–6d). The relative-difference [gf−comp] at the bottom of every uncertainty path disallows comp but includes obj, subj, $\textsc{obl}_{\theta}$, adj, and every other function. The short, bottom-only path-string comp is thus not

---

[2] In movement-based frameworks the clause-external c-structure phrase in topicalization and other constructions is often referred to as the "filler" of the dependency and the string position of a putative trace node is known as the "gap". That conventional terminology translates to the LFG functional account with the proviso that the filler refers not to the external phrase but to its corresponding f-structure, and the gap is the within-clause function assignment of that f-structure. The canonical string position for the gap function (or the position of the empty node in a trace-based analysis) is often marked by an underscore, just as a reader's guide to the intended interpretation.

available for the inadmissible example (6c). Adding XCOMP to the body of this expression allows for the bottom function to be embedded under a mixture of tensed and infinitival complements. Given (13b), the ADJ and ∈ options provide an analysis for the English sentences (16) (examples from Dalrymple 2001); presumably ADJ would not appear in the language of Icelandic paths.

(16) a. Julius teaches his class in this room.
b. This room Julius teaches his class in.
c. In this room Julius teaches his class.

Further extensions and restrictions on the TopicPaths and other path language are discussed in later sections.

Functional uncertainty has become the primary technical device for describing unbounded dependencies in LFG. Uncertainty languages can be defined by the primitive regular-expression operators of concatenation, union (curly braces), optionality (parentheses), and Kleene-star and Kleene-plus repetition. Indeed, since the regular languages are closed under intersection and complementation, a collection of attribute paths can be specified by any Boolean combination of the same regular predicates that are allowed in the right sides of LFG c-structure rules (see Kaplan & Maxwell 1996, Crouch et al. 2011). This includes the relative difference operator [GF−COMP] above and its equivalent but more succinct term-complement predicate \COMP. Path languages that describe a wide range of constructions in different languages can thus be expressed as the composition of separate, simpler formulas that encode independent linguistic generalizations, as illustrated in later sections. Also of importance, it has been shown that the satisfiability of functional descriptions remains decidable when the LFG formalism is extended with regular path languages (e.g. Kaplan & Maxwell 1988a, Backofen 1993).

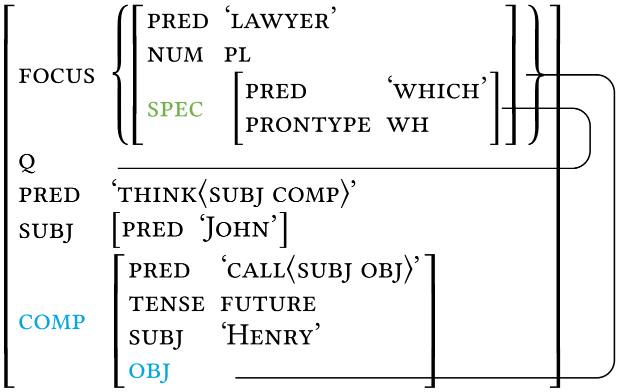
4 Constituent questions

Constituent questions in English resemble topicalization in that the f-structure of a clause-external phrase is assigned a grammatical function at some level inside its sister clause. The possibilities for the dependency path between the filler and its within-clause function are similar, but there is an additional requirement that the filler either must be an interrogative (*wh*) pronoun or must contain one. The examples of indirect questions in (17) illustrate some of the possibilities.

(17) I wonder …
   a. who John thinks Henry will call.
   b. which lawyer John thinks Henry will call.
   c. whose friend John thinks Henry will call.
   d. whose lawyer's friend John thinks Henry will call.
   e. from whom John thinks Mary will get a call.
   f. when John will call Mary.
   g. * this lawyer John thinks Henry will call.
   h. * he John thinks Henry will call.

Kaplan & Bresnan (1982) proposed the attribute FOCUS (distinct from the topicalization attribute TOPIC) as a placeholder for the communicative entailments of the question construction, and a separate attribute Q to place the interrogative pronoun in a canonical position for later interpretation. An f-structure configuration with these attributes for the embedded question in (17b) is shown in (18).

(18)



FOCUS is represented here as taking a set of f-structures as its value. It can thus hold the contributions of additional English question words that might appear in situ (19a) or the multiple question words in initial position that other languages might allow (19b).

(19) a. I wonder who John thinks would like to get what.
   b. Hungarian (from Mycock 2007)

Ki	ki-t	ki-nek	mutat-ott	be?
who-NOM	who-ACC	who-DAT	introduce-PAST-DEF.3SG	VM

'Who introduced who to who?'

The f-structure (18) for the embedded question (17b) is assigned by rule (20). The FocusPaths uncertainty resolves to the blue attribute sequence that relates the entire filler f-structure to its within-clause (non-comp) function, as for topicalization. The green path, taken from WhPaths, establishes q as an element inside the filler. The intersection with WhPro further ensures that q is an interrogative pronoun: given the off-path $=_c$ constraint, the f-structure at the end of any WhPaths string is acceptable only if it also includes the feature [prontype wh]. Off-path annotations are discussed in Section 8.1 and defined there in (55).

(20)
$$\text{CP} \longrightarrow \begin{array}{c} \text{XP} \\ \downarrow \in (\uparrow \text{FOCUS}) \\ (\uparrow \text{FocusPaths}) = \downarrow \\ (\uparrow \text{Q}) = (\downarrow \text{WhPaths} \ \& \ \text{WhPro}) \end{array} \qquad \begin{array}{c} \text{IP} \\ \uparrow = \downarrow \\ \\ \\ \end{array}$$

where FocusPaths is $\{\text{COMP}, \text{XCOMP}, \text{ADJ}\ (\in)\}^{*} \setminus \text{COMP}$
WhPaths is $\{\text{SPEC}^{*}, \text{OBJ}\}$
WhPro is $\text{GF}^{*} \underset{(\rightarrow\ \text{PRONTYPE}) =_c \text{WH}}{\text{GF}}$

In fuller treatments, of course, the uncertainty languages FocusPaths and WhPaths are supplemented with appropriate configurations of obliques, adjuncts, and other grammatical functions.

The initial phrase of the English c-structure configuration is the probable cause, the trigger, for introducing the FocusPaths uncertainty expression, and this must then resolve to the proper within-clause grammatical function for that focus phrase. In Mandarin interrogative pronouns appear in situ, at the position in the embedded clause where the proper function is assigned by normal clause-level rules. Huang (1993) discusses the following example.

(21) Mandarin
Zhangsan xiwang Lisi gen shei xue yuyanxue?
Zhangsan hope Lisi gen(with) who learn linguistics
'With whom does Zhangsan hope that Lisi will learn linguistics?'

An unbounded uncertainty is not needed here to establish the within-clause function, and indeed there is no natural place in the c-structure to specify a FocusPaths connection as in (20). But Huang notes that the pronoun must still be linked to some enclosing f-structure in order to establish the necessary scope for semantic and discourse interpretation. He proposes to include in the lexical entry of an interrogative pronoun an uncertain path language that resolves to a higher-level f-structure. Along the lines of that proposal, the lexical entry (22) places the interrogative pronoun in the focus set of a clause from which it is accessible through a path in the collection of (Mandarin-specific) FocusPaths.

(22) *shei*: ↑ ∈ ((FocusPaths ↑) focus)

This makes use of the formal device of *inside-out function application* (23a), originally introduced by Kaplan (1988) and subsequently extended by Halvorsen & Kaplan (1988) to uncertain path languages (23b).

(23) Inside-out function application

a. $(\sigma\, f) = g$ iff σ is an attribute string and $(g\, \sigma) = f$.

b. (Paths f) $= g$ iff Paths is a set of attribute strings and (g Paths) = f.

In this case also there is an explicit probable cause for the uncertainty, the interrogative lexical entry. In contrast, there is typically no local evidence to trigger the inside-out uncertainties that are attached to empty nodes in trace-based theories of unbounded dependencies (e.g. Bresnan 2001, Bresnan et al. 2016).

5 Grammaticized discourse functions?

Kaplan & Bresnan (1982) introduced the attributes topic and focus to distinguish the fillers of the different unbounded dependency constructions as separate from the establishment of their within-clause grammatical functions. These f-structure attributes were presumed to represent the syntactic features needed for subsequent interpretation by semantic and discourse components of grammar, and they were maintained as "grammaticized discourse functions" in some later work (e.g. Bresnan & Mchombo 1987). Other chapters describe the subsequent development of explicit theories of semantic representation (Asudeh 2023 [this volume]) and information structure (Zaenen 2023 [this volume]) and how LFG's Correspondence Architecture (Kaplan 1987, 1995) provides a uniform framework for integrating such independent modules with the core components of syntax. The literature surveyed in those chapters and also Dalrymple et al. (2019) suggest that the entailments of discourse functions like topic and focus can be spelled out in information structure (i-structure) features such as ±new and ±prom(inent) and by other potential i-structure concepts that help in managing how semantic content is transmitted from speaker to hearer.

With respect to the external phrases of topicalization and question formation, if their different discourse entailments can be carried over to i-structure, there may no longer be motivation to mark those with the distinguished topic and focus attributes in f-structure. Thus, to record the external element in either construction, Asudeh (2004, 2012) proposed just one "overlay function" udf (for "Unbounded Dependency Function"), Alsina (2008) suggested the attribute op (for "operator"), and Dalrymple et al. (2019) used the attribute DIS (for "dislocated"). Snijders (2015) goes even further, questioning whether the filler f-structure of either construction is needed other than at its within-clause position. This issue was foreshadowed in King's (1997) earlier and more general argument that discourse focus should be represented in the independent information-structure module. If the discourse functions do not interact with other syntactic features and if the i-structure discourse status of the within-clause function can be signaled without them, then the f-structure clutter of these grammaticized functions can be eliminated entirely. In the following, I explore this possibility.

The Correspondence Architecture is designed to encourage theoretical modularity, allowing different components of linguistic description to be organized in their own most natural ways and avoiding the complexity and confusion that comes from mixing conceptually unrelated primitives in a single representation. Dalrymple & Nikolaeva (2011) propose to relate f-structure to i-structure with the correspondence functions diagrammed in (24) (see also Dalrymple et al. 2019). The projection σ maps from units of f-structure to meaning constructors in semantic structure, and the projection ι maps meaning constructors into correlated properties in information structure.

(24) I-structure correspondences (from Dalrymple & Nikolaeva 2011)

$$\begin{tikzcd}\text{c-structure} \arrow[r, "\phi"] & \text{f-structure} \arrow[r, "\sigma"] & \text{s-structure} \arrow[r, "\iota"] & \text{i-structure}\end{tikzcd}$$

Given this arrangement and without involving any special features in f-structure, the composition of projections $\iota \circ \sigma \circ \phi$ can be used to express the fact that the filler in the topicalization construction is interpreted as an i-structure topic.

The abstract interface between the syntactic and information modules, according to this organization, is made explicit in the revision of the topicalization rule (15) shown in (25a). The TOPIC function assignment has been replaced by the invocation of the TOPIC template defined in (25b) (for more on the explanatory value of templates, see the discussion in Dalrymple et al. 2004).

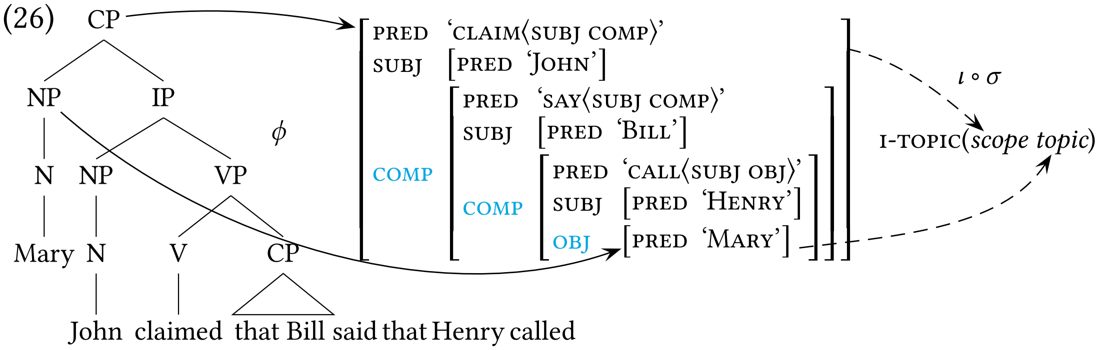
(25) a.

$$\text{CP} \longrightarrow \begin{array}{cc} \text{XP} & \text{C}' \\ @(\textsc{topic}\uparrow\ \downarrow) & \uparrow=\downarrow \\ (\uparrow \textsc{TopicPaths})=\downarrow & \end{array}$$

b. $\textsc{topic}(\textit{scope topic}) \equiv @(\textsc{i-topic}\ \textit{scope}_{\sigma\iota}\ \textit{topic}_{\sigma\iota})$

The template I-TOPIC is a placeholder for a separate i-structure theory of topic whose details are hidden from the syntactic modules, but substituting the f-structure designators ↑ and ↓ for the template parameters *scope* and *topic* makes clear that the information needed to interpret the topic is carried by the external phrase.[3] The subscript $\sigma\iota$ is the conventional way of notating the composition of projections in LFG annotations. In comparison to the structures shown in Figure 2 for sentence (1), this gives rise to the three-module relationships in (26).

(26)



Note that there is no TOPIC and no structure sharing in this f-structure. The filler f-structure appears only at the position of its within-clause function, with the projection lines indicating how the c-structure phrases relate indirectly through the f-structure to the topic in i-structure.

Rule (27a) is a similar revision of the constituent question rule (20). The three-place template FocusQ defined in (27b) makes properties of the interrogative pronoun available for i-structure interpretation in addition to information about the focus constituent and its scope.

(27) a. $$\text{CP} \longrightarrow \begin{array}{cc} \text{XP} & \text{IP} \\ @(\text{FocusQ}\ \uparrow\ \downarrow\ (\downarrow\ \text{WhPaths}\ \&\ \text{WhPro})) & \uparrow=\downarrow \\ (\uparrow\ \text{FocusPaths}) = \downarrow & \end{array}$$

b. $\text{FocusQ}(\mathit{scope}\ \mathit{focus}\ q) \equiv @(\text{i-FocusQ}\ \mathit{scope}_{\sigma\iota}\ \mathit{focus}_{\sigma\iota}\ q_{\sigma\iota})$

This results in the relationships shown in (28) for the indirect question (17a).

---

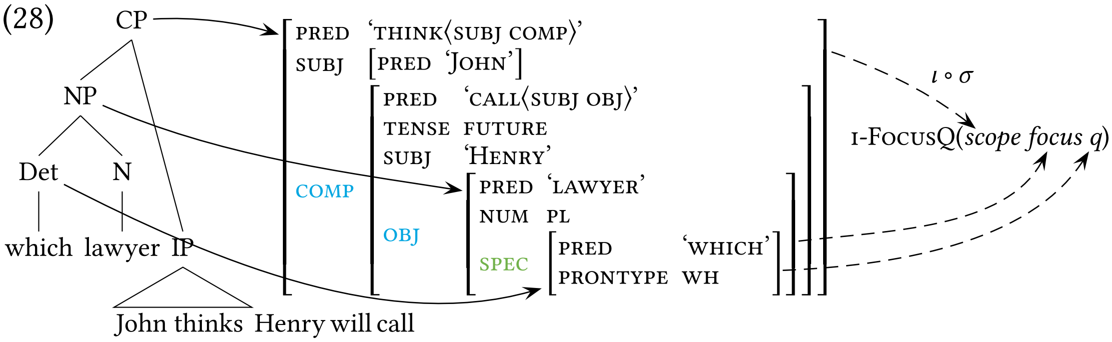
[3] Of course the original f-structure TOPIC attribute, should that be useful, can be easily resurrected by the alternative definition (i).

(i) $\text{TOPIC}(\mathit{scope}\ \mathit{topic}) \equiv (\mathit{scope}\ \text{TOPIC}) = \mathit{topic}$

(ii) $\text{TOPIC}(\mathit{scope}\ \mathit{topic/focus}) \equiv \mathit{topic} \in (\mathit{scope}\ \text{DIS})$

Definition (ii) produces the common DIS representation that Dalrymple et al. (2019) specify for both topic and focus. The set value suggests that syntactically the topic is not easily accessible.

(28)



There is no set-valued FOCUS attribute and again no structure sharing in this simplified f-structure: the discourse entailments of this construction are off-loaded to the separate i-structure module. This is attractive because it exploits the Correspondence Architecture to simplify syntactic representations, but the full consequences of this arrangement remain to be investigated.

6 The *tough* construction

The English *tough* adjectives (*easy*, *hard*, *difficult*, *impossible*...) induce unbounded dependencies with only one uncertainty, as for topicalization, but they differ from both topicalization and constituent questions in that a single phrase contributes information to grammatical functions that are governed by predicates in two clauses. These adjectives subcategorize for a subject and an open *to*-complement. If the complement has a simple transitive predicate, the adjective's subject is understood as the complement's object and its object must otherwise not be realized. The basic pattern is displayed in (29).

(29) a. Moths seem tough to kill.
(cf. It seems tough to kill moths.)
b. Moths are tough (for someone) to kill.
c. * Moths are tough to kill moths.
d. * Moths are tough to arrive.

It is also generally accepted that the adjective's SUBJ can serve as an OBJ in a clause embedded at an uncertain depth within the immediate complement, as illustrated by the examples in (30).

(30) a. Moths are tough to plan to kill.
b. This book is hard to get her to avoid reading. (Dalrymple & King 2000)

c. Kim would be difficult for me to persuade Robin to attempt to deal with. (Hukari & Levine 1991)
d. Mary is tough for me to believe that John would ever marry. (Kaplan & Bresnan 1982)
e. Kim is difficult to sit next to. (Grover 1995)

This unbounded dependency also differs from topicalization in that the uncertainty is keyed by the lexical entries of adjectives in this particular class rather than by a rule that describes a generic configuration of c-structure phrases. The uncertainty language itself is also quite different. The paths begin with sequences of xcomps that do not alternate with comps (31a-b), and they end only with obj, not just any non-comp grammatical function (31c-d). The bottom obj can be preceded by an oblique (30c), a comp (30d), or a member of a set of adjuncts (30e).

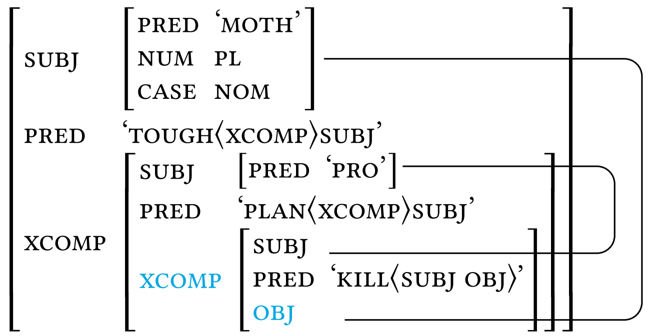
(31) a. * Mary is tough that John would ever marry.
b. * Mary is difficult for me to believe that John wanted to plan to marry.
c. * Tuesday would be difficult to take the exam. (Dalrymple & King 2000)
d. * Mary is tough for me to believe would ever marry John.

These possibiliites are expressed in the lexical uncertainty shown in (32).

(32) *tough* A (↑ pred) = ‘tough⟨xcomp⟩subj’
(↑ subj) = (↑ xcomp ToughPaths)
where ToughPaths = xcomp* {obl$_\theta$, comp, adj ∈} obj

This gives rise to the outer connection shown in (33), the f-structure corresponding to sentence (30a) (the inner line indicates the local functional control relation for *plan*).

(33)



The *tough* uncertainty establishes an identity between the SUBJ of the adjective and an OBJ somewhere within its complement. The effect is that the predicate and all other f-structure properties of the matrix SUBJ appear also in the embedded OBJ. The examples in (34) suggest that this might lead to inconsistent values for a shared CASE feature.

(34) They/*Them are tough to kill.
It is tough to kill *they/them.

This connectivity problem has received some attention in the literature (e.g. Hukari & Levine 1991, Dalrymple & King 2000). Dalrymple & King 2000 proposed to avoid this problem by removing the functional identity of the two f-structure values. Rather than linking the *tough* SUBJ directly to an embedded OBJ, they depend on an obligatory anaphoric relation between the SUBJ and a grammaticized pronominal TOPIC in *tough*'s immediate complement. It is then the TOPIC f-structure that the uncertainty identifies with an embedded OBJ, as spelled out in (35a).[4] This two-step connection preserves the intended semantic entailments while the appeal to the referential component of grammar suppresses the propagation not only of CASE but also of all other syntactic features. The entry in (35b) achieves the same effect without relying on anaphora or an explicitly grammaticized TOPIC simply by asserting that the SUBJ and the embedded OBJ share only the same uniquely instantiated PRED.[5]

(35) a. *tough* A (↑ PRED) = 'TOUGH⟨XCOMP⟩SUBJ'
(↑ XCOMP TOPIC PRED) = 'PRO'
(↑ XCOMP TOPIC) = (↑ XCOMP ToughPaths)
b. *tough* A (↑ PRED) = 'TOUGH⟨XCOMP⟩SUBJ'
(↑ SUBJ PRED) = (↑ XCOMP ToughPaths PRED)
@(TOPIC (↑ XCOMP) (↑ SUBJ))

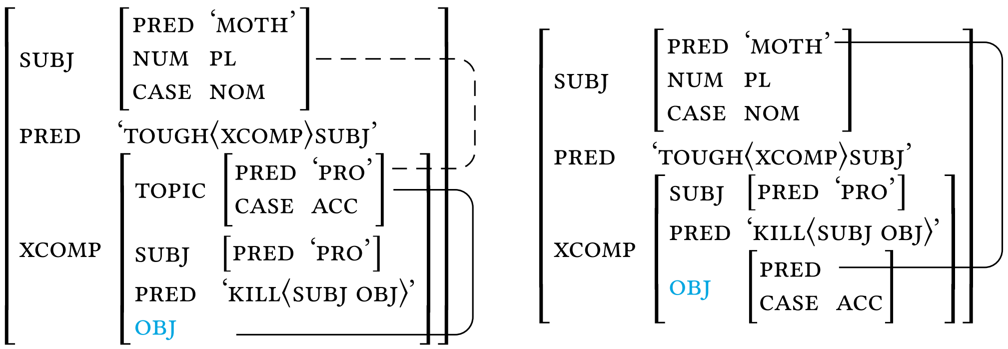
The lexical entry (35a) would assign the f-structure (36a) to sentence (29b), with the dashed lines representing an anaphoric relationship. Entry (35b) would assign the f-structure (36b).

---

[4] Dalrymple & King (2000) assign the function COMP instead of XCOMP to the immediate complement, for reasons that are not relevant to the current discussion. They also argue that the *tough* SUBJ is thematic, but here I follow the raising/non-thematic representation suggested by Kaplan & Bresnan (1982). With respect to the issues of unbounded dependencies, this is also a difference of no consequence.

[5] Since SUBJ is generally assumed to map to a position of i-structure prominence, invoking the TOPIC template in (35b) may not be necessary for proper interpretation.

(36)



a. Anaphoric binding to SUBJ

b. PRED sharing of SUBJ and OBJ

Each of these solutions supports the intended semantic interpretation while avoiding the CASE conflict. But each allows for free variation of all other syntactic features, even inherent features like gender or person that may enter into patterns of agreement that CASE does not participate in.

A more precise alternative is based on the restriction operator defined in (37). This permits relaxing the compatibility requirement for specific features (like CASE) while still enforcing consistency of all otherwise unmentioned features.

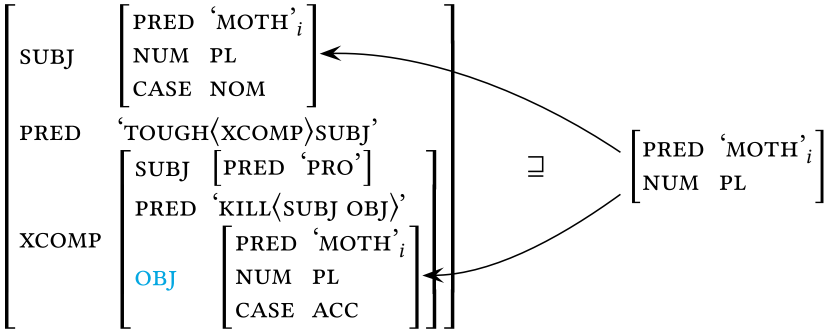
(37) Definition of restriction: (Kaplan & Wedekind 1993)
If f is an f-structure and a is an attribute, then the restriction of f by a is the f-structure $f\backslash_{a} = \{\langle s, v\rangle \in f \mid s \neq a\}$.

An f-structure f restricted by an attribute a contains all the attribute-value pairs of f except for the attribute a and its value. This formal device was used by Zaenen & Kaplan (2002) to suppress unwanted CASE conflicts in German functional control. It is applied in (38) to exclude CASE from the unbounded lexical uncertainty that holds between the *tough* SUBJ and the embedded OBJ. That particular incompatibility is thereby eliminated while all other features are shared (and may conflict).

(38) *tough* A (↑ PRED) = 'TOUGH⟨XCOMP⟩SUBJ'
$(\uparrow \text{SUBJ})\backslash_{\text{CASE}} = (\uparrow \text{XCOMP ToughPaths})\backslash_{\text{CASE}}$
@(TOPIC (↑ XCOMP) (↑ SUBJ))

The logical f-structure relationships that the CASE restriction induces are shown explicitly in (39):

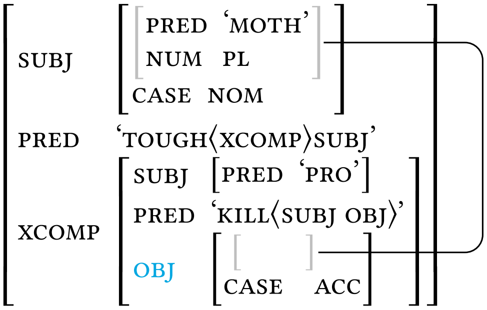
(39) Functional binding of case-restricted subj



On the right is the case-restricted f-structure that is shared across the functional uncertainty. It subsumes the subj and xcomp obj values, causing them to have all of the same syntactic features except for case.

The same logical relations are depicted more intuitively with the abbreviatory graphical convention shown in (40). While the gray brackets in this diagram are not formally part of the linguistic representation, they highlight that the functional identity induced by the restricted unbounded dependency holds only between the enclosed proper subsets of the features of the subj and xcomp obj f-structures.

(40) Functional binding of case-restricted subj (succinct)



In sum, the English *tough* construction involves an unbounded connection between two grammatical functions, the subj in the matrix clause and an obj embedded in its complement. While this has the potential of creating an undesired f-structure conflict between the values of the clause-specific case features, that potential conflict can be avoided if an anaphoric relationship disrupts the functional identity across the clauses or if only the pred value is shared. An alternative solution uses the f-structure restriction operator to suppress only the case feature without disturbing other patterns of agreement.

7 Relative Clauses

English relative clauses blend the double function assignments of the *tough* construction with the double uncertainties of constituent questions, as exemplified in (41).[6]

(41) The shop [[the owner of which] [Sue knows __]] sells books.

With respect to function assignments, *shop* is understood as both the subject of the matrix predicate *sells* and the (oblique) object of *owner*. With respect to uncertainties, the f-structure of the clause-initial *owner* phrase is the object of *knows* in this example but it could also bind to a function in a deeper complement. And the relative pronoun *which* can also appear at an arbitrary depth inside the clause-initial phrase. The examples (42a–42d) of what Ross (1967) called "Pied-piping" show some of the positions possible for the relative pronoun; example (42e) shows that the relative pronoun must appear somewhere.

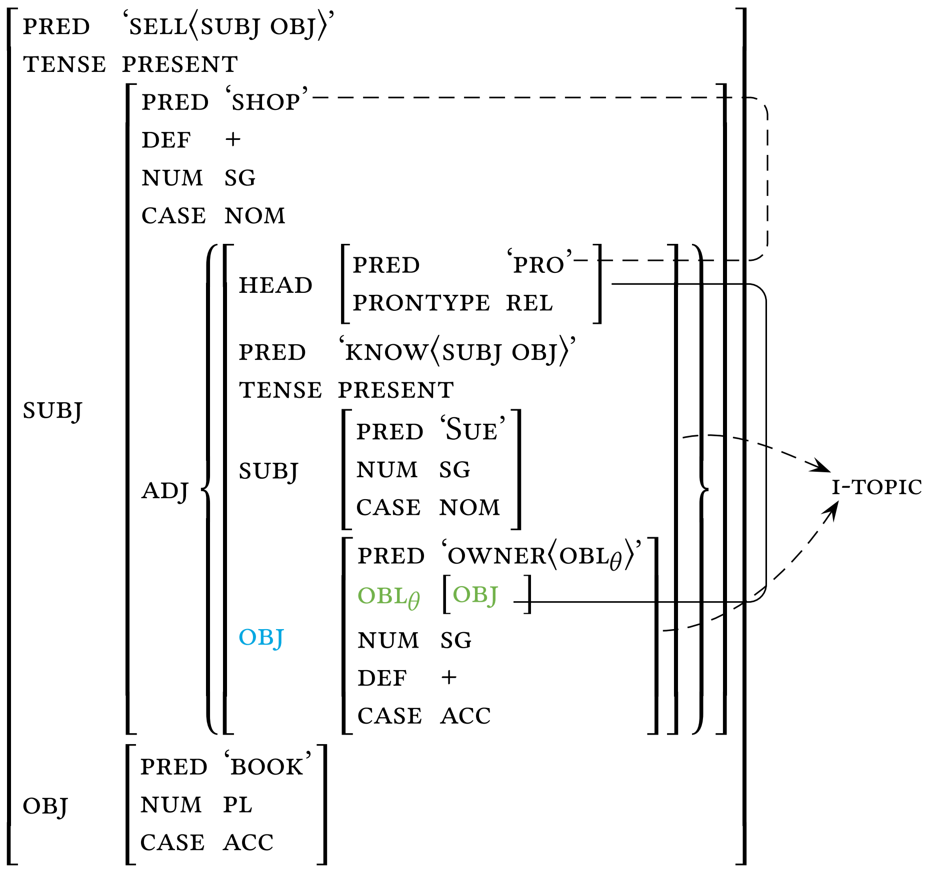
(42) a. The man who we elected …
b. The woman to whom we gave the book …
c. The boy whose book Bill said was stolen …
d. Reports the height of the lettering on the covers of which the government prescribes … (Ross 1967)
e. * The shop the owner of the car Sue knows sells books.

F-structure (43) lays out the significant grammatical relationships of sentence (41). The uncertainty of the within-clause function for the clause-initial phrase is resolved by the blue OBJ path in RelTopicPaths, and that phrase also maps to the i-structure topic. The relative pronoun is identified as the HEAD of the clause (the solid line) by virtue of the attributes on the green path from RelHeadPaths. The dashed line between the HEAD and the nominal predicate indicates a connection of obligatory anaphoric control, as in the *tough* f-structure (36a), that avoids any CASE-like inconsistencies that might stem from the double function assignment.

---

[6] As mentioned earlier, the underscore indicating the position of the 'gap' is provided only as a reader's guide to the intended interpretation. As discussed in Section 8.3, it is quite a separate question whether it should also indicate the presence of an empty node in the syntactic representation.

(43)



This f-structure is derived by the rules and lexical entry in (44). According to rule (44a), the f-structure of a single relative clause is added to the adjunct set of the NP; the recursion through the NP category allows for NP’s with multiple clauses. Rule (44b) describes the internal structure of the relative clause itself. The f-structure of the clause-initial phrase is linked to its within-clause function through a path in RelTopicPaths and is also projected to the i-structure topic by the topic template. The head at the top is set to the relative pronoun required at the end of one of the RelHeadPaths. The dashed anaphoric connection is not established in the syntax.

(44) a. $$\text{NP} \longrightarrow \underset{\uparrow=\downarrow}{\text{NP}} \qquad \underset{\downarrow\in(\uparrow\ \textsc{adj})}{\text{CP}}$$

b. $$\text{CP} \longrightarrow \begin{array}{c}\text{XP}\\ @(\textsc{topic}\uparrow\downarrow)\\ (\uparrow \textsc{RelTopicPaths})=\downarrow\\ (\uparrow \textsc{head})=(\downarrow \textsc{RelHeadPaths}\ \&\ \textsc{RelPro})\end{array} \qquad \begin{array}{c}\text{C}'\\ \uparrow=\downarrow\\ \\ \\ \end{array}$$

where RelTopicPaths is {COMP, XCOMP, ...}* \COMP
RelHeadPaths is {SPEC*, [(OBL$_\theta$) OBJ]*}
RelPro is GF* $\underset{(\rightarrow \text{ PRONTYPE}) =_c \text{REL}}{\text{GF}}$

c. *which* Pro (↑ PRED) = ‘PRO’
(↑ PRONTYPE) = REL

Sentence (45) exemplifies a pattern for English relative clauses that is not derived by rule (44b).

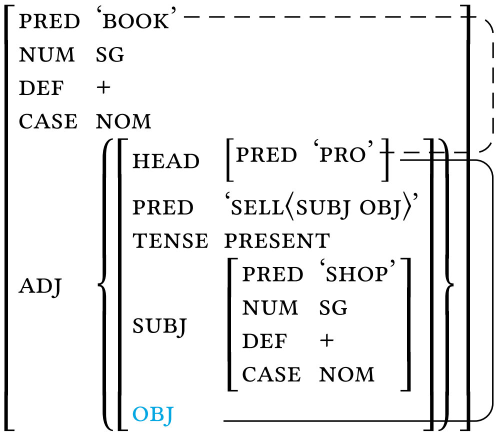
(45) The books (that) the shop sells __ are expensive.

The embedded clause in this sentence does not begin with an external XP topic phrase. Rather, the XP position of (44b) is either filled with the complementizer *that* or is left completely empty, and in either case there is no explicit relative pronoun to trigger an anaphoric interpretation. The alternative CP expansion in (46) accounts for these c-structure configurations, simulates the anaphoric link by introducing a null pronoun, and identifies directly the within-clause function for the value of the HEAD attribute.

(46) CP ⟶ *that* | *e* C′
@(TOPIC ↑ (↑ HEAD)) ↑=↓
(↑ RelTopicPaths) = (↑ HEAD)
(↑ HEAD PRED) = ‘PRO’

This produces (47) as the f-structure for the relativized matrix subject NP in (45) (now omitting the projection arrows that presumably map the HEAD by default to the i-structure topic).

(47)



The HEAD ‘PRO’ is an essential ingredient of this commonly accepted analysis of relative clauses. On this account the semantic connection between the head noun and its role within the clause is established without a direct syntactic relationship. This has the advantage that unwanted inconsistencies of any double-function syntactic feature values cannot arise (cf. the anaphoric solution for *tough*). However, Falk (2010) puts forth several arguments against what he describes as this “anaphorically mediated” analysis.

On one line of attack he points to the contrast in (48). While the word *headway* in the idiom *make headway* can be the head of a relative clause (48a), it cannot otherwise be an antecedent for a referential pronoun (48b).

(48) a. Mary praised the headway that John made.
b. * Mary always praises headway when John makes it.

As another argument, he notes (citing Maxwell 1979) that languages with pronounless relative clauses are quite common among the 49 languages listed in the NP accessibility database of Keenan & Comrie (1979). He illustrates this with examples from a number of languages, including the ones in (49) (*that* is a complementizer in the English translations, not a pronoun).

(49) a. Hebrew (from Falk 2010)
meabed hatamlilim še Bill maadif.
processor DEF.texts COMP Bill prefers
‘the word processor that Bill prefers’

b. Japanese (from Keenan & Comrie 1979)
Watashi wa sono otoko ga tataita inu o miru.
I TOP that man NOM struck dog ACC see
‘I see the dog that the man struck.’

Some languages allow relative clauses with or without relative pronouns, like English, but relative pronouns simply do not exist in Japanese and other languages. Falk thus suggests that relative clauses without mediating pronouns are the typical case cross-linguistically, and that English examples like (41) are more the exception than the rule. A general account of head dependencies, he concludes, should not rely on the machinery of anaphoric binding.

Falk (2010) thus proposes an anaphorically-unmediated account of the connection between the f-structure of the relativized NP and the HEAD f-structure of the clause. The restriction operator is used to prevent selected features from clashing, along the lines of the *tough* analysis in (38) above. His proposal in essence is to augment the relative clause introduction rule (44a) with an equation that identifies the NP's (restricted) f-structure with the (restricted) HEAD of the clause (50).[7]

(50) $$\text{NP} \longrightarrow \underset{\uparrow=\downarrow}{\text{NP}} \qquad \underset{\substack{\downarrow\in(\uparrow\ \text{ADJ})\\ \uparrow\backslash_{\{\text{CASE, ADJ}\}} = (\downarrow\ \text{HEAD})\backslash_{\{\text{CASE, ADJ}\}}}}{\text{CP}}$$

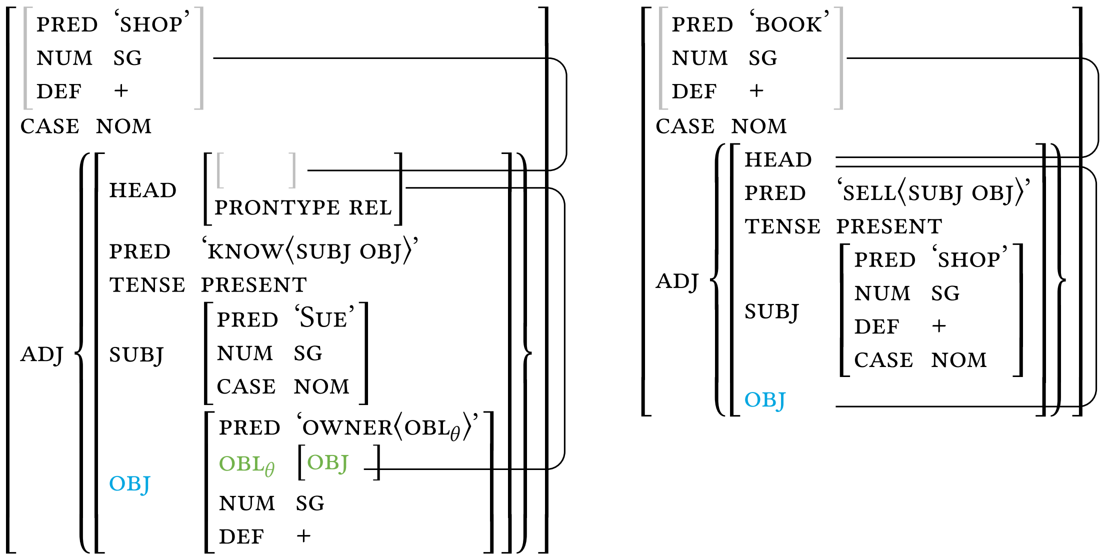
This permits the CASE feature of the NP and the relative HEAD to disagree; the relative-containing ADJ set is also restricted to avoid the technical confusion of circularity. The modified rule figures in the derivation of relative clauses with or without relative pronouns. English clauses with pronoun-containing initial XP phrases are still derived by rule (44b), but the relative pronoun no longer introduces its own pronominal PRED (51a). Instead the HEAD explicitly shares the head noun's PRED, thus establishing the semantic connection. Rule (46) is also simplified, since the null 'PRO' is not needed to compensate for the absence of an initial XP (51b).

(51) a. *which* Pro (↑ PRONTYPE) = REL

b. $$\text{CP} \longrightarrow \underset{\substack{@(\text{TOPIC}\ \uparrow\ (\uparrow\ \text{HEAD}))\\ (\uparrow\ \text{HEAD}) = (\uparrow\ \text{RelTopicPaths})}}{\textit{that}\,|\,e} \qquad \underset{\uparrow=\downarrow}{\text{C}'}$$

With these revisions the f-structure (52a) is provided for the relativized NP *shop* in (41) and (52b) is provided for *book* in (45).

(52) a. b.



---

[7] The attribute HEAD is neutral with respect to Falk's semantically-oriented OPER attribute and the attribute RELPRO that aligns more with previous anaphora-based solutions.

In these structures the link between the restricted HEAD f-structures is strictly local. The links within the clause are unbounded, as indicated by the colored attributes from paths in the RelTopicPaths and RelHeadPaths uncertainty languages.

8 Further constraints on uncertainty paths

In modern LFG theory the admissibility of particular unbounded dependencies is determined first and foremost by the attribute strings in the uncertainty path-languages. But these dependencies have been challenging for linguistic description because they are also conditioned in different constructions and different languages by second-order interactions with other structural properties. Dependencies and the phrases they pass through must sometimes be aligned with respect to special morphological or phonological feature values (Section 8.1). Separate dependencies in some languages cannot pass through the same f-structures, giving rise to island effects (Section 8.2). Unbounded dependencies are of course related indirectly to word order by virtue of a grammar's normal c-structure rules and f-structure annotations, but they may also be sensitive to additional linear order constraints (Section 8.3).

8.1 Marking of intervening f-structures

Zaenen (1983) discussed a number of languages in which f-structures on a path between a filler and its clause-internal function differ in form from f-structures that are not in the domain of an unbounded dependency. She specifically considered Irish and Kikuyu, but since then many more cases have been discussed in the literature (see e.g. van Urk 2020). Here I focus on just the Irish examples of the phenomenon, as illustrated by the contrasts in (53) (data originally from McCloskey 1979).[8]

(53) Path-dependent complementizer selection in Irish

a. Deir siad goN/*aL síleann an t-athair goN/*aL bpósfaidh Síle é.
Say they that thinks the father that will-marry Sheila him
'They say that the father thinks Sheila will marry him.'

---

[8] In the linguistic literature the complementizer *a* is typically written as *aL* or *aN*, indicating that it triggers a lenition mutation or a nasalization mutation on the following word.

b. An fear aL/*goN deir siad a shíleann an t-athair aL/*goN
The man that say they that thinks the father that
phósfaidh Síle.
will-marry Sheila
‘The man that they say that the father thinks Sheila will marry __.’

Embedded complements not on a binding path (53a) are introduced by the complementizer *goN* and not *aL*, while *aL* is required for complements that the relative-clause dependency passes through (53b). This pattern has a simple account if all and only intervening f-structures on a dependency path are marked with a distinguishing diacritic feature [UBD GAP] (for “gapped unbounded dependency”). That feature would then be available for checking by the complementizers’ lexical annotations (54).[9]

(54) Irish complementizers

aL	C	(↑ UBD)
goN	C	¬(↑ UBD)

The positive existential constraint would not be satisfied if *aL* appears with a COMP that does not have a UBD feature, and the negative existential for *goN* would fail if that feature is present.

Working within the original Kaplan & Bresnan (1982) c-structure formulation of unbounded dependencies (Section 3.1), Zaenen (1983) added the f-structure marking feature (BND in her account) at sentential bounding nodes in a successive-cyclic fashion. In the modern functional framework, a basic uncertainty leaves no footprints as it passes through the intervening f-structures along a path, but its presence can be made known by adding off-path annotations to the attributes of the regular expression. Off-path constraints were formalized originally by Kaplan & Maxwell (1996) and Crouch et al. (2011); see also Dalrymple et al. (2019).

An off-path annotation is a functional description attached to an attribute in an ordinary functional designator, much like traditional descriptions are attached to c-structure categories. The difference is that an off-path annotation can use metavariables ← and → instead of (or in addition to) ↑ and ↓. These are instantiated to the f-structure containing the annotated attribute and the value of that attribute in the containing f-structure, respectively. A formal definition is given in (55).

---

[9] This is a respelling of the LDD (“long distance dependency”) feature that appears in Dalrymple et al. (2019) and elsewhere. Ash Asudeh (p.c.) argues that UBD is a more accurate designation, since some instances of these constructions are actually quite short. Falk (2009) proposes a feature WHPATH for related path-marking purposes.

(55) Off-path annotations

$(f \underset{D}{a}) = v$ iff $(f\ a) = v$ and $D_{\substack{\leftarrow/f \\ \rightarrow/v}}$ is satisfied, where

D is a functional description and

$D_{\substack{\leftarrow/f \\ \rightarrow/v}}$ is the result of substituting f for ← and v for → in D.

This definition extends the notation and meaning of primitive function-application designators (12a) and thus immediately carries over to the path languages of functional uncertainties (cf. (13a)).

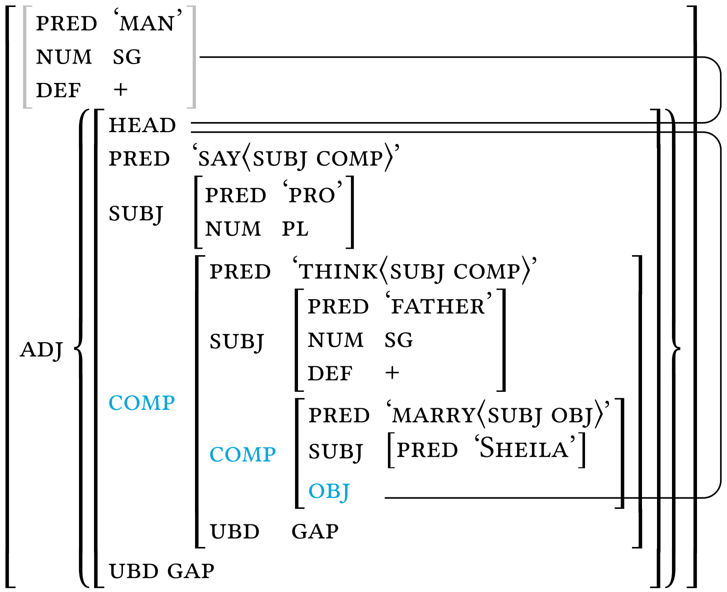
Off-path annotations were first used in a functional account of Irish complementizer marking that was developed in unpublished research by Mary Dalrymple, Ronald Kaplan, John Maxwell, and Annie Zaenen; Dalrymple (2001) provided the first published account of this approach. In essence, the uncertainty expression defined in (56a) inserts the UBD feature at every intervening f-structure without imposing any further restrictions on the grammatical functions along the path. The RelTopicPaths schema (56b) then applies regular-language intersection to mark the attributes of whatever path language is separately specified.

(56) a. $\text{Mark} = \underset{(\leftarrow\ \text{UBD})=\text{GAP}}{\text{GF}^{*}}\ \ \text{GF}$

b. RelTopicPaths = […] & Mark

The off-path annotation adds the UBD features parallel to the COMPs in (57), the f-structure for (the English gloss of) sentence (53b), and the lexical constraints (54) then assure the proper distribution of complementizers.

(57)



Asudeh (2012) discusses the more complicated relative clause patterns of Irish described by McCloskey (2002). Generally, the head nominal is assigned a within-clause function that has no surface realization (a gap), as in (57), if every intervening clause is marked with *aL*. But if the nasalization mutation triggered by *aN* appears at any clause along the way, then additional UBD marking is suspended and the head must bind to an explicit resumptive pronoun found in that clause or below. McCloskey (2002) illustrates this pattern with the relative clause in (58).

(58) Irish

aon	duine	a	cheap	sé	a	raibh	ruainne	tobak	aige
any	person	aL	thought	he	aN	was	scrap	tobacco	at-him

‘anyone that he thought had a scrap of tobacco’

This motivates the more elaborate version of the marking language shown in (59a). Here the f-structures on an arbitrary (possibly empty) prefix of an uncertainty path are marked with the feature [UBD GAP], as before. But at any point along the path the marking value for embedded f-structures can optionally switch to RES(umptive). Intersecting the language RESOLVE in (59b) forces the uncertainty to resolve to a resumptive pronoun only when the RES value has been chosen.

(59) Irish gap marking (with resumptives)

a. $\textsc{Mark} = \underset{(\leftarrow\ \textsc{ubd}) = \textsc{gap}}{\textsc{gf}^*} \quad (\underset{(\leftarrow\ \textsc{ubd}) = \textsc{res}}{\textsc{gf}^*})$

b. $\textsc{Resolve} = \textsc{gf}^* \underset{(\leftarrow\ \textsc{ubd}) = \textsc{res} \text{ iff } (\rightarrow\ \textsc{prontype}) =_c \textsc{res}}{\textsc{gf}}$

c. $\textsc{RelTopicPaths} = [\ \ldots\ ]\ \&\ \textsc{Mark}\ \&\ \textsc{Resolve}$

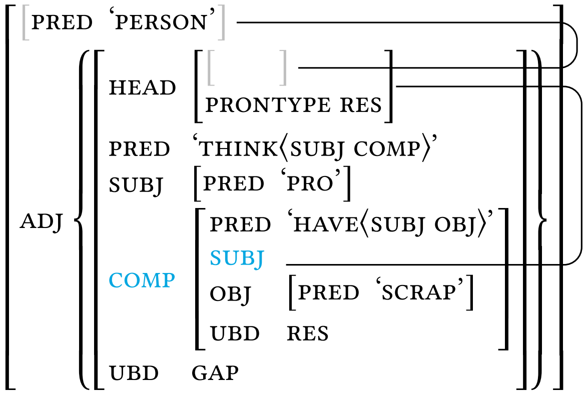
The lexical annotations (60) then make sure that the complementizers along the way are properly correlated with how the uncertainty is resolved at the bottom.

(60)

aL	C	$(\uparrow \textsc{ubd}) =_c \textsc{gap}$
aN	C	$(\uparrow \textsc{ubd}) =_c \textsc{res}$

For the relative clause (58) this analysis gives rise to the abbreviated f-structure (61).

(61)



Asudeh (2012) provides an alternative treatment of this and other patterns of Irish relatives. On his account the entire head f-structure, not just an atomic feature, is instantiated at every clause along the path. In this successive cyclic COMP-to-COMP arrangement, the head appears in the *aN*-complementizer clause in particular, and the pronoun binding is then set up there by a new uncertainty launched by *aN*'s lexical annotations. The marking strategy (59a), by comparison, offers the transition from gap to pronoun as a feature-controlled choice at any point within a single uncertainty language. It allows both the gap and the pronoun to be bound in the same end-to-end fashion, without any intermediate landing sites. This produces a less cluttered f-structure while making the claim that features of the particular head do not interact with properties of any intermediate clauses.

For Irish it is the selection of complementizers that interacts with unbounded dependency paths. The Kikuyu data cited by Zaenen (1983) and Dalrymple (2001) show that the verbs in intervening f-structures may also be sensitive to the presence of a dependency. This effect may be seen also in English: unbounded dependencies freely propagate through the complements of some verbs (62a) while (at least for some speakers) the complements of other verbs act as barriers (62b).

(62) a. Mary, we thought that Henry called.
b. * Mary, we whispered that Henry called.

Verbs like *think* are called bridge verbs, while *whisper* belongs to the class of nonbridge verbs. If the simpler MARK in (56a) is applied to the sets of English uncertainty paths, then the difference in behavior is accounted for by the negative existential in (63b).[10]

---

[10] Dalrymple et al. (2019) formalize the bridging restriction by pairing a negative defining equation (↑ LDD) = − on *whisper* with an off-path negative value constraint (↑ LDD) ≠ − in the un-

(63) a. *think* V (↑ pred) = ‘think⟨subj comp⟩’

b. *whisper* V (↑ pred) = ‘whisper⟨subj comp⟩’
¬(↑ ubd)

This captures the syntactic difference between bridge and nonbridge verbs, but that difference may be a structural reflection of a more basic semantic or pragmatic difference. Erteschik-Shir (1973) suggested that verbs that imply the manner of saying something are more likely to form islands than verbs that simply describe what is being said. It is not clear whether the various constraints on unbounded dependencies that can be formalized with LFG’s syntactic machinery are better explained by appeal to other components of grammar, or to principles of cognition, pragmatics, or computation.

In these illustrations the unbounded dependency announces itself by the value it defines for the special ubd feature, and that value can then be examined to limit the f-structures that the dependency passes through. English adjuncts appear to interact with unbounded dependencies in a different way. Sentence (64a) was cited earlier to show that adjuncts can be topicalized and that the topicalization path-language (for English, not Icelandic) should include adj (∈) as an option. But the ungrammaticality of example (64c) indicates that an additional restriction must be imposed on the general pattern (examples from Dalrymple 2001).

(64) a. This room Julius teaches his class in __.

b. We think that David laughed after we selected Chris.

c. * Chris, we think that David laughed after we selected __.

This difference has been ascribed to the fact that the adj clause is tensed in (64c) but not (64a), although there may be other pragmatic or semantic factors also at work (see Toivonen 2021 and references cited there).

Taking the bridge verbs as a model, tensed adjuncts could be excluded from unbounded dependencies by adding a negative existential constraint ¬(↑ ubd) to every tensed verb. But it is more economical to leave all the verbs alone and instead to refine just the uncertainty so that it cannot pass to or through a tense-marked adj element. The path language (65a) and the intersection (65b) impose that constraint on TopicPaths (Dalrymple 2001 and Dalrymple et al. 2019 formulate tac in a slightly different but equivalent way).

---

certainty. The ldd feature thus always appears in the complement f-structures of nonbridge verbs, even if not in the context of an unbounded dependency. In the solution outlined here that feature appears always and only along a dependency path and is available there for the bridge verb to test.

(65) Tensed Adjunct Constraint[11]

a. $\textsc{tac} = \backslash[\ \underset{(\rightarrow\ \in\ \textsc{tense})}{\textsc{adj}}\ ]^*$

b. $\textsc{TopicPaths} = [\ \{\textsc{comp}, \textsc{xcomp}, \textsc{adj}\ (\in)\}^*\ \backslash\textsc{comp}]\ \&\ \textsc{mark}\ \&\ \textsc{tac}$

The TAC restriction can be applied with a similar intersection to FocusPaths and the path languages of other constructions, as appropriate.

However, examples (66) indicate that grammaticality is not correlated with the presence of absence of the TENSE feature. The participial adjunct in (66a) is untensed and therefore the inadmissible dependency in (66b) would not be ruled out by the Tensed Adjunct Constraint.

(66) a. The cat slept after devouring the rat.

b. * What did the cat sleep after devouring __?

Instead, what is common to the ungrammatical examples in (64) and (66) is the presence of a subject, either derived from an explicit phrase (64c) or inserted as an anaphorically controlled null pronoun (66b). Unbounded dependencies may thus be more sensitive to the constraint as formulated in (67).

(67) Subject Adjunct Constraint

$\textsc{sac} = \backslash[\ \underset{(\rightarrow\ \in\ \textsc{subj})}{\textsc{adj}}\ ]^*$

Like many other conditions, restrictions on adjunct dependencies seem to be language-particular and not universal. Swedish for example seems to be more flexible than English in this regard (see Müller 2019). It is an advantage of the LFG approach that such constraints can be expressed easily within the formalism without appeal to extragrammatical (and often false) general principles.

8.2 Classical island constraints

Early interest in unbounded dependencies was mainly stimulated by the constraints on them that were first described in detail by Ross (1967). Working within a framework of transformational rules, Ross gave a list of "island" configurations that block the movement of constituents from one clause to another. He observed in particular that sentential subjects, coordinate structures, and complex NPs all seem to interfere with unbounded relationships, as the contrasts in (68) suggest (after Ross 1967).

---

[11] Intersection and term-complementation of off-path annotations can be reduced to more primitive expressions by noting the equivalences of $\underset{D_1}{a}\ \&\ \underset{D_2}{a}$ and $\underset{D_1 \wedge D_2}{a}$ and of $\backslash[\ \underset{D}{a}\ ]$ and $\{\ \underset{D}{\backslash a},\ \underset{\neg D}{a}\ \}$.

(68) Sentential Subject Constraint

a. The reporters expected that the principal would fire some teacher.

b. The teacher who the reporters expected that the principal would fire __ …

c. That the principal would fire some teacher was expected by the reporters.

d. * The teacher who that the principal would fire __ was expected by the reporters …

Coordinate Structure Constraint

e. Henry plays the lute and sings madrigals.

f. * The lute which Henry plays __ and sings madrigals …

g. * The madrigals which Henry plays the lute and sings __ …

Complex NP Constraint

h. Phineas knows a girl who __ is jealous of Maxime.

i. * Who does Phineas know a girl who __ is jealous of __?

j. * Maxime, Phineas knows a girl who __ is jealous of __.

It appeared that transformations cannot move the constituents of sentential subjects (68a–68d), that parts of individual conjuncts in a coordination cannot be moved (68e–68g), and that the complex NPs of relative clauses also form a barrier (68h–68j). Ross formulated these island constraints in phrase-structure terms and appealed to extra-grammatical (and presumably universal) stipulations to impose them on the otherwise unfettered operation of individual transformational rules.

Later transformational accounts maintained the view that unbounded dependencies are allowed except when they would cross into phrasal islands, and this conception was carried over into the early c-structure-based LFG approach. Kaplan & Bresnan (1982) and Zaenen (1983) provided a grammar-internal way of limiting the range of the bounded-domination metavariables ⇑ and ⇓ and thus enabled more fine-grained characterizations of island configurations. They permitted particular categories in c-structure rules to be marked as “bounding categories”, and nodes licensed by those categories were not allowed on the dominance paths connecting co-instantiations of ⇑ and ⇓. For example, the ungrammaticality of (68i) would follow on that theory if the CP under NP in rule (44a) is marked as a bounding category. But there is no need for such categorial distinctions in the modern LFG theory of unbounded dependencies, since the vocabulary of grammatical functions and features provides a natural platform for expressing such island-like restrictions.

Ross' Sentential Subject Constraint, for instance, can be expressed by the term-complement formula (69a). This defines paths of arbitrary length that do not pass through subjects and that bottom out in any grammatical function. And the constraint could then be enforced by intersecting this with any other long distance regular language, as in (69b). Any paths with SUBJ-containing prefixes would no longer be available.

(69) a. SSC = \SUBJ* GF
b. RelTopicPaths = […] & SSC (English)
c. RelTopicPaths = SUBJ$^+$ (Tagalog)

This restriction would be helpful for English relatives if there is an explanatory advantage in stating the basic path language in a simple but overly general way (e.g. [GF* \COMP]). But it would not be needed if the regular expression for the basic uncertainty defines the admissible paths more precisely. Either way, this is clearly not a universal constraint: Kroeger (1993) observes that the path language for Tagalog unbounded dependencies contains *only* subjects, as in (69c). Such an extragrammatical condition may have been the only way of regulating the operation of transformational rules, but it serves no particular purpose in the setting of functional uncertainty.

Coordinate structures in LFG are represented formally as conjunct-containing sets under distributive attributes, and their behavior with respect to f-structure well-formedness is specified in (12e), repeated here for convenience. A set satisfies a distributive f-structure property if all of its elements satisfy that property. While this account of coordination is defined only for local f-structure configurations, unbounded dependencies simply inherit that local behavior by virtue of the incremental, single-attribute expansion of functional uncertainty as spelled out in (13a), also repeated.

(12e) $(f\ a) = v$ iff f is a set and
$(g\ a) = v$ for all $g \in f$ if a is a distributive attribute
$\langle a, v \rangle \in f$ if a is a nondistributive attribute.

(13a) If Paths is a set of attribute strings,
$(f\ \textsc{Paths}) = v$ iff $((f\ a)\ \mathit{Suff}(a, \textsc{Paths})) = v$.

The pattern of coordinate structure violations illustrated in (68e-g), and in (10) above, follows immediately from this independent theory of coordination: without further stipulation, a dependency that crosses into a coordination cannot affect just one of the conjuncts.[12]

An NP is “complex” for Ross if it immediately dominates a clausal category (CP now, S as originally formulated). The essence of the Complex NP Constraint is that no unbounded dependency can relate an element outside such an NP to an element inside the dominated clause. Examples (68i) and (68j) are ungrammatical on this theory because the relativized NPs are complex in this way and thus are opaque to the question and topicalization dependencies. Our framework offers a different account of their ill-formedness: the clauses are represented in f-structure as adjuncts of the head noun *girl* and so do not satisfy Subject Adjunct Constraint installed in the English FocusPaths and TopicPaths path sets. As noted above, tac is not universal, it applies in English but not for instance to Swedish dependencies. It is not surprising that the Complex NP Constraint also does not seem to operate in Swedish (Müller 2019).

The CNPC characterizes English relative clauses (with assignments to adj) as islands for unbounded dependencies. It does not cover other cases where dependencies seem to be mutually exclusive. Example (70b) shows that two question dependencies cannot overlap, (70c) shows that a topicalization cannot pass into a question, and (70d) shows that a question also obstructs a relative clause dependency. None of these involve complex NPs.

(70) a. Phineas wonders which girl is jealous of Maxime.
b. * Who does Phineas wonder which girl __ is jealous of __?
c. * Maxime, Phineas wondered which girl __ is jealous of __.
d. * The girl that Phineas wondered who __ is jealous of __ left.

On one approach the path languages for each of the outer dependencies can be conditioned against tell-tale properties of the innner question f-structure, presuming that those are recognizable and independently motivated (for example,

---

[12] The suffix language for a chosen attribute must propagate into each conjunct, but Kaplan & Zaenen (1989) note that the residual uncertainties are then not required to resolve all in the same way:

(i) Mary, John expected to see __ and give the book to __.

Here the set of xcomp suffix paths resolves to obj in the first complement but obl_θ in the second. In contrast, Saiki (1985) observes that some Japanese relative clauses are constrained so that the dependencies in all conjuncts must resolve either to a subject or to a non-subject. This constraint can be imposed by intersecting [gf^* subj | gf^* \subj] with the basic Japanese path specification.

if a grammaticized focus attribute is still needed for some other reason). Falk (2009) proposes instead to make use of the path-marking feature ubd (his wh-path) that is already needed for verb and complementizer selection. It is the inner construction that then determines whether to protect itself from other unbounded dependencies. English embedded questions thus become dependency islands when a negative ubd constraint is added to the rule (71) that introduces them.

(71)
$$\begin{array}{lcc} \text{CP} \longrightarrow & \text{XP} & \text{IP} \\ & @(\text{FocusQ}\ \uparrow\ \downarrow\ (\downarrow \text{WhPaths}\ \&\ \text{WhPro})) & \uparrow=\downarrow \\ & (\uparrow \text{FocusPaths}) = \downarrow & \\ & \neg(\uparrow \text{ubd}) & \end{array}$$

It may not be an accident that the constraint that blocks an outer unbounded dependency co-occurs with an equation that launches an inner one, as in this rule. Some but not all languages may use this as a strategy to keep at bay the confusion of too many overlapping uncertainties.

8.3 Constraints on linear order

In the unbounded dependency constructions examined so far, an uncertainty is launched from an overt c-structure constituent or lexical item and binds the content of that element to a remote position in f-structure. The uncertainty is outside-in for most of the constructions, where the external element is realized perhaps far away from the normal c-structure location of its within-clause function assignment. The uncertainty is inside-out when the overt element of a dependency is in situ, as in the Mandarin example (21). These purely functional accounts go through without making reference to c-structure positions that correspond to the other, covert ends (bottom or top) of the dependencies. So far there has been no need for the phonologically empty nodes or traces that have been an essential ingredient of other theories of syntactic binding.

However, there are well known cases to suggest that the bottom end of an outside-in uncertainty must be grounded at a specific c-structure position, that the external element must be associated with a within-clause c-structure position in addition to a within-clause function. The weak crossover pattern in (72), first discussed by Wasow (1979), has received the most attention. Controlling for other possibly relevant factors, this shows an interaction between the linear position of the pronoun and the within-clause position where the obj or obl$_\theta$ function assigned to *who* would normally be expressed. The pronoun *his* and *who* cannot refer to the same individual if the pronoun comes before the assumed within-clause position of *who*:

(72) Weak crossover (examples from Dalrymple et al. 2001)

a. * Who$_i$ did his$_i$ mother greet __?
(cannot mean: Whose$_i$ mother greeted him$_i$?)

b. * Who$_i$ did Sue talk to his$_i$ mother about __?

c. Who$_i$ did Sue talk to __ about his$_i$ mother ?

The English contrast in (73) has also been taken as evidence that within-clause locations must be assigned to the external elements of question and *tough* constructions (see Kaplan & Bresnan (1982) and references cited therein). Sentence (73b) is uninterpretable because the link from *sonata* to its putative within-clause position crosses over the link from the overt appearance of *violin* to its covert linear position.

(73) Nested syntactic dependencies

a. Which violin is this sonata easy to play __ on __.

b. * Which sonata is that violin easy to play __ on __.

The ordering patterns illustrated by these examples are not found in all languages. Maling & Zaenen (1982), for example, note that crossing dependencies are acceptable in Norwegian and only dispreferred in Swedish. It must therefore be possible to parameterize or otherwise express these restrictions in the grammars of individual languages.

8.3.1 Ordering by (empty) trace nodes

Bresnan (2001) proposed to handle the linear ordering facts of weak crossover within a larger cross-linguistic theory of anaphoric binding.[13] She expands the NP at the within-clause position to an empty string, and then arranges for the ϕ

---

[13] For the general theory of anaphoric binding this proposal is part of, see Rákosi 2023 [this volume]. On the Bresnan (2001) theory a pronominal cannot be more “prominent” than its potential antecedents, where prominence for a given language may be based on relative positions on a hierarchy of grammatical functions (subj is more prominent than obj), on a hierarchy of thematic roles (agent is more prominent than patient), or on the linear order of corresponding c-structure nodes. Only the linear prominence condition is relevant for these particular examples of weak crossover in English.

correspondence function to map both the trace node and the NP at *who* to the same f-structure (e.g. OBJ or OBL_θ). That many-to-one correspondence is set up by converting the uncertainty from outside-in to inside-out and shifting its launch site to the new trace node, as illustrated in (74).[14]

(74) a. CP ⟶ XP IP
@(FocusQ ↑ ↓ (↓ WhPaths & WhPro)) ↑=↓
~~(↑ FocusPaths) = ↓~~
¬(↑ UBD)

b. NP ⟶ *e*
↑= (FocusPaths ↑)

With node mappings set up in this way, the weak crossover constraint on linear order can be stated in terms of the f(unctional)-precedence relation defined in (75): a pronoun cannot f-precede its antecedent.[15]

(75) Functional precedence (Bresnan 2001)
f f-precedes g ($f <_f g$) iff the rightmost node in $\varphi^{-1}(f)$ c-precedes the rightmost node in $\varphi^{-1}(g)$.

However, separating the uncertainty specification from the dependency's overt element comes at a descriptive cost. Without some further stipulation the grammar would accept a phrase in the XP position of (74a) even when it corresponds to no FocusPath trace node in the clause c-structure and thus is assigned no within-clause function. This issue has been addressed by introducing a global condition on well formed f-structures, the Extended Coherence Condition. This was first proposed by Zaenen (1985); this version is taken from Dalrymple (2001):[16]

---

[14] This analysis was also carried over into Bresnan et al. (2016), but the later co-authors are not in full agreement about the status of empty elements and whether dependencies should run outside-in or inside-out (Ash Asudeh, p.c.).

[15] Bresnan's f-precedence definition (75) differs from the proposals of other authors. It compares the positions of only the right-most nodes of the inverse-ϕ images, while Kaplan & Zaenen (1989) and others take into account all nodes in the correspondence.

(i) Functional precedence (Kaplan & Zaenen 1989)
$f <_f g$ iff for all $n_1 \in \varphi^{-1}(f)$ and all $n_2 \in \varphi^{-1}(g)$, n_1 c-precedes n_2 ($n_1 <_c n_2$).

These definitions are equivalent for purposes of this discussion.

[16] If grammaticized discourse functions are not represented in f-structure, the intuition behind this constraint would have to be reformulated as a condition on i-structure correspondences.

(76) Extended Coherence Condition
FOCUS and TOPIC must be linked to the semantic predicate argument structure of the sentence in which they occur, either by functionally or anaphorically binding an argument.

This important requirement can be reconstrued as a well-formedness condition on grammars rather than on representations. Functional binding is guaranteed if a simple existential constraint (77) is attached by convention as an additional annotation to the filler XP in (74a).

(77) Extended coherence constraint
$(\text{GF} \downarrow)$

Depending on how the relationships of anaphoric binding are made formally explicit, a similar constraint can be defined for those linkages.

Another convention is needed to prevent the proliferation of trace nodes at different c-structure positions whose inside-out uncertainties would bind a single filler to the same or different within-clause functions (but see Section 9). One motivation for Bresnan's Economy of Expression principle (78) is to exclude derivations that contain such unwarranted trace bindings.[17]

(78) Economy of Expression (Bresnan et al. 2016)
All syntactic phrase structure nodes are optional and are not used unless required by independent principles (completeness, coherence, semantic expressivity).

Extended Coherence and Economy help to control the promiscuous behavior of trace-launched uncertainties, those that are not directly associated with overt triggering configurations.[18]

---

[17] Separately, Dalrymple et al. (2015) present a critical discussion of Economy as a general principle of syntax.

[18] Although it has not been explored in the literature and I am not advocating for it here, there is a trace-based alternative that may be somewhat less unattractive. On this analysis the trace is used only to establish a within-clause linear position for the uncertainty: it does not serve as a launching site. The uncertainty remains with the overt external element, but each path language (e.g. FocusPaths) is intersected with the off-path annotations in Locate (i) to guarantee that it ends at a function assigned at a c-structure trace node. The bookkeeping feature TRACE is defined at all and only trace nodes.

(i) $$\text{Locate} = \text{GF}^* \underset{\substack{(\rightarrow\ \text{TRACE})\\ (\rightarrow\ \text{UBD}) = \text{GAP}}}{\text{GF}} \qquad \text{NP} \longrightarrow \underset{\substack{(\uparrow\ \text{TRACE}) = +\\ (\uparrow\ \text{UBD})}}{e}$$

As a final observation, it is also not clear whether or how well the Bresnan account of weak crossover ordering extends to characterize the nested dependency pattern in examples (73), given that the path languages for the question and *tough* constructions are not the same. Careful regulation of empty-node ordering offered a solution to the *sonata/violin* contrast in the original LFG theory of unbounded dependencies (Kaplan & Bresnan 1982), but the c-structure stipulations of that theory do not naturally carry over to the path languages of modern approaches.

8.3.2 Ordering by coarguments

Dalrymple et al. (2001) use a different definition of linear prominence based on the notion of coargumenthood and a relation between the pronoun and the f-structure that contains the wh-term (called the "operator"). With this formulation they show that the linear order constraints of weak crossover can be modeled without appealing to traces. They define coarguments as the arguments and adjuncts of a single predicate[19] and propose that both of the following prominence conditions must be satisfied:

(79) Let CoargOp and CoargPro be coargument f-structures such that CoargOp contains the within-clause function of the operator (wh-term) and CoargPro contains the pronoun. Then:

Syntactic [= Functional] Prominence: An operator O is more prominent than a pronoun P if and only if CoargOp is at least as high as CoargPro on the functional hierarchy.

Linear Prominence: An operator O is more prominent than a pronoun P if and only if CoargOp f-precedes CoargPro.

The key idea is that Linear Prominence depends on the f-precedence relations of the coarguments, the clause-internal f-structure sisters that contain the operator and pronoun. The positions of the nodes that the outside-in uncertainty maps to the coarguments in the weak crossover example (72a) are indicated in (80a). Note that CoargOp is located only at the leading position because its function OBJ is not projected from any clause-internal (trace) node. This sentence meets the Linear Prominence requirement, but fails the Syntactic Prominence test because OBJ is lower than SUBJ on the function hierarchy.

---

[19] Dalrymple et al. (2019) note that "co-dependent" may be a more accurate label for this concept, since adjuncts are included along with arguments. Here I continue to use the terminology of the original paper.

(80) a. * Who$_i$ did [his$_i$ mother] greet?
CoargOp CoargPro

b. * Who$_i$ did Sue talk [to his$_i$ mother] about?
CoargPro CoargOp

c. Who$_i$ did Sue talk to [about his$_i$ mother]?
CoargOp CoargPro

For examples (72b) and (72c) the oblique functions are at the same position on the functional hierarchy so they both meet the Syntactic Prominence condition. This grammaticality difference follows from the locations of the within-clause coargument nodes as annotated in (80b) and (80c) respectively. CoargPro is the OBL$_{\text{TO}}$ of *talk* in (80b) (because *his* is contained in the *to*-phrase) and CoargOp is the OBL$_{\text{ABOUT}}$ (because the outside-in uncertainty resolves to that function). The sentence is ungrammatical because the nodes mapping to CoargPro and CoargOp are in the wrong order. The Coargs and their order are switched in the grammatical sentence (80c).

On this proposal, the operator's within-clause function is first determined by an outside-in uncertainty. After that the coarguments are identified in the clause at which the paths to the operator and pronoun functions first diverge. Linear order is then defined on the nodes that map to those overt, lexicalized coargument functions. Weak crossover is the target of this particular account, but coargument precedence may apply more generally. The nested dependency constraint (73) may follow from a different coargument ordering requirement once the coargument functions are identified for the *violin* and *sonata* phrases.

(81) a. [Which violin] is [this sonata] easy to play on?
1 2/Coarg2 Coarg1

b. * [Which sonata] is [that violin] easy to play on?
1/Coarg1 2 Coarg2

The formal details of such an ordering principle have not yet been worked out.

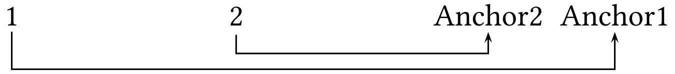
8.3.3 Ordering by subcategorizing PREDicates

The subcategorizing predicate for a given grammatical function is the semantic form that licenses that function in a local f-structure, via the Coherence and Completeness conditions. The value of those conditions in linguistic description is obvious, but Kaplan & Maxwell (1988a) noted that they are also key to the computationally efficient resolution of functional uncertainties. A typical uncertainty allows for the full array of grammatical functions each of which must be hypothesized in principle at every level of embedding. The overall computational complexity is much reduced if that exploration is deferred until the subcategorizing predicate is reached: the possible realizations can then be limited to all and only the functions that it governs. Kaplan (1989a) made a related psycholinguistic processing observation: the results of early trace-inspired measures of word-by-word cognitive load experiments (Kaplan 1974, Wanner & Maratsos 1978) could also be attributed to additional activity when the subcategorizing predicate is first encountered. It was not recognized in these early studies that subcategorizing predicates could also be the basis for a trace-free account of linear order grammaticality conditions.

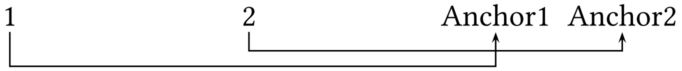
Pickering & Barry (1991) made a much more systematic sentence-processing argument that overt subcategorizing predicates and not empty categories determine how external elements are integrated into embedded clauses. Adopting their Direct Association Hypothesis, Dalrymple & King (2013) sketch an account of nested dependencies that depends on the linear order of the predicates that subcategorize for the bottom functions of overlapping uncertainty paths. They use the term "anchor" for the subcategorizing predicate of the bottom function, as illustrated in (82).[20]

(82) Anchor ordering

a. [Which violin] is [this sonata] easy to play on?



b. * [Which sonata] is [this violin] easy to play on?



In (82a) *violin* is anchored at the *on* predicate, as indicated by the arrow, because the outer uncertainty resolves to *on*'s OBJ. Similarly, the anchor for *sonata* is *play*. The anchoring predicates are the same in (82b), but they occur in the opposite linear order. Dalrymple and King make precise what it means for two dependencies to interact (intuitively, that the outer dependency unfolds through a clause

---

[20] This notion of "anchor" should not be confused with the formal definition used in the decidability proofs for LFG parsing and generation (Kaplan & Wedekind 2023 [this volume]).

containing the inner one). The difference between (82a) and (82b) then follows from their nesting condition: if two dependencies 1 and 2 interact, then Anchor1 must not precede Anchor2. Nadathur (2013) accounts for the linear order of weak crossover by a separate anchor-ordering constraint: the anchor of the operator must precede the pronoun.

Although Dalrymple & King (2013) and Nadathur (2013) do not give a detailed specification of their outside-in, anchor-based approaches to linear order, the basic notions are easy to represent within the existing LFG formalism. First, the anchor of an uncertainty path is the PRED of the f-structure one up from the bottom. The off-path annotation on the path language (83) picks out that PRED and adds it as a diacritic feature to the f-structure at the top of the path, where the uncertainty is launched.

(83) $$\text{ANCHOR} = \text{GF}^{*} \quad \underset{(\uparrow\ \text{ANC}) = (\leftarrow\ \text{PRED})}{\text{GF}}$$

The effect of intersecting ANCHOR with any other path language (e.g. FOCUSPATHS or TOUGHPATHS) is to make the within-clause anchor directly available at the top, presumably at the operator's f-structure.

Second, PRED semantic forms in LFG are composite entities that encapsulate succinctly a collection of syntactic and semantic properties. These are accessible by distinguished attributes REL, ARG1, ARG2, etc. Semantic forms are also instantiated, and Kaplan & Wedekind 2023 [this volume] make explicit that the instantiating index of a PRED is the value of another distinguished attribute SOURCE. Moreover, the value of SOURCE is the daughter node, formally denoted by $*$, at which the PRED is introduced into the f-description. Thus a defining equation (84) is implicitly carried along with every PRED.

(84) PRED instantiation (from Kaplan & Wedekind 2023 [this volume])
$$(\uparrow\ \text{PRED SOURCE}) = *$$

A PRED-precedence relation (85) follows naturally from the immediate connection between instantiated semantic forms and c-structure nodes: semantic forms are ordered by the c-structure order of their instantiation SOURCE nodes.

(85) PRED precedence
$$p_1 <_p p_2 \text{ iff } (p_1\ \text{SOURCE}) <_c (p_2\ \text{SOURCE}).$$

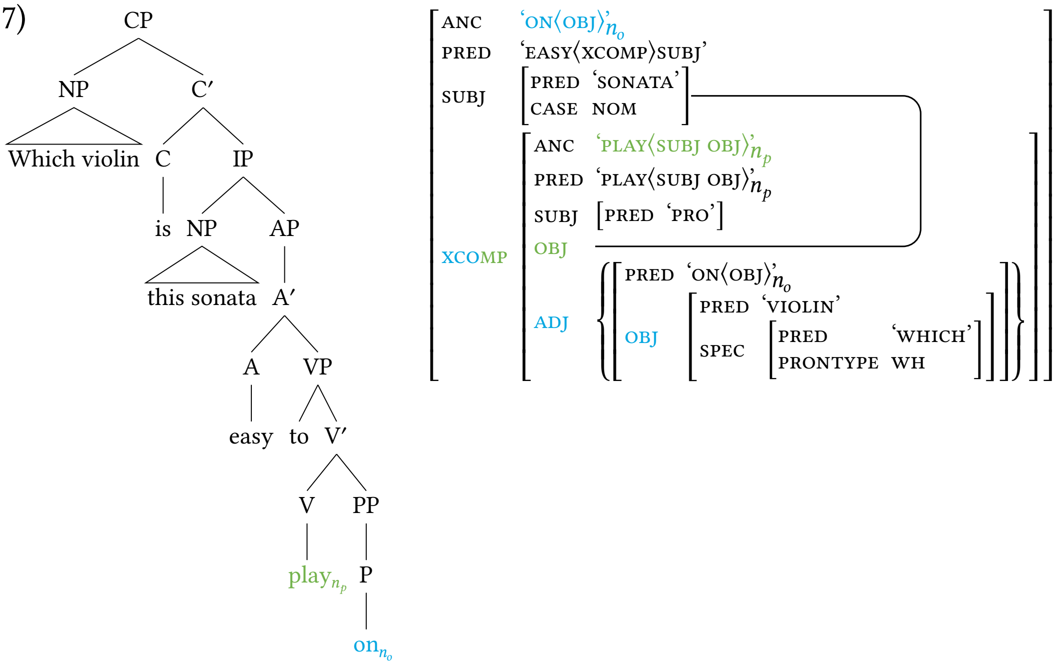
This is a simpler relation than f-precedence since it is defined directly on singleton nodes, not on ϕ^{-1} sets of nodes. Finally, the path language (86) encodes the nested-order constraint.

(86) $$\text{Nested} = \underset{(\uparrow \text{ANC}) \not\prec_p (\rightarrow\ \text{ANC})}{\text{GF}^* \qquad\quad \text{GF}}$$

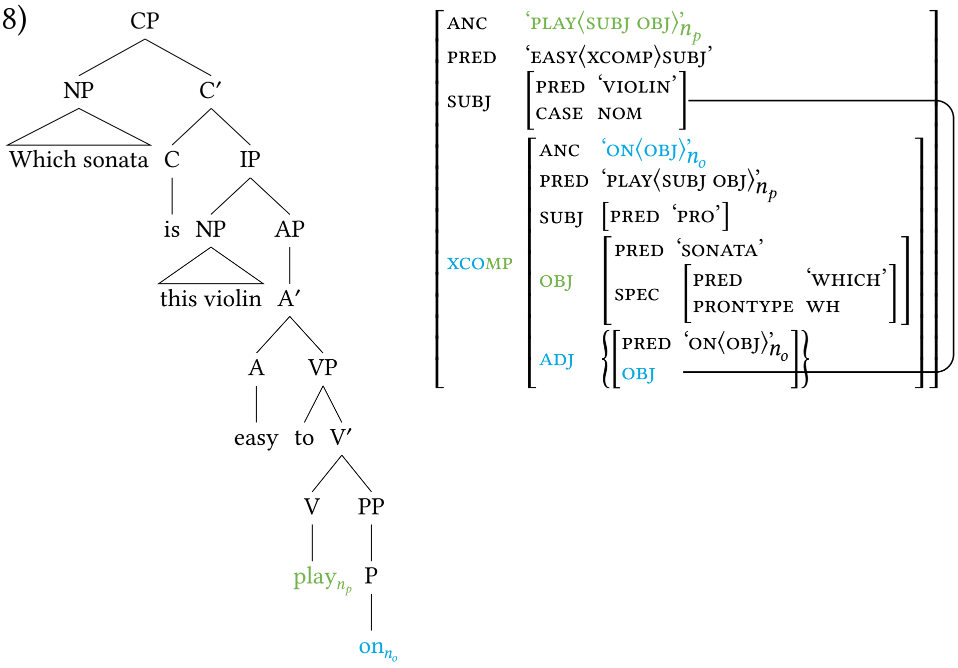
(↑ ANC) is the anchor of the outer uncertainty (*on* in (82a), *play* in (82b)). That remains constant as the uncertainty unfolds. If the outer uncertainty (the *wh* phrase) overlaps an inner uncertainty (*easy*), the ordering condition will compare their two anchors. The nesting follows from the fact that the hierarchical positions of the anchors in f-structure are reversed relative to the linear c-structure order. The nested-order constraint can be imposed (for a language where it applies) by intersecting (86) with the path languages for the various constructions.

The c-structure and f-structures for the nested sentence (82a) are sketched in (87). The attributes and anchor are blue for the outer question dependency and green for the inner *easy* dependency. The outer path overlaps the inner path at the XCOMP of *easy* and then diverges. At that point (↑ ANC) in the question uncertainty denotes the *on* semantic form with source node n_o and the source of (→ ANC), the *play* form, is node n_p. The nesting test succeeds because n_o does not precede n_p. For the ungrammatical (82b) the anchors are reversed (88) and the test fails.

(87)



(88)



9 Multiple gap constructions

It is unremarkable in LFG that a given subsidiary f-structure may appear as the values of several attributes at different levels inside a higher structure. This is a consequence of the equality relation in functional descriptions and is the basis for accounts of functional control, agreement, distributed coordination, and the unbounded dependency of *tough* adjectives (and other unbounded dependencies if grammaticized discourse functions are retained in f-structure). Other identities might be consistent with the set of assertions in an f-description, but the linguistically-relevant minimal models contain only those that follow from the basic propositions and the transitivity of equality. This simple picture is violated by the well-known instances wherein a single unbounded-dependency filler appears to resolve to more than one (uncoordinated) within-clause grammatical function (in LFG terms) or somehow binds to more than one trace position (in other frameworks).

Sentence (89) from Engdahl (1983) is a paradigmatic example of such a multiple gap dependency.

(89) Which articles did John file __ without reading __?

This is understood as asking about a particular set of articles that were filed by John but not read by him. The second gap is usually described as "parasitic" on the first because of the contrast in (90) (following the literature, the parasitic gap is now labeled with the subscript *p*).

(90) a. * Which articles did John file the book without reading __$_p$?
b. Which articles did John file __ without reading more than their titles?

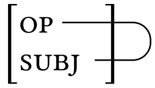
Example (90a) is ungrammatical for the usual reason that its putative gap is in an island-forming adjunct with respect to unbounded dependencies (in an LFG analysis its FocusPaths uncertainty would not satisfy the path language sac, the Subject Adjunct Constraint (67)). (89) shows that that barrier is inactive in the presence of the earlier gap, and (90b) shows that resolving to the direct object does not require the support of an adjunct gap.

Multigap dependencies have received relatively little attention in LFG compared to other grammatical frameworks. If an outside-in uncertainty is used to characterize an unbounded dependency, the natural interpretation is that the minimal model for the resulting f-description will establish only one within-clause function for the clause-initial phrase. And even if some technical adjustment is made to allow for multiple function assignments in general, it would still be necessary to account for the fact that the sac constraint of the normal FocusPaths can be abrogated just in (89) and similar multigap configurations.

Alsina (2008) discusses parasitic gaps in the context of a new general architecture for structure sharing in LFG. On his proposal the f-structure for a sentence is not the minimal model for an f-description derived from the annotations of particular c-structure rules. Rather, the universe of all formally well-formed f-structures, with unlimited structure-sharing relationships, is filtered by a collection of restrictive principles, and the sentence is assigned all and only the f-structures that are not thereby eliminated. As an example, the filter (91a) disallows structure-sharing of an op and subj at the same level (recall that op(erator) is the undifferentiating attribute that Alsina uses to represent the filler in f-structure).

(91) Alsina's (2008) "Same-clause op-subj ban"

a. *



b. For all f-structures f, $(f\ \textsc{op}) \neq (f\ \textsc{subj})$.

A formal expression of this principle is given in (91b). The basic proposition is expressed in the ordinary notation of functional annotations. But this differs from the annotations of the conventional LFG architecture in that the f-structure variable is instantiated by universal quantification over the space of all f-structures and not by mapping particular c-structure nodes through the ϕ correspondence. Alsina (2008) argues that this new architecture and the set of principles he puts forward can provide a unified treatment of bounded (raising) and unbounded dependencies, and that appropriate f-structures can be assigned to sentences with parasitic gaps. This architecture and its principles have not yet been widely adopted, however.

Falk (2011) addresses the multigap problem by an alternative analysis within the conventional LFG architecture. He reasons that if a single uncertainty can license only one dependency and if a sentence has multiple dependencies for one filler, then the f-description for that sentence must have multiple uncertainties. Further, since the number of dependencies in a multigap sentence is determined by the number of within-clause functions assigned to a given filler, the uncertainties for those dependencies must be introduced inside-out at each of the gap locations and not outside-in at the single clause-initial phrase. Thus, he proposes a trace-based, inside-out analysis that freely anticipates any number of unbounded dependencies, even though there may be no local evidence to trigger the empty c-structure nodes. Falk reviews much of the literature on parasitic gaps and other multiple gap constructions, suggesting that many of their restrictions are due to mixtures of pragmatic and processing factors and others are the result of syntactic constraints carried by the inside-out uncertainty paths with their off-path annotations.

The key fact about parasitic gaps is that they are, indeed, parasitic. That fact is not exploited directly by either the Alsina (2008) or Falk (2011) solutions to the multigap problem. In an intuitively straightforward account, an outside-in uncertainty launched at the filler phrase would resolve to the main gap (OBJ in (89)) in the ordinary one-to-one way. But then, optionally, a secondary uncertainty would be launched to bind that same filler also to the grammatical function of the parasitic gap. This is what happens if the PARA path language (92a) is imposed by intersection on the FocusPaths uncertainty (92b).

(92) a. $\textsc{para} = \textsc{gf}^{*} \underset{(\rightarrow\, = (\leftarrow\ \textsc{adj} \in \textsc{gf}^{+}))}{\backslash \textsc{subj}}$

b. FocusPaths = [...] & PARA & SAC

If FocusPaths resolves to a non-SUBJ within-clause function, the right arrow → in the optional off-path annotation denotes the top-level filler f-structure. Thus, if the option is taken, this equation launches a new uncertainty that must resolve to some function inside one of the elements of an ADJ set. By virtue of the left arrow ←, that ADJ must be an f-structure sister of the non-SUBJ. The non-SUBJ restriction is included in this example to illustrate one way of accounting for the ungrammaticality of (93); obviously, other factors may also be at work.

(93) * Which articles did you say __ got filed by John without him reading $\_\__p$?
(from Engdahl 1983)

The underlying idea of this solution is that a single filler can be bound to two gaps within an outside-in, one-to-one setting if one uncertainty is allowed to launch another one. The details of an analysis along these lines remain to be developed.

In fact, Falk (2011) notes that parasitic gaps may be a special case of a more general pattern of multiple-gap constructions. Sentences (94b–94c) show that each of the gaps in (94a) can be filled without the support of the other one.

(94) a. Who did you tell __ that you would visit __ ?
b. Who did you tell __ that you would visit your brother?
c. Who did you tell your brother that you would visit __ ?

This pattern can be assimilated to the PARA outside-in off-path solution simply by enlarging the path language of the secondary uncertainty. For this example COMP OBJ would be added as an alternative to the paths beginning with ADJ. There is still an asymmetry between the dependencies for the two gaps: only the primary uncertainty (resolving to the shorter path) is launched from the top, while the secondary one is optionally introduced at the bottom of the first. On this theory what distinguishes adjunct parasitic gaps from other multiple gap examples is just the adjunct island created by the intersection of SAC with the primary path language; that constraint is not incorporated into the secondary uncertainty.[21]

---

[21] Further research and consideration of more examples might show that multiple gaps operate symmetrically and that the sequential chaining of secondary uncertainties is therefore inadequate. That would add weight to Falk's (2011) preference for an inside-out solution. Another possibility, indifferent as to inside-out or outside-in, is to extend the interpretation of uncertainty languages in general so that multiple gaps are no longer seen as exceptional:

(i) Multi-gap functional uncertainty
If PATHS is a set of attribute strings and $\emptyset \subset \mathrm{P} \subseteq \mathit{Pref}(\textsc{Paths})$,
$(f\ \textsc{Paths}) = v$ iff $((f\ a)\ \ \mathit{Suff}(a, \textsc{Paths})) = v$ for all $a \in \mathrm{P}$
where $\mathit{Pref}(\textsc{Paths}) = \{a \mid a\sigma \in \textsc{Paths}\}$.
(the set of single-attribute prefixes of strings in PATHS)

A subset P of the available attributes would be selected at each point as an uncertainty unfolds, and the uncertain suffix of each of those attributes must recursively resolve. This is an easy adjustment, technically, but it may be difficult to define path languages so that P subsets properly handle any cross-path interactions.

10 Summary

Unbounded dependencies interact in complicated ways with the syntactic properties that define the local organization of clauses and sentences. This chapter provides a sample, clearly incomplete, of the many theoretical and empirical issues that have been discussed in the LFG literature and in the linguistic literature more broadly. The earliest LFG approaches to such dependencies were modeled after the phrase structure solutions of other frameworks, but it is now generally recognized that the functional configurations enshrined in f-structure support the most natural and direct descriptions and explanations. Accounts based directly on f-structure were made possible by extending the basic LFG formalism with the technical device of functional uncertainty.

Functional uncertainty permits the backbone dependencies of topicalization, constituent questions, relative clauses, and the *tough* construction to be stated as regular languages containing the f-structure paths that connect fillers to their within-clause functions. But unbounded dependencies are additionally challenging because they can be sensitive to various features of the f-structures they pass through. The intervening f-structures may be marked in distinctive ways, they may form dependency-blocking islands, and there may be restrictions based on linear order. This chapter has suggested that many of these ancillary effects can be accounted for by attaching off-path annotations to the uncertainty-path attributes.

In sum, the combination of functional uncertainty with off-path annotations is an expressive tool for describing the rich and varied properties of unbounded dependencies. It integrates well with the other formal devices of LFG theory, and it is the foundation for modern LFG treatments of these phenomena.

Acknowledgements

I am very grateful to Annie Zaenen for significant contributions to earlier drafts of this chapter. I thank Ash Asudeh, Mary Dalrymple, and Ida Toivonen for helpful comments and guidance along the way, and the anonymous reviewers for thoughtful criticism and advice. I of course am responsible for any remaining errors.

Chapter 11

Negation

Oliver Bond
University of Surrey

Negation is one of the few grammatical features observed in all languages. While typically thought of as a property of predicates, it can be manifested in a wide range of structural positions associated with verbs (typically, V, I or $\hat{\mathrm{I}}$ or as a verbal adjunct, represented as NEG), but is also observed on other parts of speech (e.g. D/N, C, P and CONJ) and is sometimes expressed across two or more nodes within c-structure (e.g. Butt et al. 1999, Alsharif & Sadler 2009, Laczkó 2014, Bond 2016, Alruwaili & Sadler 2018).

In the most straightforward cases there is one representation of negation at f-structure, with a binary feature indicating the presence or absence of this value. However, distributional differences between superficially similar negators, and evidence from structures with multiple negative forms within a single clause, suggest that more than one feature may be necessary to account for the syntactic and semantic effects observed in negative contexts. For instance, when a negation scopes over a sub-constituent in c-structure (so-called constituent negation or cneg) which is part of a finite syntactic structure which is also negated (known as eventuality negation or eneg) two representations of negation appear to be required within the same f-structure (Przepiórkowski & Patejuk 2015). The distribution of Negative Concord Items (NCIs), Negative Polarity Items (NPIs) and case-forms licenced by negation also suggests that multiple features must also play an important role in accounting for restrictions on the occurrence of certain forms in antiveridical contexts (Sells 2000, Camilleri & Sadler 2017).

1 Introduction

No theoretical model of language is complete without a way to represent negation or the range of grammatical effects that it induces in linguistic structures.

Oliver Bond. 2023. Negation. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 483–522. Berlin: Language Science Press. DOI: 10.5281/zenodo.10185956

Superficially, this is necessary because negation is one of the few grammatical categories that is uncontroversially universal in nature. Yet, as we will see, this does not mean that negation is especially uniform across languages: the cross-linguistic manifestations of negation are diverse and the structural consequences associated with the presence of negation are manifold and varied.[1]

For the purposes of the current chapter, I take negation to be the formal manifestation of a semantic operator $\neg$ that combines with an argument A to form a complex semantic expression $\neg A$. In propositional logic, negation combines with a propositional argument P to form $\neg P$. The presence of negation indicates that the conditions under which the proposition P is true are not satisfied at reference time.

Consider the proposition P given in (1):

(1) P: Eva is an experienced astronaut.

The truth conditions for the proposition P in (1) are not met if Eva is considered to be an inexperienced astronaut, or if she isn't an astronaut at all. In such cases we can say that P is false, and express this using negation.[2] An important logical property of negation, is that if P is false, $\neg P$ must be true. Similarly, if $\neg P$ is true, P must be false. $\neg P$ can also be paraphrased as "it is not the case that P", as shown for (1) in (2). The ability to form this paraphrase has been proposed as a rough semantic test for what Jackendoff (1969) calls *sentential negation*.

(2) $\neg P$: It is not the case that Eva is an experienced astronaut.

Jackendoff's concept of sentential negation is associated with a wide-scope reading of negation. Negation is maximally wide-scoping when the whole proposition – including the subject – is in the scope of negation.[3] In practice, in natural languages, the subject is usually an established discourse referent outside the

---

[1] For instance, negation is frequently seen as an important diagnostic tool for discriminating between different lexical categories (e.g. Stassen 1997) or structures (e.g. Brown & Sells 2016), where differential behaviour under negation is used to support linguistic argumentation. At the same time, what we intuitively think of as negation is, itself, commonly subject to diagnostics, which attempt to distinguish negatives from affirmatives, or to distinguish different subtypes of the phenomena (e.g. Jespersen 1917; Klima 1964; Jackendoff 1969; de Haan 1997; Zanuttini 2001; Giannakidou 2006; Przepiórkowski & Patejuk 2015).

[2] In this chapter, I discuss only contradictory negation. See Horn (2020) for a recent discussion.

[3] In strictly semantic terms, the scope of negation describes its operational domain. It is said to be wide, rather than narrow, when other semantic operations occur *before* negation applies. Negation with propositional scope is also commonly referred to as EXTERNAL NEGATION because the negative operation is external to the proposition.

scope of negation (Keenan 1976; Givón 1979). Consequently, the negative structures that are typically reported in grammars and general discussions of negation are examples of PREDICATE NEGATION, where negation is an evaluation of the relationship between the subject and the predicate.[4] What sentential negation and predicate negation share in common is that the *main predicate* is within the scope of negation, and the negative operator scopes over other predicate level operators (see Payne 1985; Acquaviva 1997, De Clercq 2020).

Some examples of clauses in which the predicate is negated can be seen in (3)-(5) from Polish, Modern Standard Arabic and Eleme (Niger Congo, Ogonoid; Nigeria). In the Polish example in (3) negation is marked with a negative particle *nie* (see Section 2.1). In (4), from Modern Standard Arabic, negation is expressed by a negative auxiliary *laysuu* (see Section 2.3). In the Eleme example in (5), negation is signalled through morphological means, and the affirmative verb form is quite distinct from the form employed in the negative (see Section 2.2).

(3) Polish (Przepiórkowski & Patejuk 2015: 324; own data)

a. Janek lubi Marię.
Janek.NOM likes Maria.ACC
'Janek likes Maria.'

b. Janek nie lubi Marii.
Janek.NOM NEG likes Maria.GEN
'Janek doesn't like Maria.'

(4) Modern Standard Arabic (Alsharif & Sadler 2009: 23; own data)

a. al-awlad-u ya-ktub-uu-n
the-boys-NOM 3M-study.IPFV-3MP-IND
The boys write/are writing.

b. al-awlad-u lays-uu ya-ktub-uu-n
the-boys-NOM NEG-3MP 3M-write.IPFV-3MP-IND
The boys do not write/are not writing.

(5) Eleme (Bond 2016: 283; own data)

a. òsáro è-dé-a òfí́
Osaro 3[SG]-eat-HAB mango
'Osaro (usually) eats mango.'

---

[4] cf. Jespersen's (1917) NEXAL NEGATION, Klima's (1964) SENTENCE NEGATION, and Payne's (1985) STANDARD NEGATION.

b. òsáro è-dé~dè òfí
Osaro 3[SG]-NEG~eat[HAB] mango
‘Osaro doesn’t (usually) eat mango.’

As well as having means to negate the main predicate of the clause, languages frequently have negators with distinct behavioural properties that do not have scope over the finite predicate and hence can be said to have low(er) negative scope (De Clercq 2020). Negators of this type are typically bundled together in descriptions as examples of CONSTITUENT NEGATION. The term ‘constituent negation’ has its origins in the work of Klima (1964), who formulated a range of now famous tests to distinguish it from negation with scope over the predicate (see Payne 1985, de Haan 1997 and De Clercq 2020 for discussion). An example of constituent negation in English can be seen in (6). Here a verbless secondary predication modifying a noun is in the scope of negation, but not the main predicate. Such negators are said to have narrow scope.

(6) Dora found a job [not far away].
(cf. Dora found a job that is not far away.)

It is common to find that negators used to negate predicates may also be used in narrow scope negation (De Clercq 2020). The following Hungarian data from Laczkó (2014: 306–7) illustrate predicate negation (7a) and narrow-scope negation over the object referent (7b). Small caps indicate focussed elements. In (7a) negation scopes over the predicate, or put another way, the truth conditions for the relationship between the predicate and its subject are not met. In (7b), narrow scope negation indicates that it is the relationship between the object referent and the rest of the assertion that is relevant.

(7) Hungarian (Laczkó 2014: 306–307)

a. Péter nem hívta fel a barátjá-t.
Peter.NOM not called up the friend.his-ACC
‘Peter didn’t call up his friend.’

b. Péter NEM A BARÁTJÁ-T hívta fel
Peter.NOM not the friend.his-ACC called up
‘It wasn’t his friend that Peter called up.’

In (8) these two strategies are combined within the same clause, providing evidence for the need to be able to simultaneously distinguish these types of negation within formal models (see Section 3 for discussion).

(8) Hungarian (Laczkó 2014: 306–7)
Péter NEM A BARÁTJÁ-T nem hívta fel.
Peter.NOM not the friend.his-ACC not called up
'It wasn't his friend that Peter didn't call up.'

Cross-linguistically, narrow-scope negation is formally distinguished from wider-scoping predicate negation by a variety of means, including differences in syntax, the use of different negators or prosodic alternations, etc.

Other examples that are described as constituent negation involve negative quantifiers modifying a noun, as in (9). In such cases the negation of the predicate is achieved through a more complex process of logical implication:

(9) Dora found no [reason to worry].
(cf. Dora didn't find a reason to worry.)

Informally, we can say of (9) that if Dora found no reason to worry, the reasons to worry equal zero, therefore Dora didn't find any (i.e. > 0) reason to worry. Quantifiers interact with negation in a number of complex ways and the literature on this topic is extensive (see Krifka 1995; de Swart 2009; Penka 2010 amongst others). While negation and quantification have been subject to some discussion in the LFG literature (Fry 1999; Dalrymple 2001: 291–295; 309–311), I will leave this topic aside.

While syntax and semantics often align, the scope of negation should really be considered to be a semantic phenomenon (see Penka 2016 for an overview of negation in formal semantics), and must be analysable within the semantic component of grammar in parallel to considering how this is played out in syntax and prosody. In practice, when authors talk about scope, they often treat it as a syntactic phenomenon because of differences in the syntactic domain in which the effects of negation can be observed (see Reinhart 1979; Szabolcsi 2012). Because of this, the term SCOPE is typically also used to refer to the syntactic domain in which the effects of negation are observed. However, it is useful to untangle these two properties of negative clauses. This is – in theory – easy to do in a model like LFG because syntax and semantics are dealt with in separate, yet parallel modules of grammar. Establishing the extent to which the two are independent is one of the major goals of investigating the syntax-semantics interface.

It should be clear from this brief overview that an adequate discussion of the topic necessitates not only an exploration of the formal devices used to express negation (and the domains in which the effects of negation are observed), but also how this relates to the semantic interpretation of the utterance.

Most analyses of negation in LFG to date have focussed on the syntactic properties of negation constructions by examining the role of negation in c-structure and f-structure, most notably Sells (2000) on Swedish, Alsharif & Sadler (2009) on Arabic, Przepiórkowski & Patejuk (2015) on Polish and Camilleri & Sadler (2017) on Maltese. Despite a growing body of work in this domain (some of which is briefly outlined in Dalrymple et al. 2019: 67–69), negation has remained focussed on the syntactic properties and effects of negation. A rare exception is Dalrymple & Nikolaeva (2011) who briefly discuss the semantic contribution of negation within the context of information structure, while Bond (2016) examines issues related to the morphological expression of negation (Section 2.2).

Negation is manifested using a variety of formal devices which differ according to the extent to which this affects (i) syntactic constituency of negative clauses and (ii) the domains in which operations sensitive to negation occur. In what follows, we first look at the arguments that support possible representations of syntactic components of grammar (Section 2) before exploring the representation of negation in a component of grammar unique to LFG, namely f-structure (Section 3).

2 Representations of negation as a formative

Negation of verbal predicates can be manifested in a wide variety of ways, most commonly by (adverbial) particles (Section 2.1), changes in verbal morphology (Section 2.2) or through the use of a negative auxiliary (Section 2.3). A combination of these strategies is also widely attested (Section 4).

2.1 Negative particles

A large body of cross-linguistic work (Dahl 1979; Dryer 1989; Payne 1985; Miestamo 2005; Dryer 2013) indicates that the most common way in which the world's languages express the negation of propositions about (epistemically unmodified) dynamic events, i.e STANDARD NEGATION (Payne 1985; Miestamo 2005) or 'clausal negation in declarative sentences' (Dryer 2013)) is through the use of a uninflecting negative particle. This is observed in at least 44% (n=502) of Dryer's 2013 sample of 1157 languages. Further languages in his sample including a particle as part of a more complex strategy consisting of multiple formatives (n=119), and others still classified as unclear with respect to whether they are particles or uninflecting negative auxiliary verbs (n=73).[5] Given their isomorphic nature,

---

[5] The numbers from the *World Atlas of Language Structures* reported here are those from Dryer (2013); those presented in the earliest editions were lower due to a programming error.

Bond (2013) takes the expression of negation through the use of particles to be a property of canonical negation.

In typological work on negation, the term PARTICLE is used as a general term for an independent word whose distribution is not better characterised in reference to a larger class of items, and includes negators described as negative adverbs. The syntactic status of negative particles (in this typological sense) has been one of considerable attention within the theoretical syntactic literature (see Pollock 1989; Haegeman 1995; Zanuttini 1997; Rowlett 1998 among others), including LFG (see Butt et al. 1999; Przepiórkowski & Patejuk 2015). This is in part motivated by the fact that the negative particle in English (and similar forms in related languages) are usually described as adverbs. While they frequently share some of the properties of adverbs in the language in which they are found, they also tend to have special syntactic characteristics that make them distinct. These characteristics, such as restrictions on their syntactic position, or the inability to be modified, make them unlike regular phrasal heads (e.g. Butt et al. 1999: 141–142). Crucially, these properties differ even among closely related languages, demonstrating that adopting the category 'particle' in broadscale typological work presents a convenient opportunity to be vague rather than explicit about the syntactic properties of any given negative formative. For instance, taking a minimalist approach, Repp (2009) argues that while both are described as adverbs in their respective descriptive traditions, German *nicht* and English *not* have different syntactic behaviour. The former is proposed to be a simple adverbial adjoining to the verb phrase (VP) while the latter is a functional head projecting a NegP. Butt et al. (1999: 141–142) conclude that *nicht* and *not* both belong to a special category NEG that distinguishes them from other adverbs, with the differences in their distribution encoded in c-structure rules.

In many Chomskian treatments of negation in English, *not* is the specifier of NegP, a separate negative projection (see Pollock 1989; Repp 2009; amongst others). Even if the validity of the NegP approach seems appropriate in some analyses, the existence of such a functional head for all instances of negation would not be consistent with the lexicalist approach to syntax. Negation is commonly expressed through morphological alternations that suggest this is a considerably less useful tool for accounting for negation in languages where the category is expressed through non-concatenative morphology (Section 2.2).

This leads to us to the first problem of determining how negative particles should be represented in the X-bar theory employed to represent c-structure in most LFG work. Given that negation can be associated with almost any part of speech, and a functional projection in LFG is not required for the purposes of movement, is a NegP motivated within a declarative theory of syntax at all?

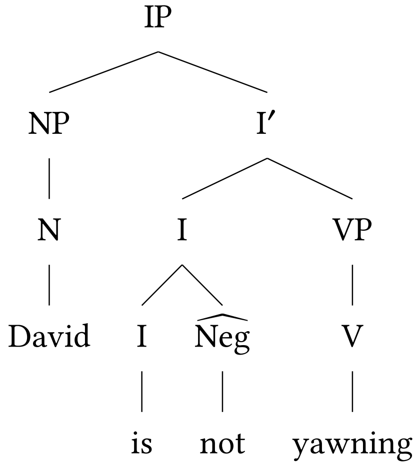
There are several possibilities with respect to dealing with this issue: first, that a node in constituent structure is required that has the properties of a regular phrasal head (e.g. AdvP), second that a special functional head is required (i.e. NegP), or third that the negative particle occupies a non-projecting phrase (in the sense of Toivonen 2003).

The first major paper dedicated to tackling negation with the LFG framework is Sells (2000), who proposes an account of negation in Swedish. Therein, he considers whether a NegP is required to account for the distribution of the negative adverb *inte*. He reviews the evidence in favour of positioning the Swedish negative adverb *inte* inside or outside the VP, concluding that neither the negation adverb *inte* nor negative quantifiers can appear within the VP. Sells observes that the unmarked position for negation is to the left of VP, though positions higher up in IP and CP are also possible. He concludes that *inte* occupies a special NEG node in c-structure, but argues against the view that a NegP is required to account for its syntactic properties.

As with Swedish *inte*, English *not* is usually described as an adverb, but they have different distributions. Since *not* must be preceded by a tensed auxiliary verb when expressing sentential negation, as in (10), Dalrymple (2001: 61) assumes that it is adjoined to the tensed verb in I, as illustrated in (11). A similar structure is proposed in Bresnan (2001a).

(10) David is not yawning.

(11) English non-projecting negative particle *not* (based on Dalrymple 2001: 61)



While brief, Dalrymple's (2001: 61) analysis captures an observation that some negative particles are non-projecting categories that are not heads of phrases, but adjoin to heads. Toivonen (2003) proposes that non-projecting categories have distinct characteristics that make then unlike regular phrases:

- They are independent words which do not project a phrase.
- They must adjoin to X^0 (i.e. at the lexical level).
- They cannot take complements or modifiers.

In (11), *Neg* is not a NegP, but a non-projecting word adjoined to I.

A similar analysis of negative particles is proposed by Alsharif & Sadler (2009) and Alsharif (2014), who examine negation in Modern Standard Arabic (MSA). MSA has three negative particles used with imperfective predicates *laa*, *lam* and *lan*. The particles differ according to the grammatical categories with which they combine. Each occurs with a verbal element as the main predicate: *laa* occurs with the indicative imperfective, *lam* with the jussive imperfective expressing negation in the past, and *lan* with the subjunctive imperfective, expressing negation in the future (Alsharif & Sadler 2009: 8). Regardless of combinatorial potential, their default syntactic distribution is the same – immediately before the auxiliary – as illustrated in (12).[6]

(12) MSA (Benmamoun 2000: 95 cited in Alsharif & Sadler 2009: 7-8)

a. t-tullaab-u laa ya-drus-uu-n
the-students-nom neg 3m-study.ipfv-3mpl-ind
'The students do not study/are not studying.'

b. t-tullaab-u lan ya-dhab-u
the-students-nom neg.fut 3m-go.ipfv-mpl.sbjv
'The students will not go.'

c. t-tullaab-u lam ya-dhab-uu
the-students-nom neg.pst 3m-go.ipfv-mpl.juss
'The students did not go.'

Given strong adjacency restrictions between the particle and the following auxiliary verb, Alsharif & Sadler (2009) propose they are non-projecting categories adjoined to I. The c-structure representation for (13) (without the time adverbial) is given in (14). Syntactically, the particle *laa* occupies a node $\widehat{\text{I}}$ that is defined according to that on which it is structurally dependent, I.

---

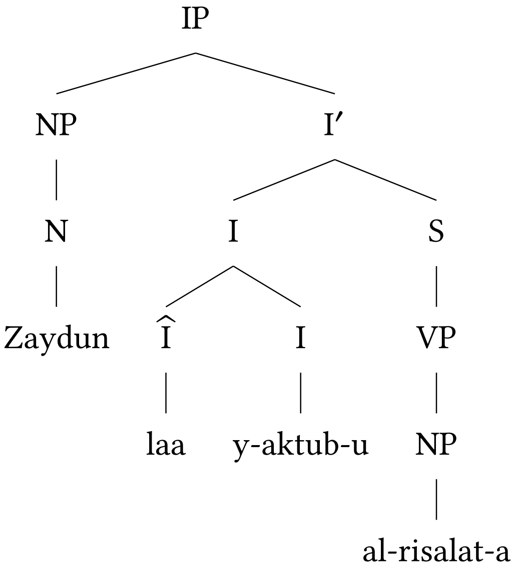
[6] I have adjusted the glosses in these examples to correct segmentation issues in the original examples.

(13) MSA (Alsharif & Sadler 2009: 7)

Zayd-un	laa	y-aktub-u	al-yawm-a	al-risalat-a
Zayd-NOM	NEG	3M-write.IPFV-3MS.IND	the-day-ACC	the-letter-ACC

Zayd is not writing the letter today.

(14) MSA non-projecting negative particle *laa* (Alsharif & Sadler 2009: 14)



The lexical entry for *laa* is given in (15).

(15) *laa* $\hat{\text{I}}$ (↑ TENSE PAST) ≠ +
(↑ POL) = NEG
(Alsharif & Sadler 2009: 16)

It specifies that its f-structure has the polarity value NEG , but also that it cannot have the tense value PAST. Equations of this type can be used to account for the distribution of different negative forms within the same language, as indicated by the lexical entries in (16) and (17) for *lam* and *lan*.

(16) *lam* $\hat{\text{I}}$ (↑ TENSE PAST) = +
(↑ POL) = NEG
(↑ MOOD) $=_c$ JUSS
(Alsharif & Sadler 2009: 16)

(17) *lan* $\hat{\text{I}}$ (↑ TENSE FUT) = +
(↑ POL) = NEG
(↑ MOOD) $=_c$ SBJV
(Alsharif & Sadler 2009: 16)

The possibility within LFG to formulate different lexical entries for different negators provides an additional opportunity to account for differences in their behavioural distribution and the features with which they are compatible.

2.2 Negative verbal morphology

Negation is indicated by verbal morphology in at least 36% of the word's languages (Dryer 2013).[7] There is a slight preference for prefixation of negative affixes over suffixation (Dryer 2013), which reflects a general cross-linguistic preference for negators to precede the verb (Dryer 1989).

In a lexicalist approach to syntax like LFG, it is notionally straightforward for negation to be expressed morphologically, but there is little consensus about how morphology itself should be modelled. The main issue is that affixes are often presented as having lexical entries that are distinct from their hosts. This suggests that an incremental model of morphology has been used in which morphosyntactic information gets added incrementally as morphemes are added to a stem (see Camilleri & Sadler (2017: 158) on the lexical entries for Polish *nie* discussed in Section 3.3). However, there are strong arguments for adopting a realizational approach in accounting for morphology, whereby a word's association with certain morphosyntactic properties licenses morphological operations. Under an approach of this kind, having distinct lexical entries for negative morphemes is highly questionable.

The first detailed LFG analysis of negation expressed through morphological means is provided in Bond (2016), who examines the expression of negation through tone and reduplication within Eleme (Niger-Congo, Cross River, Ogonoid) spoken in Rivers State, Nigeria. Like many other languages across Africa, Eleme has a multitude of means for expressing negation, many of which involve negation morphology. Negation in Eleme is distinctive from a cross-linguistic perspective in that in addition to affixation, negation of verbal predicates is also indicated though other morphological means, notably tonal alternations and stem reduplication. Two of the basic alternations, between perfectives and habituals are shown in (18) and (19).

Negation of perfectives is realised using a set of prefixes with the shape *rV́-*. The quality of the vowel is dependent on several factors: (i) the person and number of the subject, (ii) vowel harmony with the initial segment of the verbs stem (Bond 2016: 280).[8] The negative prefix is obligatorily realised on Negative Per-

---

[7] This is a conservative figure calculated from the addition of two categories in Dryer's sample of 1157 languages: *negative affix* (n = 395) and *variation between negative word and affix* (n =21).

[8] There is also intra-speaker variation in the realisation of the initial consonant, which varies between an alveolar nasal and alveolar approximant.

fective verb forms.[9] It is the only clear exponent of negation in (18b). However, in certain discourse contexts, prefixation is accompanied by pre-reduplication of the initial mora of the verb stem – shown in parentheses in (18b). This results in full reduplication of monomoraic stems and partial reduplication of bimoraic stems (see Bond 2016: 281 for examples).

(18) Eleme (Bond 2016: 281)

a. ǹ-sí
1sg-go
'I went.'

b. rī́-(si)~sí
neg.1sg-(neg)~go
'I didn't go.'

Habitual predicates in Eleme are distinguished by the presence of a Habitual suffix *-a* on the lexical verb stem, as in (19a). Negative Habituals are formed through the obligatory pre-reduplication of the first mora of the verb stem, as in (19b). The presence of the Habitual suffix *-a* is not attested in Negative Habituals, giving rise to an asymmetric pattern of negation in the sense of Miestamo (2005). Negative Habituals do not have a negative prefix. In (19b), negation is expressed though stem reduplication and tone.

(19) Eleme (Bond 2016: 278)

a. ǹ-sí-a
1sg-go-hab
'I (usually) go.'

b. ǹ-sí~sì
1sg-neg~go
'I don't (usually) go.'

Some examples of transitive constructions are given in (20).

(20) Eleme (Bond 2016: 283; own data)

a. òsáro ré-de~dé òfī́
Osaro neg.3sg-(neg)~eat[hab] mango
''Osaro didn't eat (any) mango.'

---

[9] Perfectivity is a default category in Eleme and is not overtly realised on verb stems by segmental morphology.

b. òsáro è-dé~dè òfí́
Osaro 3[SG]-NEG~eat[PFV] mango
‘Osaro doesn’t (usually) eat mango.’

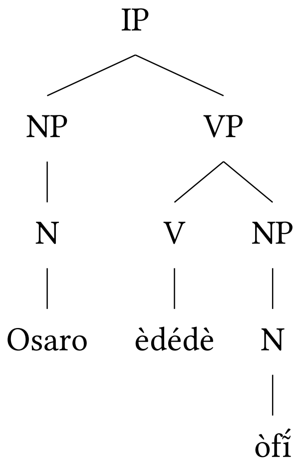
The examples show that there is no single affix that can be picked out for accounting for negation in Eleme, rather a number of different morphological processes are responsible for deriving negative verb stems (and a distinct theory of morphology is required to account for that because LFG does not yet have its own established native approach). In languages like Eleme, the feature responsible for contributing negation to the f-structure for clauses of this type comes directly from the lexical entry for the verb. Lexical entries for these verb forms are given in (21) and (22):

(21) *rédedé* V (↑ PRED) = ‘EAT⟨SUBJ,OBJ⟩’
(↑ POL) = NEG
(↑ ASP) = PFV
(↑ SUBJ PERS) = 3
(↑ SUBJ NUM) = SG

(22) *èdédè* V (↑ PRED) = ‘EAT⟨SUBJ,OBJ⟩’
(↑ POL) = NEG
(↑ ASP) = HAB
(↑ SUBJ PERS) = 3
(↑ SUBJ NUM) = SG

The c-structure for (20b) is provided in (23).

(23) C-structure containing an Eleme Negative Habitual verb *èdédè*



The central claim about negative verbs of this kind, whether negation is expressed by affixation, stem modification, reduplication, tone or any other morphological means, is that morphological negators do not occupy a syntactic node distinct from the element of which they are part, and any morphological exponent that can be identified as marking negation should be understood to be a property of a verb form (i.e. part of a paradigm) rather than having its own distinct lexical entry.

HPSG analyses of the morphological expression of negation (e.g. Borsley & Krer 2012, Kim 2000, Kim 2021) likewise propose that morphological exponence is dealt within the lexical component of grammar and, therefore, individual morphological exponents have no syntactic status distinct from the word of which they are part. Kim (2000) proposes that negation marked by affixation is achieved by a lexical rule (see Kim 2021 for a summary). The view of morphology proposed in Bond (2016) is a more complex one, chosen to deal with non-concatenative exponents as well as more straightforward instances of affixation. However, the basic underlying assumption is the same; morphology is governed by autonomous, non-syntactic principles (Bresnan & Mchombo 1995).

In derivational theories of syntax in which morphology is considered to be a post-syntactic process, there is no divide between the construction of words and sentences. In Distributed Morphology (DM), for instance, words are formed through syntactic operations like Merge and Move. Negative affixes – like other affixes expressing inflectional information – are realisations of abstract morphemes that are merged with roots. No such motivation for morphological operations needs to be justified within a lexicalist theory like LFG. There are two main approaches to accounting for reduplication in DM (see Frampton 2009, Haugen 2011 for discussion). Reduplication is proposed either to result from a readjustment operation on some stem triggered by a (typically null) affix, or through the insertion of a special type of affix which is inserted into a syntactic node in order to discharge some morphosyntactic feature(s), but which receives its own phonological content, distinct from its base. Recent proposals concerning the analysis of tone expressing grammatical categories can be found in Rolle (2018) and Pak (2019). See Chung (2007) on negation and suppletive forms in DM. A combination of these approaches would be required to account for morphologically complex expressions of negation like those seen here.

2.3 Negative auxiliaries

Negative auxiliaries are widely attested in the world's languages. Alongside the negative particles discussed in Section 2.1, MSA also has a negative auxiliary *laysa* employed in negative imperfectives.

Alsharif & Sadler (2009) argue that *laysa* is a fully projecting I, taking a range of complements. Unlike the particles discussed in Section 2.1, it is not subject to verb-adjacency restrictions, as illustrated in (24).[10] If the negative auxiliary verb is preceded by its subject, it agrees with it in gender and number. If the subject follows the auxiliary, number agreement is defective, and a default singular form is used.

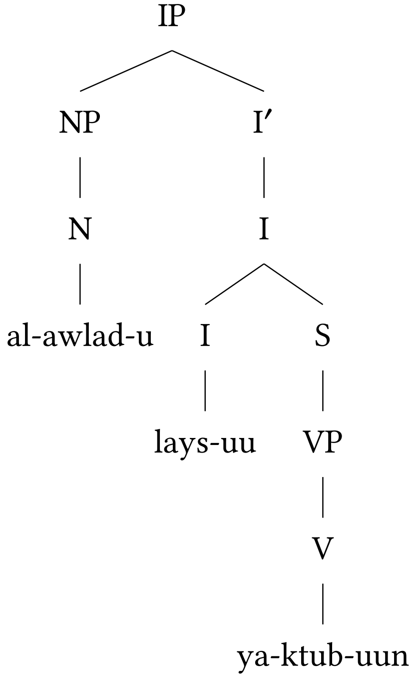
(24) MSA (Alsharif & Sadler 2009: 23)

a. al-awlad-u lays-uu ya-ktub-uun
the-boys-NOM NEG-3MP 3M-write.IPFV-3MP-IND
The boys do not write/are not writing.

b. lays-a al-awlad-u ya-ktub-uun
NEG-3MS the-boys-NOM 3M-write.IPFV-3MP-IND
The boys do not write/are not writing.

The corresponding c-structures for the examples in (24) are given in (25) and (26).

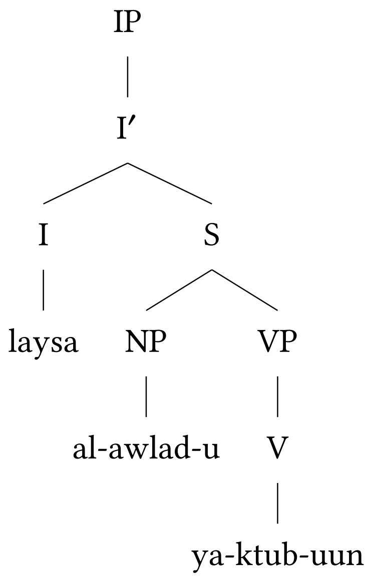
(25) MSA negative auxiliary *laysa* in S-AUX order (Alsharif & Sadler 2009: 23)



---

[10] The gloss in (24b) has been corrected from the original source to show that number on the negative auxiliary is defective when it precedes the subject (Alsharif & Sadler 2009: 7).

(26) MSA negative auxiliary *laysa* in AUX-S order (Alsharif & Sadler 2009: 23)



The differences between the behaviour of the negative particles (see discussion in Section 2.1) and the negative auxiliary in MSA are captured by differences in their lexical entries. The lexical entry for *laysa* is provided in (27).

(27) *laysa* I (↑ TENSE PAST) = −
(↑ TENSE FUT) = −
(↑ POL) = NEG
(↑ SUBJ PERS) = 3
(↑ SUBJ GEND) = MASC
V ∈ CAT(↑) ⇒ (↑ ASP) $=_c$ PROG
(Alsharif & Sadler 2009: 24)

Dalrymple & Nikolaeva (2011: 87) propose that English *didn't* also occupies the I node in c-structure (cf. *not* as a non-projecting head adjoined to I in Section 2.1).

3 Representations of negation as a feature

Negation is usually thought of as a property of a predicate, closely associated with verbal elements within the clause. Within f-structure representations, negation is typically represented in one of three distinct ways: as a feature-value pair (Section 3.1), as an adjunct with a negative value (Section 3.2), or by recognising that negation may be represented by multiple features within the same f-structure (Section 3.3).

3.1 Single feature-value pair

The majority of LFG analyses of negation treat negation as a value of predicate-level feature pol(arity). Like other attributes in the f-structure such as [tense] and [asp], the [pol] specification has more than one possible value, either represented as a binary feature (i.e. = ±pol or ±neg), or a feature with multiple values, e.g. [aff] and [neg]. The former approach is used by King (1995), Niño (1997), Butt et al. (1999), Bresnan (2001b: 183) and Dalrymple & Nikolaeva (2011: 87) , while Alsharif & Sadler (2009) and Bond (2016) employ the multiple value approach (i.e. pol: neg). Falk (2001: 12, 149) uses neg+ and pol: neg within the same book.

In each case, it is always possible to identify an inherently negative element; this element always contributes the specification [pol −], [neg +] or [pol neg] to f-structure. They are all used to represent exactly the same thing, using different notation systems. In the lexical entries so far, I have used the attribute pol, with the value neg, to account for sentential negation.

In the illustrations of the different proposals that follow, I use the representation system proposed in the original analysis.

Let's start by considering the English example in (28) from Dalrymple & Nikolaeva (2011: 87), with the f-structure in (29).

(28) John didn't love Rosa.

(29)
$$\begin{bmatrix} \textsc{pol} & - \\ \textsc{pred} & \text{‘}\textsc{love}\langle\textsc{subj}, \textsc{obj}\rangle\text{’} \\ \textsc{subj} & \begin{bmatrix} \textsc{pred} & \text{‘John’} \end{bmatrix} \\ \textsc{obj} & \begin{bmatrix} \textsc{pred} & \text{‘Rosa’} \end{bmatrix} \end{bmatrix}$$

Here, the only representation of negation in the f-structure is with the feature pol (Dalrymple & Nikolaeva 2011: 87). The '−' specification indicates that it does not have affirmative polarity.

3.2 Adjunct value

In contrast to introducing negation through a binary feature (e.g. neg), in some LFG analyses, negation is introduced as an appropriate element of the adj(unct) feature, as illustrated in (31) for (30), discussed in Przepiórkowski & Patejuk (2015: 323–324).[11]

---

[11] Przepiórkowski & Patejuk (2015) state that, within PARGRAM, the majority of XLE implementations of negation to date take this approach, but this is not reflected in the LFG literature, in which verbal negation is nearly always represented by a feature in works that predate their paper (e.g. Sells 2000, Alsharif & Sadler 2009).

(30) John doesn't like Mary.

(31)
$$\begin{bmatrix} \textsc{pred} & \text{`}\textsc{like}\langle\textsc{subj, obj}\rangle\text{'} \\ \textsc{subj} & \begin{bmatrix}\textsc{pred} & \text{`}\textsc{John}\text{'}\end{bmatrix} \\ \textsc{obj} & \begin{bmatrix}\textsc{pred} & \text{`}\textsc{Rosa}\text{'}\end{bmatrix} \\ \textsc{adj} & \left\{\begin{bmatrix}\textsc{pred} & \text{`}\textsc{not}\text{'} \\ \textsc{adj-type} & \textsc{neg}\end{bmatrix}\right\} \end{bmatrix}$$

Here, the ADJ(unct)-TYPE feature enables the syntactic properties of negative adjuncts to be distinguished from other adjuncts.[12] One rationale for adopting this approach is that it makes it easy to represent multiple negation (via multiple negative elements of the ADJ set). This is the approach taken by Laczkó (2014) in his account of negation in Hungarian, where both predicate negation and narrow-scope negation are treated as adjuncts because they can co-occur, as in (32) repeated from (8).

(32) Hungarian (Laczkó 2014: 307)
Péter NEM A BARÁTJÁ-T nem hívta fel.
Peter.NOM not the friend.his-ACC not called up
'It wasn't his friend that Peter didn't call up.'

Importantly, both instances of *nem* occur in the same clause, although not in the same f-structure (cf. the bi-clausal translation in English). The simplified f-structure in (33), representing (32), is consistent with the essence of Laczko's (2014) analysis of similar sentences.[13]

(33)
$$\begin{bmatrix} \textsc{pred} & \text{`}\textsc{call.up}\langle\textsc{subj, obj}\rangle\text{'} \\ \textsc{subj} & \begin{bmatrix}\textsc{pred} & \text{`}\textsc{Peter}\text{'} \\ \textsc{case} & \textsc{nom}\end{bmatrix} \\ \textsc{obj} & \begin{bmatrix}\textsc{pred} & \text{`}\textsc{his friend}\text{'} \\ \textsc{case} & \textsc{acc} \\ \textsc{adj} & \left\{\begin{bmatrix}\textsc{pred} & \text{`}\textsc{not}\text{'} \\ \textsc{adj-type} & \textsc{neg}\end{bmatrix}\right\}\end{bmatrix} \\ \textsc{adj} & \left\{\begin{bmatrix}\textsc{pred} & \text{`}\textsc{not}\text{'} \\ \textsc{adj-type} & \textsc{neg}\end{bmatrix}\right\} \end{bmatrix}$$

---

[12] An anonymous reviewer points out that there are added complications associated with this model in accounting for the presence of *do* in English negatives if *not* is added as an adjunct.

[13] Laczko's (2014) formalisations are somewhat idiosyncratic in that his f-structure representations deviate from those typically seen in the LFG literature. While he does not actually provide an f-structure containing two instances of *nem*, there is much more analysis included in the paper than can be discussed here, and readers are directed to his paper for an extensive discussion of negation in Hungarian.

One of the major issues with this approach concerns how to limit the number of instances of the adjunct with clauses. Przepiórkowski & Patejuk (2015) report that in a later presentation, Laczkó (2015) revises his account, suggesting that two binary features may be necessary to account for the negation in Hungarian. He proposes distinguishing between ±POL and ±NEG, where each is a different feature (rather than different ways of notating the same feature).

3.3 Multiple feature-value pairs

Building on the observations made by Laczkó (2015) for Hungarian, Przepiórkowski & Patejuk (2015) propose that two different types of binary-valued attributes are required to account for negation in Polish. This distinction is motivated by (i) the distinctive behaviour of two sets of negative constructions in which the negator *nie* exhibits different degrees of syntactic independence, and (ii) the possibility that two instances of negation can occur within the same clause. This leads them to propose two distinct features known as EVENTUALITY NEGATION (ENEG) and CONSTITUENT NEGATION (CNEG).

While typically represented orthographically as a separate word, manifestations of *nie* can be broadly distinguished as 'bound' and 'independent'. Bound *nie* has a strong adjacency requirement with its host, and is described as a prefix that forms a prosodic unit with the stem to which it attaches (Kupść & Przepiórkowski 2002; Przepiórkowski & Patejuk 2015: 324). Negation expressed by prefixal *nie* cannot scope over co-ordinands, demonstrating that its semantic effects are bounded. It triggers a range of syntactic effects: first, it requires that otherwise accusative arguments of the element that is negated occur in the genitive case (the so-called 'genitive of negation'), seen in (34a), and second, it licences a syntactic domain in which negative indefinites occur, shown in (34b).

(34) Polish (Przepiórkowski & Patejuk 2015: 324)

a. Janek nie lubi Marii.
Janek.NOM NEG likes Maria.GEN
'Janek doesn't like Maria.'

b. Nikt nie lubi nikogo.
nobody.NW.NOM NEG likes nobody.NW.GEN
'Nobody likes anybody.'

Bound *nie* is associated with eventuality negation, so called because it is used to negate eventualities (i.e. events and states). The syntactic properties associated with ENEG are observed when *nie* is realised on verbs, adjectives and deadjectival adverbs, and it is for this reason that they favour the adoption of the term eventuality negation over sentential negation or predicate negation (Przepiórkowski & Patejuk (2015: 324–326) for discussion of this). Negative indefinite pronouns (see Section 5.2) are also licensed by the preposition *bez* 'without', leading Przepiórkowski & Patejuk (2015: 326) to suggest that this also introduces a value for the ENEG feature.

In contrast to the bound realisation, independent *nie* may be separated from the constituent over which it scopes (Przepiórkowski & Patejuk 2015: 329), indicating that it is not a morphological exponent of negation. This structural difference is reflected in a number of associated effects. Unlike the bound negator, it can scope over co-ordinands, and it does not licence negative case alternations or negative indefinites, as shown by the ungrammaticality either of the genitive object *Marii* or an negative indefinite pronoun object, in (35).

(35) Polish (Przepiórkowski & Patejuk 2015: 326)
Nie Janek lubi Marię \ *Marii \ *nikogo (lecz
NEG Janek.NOM likes Maria.ACC Maria.GEN nobody.NW.ACC/GEN but
Tomek).
Tomek.NOM
'It is not Janek that likes Maria (but Tomek).'

Crucially, the two different types of negation are sometimes attested in superficially similar environments, as seen with infinitival clauses. In (36), in which the infinitival clause, but not the head of the main predicate is within the scope of negation, the genitive of negation is not permitted. This is an example of CNEG. In (37), where the negated infinitival clause functions as the post-verbal subject, only genitive case is permitted: this is an example of ENEG. Similar effects are observed with the licensing of negative indefinites (Przepiórkowski & Patejuk 2015: 327).

(36) Polish (Przepiórkowski & Patejuk 2015: 326)
Ma skakać, a nie pisać wiersze \ *wierszy.
has jump.INF and NEG write.INF poems.ACC poems.GEN
'He is to jump, and not to write poems.' [of a sportsman]

(37) Polish (Przepiórkowski & Patejuk 2015: 327)
Poetyckim marzeniem Karpowicza było: nie pisać wierszy \
poetic.INS dream.INS Karpowicz.GEN was NEG write.INF poems.GEN
*wiersze.
poems.ACC
'The poetic dream of Karpowicz was not to write poems.'

Building on these observations, Camilleri & Sadler (2017: 158) propose the following (basic) lexical entries for the two types of negation, in order to provide an explicit characterisation of their differences:

(38) nie: ENEG (↑ ENEG) = +
(Camilleri & Sadler 2017: 158)

(39) nie: CNEG (↑ CNEG) = +
(Camilleri & Sadler 2017: 158)

In their formalisation, the lexical entries are identical other than the feature they introduce. However, since *nie* is a prefix when introducing the ENEG value, and is therefore part of the morphology of the verb, this should not be considered to have a lexical entry that is distinct from that of the verb form of which it is part (cf. Bond's 2016 analysis of negative verbs forms in Eleme, discussed in Section 2.2). A minimal lexical entry for *niepisác* is provided in (40).

(40) *niepisác* V (↑ PRED) = ‘WRITE⟨SUBJ, OBJ⟩’
(↑ ENEG) = +

These two different features are required to account for the fact that both types of negation may occur in the same clause, as shown in (41) (cf. ‘The Catholic Church not cannot…’). Przepiórkowski & Patejuk (2015: 327) do not distinguish the two types of negation in their glossing.

(41) Polish (Przepiórkowski & Patejuk 2015: 327)

Kościół	katolicki	nie	nie	portrafi,	ale	nie	chce.
church.NOM	catholic.NOM	NEG	NEG	can	but	ENEG	want

‘It's not that the Catholic Church cannot, but rather that it doesn't want to.’

Przepiórkowski & Patejuk (2015: 327) propose the following f-structure to account for the first part of (41):

(42)
$$\begin{bmatrix} \text{ENEG} & + \\ \text{CNEG} & + \\ \text{PRED} & \text{‘CAN}\langle\text{SUBJ, XCOMP’}\rangle \\ \text{SUBJ} & \left[\text{PRED ‘CATHOLIC CHURCH’}\right] \\ \text{XCOMP} & [\ldots] \end{bmatrix}$$

Other scholars have also observed that more than one negation may be required within a clause (e.g. Butt et al. 1999, Sells 2000, Laczkó 2014). We now explore this subject in Section 4 in relation to bipartite negation, and in Section 5 in relation to antiveridical contexts.

4 Multipartite negation

In many languages, negation is reflected in the formal properties of multiple elements with the clause. For instance, Standard (Written) French usually requires the use of preverbal *ne* and post-verbal *pas* in the formation of negative clauses.[14] In a very brief analysis, Butt et al. (1999: 142–143) propose that both elements should be represented in f-structure, with the initial component *ne* contributing a neg feature, and *pas* contributing a related feature neg-form, as illustrated for (43) in (44) from Dalrymple et al. (2019: 67).

(43) French (adapted from Butt et al. 1999: 143, following Dalrymple et al. 2019: 67)
David n' a pas mangé de soupe.
David neg have postneg eaten of soup
'David did not eat any soup.'

(44)

$$\left[\begin{array}{ll} \textsc{neg} & + \\ \textsc{neg-form} & \textsc{pas} \\ \textsc{pred} & \text{‘}\textsc{eat}\langle\textsc{subj}, \textsc{obj}\rangle\text{’} \\ \textsc{subj} & \left[\textsc{pred}\ \text{‘David’}\right] \\ \textsc{obj} & \left[\textsc{pred}\ \text{‘}\textsc{soup}\text{’}\right] \end{array}\right]$$

In the analysis of Butt et al. (1999: 142–143), the marker providing the neg + feature at f-structure may only appear if the neg-form feature, contributed by the other negative particle, is present.

Their proposal aims to capture the view that (i) two distinct manifestations of negation are required to negate a clause, (ii) that there is an asymmetry between the roles of the negators in terms of their featural specification, and (iii) that the presence of *ne* is dependent on the presence of some other negative formative. This helps to account for the distribution of *ne* in clauses like (45), where it co-occurs with the adverb *jamais* 'never'.[15] However, their analysis does not deal with the use of *pas* as the only negator of a clause, as typically found in spoken French varieties. In such cases, *pas* must either be treated as separate negative item that contributes a neg feature without *ne*, or a more serious revision to this analysis is required.

---

[14] This is not true of colloquial varieties of French, in which *pas* is usually used without *ne*.

[15] However, *jamais* only has this interpretation within the context of negation, meaning 'ever' in non-negative contexts. If their analysis is correct, a separate lexical entry must exist for *jamais* when it is not negative, or this proposal requires revision in some other way.

(45) French (adapted from Butt et al. 1999: 143)
David ne mange jamais de soupe.
David NEG eat POSTNEG.NEVER of soup
'David never eats soup.'

Working with HPSG, Kim (2000, 2021) takes a different approach to analysing the distribution of *ne* and *pas* in spoken French, proposing that *ne-pas* are part of a single lexical entry, and in this sense parallel the type lexical entry for *not* in English.

Expression of negation by multiple negative formatives is extremely common in the Niger-Congo languages of Africa. For instance, this is the case in Ewe (Niger-Congo, Kwa; Ghana), where negation is simultaneously expressed by a negative particle *mé* that precedes the VP and a post-VP particle *o*, that follows objects and adverbial elements within the VP, as illustrated in (46).[16] Both NEG1 and NEG2 are obligatory.[17]

(46) Ewe (Collins et al. 2018: 333–334, 361)

a. Kofi mé-ɖu nú o
Kofi NEG1-eat thing NEG2
'Kofi didn't eat.'

b. nye-mé-ƒo nu kplé Kofí o
1SG-NEG1-hit mouth with Kofi NEG2
'I didn't speak with Kofi.'

c. Kofí mé-wɔ-a é-ƒé aƒéme-dɔ́ gbeɖé o
Kofi NEG1-do-HAB 3SG-POSS home-work ever NEG2
'Kofi never does his homework.'

When an auxiliary is present, it hosts the negative marker, as in (47) with the future auxiliary *-á* and in (48) with the 'not yet' auxiliary *kpɔ́*:

---

[16] Although Collins et al. (2018) adopt an orthographic convention in which *mé* is written as a prefix, their description, taken together with discussion in Ameka (1991: 64–69) and Aboh (2010: 64–69), suggests that *mé* occupies a node in syntax distinct from its host. Ameka (1991: 64–69) notes that *mé* usually encliticises to the verb.

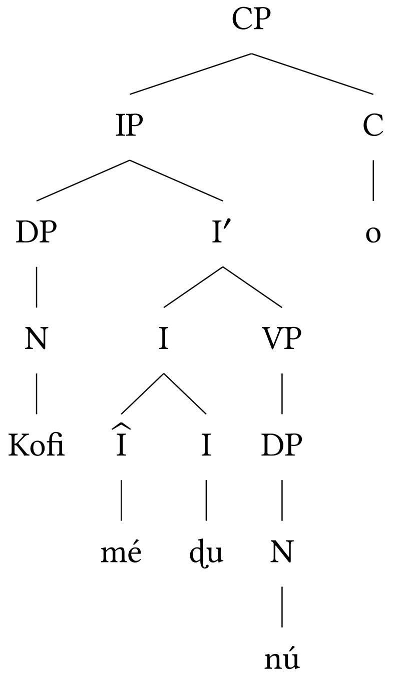
[17] This is unlike typical examples of negative concord, in which so called *n*-words are licensed only in the presence of sentential negation, and can be the answer to a sentence fragment question (see Section 5.2). Most fragment answers obligatorily require the presence of *o*, but this is because it occurs together with an NPI, not an *n*-word (Collins et al. 2018: 350–354).

(47) Ewe (Collins et al. 2018: 360)
nye-mé-á yi China gbeɖé o
1sg-neg1-fut go China ever neg2
‘I will never go to China.’

(48) Ewe (Ameka 1991: 50)[18]
nye-mé kpɔ́ wɔ dɔ lá o
1sg-neg mod do work def neg2
‘I have not had the opportunity to do the work’

Collins et al. (2018) analyse sentences such as those in (46) as having a structure in which neg1 and neg2 are not part of the same inflectional phrase. In their analysis, neg2 occupies a syntactic position outside the TP (this would be an IP in a typical LFG analysis), in the specifier position of a C (see Collins et al. 2018: 293 for the structure). The c-structure in (49) reflects the principal aspects of their descriptive analysis, although the neg1 particle *mé* is analysed as adjoined to I (rather than as the specifier of T), in a similar way to the analysis from Alsharif & Sadler (2009) discussed in Section 2.1. Assuming that *o* takes an IP complement, neg2 is rendered here as C (rather than in the specifier position of an empty C).

(49) Ewe bipartite negation based on Collins et al. (2018: 293)



---

[18] The glosses have been adjusted slightly to reflect the conventions in Collins et al. (2018), but the text line remains unchanged.

As with French, the question arises as to whether these two manifestations of negation should be represented in f-structure by multiple features, or whether a single feature is sufficient. I propose that it is the latter that is true; despite having multiple attestations within the clause, only one f-structural representation of negation is required, as illustrated by the f-structure in (50).[19]

This corresponds to the f-structure in (50).

(50)
$$\begin{bmatrix} \textsc{eneg} & + \\ \textsc{compform} & \textsc{neg} \\ \textsc{pred} & \text{`}\textsc{eat}\langle\textsc{subj}, \textsc{obj}\rangle\text{'} \\ \textsc{subj} & \begin{bmatrix}\textsc{pred} & \text{`}\textsc{Kofi}\text{'}\end{bmatrix} \\ \textsc{obj} & \begin{bmatrix}\textsc{pred} & \text{`}\textsc{thing}\text{'}\end{bmatrix} \end{bmatrix}$$

Crucially, both negative elements are obligatory, but, in the analysis I propose for Ewe in (50), the negative particles constrain a single attribute-value pair. This type of analysis is commonly encountered when dealing with features in LFG – for instance when featural specifications of a GF (e.g. SUBJ) are specified by both the predicate and its subject noun phrase (see Dalrymple 2001: 100–104 for an introduction). Because it is possible and indeed common for two f-structure descriptions to constrain the same attribute value pairs, it should not be particularly strange that negation can also behave in this way. In other languages, where the value of the POL feature must be contributed by a single form, and where multiple contributions are consequently disallowed, then an instantiated symbol can be used as the value of the POL attribute. See Section 5.2 for an example of the usage of this symbol.

In order to ensure that both elements are present in a well formed negative sentence, a constraining equation needs to be specified to impose an additional requirement on the minimal solution obtained from the defining equations in the f-description. A complete analysis of these structures requires that the presence of *o* is constrained (since it is obligatory here). Without a very detailed examination of the Ewe negation system, it is difficult to say exactly what type of constraint might be most appropriate. However analyses of other languages with bipartite negation have involved the addition of a special feature in f-structure, NEG-FORM, which must be contributed by the second negative formative (see Section 3.1).

---

[19] Cf. the representation of clitic doubling in Dalrymple (2001: 79–81).

5 Negative Sensitive Items

Much of the theoretical literature on the syntax of negation examines the distribution of so-called Negative Sensitive Items (NSIs), that is, words whose distribution is sensitive to the presence of negation within a clause. Here we consider three types of sensitivity. The first, which I will refer to as Polarity Sensitive Cases (PSCs) is discussed in Section 5.1. Two further main types of NSIs are distinguished in the literature: Negative Concord Items (NCIs), introduced in Section 5.2, and Negative Polarity Items (NPIs), discussed in Section 5.3.

5.1 Polarity Sensitive Case

Polarity Sensitive Cases are observed when the case-marking of an argument is sensitive to the polarity of its clause. The most well-known example of this is seen in the genitive of negation in Slavic languages (e.g. Neidle 1988, Brown 1999). The basic contrast in case assignment is illustrated by (51) and (52) from Patejuk & Przepiórkowski (2014) using Polish examples from the Polish National Corpus.

(51) Polish (Patejuk & Przepiórkowski 2014: 431)
Poczytam książkę.
read.1SG book.ACC
'I'll read a book.'

(52) Polish (Patejuk & Przepiórkowski 2014: 431)
Nie poczytają książki czy gazety.
read.3PL NEG book.GEN or newspaper.GEN
'They won't read a book or a newspaper.'

Patejuk & Przepiórkowski (2014) propose that structural case assignment generalisations of this type could be formalised using constraints placed in the lexical entries of verbs that follow this pattern.

The STRCASE constraint in (53) indicates that verbs that follow structural case assignment rules follow different disjunctive constraints, labelled as AFFIRMATIVE and NEGATIVE. Note that in Patejuk and Przepiórkowski's (2014) analysis, negation is assumed to be a binary feature represented by the attribute NEG in f-structure.

(53) $\text{STRCASE} \equiv [\text{AFFIRMATIVE} \vee \text{NEGATIVE}]$

(54) $\text{AFFIRMATIVE} \equiv [\neg(\uparrow \text{NEG}) \wedge (\uparrow \text{OBJ CASE}) =_c \text{ACC}]$

(55) $\text{NEGATIVE} \equiv [(\uparrow \text{NEG}) =_c + \wedge (\uparrow \text{OBJ CASE}) =_c \text{GEN}]$

The AFFIRMATIVE constraint in (54) ensures that when there is no negation in the f-structure of the head ($\neg(\uparrow \text{NEG})$) , the object is marked for accusative case: $(\uparrow \text{OBJ CASE}) =_c \text{ACC}$. The NEGATIVE constraint in (55) ensures that when the f-structure of the head is negative ($(\uparrow \text{NEG}) =_c +$), the object is marked for genitive case: $(\uparrow \text{OBJ CASE}) =_c \text{GEN}$.

Patejuk & Przepiórkowski (2014) demonstrate that while such constraints can account for simple cases of structural case assignment, case assignment in constructions with control or raising verbs combining with (open) infinitival arguments (i.e. XCOMPs) do not follow these constraints. Consider (56). In this example, the verb *chcesz* 'want' takes an infinitival complement whose subject is controlled by the subject of the higher verb.

The verb subcategorising for the object (i.e. the infinitival verb *poczytać* 'read') is not negative, yet the genitive of negation is still required because *chcesz* 'want' is negative. Negation is present in (56), but it is 'non-local' to the infinitival clause of the verb subcategorising for the object.

(56) Polish (Patejuk & Przepiórkowski 2014: 432)
Nie chcesz poczytać Kodeksu.
NEG want.2SG read.INF Code.GEN
'You don't want to read the Code.'

While the genitive of negation is possible when negation is non-local, they observe that there appears to be some variation as to whether the lower object should occur in the accusative or in the genitive, citing semantic and structural or linear distance factors as potentially important.

For instance, in (57), the object is marked for accusative case (*książkę* 'book'), even though there is (non-local) verbal negation present higher in the structure of the sentence (at the main verb *chce* 'wants'). This illustrates that the presence of negation in a higher clause is not sufficient to ensure that the genitive of negation occurs.

(57) Polish (Patejuk & Przepiórkowski 2014: 432)
Mama nie chce iść poczytać książkę.
mum NEG want.3SG go.INF read.INF book.ACC
'Mum doesn't want to go and read a book.'

To account for this difference in case-marking, they propose that the constraints in (53)–(55) could be rewritten as (58)–(60).

(58) $\textsc{strcase} \equiv [\textsc{affirmative} \vee \textsc{negative}]$

(59) $\textsc{affirmative} \equiv [\neg(\uparrow \textsc{neg}) \wedge (\uparrow \textsc{obj case}) =_c \textsc{acc}]$

(60) $\textsc{negative} \equiv [((\textsc{xcomp}^{*} \uparrow)\ \textsc{neg}) =_c + \wedge (\uparrow \textsc{obj case}) =_c \textsc{gen}]$

The constraint in (59) states that accusative case is necessary whenever there is no local negation, while (60) indicates that genitive case is possible whenever sentential negation is available somewhere in the verb chain, locally or non-locally. Specifically, this is achieved by using an inside-out path $((\textsc{xcomp}^{*} \uparrow)\ \textsc{neg}) =_c +$ which makes it possible to reach into any number of successive higher predicates subcategorising for an infinitival complement (i.e. an XCOMP), and check if any of these predicates is negated.

5.2 Negative Concord Items

In many languages negation may be expressed through the use of negative indefinite pronouns such as English *nothing* and Polish *nikt* 'nobody'. Haspelmath (1997) argues that there are three main subtypes of construction involving negative indefinite pronouns. First, in some languages there are negative indefinites that always co-occur with verbal negation, e.g. the Polish *ni-* series, as in (61).

(61) Polish (Haspelmath 1997: 194)

a. Nikt nie przyszedł.
nobody NEG come.PST.3SG
'Nobody came.'

b. Nie widziałam nikogo.
NEG saw nobody
'I saw nobody.'

The second type of negative indefinites do not usually co-occur with verbal negation, e.g. the Standard British English *no*-series: *Nobody came* and *I saw nobody*. If they do co-occur, they are rejected by speakers, or are interpreted as having a 'double negative' reading cf. *Nobody didn't come* (=*Everybody came*).[20]

His third type of negative indefinites sometimes co-occur with verbal negation and sometimes do not, e.g. the Spanish *n*-series, exemplified in (62).[21]

---

[20] Negative indefinites in the *no*-series in some other varieties of English do not behave in this manner, and thus they belong to one of the other types.

[21] The fact that the languages used to exemplify these types all come from European languages indicates the prevalence of indefinite pronouns in this area. It is largely unknown to what extent indefinite pronouns might be restricted by areal or genetic factors.

(62) Spanish (Haspelmath 1997: 201)

a. Nadie vino.
nobody came
'Nobody came.'

b. No vi a nadie.
NEG I.saw ACC nobody
'I saw nobody.'

The role that a negative pronoun plays in negating a clause depends on its ability to appear independently of another negation strategy. Negative pronouns like those in Polish which do not appear without an expression of negation are Negative Concord Items (NCIs), sometimes known as *n*-words. By definition, NCIs never occur outside of negative contexts, and when they combine with other expressions of negation, they contribute to a single semantic negation (Labov 1972). NCIs must combine with sentential negation as in (34b) and (61) with Polish *nikt* 'nobody'. NCIs are important tools for investigating the domains in which negation has structural affects. The following definition, based on Giannakidou (2006: 328), is adopted by Camilleri & Sadler (2017: 150):

(63) An *n*-word or NCI is understood to be an expression α that can be used in structures containing sentential negation or another α -expression to yield a reading equivalent to one logical negation, and which can provide a negative fragment answer.

Because NCIs in Polish always occur with another negator, the lexical entries for *n*-words such as *nikt* 'nobody.NOM' and *nikogo* 'nobody.ACC/GEN' must include a constraining equation that ensures their f-structure is specified for eventuality negation (Przepiórkowski & Patejuk 2015: 331):

(64) *nikt* N (↑ CASE) = NOM
((XCOMP* GF+ ↑) ENEG) $=_c$ +

(65) *nikogo* N (↑ CASE) ∈ {ACC, GEN}
((XCOMP* GF+ ↑) ENEG) $=_c$ +

There is much more to say about how differences in the distribution of NCIs cross-linguistically could be modelled in LFG, but I leave this aside as a topic for further investigation.

5.3 Negative Polarity Items

Negative Polarity Items (NPIs) are a set of elements that, while not inherently negative, are licensed within a set of restricted contexts including negative ones. Examples from English include the indefinite quantifier *any* and the adverb *yet*, as illustrated in (66).

(66) a. Isaac wouldn't give her any/*Isaac would give her any.
b. Eva hasn't finished yet/*Eva has finished yet.

Since NPIs are also observed in a range of other syntactic contexts, such as comparatives, modal and conditional contexts and polar interrogatives, as in (67), they are not inherently negative, and the term, attributed to Baker (1970) by Haspelmath (1997), is somewhat misleading.

(67) a. Would Isaac give her any?
b. Has Eva finished yet?

However, assuming that all items described as NPIs can be minimally licensed in negative contexts, they can be further divided into two main types, that may exist within one and the same language:

- Weak Negative Polarity Items: NPIs that exhibit a range of non-negative contexts of use. These are sometimes referred to as Affected Polarity Items (api) (Giannakidou 1998).
- Strong Negative Polarity Items: NPIs that are only licensed in antiveridical contexts (Giannakidou 1998), i.e. sentential negation and '*without*' clauses (cf. eventuality negation).

For Weak Polarity Items, such as those in (66) and (67), negation is a sufficient, but not necessary condition for the licensing. For Strong Negative Polarity items, the context must be antiveridical (see Zwarts 1995 and Giannakidou 1998).

Consider the technical definition in (68) from Giannakidou (2002), who treats veridicality as a propositional operator:

(68) A propositional operator F is veridical iff Fp entails p: $Fp \rightarrow p$; otherwise F is nonveridical. Additionally, a nonveridical operator F is antiveridical iff Fp entails not p: $Fp \rightarrow \neg p$.

A veridical context is one in which the semantic or grammatical assertion about the truth of an utterance is made. The presence of a veridicality entails that the truth conditions for the underlying proposition are met, while non-veridical expressions do not entail that the truth-conditions for the underlying proposition have been met. Though (69a) is veridical, with or without the auxiliary, (69b-69c) are both nonveridical.

(69) a. I (do) like her.
     b. I might like her.
     c. I don't like her.

Nonveridical operators are antiveridical if (and only if) the truth conditions for the underlying proposition are not met, as in (69c). Strong NPIs are sensitive to such environments.

These differences in behaviour raise important questions about how best to account for the distribution of NSIs and in which structures of grammar – essentially – to what extent can and should the distribution of NCIs and NPIs be accounted for through c-structure and f-structure representations. Problems of this kind have been addressed by Sells (2000) in relation to Swedish, and Camilleri & Sadler (2017) with respect to Maltese.

Camilleri & Sadler (2017) examine the relationship between sentential negation in Maltese and the set of negative sensitive items (NSIs). They demonstrate that the *n*-series of negative indefinites in Maltese exhibit mixed behaviour with respect to the environments in which they occur (Camilleri & Sadler 2017: 154–156). The majority of items can occur in a range of non-veridical contexts, and are not limited to antiveridical ones, exemplifying properties consistent with being classified as weak NPIs. However two NSIs show a more limited distribution: the determiner *ebda* is strictly limited to antiveridical contexts (and thus is a Strong NPI), while *ħadd* is largely restricted outside of antiveridical contexts, showing less categorical behaviour.

In finite verbal predicates in Maltese, negation is expressed through the use of the particle *ma* together with a verbal form inflected with the suffix *-x*, as illustrated in (70) and (71).[22]

(70) Maltese (Camilleri & Sadler 2017: 147)
Ma qraj-t-x il-ktieb.
neg read.pfv-1sg-nvm def-book
'I didn't read the book.'

---

[22] I have adjusted the glosses in these examples so that *-x* is glossed as nvm rather than neg, to reflect the final analysis proposed by Camilleri & Sadler (2017). .

(71) Maltese (Camilleri & Sadler 2017: 147)
Ma n-iekol-x ħafna.
NEG 1-eat.IPFV.SG-NVM a.lot
'I don't eat a lot.'

Imperfectives can also be negated using a different strategy otherwise associated with non-verbal predicates and non-finite forms. In (72) , *m(a)-* is prefixed to a form identical to a nominative pronominal, which, like the verbs in (70) and (71), is suffixed with *-x*. This pronominal may occur in a default third person singular masculine form, or vary according to the features of the subject, as shown here.

(72) Maltese (Camilleri & Sadler 2017: 148)
Mhux ~ minix n-iekol ħafna.
NEG.3SGM.NVM ~ NEG.1SG.NVM 1-eat.IPFV.SG a.lot
'I am not eating a lot.'

Although the formation of negative indicative clauses of the type in (70) and (71) involves both the particle *ma* and the suffix *-x*, verb forms only inflected with *-x* cannot license a domain in which items from the *n*-series or any NSI are permitted. Rather, such items are in complementary distribution with *-x*. Camilleri & Sadler (2017: 150) consequently propose that *ma* expresses eventuality negation (ENEG), that introduces a syntactic requirement for a further element, which they call a non-veridical marker (NVM). In examples like (70) and (71), the presence of *-x* on the verb satisfies this requirement, while in examples like (73) it is satisfied by the presence of an NCI, such as *xejn* 'nothing'.

(73) Maltese (Camilleri & Sadler 2017: 159)
Ma qraj-t xejn.
NEG read.PFV-1SG nothing
'I read nothing.'

Examples such as (74) indicated that the NCI satisfying this requirement need not be local, and can be deeply embedded.

(74) Maltese (Camilleri & Sadler 2017: 153)
Ma smaj-t li qal-u li
NEG hear.PFV-1SG COMP say.PFV.3-PL COMP
qal-t-i-l-hom li gèand-hom
say.PFV.3SGF-EPENT.VWL-DAT-3PL COMP have-3PL.GEN

j-i-xtr-u xejn.
3-FRM.VWL-buy.IPFV-PL nothing
'I didn't hear that they said she told them they have to buy anything.'

This is prohibited if the embedded clause containing the negative indefinite is itself marked with *ma*. Camilleri & Sadler (2017) propose the following lexical entries to account for this:

(75) *xejn* N $(\uparrow \text{NVM}) = +$
(Camilleri & Sadler 2017: 159)

(76) *-x* $(\uparrow \text{NVM}) = +$
$\neg(\uparrow \{\text{XCOMP}|\text{COMP}|\text{ADJ}\}^{*}\ \text{GF}^{+}\ \text{NVM}) = +$
$\neg(\rightarrow \text{ENEG})$
(Camilleri & Sadler 2017: 160)

The entry for *xejn* in (75) ensures that its f-structure has the NVM value +. The entry for *-x* – which should really be understood to be part of the lexical entry for the verb form of which it is part – does a similar thing. It ensures that its f-structure instantiates the NVM feature with the value +. But the second line of (76) further stipulates that this form is incompatible with any XCOMP, COMP, ADJ or grammatical function with NVM+ (e.g. *xejn*), except embedded clauses which are themselves marked for sentential negation.

The entry for *ma* in (77) contributes the ENEG feature with the value +. The underscore following the + marks the feature as 'instantiated'. This means it is required to be uniquely contributed, so expressed only once in the f-structure. It also places the requirement that an element NVM is present, but this may be non-local or local. The path definition for GF is given in (78).

(77) *ma* ENEG $(\uparrow \text{ENEG}) = +\_$
$\{ (\uparrow \{\text{XCOMP}|\text{COMP}|\text{ADJ}\}^{*}\ \text{GF}^{+}\ \text{NVM}) \mid (\uparrow \text{NVM}) \} =_{c} +$
$\neg(\rightarrow \text{ENEG})$
(Camilleri & Sadler 2017: 160)

(78) $\text{GF} \equiv \{ \text{SUBJ} \mid \text{OBJ} \mid \text{OBJ}_{\theta} \mid \text{OBL} \mid \text{POSS} \mid \underset{\neg(\rightarrow \text{TENSE})}{\text{ADJ} \in} \}$

Camilleri & Sadler's (2017) observation that some formal elements that at first sight look like negator (e.g. *-x*) may actually be better described as non-veridical markers is an important development not only in terms of descriptive linguistics, but also in the context of how co-occurrence of different elements in negative construction can be constrained.

6 Conclusion

Negation is found in every language, yet can be manifested in a vast number of ways and forms that can occur in practically every position in c-structure. While Chomskian models of syntax usually adopt an approach in which negators head their own functional projection NegP, with LFG, negators occupy the structural position that most closely accounts for their distribution. This allows for an approach in which cross-linguistic variation in the distribution and category of negative word forms is captured using existing means for determining and modelling constituency. Indeed, in many languages negators exhibit properties of non-projecting heads, indicating that adopting a single functional phrase type fails to capture the variation encountered across languages.

While a range of approaches have been proposed to model the featural properties of negation, recent research into modelling negation with LFG suggests that two different f-structure features are required to account for the distribution of negative forms and the syntactic and semantic domains that they license. These are known as ENEG, or eventuality negation, and CNEG or constituent negation. The presence of ENEG is typically associated with a broader range of syntactic and semantic effects than CNEG. The pragmatic distribution is also different, with CNEG notably employed in cases where there is a negated proposition.

While they typically occur independently of one another, a formal analysis of negation requires the availability of both features for negation, such that both may simultaneously be present in f-structure. The distribution of Negative Concord Items (NCIs), Negative Polarity Items (NPIs) and case-forms licensed by negation also suggests that multiple features must also play an important role in accounting for restrictions on the occurrence of certain forms in antiveridical contexts.

As a lexicalist model of grammar, many facets of the distribution of negative formatives are accounted for by their lexical entry. This is most clearly observed when the presence of one negator places a stipulation on the occurrence of another, or some other marker of non-veridicality.

Acknowledgements

I am grateful to Mary Dalrymple and the three anonymous reviewers for very helpful feedback on earlier versions of this chapter, and to Dávid Győrfi for discussion of Hungarian and Polish.

Abbreviations

Besides the abbreviations from the Leipzig Glossing Conventions, this chapter uses the following abbreviations.

aff	affirmative
api	Affected Polarity Item
cneg	constituent negation
eneg	eventuality negation
epent.vwl	epenthetic vowel
frm.vwl	form vowel
hab	habitual
juss	jussive
mod	modal
MSA	Modern Standard Arabic
NCI	Negative Concord Item
neg1	first negative formative in multipartite expression of negation
neg2	second negative formative in multipartite expression of negation
NegP	negation phrase
NPI	Negative Polarity Item
NSI	Negative Sensitive Item
nvm	non-veridical marker
nw	n-word
pol	polarity
postneg	post verbal negator

Chapter 12

Noun phrases in LFG

Kersti Börjars
University of Oxford

John J. Lowe
University of Oxford

In this chapter we consider the analysis of noun phrases in LFG. As a preliminary, in Section 1 we go through a number of criteria that can be used to distinguish noun phrases from other phrase types. Degree of configurationality at clause level and its consequences for c-structure is a well-studied phenomenon in the LFG literature, and in Section 2 we evaluate how the conclusions drawn for clausal structure can be applied to noun phrases. In Section 3 we review the different approaches that have been taken to the functional structure and argument structure of noun phrases. In Section 4 we explore briefly how discourse functions may be expressed within the noun phrase.

1 Defining noun phrases

Before discussing the syntax of noun phrases, it is helpful to consider briefly the definition or delimitation of the category: how do we know what is and is not a noun phrase, and what are the essential properties of the class of noun phrases? In regard to most relevant phenomena in most languages, there is little difficulty in distinguishing a particular class of words which we label as "nouns" in distinction from verbs and other categories such as adjectives, adverbs, adpositions etc. We informally utilize different criteria in making these distinctions: the core meaning and basic function of the words, their morphology and the structure of the phrases they head. Some words, and some phrases, may be more problematic, however, aligning with our basic category of nouns in some respects, but

Kersti Börjars & John J. Lowe. 2023. Noun phrases in LFG. in Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 523–561. Berlin: Language Science Press. DOI: 10.5281/zenodo.10185958

not in others. Moreover, if we want to talk about the properties and analysis of noun phrases crosslinguistically, we need to be clear about the criteria used for categorization, and to ensure that our criteria for categorization are applicable crosslinguistically.

According to Kornfilt & Whitman (2011: 1297–1298), approaches to categorizing phrases and words can be broadly divided into two types: "distributionalist" approaches define categories with exclusive reference to syntactic criteria, while "essentialist" approaches make use of nonsyntactic criteria, such as lexical semantics. Some approaches to categorization make use of both types of criteria; this is true, for example, of Baker's (2003) theory of syntactic categories.

Given the separation of syntax and semantics in the LFG architecture, "essentialist" criteria have relatively little weight in the definition of categories in LFG. As discussed by Lowe (2020), there are three types of "distributionalist" criteria commonly used for defining categories in LFG, by authors such as Spencer (2015) and Bresnan et al. (2016); we discuss each of these in turn.

The first type of criteria is the internal syntax of the phrase in question; that is, what sorts of words and phrases may appear together with the head inside the phrase in question. For example, we might say that noun phrases typically may contain determiners (in those languages that have them) and adjectives, while other types of phrase cannot contain these. There may also be differences in the configurational possibilities of different phrase types. For example, under some approaches to the phrase structure of English, noun phrases are the only lexical phrase type which contain a specifier (e.g. Dalrymple 2001); for others (e.g. Falk 2001b) no lexical phrases may contain specifiers, while functional phrases can. We discuss the phrasal structure of noun phrases in detail in Section 2.

Furthermore, there may be differences between phrases of different categories in terms of the grammatical functions which can appear with them, i.e. in terms of which grammatical functions a head of a particular category may or may not subcategorize for. Given the LFG architecture and the concept of structure-function mapping principles (Bresnan et al. 2016: 105, 117, see also Section 3), these issues are related to configurational differences between phrase types, but are not fully defined by them. For example, a grammatical function POSS for the possessor in a noun phrase is often assumed, and sometimes contrasted with SUBJ, such that POSS may be a grammatical function exclusively associated with noun phrases, and SUBJ a grammatical function exclusively associated with verb phrases. Similarly, it is widely assumed that nouns and adjectives do not, at least usually, subcategorize for OBJ (though see Mittendorf & Sadler 2008, Al Sharifi & Sadler 2009, and Vincent & Börjars 2010 for OBJ with adjectives and Lowe 2017 for further discussion). We discuss grammatical functions within the noun phrase in detail in Section 3, and discourse functions within the noun phrase in Section 4.

The second type of criteria used for defining categories within LFG is the external syntax of the phrase in question (labelled "distribution" by Lowe 2020). This means that there are a certain set of positions within other phrase types where noun phrases may appear, and others where they may not. For example, in English, noun phrases may appear in the specifier of IP, in the complement position of VP and PP, but not in the complement position of AdjP or NP (though see references to OBJ with adjectives above).

The third type of criterion used for defining categories in LFG is the morphosyntax of the head of a phrase (or of the phrase itself): typically languages show differences between the morphosyntactic properties of, say, nouns, adjectives, and verbs. In many Indo-European languages, for example, nouns inflect for case and number, while verbs inflect for tense/aspect, person and number; adjectives inflect for case and number, but also inflect for gender, which is an inherent property of nouns.

The use of all three types of criteria is widespread in LFG approaches to categorization. Although each of the criteria can be problematic when applied in individual cases, in most cases the three types of criteria align unproblematically, such that it is relatively easy to distinguish broad categories of noun phrases, adjective phrases, verb phrases, etc. For example, while there are differences in the internal syntactic possibilities of noun phrases and verb phrases, there is also a degree of overlap: some noun phrases may be indistinguishable from verb phrases, purely in terms of their internal syntax. In such cases, however, external syntax and morphosyntactic criteria may help to distinguish noun phrases from verb phrases.

In rare cases there are serious mismatches between the criteria for categorization. This is perhaps most common in the case of noun-verb mixed categories: phrases which show properties of both noun and verb categorization. We avoid discussions of such mixed categories in this paper (for discussion see Lowe 2020), restricting ourselves to phrases which can (fairly) unambiguously be defined as purely noun phrases based on the sorts of criteria discussed above.

2 Configurationality and noun phrases

In this section we investigate the analysis of the surface configurational structure, the c-structure, of noun phrases in LFG. We consider how generalizations developed for degrees of configurationality at clausal level can be applied to noun constituents and how these can be represented at c-structure (cf. Andrews 2023 [this volume]).

Abney (1987) changed the way in which noun phrases are analysed within mainstream generative approaches to syntax. Projecting functional categories at clausal level had been introduced in the work that led to the publication of Chomsky (1986), and Abney's work was intended as "a defense of the hypothesis that the noun phrase is headed by a *functional element* (...) D, identified with the determiner. In this way, the structure of the noun phrase parallels that of the sentence, which is headed by Infl(ection)" (Abney 1987: 3).

In this chapter, we will make comparisons between clausal and nominal constituents, but not with the aim of emphasizing parallels. Within LFG, the approaches to c-, f- and a-structure have been developed more on the basis of clausal structures than anything else, and we will explore the extent to which the resulting assumptions can be applied also to noun constituents. Our aim here is not to provide full analyses of any language, but to illustrate how a particular interpretation of a data set might be analysed in LFG.

Three levels of configurationality are generally distinguished within LFG at clausal level: configurational, illustrated in (1), part-configurational (3) and non-configurational (5), with S being an exocentric clause-level category (Andrews 2023 [this volume]). If we assume a corresponding exocentric category NOM for noun phrases, then we can set up the parallel noun phrase structures in (2), (4) and (6). Different combinations of these options may be motivated for different languages; for discussion see Nordlinger (1998) and Bresnan et al. (2016: 118–9). Specifiers of functional projections are assumed to be either syntactically prominent, illustrated here with SUBJ and POSS, or information-structurally prominent functions, here we have used DF for discourse function (see Snijders 2015, Bresnan et al. 2016: 104–11 and Dalrymple et al. 2019: 121–6). As we will see in Section 3, functions such as SUBJ and POSS may be seen to have a dual role in this respect. We will return to what DF may mean for noun phrases in Section 4. In (1) – (4), we have only annotated the specifier node, for information about annotations and how they work, see Belyaev 2023c: Section 4.2 [this volume] and Belyaev 2023a: Section 4.1 [this volume].

2.1 Degrees of configurationality

Criteria commonly applied to strings to establish degrees of configurationality are (i) word order, (ii) capacity for discontinuity, and (iii) structural vs. non-structural determination of grammatical functions (for an excellent summary of arguments, see Nordlinger 1998).[1]

---

[1] The concept of null anaphora is also called upon quite widely to justify a configurational analysis of languages like Warlpiri that are characterized by freedom of word order (see for instance Jelinek 1984, Hale 1993). This approach has been criticized by Austin & Bresnan (1996) for lacking empirical support when a broader set of languages is considered, and we will not consider this further here.

English is a language in which noun phrases display strict word order and relatively little discontinuity. Examples of discontinuity such as (7) are generally not taken to indicate non-configurationality, but are assumed to be due to a more general principle of extraposition due to weight. Noun phrase internal grammatical functions such as POSS are generally marked by structural position in English (though see Section 3 for more detailed discussion).

(7) A *book* was published last year *on a new theory.*

English noun phrases can therefore be assumed to be thoroughly configurational and best represented by a tree such as (2), though we will return to the issue of functional categories in Section 2.2.

Turning now to the other end of the configurationality spectrum, for a number of languages which may at first sight appear to have non-configurational noun phrases, it has been argued that they do not in fact have noun phrases at all (see for instance Blake 1983). A string of elements that refer to the same referent – we will use the term NOMINAL STRING for these – whether continuous or not, may in some languages be best analysed as a number of independent nominal elements in apposition. In order to find a language with non-configurational noun phrases we must therefore first make sure that there is reason to assume that there are noun phrases in the language. Louagie & Verstraete (2016), in an evaluation of claims about non-configurationality in noun phrases in Australian languages, propose five criteria for establishing whether nominal strings form noun phrases: (i) contiguity, (ii) word order, (iii) diagnostic slots, (iv) phrasal case marking and (v) intonation.

Contiguity (i) is a necessary but not sufficient criterion; where the elements do occur together, they could still be assumed to occur in apposition, just as in the discontinuous examples. For our purposes, (relative) freedom of word order (ii) within a string for which there is other evidence of it forming a constituent will be taken as evidence of a flat structure. Some of the languages we will consider have an identifiable position (iii) at clausal level in which only a single constituent can occur, hence if a nominal string can occur in this position it can be assumed to form a structural unit. In a similar vein, if case is marked only once in a nominal string (iv), this string can be assumed to form a constituent. If a nominal string has a single intonation contour (v), it can be assumed to form a noun phrase (see also Schultze-Berndt & Simard 2012). The conclusion Louagie & Verstraete draw is that statements about the lack of noun phrase constituents in Australian languages have been overstated, but this is to some extent dependent on how they apply the criteria. For instance, whereas discontinuity has been taken as evidence against constituency, they say that "the existence of discontinuous constructions is not invariably an argument against NP constituency" (2016: 28).

With respect to Warrongo (Pama-Nyungan), Louagie & Verstraete (2016: 35) conclude: "This is really the only type of language where flexibility provides evidence against constituency." This is based on the description by Tsunoda, who argues on the basis of evidence such as (8) that "the relative order of NP constituents is not fixed and it is difficult to generalize about it" (2011: 347).[2]

(8) Warrongo

a. yarro-∅ gajarra-∅ ngali-ngo
this-acc possum-acc 1du-gen
'this possum of ours' (Tsunoda 2011: 348)

b. yarro-∅ ngaygo gajarra-∅
this-acc 1sg.gen possum-acc
'this possum of mine' (Tsunoda 2011: 348)

c. yino gornggal-∅ ngona-∅ nyon.gol-∅ jarribarra-∅
2sg.gen husband-acc that-acc one-acc good-acc
'that one good husband of yours' (Tsunoda 2011: 347)

d. ngaygo yarro-∅ jarribara-∅ wobirri-∅
1sg.gen this-acc good-acc English.bee-acc
'this nice English bee of mine' (Tsunoda 2011: 347)

Though nominal strings in Warrongo are generally contiguous, there are examples of discontinuity, as exemplified in (9).

(9) Warrongo

a. yinda **gagal**-∅ wajo-ya **bori**-∅.
2sg.erg big-acc burn-imp fire-acc
'Make a big fire.' (Tsunoda 2011: 349)

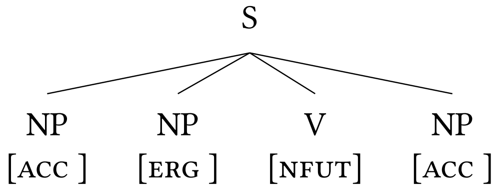
b. **gajarra**-∅ nyola ganyji-n **goman**-∅.
possum-acc 3sg.erg carry-nfut another-acc
'She carried [i.e. brought] another possum.' (Tsunoda 2011: 349)

---

[2] We use the Leipzig glossing rules also when these have not been used in the source of the example. For a number of glosses used in our sources, there is no equivalent in the Leipzig glossing rules, and we have maintained the original. This applies to the following: an action nominal, dub dubitative, emph emphatic, min minimal, pot potential, only restrictive and seq sequential.

The examples in (8) and (9) show that each element of the nominal string is separately case marked, apart from the genitive possessor, regardless of whether the string is contiguous or not. Furthermore, with the exception of the genitive, the parts can each form an independent noun phrase. There is no diagnostic slot at clause level in Warrongo, and we do not have enough information about prosody to use that as evidence. Hence, based on the evidence available, we can assume that Warrongo is best analysed as a language where each part of a nominal string forms an independent nominal phrase, even when there is no discontinuity, so that in both (8) and (9), the individual words occur as daughters of a flat clausal structure. Though it is not our aim to provide a detailed analysis of Warrongo clause structure, our conclusions can be illustrated schematically as in (10) for (9b), where the case feature on the initial and final elements would ensure that they both become associated with obj in the associated f-structure (compare the analysis of Kalkatungu in Blake 1983).

(10)



We turn now to Bilinarra (Pama-Nyungan), as described by Meakins & Nordlinger (2014). Discontinuous noun phrases are possible in Bilinarra, as illustrated in (11), and for these cases Meakins & Nordlinger (2014: 107–108) assume an analysis where each part forms a structurally independent constituent, in line with the conclusions drawn about Warrongo above.

(11) Bilinarra (Meakins & Nordlinger 2014: 108)
Ngurra-nggurra=rna=rla ga-nggu, **ngayiny-jirri**, warrba=ma.
house-all=1min.s=3obl take-pot 1min.dat-all clothes=top
'I'm going to take them to **the house**, to **my** (house), the clothes I mean.'

However, there is also evidence in Bilinarra that contiguous nominal strings do form constituents and hence can be NPs. Pronominal clitics, such as *yi* in (12), can occur in different positions in the clause, but most commonly occur in second position. When they do, they can be preceded by a word or a phrase. When a nominal string occurs in this pre-clitic position, as in (12a) it can be assumed to form a constituent. It should be added here that the clitic can also be preceded by just one word of a nominal string as illustrated in (12b), and in such cases Meakins & Nordlinger analyse all elements of the string as separate noun phrases in apposition.

(12) Bilinarra

a. Ngayiny-ju=ma ngamayi-lu=ma=**yi** wanyja-rni
1min.dat-erg=top mother-erg=top=1min.obj leave-pst
yabagaru=rni.
small=only
'My mother left me as a child.' (Meakins & Nordlinger 2014: 102)

b. Yalu-lu=**yi** ngumbid-du ba-ni, garndi-lu.
that-erg=1min.obj man-erg hit-pst stick-erg
'That one, the man hit me with a stick.' (Meakins & Nordlinger 2014: 102)

Prosodic criteria are also used by Meakins & Nordlinger to identify a difference between strings that form noun phrases and strings that involve separate constituent parts in apposition. In (13a), the comma between *nyanuny-jirri* and *munuwu-yirri* indicates an intonational break and the possessor and the noun are assumed to form two phrases in apposition. In (13b), on the other hand, the two form part of the same prosodic unit and can be assumed to form a noun phrase constituent like they do in (12a). The resulting difference in meaning is captured by the idiomatic translations.

(13) Bilinarra (Meakins & Nordlinger 2014: 103)

a. Jardila=ma ya-n.gu=nga na, lurrbu na, **nyanuny-jirri**,
tomorrow=top go-pot=dub seq return seq 3min.dat-all
munuwu-yirri.
home-all
'Tomorrow she might go home **to hers**, **to home**.'

b. Jardila=ma ya-n.gu=nga na, lurrbu na, **nyanuny-jirri**
tomorrow=top go-pot=dub seq return seq 3min.dat-all
munuwu-yirri.
home-all
'Tomorrow she might go home **to her home**.'

We can then follow Meakins & Nordlinger and assume that nominal strings may form noun phrases in Bilinarra; when the string is contiguous, not interrupted by a pronominal clitic and forms one prosodic unit. On the assumption that there is no evidence in favour of a functional projection in Bilinarra (see Section 2.2), we can assume that a tree like that in (6) is appropriate for these noun phrases. For examples of other languages that warrant (partially) flat analyses of noun phrases, see for instance Simpson (1991) on Warlpiri, Raza & Ahmed Khan (2011) on Urdu, Lowe (2015) on Old English, Börjars et al. (2016) on Old Icelandic and for constraints on discontinuity of Latin noun phrases see Snijders (2012).

2.2 Headedness of noun phrases

There were early suggestions in the literature that noun phrases may in fact be headed by determiners (see for instance Lyons 1977 and Hudson 1984) and a debate between Zwicky (1985) and Hudson (1987) attempted to establish criteria on the basis of which the issue could be settled. However, these criteria do not lead to an unambiguous empirical conclusion, but theoretical assumptions determine the choice. Generally, after Abney (1987) all noun phrases were assumed to be (at least) DPs within Chomskyan approaches, but more recently the suggestion has been made within this architecture that a DP may not be motivated for all noun phrases (Bošković 2008, 2012). LFG generally takes a more restrictive approach to functional categories; they are assumed when a functional feature is associated with a particular structural position (Kroeger 1993: 6, Börjars et al. 1999, Sadler 2000: 92, 108). LFG's universal principles of endocentric structure-function association also state that the specifier of a functional category hosts a DF (Bresnan et al. 2016: 105, 117, see also Section 3), so that if a DF can be found to be associated with a particular structural position, this can be used to argue in favour of a functional category (see Section 4 for further discussion). Only one functional category is generally assumed within noun phrases, though there are some language-specific exceptions, for instance as in the analysis of Welsh by Mittendorf & Sadler (2005) and Chinese by Börjars et al. (2018); for further examples, see Dalrymple et al. (2019: 102–103).[3]

There has not been much discussion in the LFG literature of the headedness of noun phrases. Bresnan et al. (2016) assume that English noun phrases are DPs, but without much motivation. Dalrymple (2001) analyses them as NPs, with determiners located in specifier of NP, and this is maintained in Dalrymple et al. "for simplicity" (2019: 101). NP analyses for English can also be found in Chisarik & Payne (2003), Arnold & Sadler (2014), and Lowe (2015).[4] Börjars et al. (2019) include a brief discussion of the issue and conclude that there is no unambiguous evidence either way in the case of English noun phrases, but analyse them as DPs on the basis of the definiteness feature being associated with the left edge.

---

[3] Mittendorf & Sadler (2005) say explicitly "Determining the precise c-structure is not our main concern here."

[4] However, in Lowe (2015) an NP-internal possessor is a DP, and the *'s* is structure shared.

Sadler (2000: 92) argues explicitly for an NP analysis of Welsh on the basis of lack of evidence for a DP. POSS, which shares some properties with SUBJ and hence is a DF, occurs in the specifier position of NP in this analysis. However, Sadler points out in a footnote that "the discourse-oriented functions are canonically associated with specifier of functional categories" (2000: 97) and suggests an alternative DP analysis in which POSS is found in the specifier of DP position. Charters (2014: 211) also uses the role of the specifier of a functional category in determining the headedness of noun phrases: "These days a DP analysis is more generally assumed, is a "universal default" under the EMPs [Endocentric Mapping Principles] …". We will return to Sadler's analysis in Section 3.4.

There are languages for which the marking of definiteness can be argued to provide clearer evidence of headedness. Consider the Amharic data in (14), from Kramer (2010: 197–199).

(14) Amharic

a. bet=**u**
house=DEF
'the house' (Kramer 2010: 197)

b. tɨllɨ=**u** bet
big=DEF house
'the big house' (Kramer 2010: 198)

c. bätam tɨllɨ=**u** bet
very big=DEF house
'the very big house' (Kramer 2010: 198)

d. ɨʤʤɨg bätam tɨllɨ=**u** bet
really very big=DEF house
'the really very big house' (Kramer 2010: 198)

e. lä-mist-u tammaññ=**u** gäs'ä bahriy
to-wife-his faithful=DEF character
'the faithful-to-his-wife character' (Kramer 2010: 199)

f. ɨbab yä-gäddäl-ä=**w** lɨʤ
snake COMP-kill.PFV-3M.SG=DEF boy
'the boy who killed a snake' (Kramer 2010: 199)

Here we see that the definiteness marker attaches to the first constituent. The status of the definiteness marker is problematic.[5] The marker attaches to whatever word ends the first constituent, including nouns (14a), adjectives (14b–e) and finite verbs (14f). Following the arguments of Lowe (2016: 161), this freedom of attachment to in principle any word class suggests a clitic, an analysis also followed by Lyons (1999), and hence we have used = in the glossing. In that case, the definiteness marker is most naturally interpreted as a D head, with a specifier position preceding it. By the structure-function association principles, the specifier position would be expected to be able to house a DF, and this can indeed be argued to be the case in Amharic. In Amharic, possessors, which can be argued to have discourse-functional properties (see Section 3.2 for discussion), take the shape of a PP with the preposition *yä* as in (15), and are found in the pre-definiteness position.[6] The annotated tree is provided in (16).

(15) Amharic
yä=lɨʤ=**u** däbtär
of=boy=DEF notebook
'the boy's notebook' (Kramer 2010: 202)

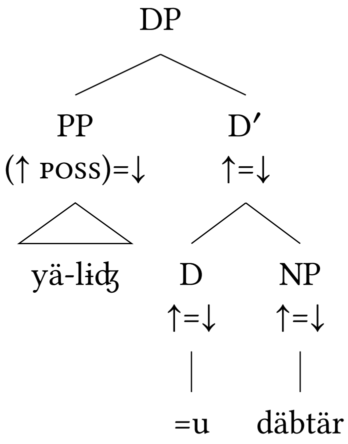
If we apply the argument based on the relation between free word order and a flat structure conversely, and assume that lack of flexibility of word order indicates a hierarchical structure, then the tree in (16) would be appropriate for Amharic. This is a version of the skeletal tree in (2). However, as we shall see in Section 4, word order may be fixed even in languages for which there is evidence in favour of a flat structure; this is unproblematic to analyse within LFG.

---

[5] Kramer formulates her analysis within Distributed Morphology, where the distinction between affix and clitic is not directly relevant. In her analysis the element is found under D, with an indication that it is bound, but this is the case regardless of the nature of its prosodic and morphological dependency.

[6] As noted, the status of the definiteness marker is problematic, and besides the evidence for clitic status there is also evidence for affixal status, including the possibility for multiple definiteness marking: in noun phrases with more than one modifier, the first one is obligatorily marked, and any following modifiers are optionally marked (Kramer 2010: 202). Beermann & Ephrem (2007) assume affixal status within their HPSG analysis. Even if the definiteness marker is taken to be an affix, it still unambiguously marks the right edge of a constituent which can host a DF function, and thus represents a specifier position. Similar distribution of DEF can be found in Balkan languages and there are a range of analyses, in part dependent on the view of the morpho-syntactic status of DEF (e.g. Sadock 1991: 117–120, Halpern 1995: 153–157, Dimitrova-Vulchanova & Tomić 2009, Bermúdez-Otero & Payne 2011, Franks 2015). We will return to elements that display properties of both affix and clitic in Section 3.4.

(16)



A DP analysis of noun phrases has been proposed also for Catalan (Alsina 2010),[7] Faroese (Börjars et al. 2016), German (Dipper 2005),[8] Hungarian (Laczkó 2007, 2017),[9] Low Saxon (Strunk 2005), Old English (Allen 2007) and Welsh (Mittendorf & Sadler 2005) (compare deP for Mandarin in Charters 2004). NP analyses have been proposed for Arabic (Al Sharifi & Sadler 2009), Chimane (Ritchie 2016), Hebrew (Falk 2001a, 2007, Spector 2009),[10] Hindi (Lee 2003), Hungarian (Chisarik & Payne 2001, 2003), Russian (King 1995), Swedish (Sells 2001), Tagalog (Kroeger 1993), Tz'utujil (Duncan 2003), Urdu (Bögel et al. 2008, Raza & Ahmed Khan 2011), Vedic (and other Early Indo-Aryan varieties) (Lowe 2017), Welsh (Sadler 2003, Mittendorf & Sadler 2008), and widely for Australian languages (e.g. Simpson 1991, Austin & Bresnan 1996, Nordlinger 1998 and many more). In many of these publications, establishing the structure and category status of the noun phrases is not the main issue, so that there are varying degrees of commitment to the structure assumed.

Complements of nouns are generally assumed to be the sister of N in c-structure, though as we shall see in Section 3.3.3, some argue that it is not possible to draw a clear structural distinction between complements and adjuncts. We will return to the f-structure feature of complements of nouns in Section 3.3. Modifying elements like APs or modifying PPs have the function ADJunct, and can be assumed to adjoin either at phrasal or X′ level (see Bresnan et al. 2016: 127, Butt et al. 1999: 105–114). In a DP analysis, they may attach either within the D spine or the N spine. Their position is established empirically, and there may be

---

[7] This is an analysis within a lexical sharing approach.

[8] Note that Dipper has a flat structure under D′.

[9] Laczkó (2017: 250) comments: "when there is no need for a DP projection from an LFG perspective, I use the NP maximal projection".

[10] Though note that Falk (2001a) has a KP (case phrase) inside this NP.

arguments within a particular language for attaching different types of modifiers at different levels within the noun phrase.

3 Noun phrases, GFS and argument structure

In this section we review the different grammatical functions that have been used for noun phrases and the arguments for the different approaches. We also consider how the relevant aspects of the structure-function association principles apply within the noun phrase.

While there is in general a good understanding and broad agreement on how to identify and define the grammatical functions of arguments within verb phrases and clauses (Belyaev 2023b [this volume]), there are a variety of contrasting approaches to arguments within the noun phrase in LFG, and little sign of a developing consensus. We begin this discussion by considering the universal principles of endocentric structure-function association proposed by Bresnan et al. (2016: 105, 117):[11]

1. c-structure heads are f-structure heads;
2. complements of functional categories are f-structure coheads;
3. specifiers of functional categories are the grammatical discourse functions;
4. complements of lexical categories are nondiscourse argument functions or f-structure co-heads;
5. constituents adjoined to phrasal constituents are optionally nonargument functions.

These principles are fundamentally developed on the basis of, and exemplified using, verb phrases and clauses, but as universal principles of endocentric

---

[11] In Dalrymple et al. (2019), some of these principles are modified slightly. Dalrymple et al. note that according to Laczkó (2014), Hungarian is an exception to Bresnan's claim that SUBJ cannot be the complement of a lexical category. Dalrymple et al. (2019: 121) further "propose that specifier positions are filled by phrases that are prominent either syntactically or in information-structural terms. …Syntactically prominent phrases that can appear in specifier positions in the clause are those bearing either the function SUBJ or the overlay function DIS heading a long-distance dependency. Information-structurally prominent phrases can also appear in specifier position; if they are not syntactically prominent, they may bear any grammatical function within the local clause."

structure-function mapping, there is an implicit assumption that these principles should hold also for noun phrases. One explicit acknowledgement of the applicability of these principles to noun phrases is by Sadler (2000: 94), who notes that her proposed annotated c-structure rules for Welsh NPs are "fully consistent with the structure-function mapping principles for configurational languages proposed in Bresnan 2000 [2001]."

Based on the current state of research, it seems that noun phrases crosslinguistically do in fact tend to conform to the structure-function association principles (but see also Section 4). However, this still leaves a significant degree of flexibility in how grammatical functions within the noun phrase may be analysed, as discussed in the rest of this section.

3.1 Types of nouns involving possessors (in the broadest sense)

We can distinguish at least three broad categories of noun: common nouns (e.g. *dog*, *book*), relational nouns (e.g. *sister*, *friend*), and nouns derived from verbs (e.g. *arrival*, *destruction*, *playing* etc.). Common nouns can unproblematically, and commonly do, occur without any dependent argument or possessor phrase, though they can, of course, have possessors. Relational nouns differ in that they seem to entail the existence of an entity to which the referent of the noun bears the relevant relation; and this entity is regularly expressed as a possessor phrase within the relational noun phrase. There are different types of nouns derived from verbs, and it is not always easy to distinguish the different types crosslinguistically (see amongst others Comrie 1976; Grimshaw 1990; Koptjevskaja-Tamm 1993, 2002).

But in different ways and to different degrees, all nouns derived from verbs necessarily bear a relation to a lexeme which has an argument structure (i.e. the verb), and thus can or do entail the existence of other participants corresponding to the arguments of the base verb, and may also inherit some of the selection properties of the base verb.

In the case of nouns derived from verbs, questions of nominal argument structure intersect with questions of verbal argument structure, and so it is here that the theoretical implications of the similarities and/or differences between nominal and verbal argument structure are most significant (for verbal argument structure and its mapping to f-structure, see Findlay et al. 2023 [this volume]). Within LFG, this was first explored by Rappaport (2006 [1983]). In event nominalizations, for instance, noun phrases may contain two phrases that bear a grammatical relation in a way that closely parallels that of a corresponding clause:

(17) a. The sea water constantly hit the loose stones on the beach.

b. the sea water's constant hitting of the loose stones on the beach

But there are a wide variety of views on the necessary inheritance of verbal argument structure by derived nouns. At one extreme, Rappaport (2006 [1983]: 135) assumes that "in the unmarked case, a derived nominal inherits the argument structure of its related verb". At the other, Lowe (2017: 15) argues that a derived noun like *destruction* (in e.g. *the destruction of the city by the invaders*) has no syntactic or semantic arguments, the agent and patient relations of the prepositional dependents being "pragmatically inferrable". In between these two positions, Butt et al. (1999: 46) treat phrases like *of the city* and *by the invaders* as adjuncts (like Lowe) but assume there is a dependency relation between the head noun and its modifiers at the level of semantics.

A key element of this debate is the greater optionality of the arguments found with derived nominals, compared with the obligatoriness of the arguments of corresponding verbs. But there is crosslinguistic variation here: Laczkó (1995, 2000) shows that argument realization is obligatory for Hungarian complex event nominals, and he therefore naturally adopts an analysis involving full verbal argument structure inheritance by the derived nominals.

3.2 GFs used for primary arguments

Many languages have a special marking for what we will call the primary argument of a noun; this will often be a possessor, or may be a thematic argument in the case of nouns derived from verbs. Some languages have more than one means of marking the arguments of nouns, but if so there is usually one means of marking which is the more common and basic, and which is thus in a second sense the more primary means of marking arguments of nouns. In English, this primary marking is the so-called genitive or possessive *'s* marker. Much of the following discussion is based on the English possessive *'s*, but the principles apply more widely to primary markers of arguments of nouns in other languages.

There are three main approaches to the analysis of primary-marked possessors in noun phrases. The most common assumption is that such possessors fill the grammatical function POSS (e.g. Rappaport 2006 [1983], Sadler 2000, Falk 2001b, Bresnan 2001, Bresnan et al. 2016, Laczkó 2000, 2007, 2017, Strunk 2005, Charters 2014, Lowe 2017, Dalrymple et al. 2019). A few authors, including Williford (1998), Butt et al. (1999), and Dalrymple (2001), treat these possessors rather as SPEC. However, the function SPEC is also widely used for the function of determiners and/or quantifiers, and as noted by Sadler (2000) and Falk (2002) this is problematic for languages in which determiners and possessors (e.g. Romanian) and/or quantifiers and possessors (e.g. English) can co-occur. On this basis Dalrymple et al. (2019: 83–84) argue that SPEC should be restricted to quantifiers; instead they use POSS for possessors and features such as DEF and DEIXIS for articles and demonstratives.[12]

Chisarik & Payne (2001, 2003) argue that primary possessors have the function SUBJ. The close relation between possessors and the SUBJ function is clear in the case of nouns derived from verbs (cf. 17), and is acknowledged also by some of those who treat possessors as POSS. For example, Sadler (2000: 106) defines POSS as a "SUBJective" function; similarly, Laczkó (2007: 358) refers to the "subject-like nature of the possessor". Like SUBJ, POSS includes discourse-functional properties, and may be associated with topicality (Rosenbach 2002); see further Section 4.

In some sense, POSS can be seen as the nominal equivalent of SUBJ, the most basic, most common, and semantically most variable verbal argument function. Yet there are important differences between the two. For example, expletives can fill SUBJ, but cannot be possessors in English:[13]

(18) a. There appears to be a reindeer on the roof.
b. * There's appearing to be a reindeer on the roof is an illusion.

(19) a. It appears that there's a reindeer on the roof.
b. ? Its appearing that there's a reindeer on the roof is an illusion.

SUBJ is generally assumed to be associated with specifier of IP, or to be morphologically marked as a SUBJ (or both); POSS is assumed to be associated with

---

[12] It should be pointed out here that quantifiers have not been fully explored from a c-structure perspective. They are sometimes assumed to head a QP, but without detailed argumentation (e.g. Wescoat 2007, Bresnan et al. 2016: 211–212). A referee suggests that one reason form and function of quantifiers have not been so well-explored in LFG is that the distinction is either trivial or problematic for these elements. However, Dipper (2005) is an example of how the distinction can be made; she provides detailed argumentation that elements in German which function as quantifiers in fact belong to two different c-structure categories, some sharing properties with adjectives and some with determiners. Note that beyond LFG, Payne & Huddleston (2002) do distinguish between the category 'determinative', to which quantifiers belong, and the function "determiner". The semantics of quantifiers has been well explored in LFG; see Dalrymple et al. (2019: 302–312).

[13] The examples are taken from Bresnan et al. (2016: 315). A referee points out that the noun phrase status of the constituent built around *appearing* in (18b) and (19b) is controversial, and suggests that using *tend* and *tendency* in examples (18) and (19) would be more convincing.

a broad range of positions crosslinguistically.[14] The semantic relation between a poss and its possessum is considerably more flexible than that between a subj and its verbal head, and there does not appear to be a nominal equivalent of the Subject Condition (Findlay et al. 2023 [this volume]), for example.[15] Thus there does seem to be some justification for distinguishing subj from the grammatical function of possessors.

subj is a governable grammatical function, and so must be subcategorized for. The status of poss is arguable: some authors treat poss as an argument function, others as a non-argument function, and others as both. For Sadler (2000: 97), poss is a non-argument function for common nouns and an argument function for deverbal nouns, this is illustrated in (20).

(20) Welsh
a. *llyfr* N 'book⟨ ⟩(↑poss)' (common noun)
b. *disgrifiad* N 'description⟨(↑poss)⟩' (deverbal noun)

Bresnan et al. (2016: 315–319) assume a lexical predication template which converts nouns, including deverbal nouns, into predicates with an optional poss argument:[16]

(21) a. *horse* N (↑pred) = 'horse⟨ ⟩'
'horse⟨ ⟩' ⇒ 'horse-of⟨(↑ poss)⟩'
b. *singing* N (↑pred) = 'singing⟨(↑ obl$_{\text{of}}$)⟩'
'singing⟨(↑ obl$_{\text{of}}$)⟩' ⇒ 'singing-of⟨(↑poss) (↑ obl$_{\text{of}}$)⟩'

Laczkó (2007) proposes a slightly different lexical redundancy rule which converts a noun without argument structure into a one-place "raising" predicate, and a relational noun to an "equi" predicate:[17]

---

[14] Charters (2014: 209) sums up: "Possessors have been said to occur in Spec NP (Sadler 2000, Charters 2004, Laczkó 2007, Lødrup 2011); Spec DP/FP (Charters 2004, Strunk 2005); adjoined to NP (Chisarik & Payne 2001); adjoined to N (Lødrup 2011), and in the complement of N (Chisarik & Payne 2001)."

[15] In fact, arguments of nouns are rarely obligatory, with only a few possible exceptions in English (like *behalf* and *sake*). To account for the obligatory realization of arguments with complex event nominals in Hungarian, Laczkó (1995) proposes a nominal equivalent to the subject condition, namely the "poss condition".

[16] Similarities and differences between poss and subj are referred to but poss is not classified with respect to argument or discourse function. For verbal gerunds like *Mary's frequently visiting Fred* poss is equated to subj.

[17] The templates used by both Bresnan and Laczkó have the effect of adding an optional argument. For an alternative way of capturing the optionality of arguments of nouns, see Lowe (2017: 293–294) with reference to Asudeh & Giorgolo (2012), Giorgolo & Asudeh (2012), and Asudeh et al. (2014).

(22) Hungarian

a. *kalap*$_1$ N ‘hat⟨ ⟩’ ⇒
kalap$_2$ N ‘hat⟨(↑xcomp)⟩(↑poss)’
(↑poss) = (↑xcomp poss)

b. *húg*$_1$ N ‘younger-sister-of⟨θ⟩’ ⇒
húg$_2$ N ‘younger-sister-of⟨(↑poss)(↑xcomp)⟩’
(↑poss) = (↑xcomp poss)

Payne et al. (2013: 804–805) argue that no clear distinction can be drawn between inherently relational and non-relational nouns, they propose to treat all nouns grammatically as nonrelational until combined with a dependent.

3.3 Secondary argument marking

In many languages the primary means of marking a possessor or other argument of a noun can only mark one such argument, and there is a secondary means of marking arguments which can be used alongside, or sometimes instead of, the primary marking. This is not the case in all languages, for example in Estonian the genitive case is the primary means of marking possession, but two arguments of a noun can be marked in the genitive:

(23) Estonian (Koptjevskaja-Tamm 2002: 732)

a. Jaan-i Inglisma-a kaart
Jan-gen.sg England-gen.sg map.nom.sg
‘Jan’s map of England’

b. Peetr-i maja-de ehita-mine
Peter-gen.sg house-gen.pl build-an.nom.sg
‘Peter’s building (of) houses’

In contrast, in English, as illustrated by the translations above, any second argument of a noun must be expressed by means of a prepositional phrase, and this can also be the case for single arguments of a noun. This can include possessors, marked in English with *of*.

The grammatical function of such secondary argument phrases, such as English *of* possessors, is also a matter of debate. Such possessors are sometimes treated as adj, e.g. by Butt et al. (1999), Sadler (2000), and Lowe (2017), sometimes as an obl$_{\text{of}}$, e.g. by Rappaport (2006 [1983]) and Bresnan et al. (2016).[18] We consider the major grammatical functions associated with secondary argument marking in the following subsections.

---

[18] Laczkó (1995) permits English *of* possessors to realize either obl$_\theta$ or poss.

3.3.1 Secondary argument marking and OBJ

It is significant that while the close relation between POSS and SUBJ is widely recognized, and the two are sometimes conflated, a clear distinction is always maintained between secondarily marked possessor phrases and the OBJ function, despite, for example, the positional similarity between *of* possessors and objects (as seen in (17)). It is taken as a strong, if not definitional, generalization, that nouns cannot take OBJ (Bresnan & Kanerva 1989, Bresnan & Moshi 1990, Bresnan & Mugane 2006, Chisarik & Payne 2001, 2003, Lowe 2017, 2020). Lowe (2017, 2020) argues that noun phrases which appear to include object dependents are in fact mixed projections, incorporating a verbal projection which licenses the object.

Chisarik & Payne (2001, 2003) propose a specialized nominal argument function NCOMP/ADNOM, which is intended to capture the relevant similarities between the secondary possessor function and OBJ, while keeping them distinct. In argument structure terms, NCOMP is, like SUBJ and OBJ, an unrestricted function [−*r*]. Like SUBJ and unlike OBJ, however, NCOMP is also [−*o*] (for an explanation of these features, see Findlay et al. 2023 [this volume]).

As with POSS and SUBJ, secondarily marked possessors are considerably less semantically restricted than any corresponding verbal argument function (including OBJ). For example, secondarily marked possessors differ from clausal OBJ in that they can be mapped to Agent:

(24) a. the love of a good woman
b. the poor performance of the team

Moreover, primary and secondary possessors are unrestricted to different degrees. Payne & Huddleston (2002: 473–478) argue that the set of semantic relationships that can be expressed by an *of*-phrase in English is a proper superset of those that can be expressed by an *’s* phrase. For example, genitive POSS has to be affected: **history’s knowledge* vs. *knowledge of history*. The following examples, from Payne et al. (2013: 809), illustrate how widely the relation between a prepositional possessor and its head can (and must) be interpreted in English.

(25) a. David Peace’s Red Riding Quartet, which spins a fictional plot alongside **the murders of the Yorkshire Ripper**, is all the more potent for its true crime background.
b. One of two sisters who bombed the Old Bailey in the 1970s is in custody today being questioned about **the murders of two soldiers** in Northern Ireland in March.

c. Paul Temple is part of the era between **the upper class murders of Agatha Christie** and **the gritty murders of today**.

d. The driving rhythms of London's fiercely competitive cat-walks may seem a thousand miles away from **the cosy cottage murders of Miss Marple**, but they provide a perfect environment for the more chilling edge of Agatha Christie's short stories.

3.3.2 Secondary argument marking and ADJ

Sadler (2000: 94) claims that "there are several reasons for believing that PP dependents of nouns do not map to complement functions". She analyses PP dependents of nouns in Welsh as ADJ because they show relatively free word order with respect to each other, but are fixed with respect to a possessor DP/NP (2000: 94–97). The argument to some extent works also for English; in the following examples, the *of*-possessor phrase follows an optional *by*-phrase, even when the latter is heavy, as in (26b).[19]

(26) a. the description by the victims of their attacker

b. the description by the surgeon, Sir Zachary Cope, author of a highly regarded monograph on the early diagnosis of the acute abdomen, of his own experience with cholecystitis

3.3.3 Secondary argument marking and OBL

Rather than ADJ, Rappaport (2006 [1983]: 135–136) considers OBL_θ to be the best analysis of postnominal preposition phrases in English, on the grounds that postnominal noun phrases always "appear as the object of a preposition which reflects its thematic role." Possessive *of*-phrases are assumed to be $\text{OBL}_{\text{THEME}}$ explaining the restriction on *of*-phrases with some deverbal nouns:

(27) a. Randy instructed Deborah to meet him at two.

b. * Randy's instruction of Deborah to meet him at two

c. Randy's instructions to Deborah to meet him at two

(28) a. John fled the city.

b. * John's flight of the city

c. John's flight from the city

---

[19] The example in (26b) is taken from Flegel (2002: 1379).

(29) *the destruction of the Romans (with *the Romans* as Agent)

Another argument in favour of OBL_θ over ADJ is the treatment of deverbal nouns from verbs like *put* which subcategorize for both OBJ and OBL_θ. If the verb *put* requires SUBJ, OBJ and OBL_{LOC}, does the gerund *putting* require POSS, OBL_{LOC} and ADJ? Given that the semantic restrictions on the locational phrase remain in the deverbal noun phrase, OBL_{LOC} seems reasonable; but then it seems odd to assume that the OBJ of the verb is demoted to ADJ, moving below the OBL_{LOC} argument on the grammatical function hierarchy (Belyaev 2023b [this volume]). It would mean that in examples such (30), the ADJ would naturally precede a subcategorized OBL.[20]

(30) a. All right, Republicans are denouncing President Donald Trump because of his apparent defense of Russian President Vladimir Putin and **his putting of the United States and Putin's Kremlin on moral equivalent grounds**.

b. her constant placing of the Hills on a pedestal

On the other hand, Payne et al. (2013: 795) argue that "the empirical facts show the distinction between complements and modifiers of nouns to be unfounded. There is no rational way to motivate drawing the distinction between them… We assume no structural differentiation of the phrases formerly classified as either complements or adjuncts: all nouns are treated grammatically as nonrelational until they combine with a dependent." Payne et al.'s analysis is not formalized within LFG, but correlates with recent LFG work by Przepiórkowski (2016, 2017), who argues against the argument vs. adjunct distinction. If this is accepted, the OBL_θ vs. ADJ question with respect to noun phrase dependents is moot.

In some languages, the distribution of primary and secondary argument marking differs from the patterns seen above in English. As shown by Laczkó (1995, 2000; see also Laczkó 2007, 2017), event nominalizations in Hungarian require the theme argument to be expressed as either a dative or a nominative possessor, whereas the agent must be treated as an adjectivalized postpositional modifier. There is therefore no mapping in Hungarian equivalent to the mapping involved in the English *Edith's smashing of the vase.*

For Laczkó (2000), the Hungarian linking pattern for event nominals is essentially ergative: the SUBJ of an intransitive event nominal and the OBJ of a tran-

---

[20] The examples in (30a) and (30b) are from http://edition.cnn.com/TRANSCRIPTS/1702/06/nday.06.html (accessed 6 July 2021) and https://www.goodreads.com/review/show/1326602940 (accessed 6 July 2019), respectively.

sitive event nominal are mapped to poss, while the subj of a transitive event nominal is mapped to a *by*-phrase.

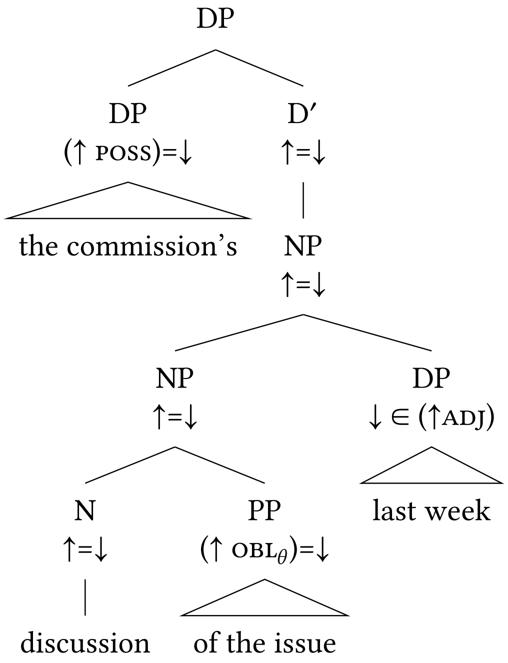
3.4 Sample analyses

It will have become clear from Section 3.2 and Section 3.3 that there are different views on what grammatical functions are available within the noun phrase and what their positions are within the c-structure. Here we will illustrate with two analyses of English noun phrases based on different assumptions, and one of Welsh, which shows interestingly different properties.

Based on some of the assumptions with respect to c-structure and noun-phrase internal grammatical functions, we would get the annotated tree in (32) for the noun phrase in (31), with the associated f-structure in (33), where we have simplified the pred values for the obl$_{\text{OF}}$ and the adj.

(31) the commission's discussion of the issue last week

(32)

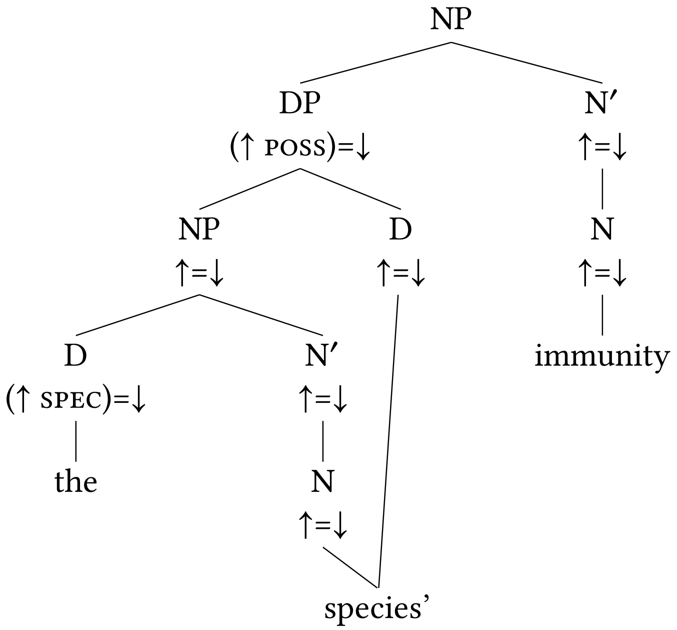


(33)
$$\left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{discussion}\langle(\textsc{poss}),\ \textsc{obl}_{\textsc{of}}\rangle\text{'} \\ \textsc{obl}_{\textsc{of}} & \left[\textsc{pred}\ \ \text{`}\textsc{issue}\text{'}\right] \\ \textsc{poss} & \left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{commission}\text{'} \\ \textsc{def} & + \end{array}\right] \\ \textsc{adj} & \left\{\left[\textsc{pred}\ \ \text{`}\textsc{last week}\text{'}\right]\right\} \end{array}\right]$$

In (32) and (33) we have opted to use the functions POSS and OBL_θ for the primary and secondary arguments, respectively, and assumed that these are optional arguments of *discussion*. With respect to c-structure, we have assumed that a distinction in attachment can be made between the complement *of the issue* and the adjunct *last week*, though we recognise that the arguments for this distinction are by no means unambiguous. There is no determiner element present in this analysis and hence the head of the DP is eliminated by what is generally referred to as the Principle of Economy of Expression (see Belyaev 2023a [this volume] for a summary, for different versions, see Bresnan et al. 2016: 90–2 and Toivonen 2003, and for a critical discussion see Dalrymple et al. (2015)). An alternative, if *'s* is analysed as a clitic, is to assume that it fills the D position (cf. similar assumptions for the Amharic definiteness marker in (16)), and this could then also account for the complementary distribution between the determiner and the POSS. However, Lowe (2016) provides arguments against this type of analysis and instead provides a lexical sharing analysis in which *'s* can be analysed as both an affix and a clitic. The lexical sharing analysis makes use of the dimension representing the string of words, the s-string, which is mapped to the hierarchical c-structure. Under certain circumstances, one element in the s-string can be associated with two nodes in the c-structure, and in this case *'s* is mapped both to the N and the D head of the possessor. In this analysis, though possessors are of category DP, non-possessor noun phrases are assumed to be of the category NP, where the specifier position can be filled either by a non-projecting D (represented as $\widehat{\text{D}}$ in LFG) (Belyaev 2023a: Section 2.1 [this volume]), or by a possessor DP, thereby accounting for the complementarity of possessors and determiners. The analysis is best demonstrated with an example where there is evidence of affix status, for instance where the *'s* is unexpressed because some property of the final word of the phrase it attaches to, as in (34), where *species* has the irregular "possessive" form *species'*. The annotated tree capturing the lexical sharing analysis is found in (35).

(34) the species’ immunity

(35)



Sadler (2000) provides an LFG analysis of Welsh noun phrases that she contrasts with the head movement analysis proposed by Rouveret (1994). Sadler assumes an NP structure, with the function poss found in the specifier of NP position.[21] This analysis captures the complementarity of a possessor and the definite determiner, which is a property also of Welsh, and it accounts for the definiteness of the noun phrase as a whole. The definiteness of a noun phrase containing a possessor is determined by the presence of the definite article *y*(*r*) within the possessor, and if there are nested possessors, within the most deeply embedded possessor. The complementarity is assumed to be a property of the definite article. The first equation in the lexical entry in (36) captures the complementarity and the second the definiteness feature.

(36) y*(*r*) ‘the’* ¬ (↑ poss)
(↑ def) = +

Consider the noun phrase in (37), where we have three layered possessors (note that ‘bank’ in ‘bank manager’ is realized as a possessor in Welsh).

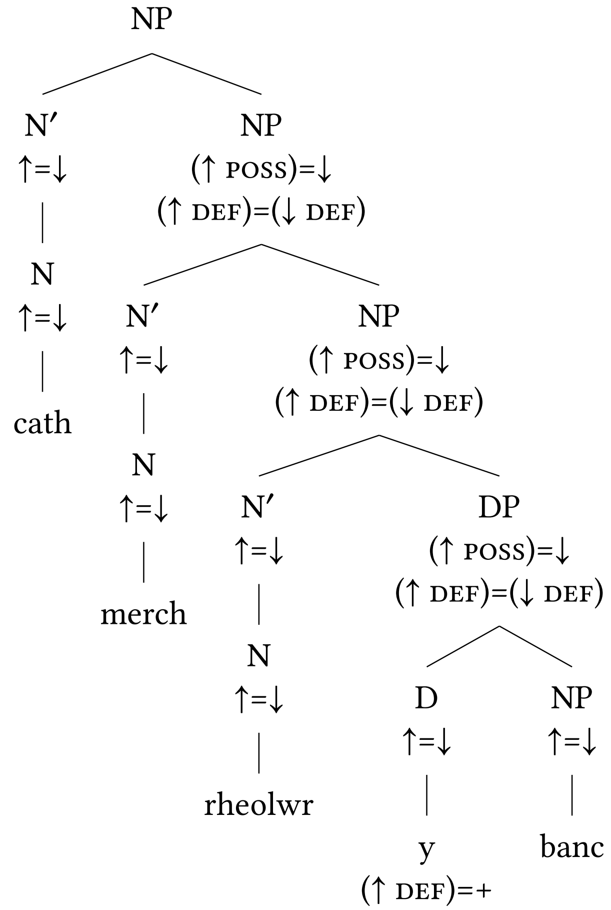
---

[21] Note that Sadler (2000: 97, fn 17) points out that if one accepts the claim that discourse-oriented functions such as poss are found in the specifier of a functional category, then a DP analysis of Welsh noun phrases would be appropriate, but states that the analysis developed in the paper can be recast in a DP structure.

(37) Welsh
cath merch rheolwr y banc
cat daughter manager the bank
‘the bank manager’s daughter’s cat’

The annotated c-structure tree assumed by Sadler (2000: 101) and the associated f-structure can be found in (38) and (39). Here we see how a possessor is annotated as sharing its DEF feature with its daughter, ensuring that the definiteness of the most deeply embedded possessor determines the definiteness of the noun phrase as a whole. In (39), we also see illustrated the difference in argument status of POSS between common (*cat* and *manager*) and relational (*daughter*) nouns illustrated for common and deverbal nouns in (20).

(38)



(39)
$$\left[\begin{array}{ll} \text{PRED} & \text{`CAT}\langle\,\rangle(\uparrow \text{POSS})\text{'} \\ \text{DEF} & + \\ \text{POSS} & \left[\begin{array}{ll} \text{PRED} & \text{`DAUGHTER}\langle(\uparrow \text{POSS})\rangle\text{'} \\ \text{DEF} & + \\ \text{POSS} & \left[\begin{array}{ll} \text{PRED} & \text{`MANAGER}\langle\,\rangle(\uparrow \text{POSS})\text{'} \\ \text{DEF} & + \\ \text{POSS} & \left[\begin{array}{ll} \text{PRED} & \text{`BANK'} \\ \text{DEF} & + \end{array}\right] \end{array}\right] \end{array}\right] \end{array}\right]$$

4 Noun phrases and "discourse functions"

In Section 3, we referred to the principle of structure-function association, which states that the specifier of functional categories houses discourse functions. This does not, of course mean that this is the only position where DFs can occur (see for instance Laczkó 2014, who provides evidence for a DF in the specifier of VP for Hungarian). Though noun phrases are unlikely to allow the same range of grammatical discourse functions as clausal constituents, languages may have positions reserved for emphasis or contrastive focus within the noun phrase, and in what follows we will use DF in its broadest sense as any information-structurally marked position (Zaenen 2023 [this volume]).

Babungo (Grassfields, Benue-Congo) has radically head-initial noun phrases. The examples in (40) illustrate this for a range of elements.[22]

(40) Babungo

a. ká wî
money that
'that money' (Schaub 1985: 73)

b. yílwáŋ têe
hammers five
'five hammers' (Schaub 1985: 74)

c. ŋgá kwàlə̀
antelope big
'a big antelope' (Schaub 1985: 72)

d. təsàw tə̂
pipes your
'your pipes' (Schaub 1985: 72)

---

[22] PST2 and PST4 refer to different past tense markers.

e. ghɨ́ ꜝwée
loaf child
‘the loaf of the child’ (Schaub 1985: 76)

f. wěembwā fáŋ tǐi wi sɨ́ sáŋ (ŋwə́)
child who father his PST2 beat.PFV him
‘a child whom his father had beaten’ (Schaub 1985: 34)

g. shúu ŋìi wúumbǎ wī
mouth house friend his
‘the door of his friend’s house’ (Schaub 1985: 76)

Babungo has a number of elements indicating emphasis. The elements *ŋkèe* and *shèˈ*, which can be associated with noun phrases as in (41), are described as emphasis adverbials. However, since these can also modify PPs, A(P)s and Adv(P)s, we can assume they are external to the noun phrase.

(41) Babungo

a. ŋkèe ŋkáw kāŋ
very chair my
‘my own chair’ (Schaub 1985: 74)

b. shèˈ ŋkáw kə́bwə̄
only chair bad
‘only a bad chair’ (Schaub 1985: 74)

More relevant to our exploration of DFs within the noun phrase are the emphatic forms of possessors and demonstratives, which precede the noun, as illustrated in (42).[23]

(42) Babungo

a. yíŋkíi tɨ̄
that.EMPH tree
‘that particular tree’ (Schaub 1985: 73)

b. ntɨ̌ɨ tə́sáw
your.EMPH pipes
‘your own pipes’ (Schaub 1985: 73)

There is also a negation focus element *tǔu*, which may precede the head noun as in (43).

---

[23] Emphatic demonstratives may also follow the noun (Schaub 1985: 73).

(43) Babungo

a. tǔu wə̀ mùˈ (nè kée lùu shɔ́ mē)
even person one PST4 NEG be there NEG
'Not even one person was there.' (Schaub 1985: 75)

b. (ŋwə́ nə̀ kée kɔ̀) tǔu fá (shée mē)
he PST4 NEG give.PFV even thing to.me NEG
'He didn't give me anything at all.' (Schaub 1985: 75)

As shown in (44), the emphasis adverbials, which we hypothesize occur outside the noun phrase, can co-occur with emphatic possessors and demonstratives.

(44) Babungo

a. shèˈ yíŋkíi ŋkáw
only that.EMPH chair
'only that particular chair' (Schaub 1985: 77)

b. shèˈ ŋkǎŋ ŋkáw kî
only my.EMPH chair that
'only that chair which is mine' (Schaub 1985: 77)

An unfocused demonstrative and an unfocused possessor can co-occur (45a), as can an focused possessive and an unfocused demonstrative (45b).

(45) Babungo

a. ŋkáw kāŋ kî
chair my that
'that chair of mine' (Schaub 1985: 77)

b. ŋkǎŋ ŋkáw kî
my.EMPH chair that
'that chair which is mine' (Schaub 1985: 77)

However, an emphatic demonstrative and an emphatic possessive cannot co-occur.[24] Similarly, the emphatic negative *tǔu* cannot co-occur with either the emphatic demonstrative or the emphatic possessive. The examples in (44) indicate that there is no general restriction on two emphatic elements being associated with the same noun phrase, so we can assume that the constraint that rules

---

[24] Emphatic demonstratives cannot co-occur with any possessor.

out the co-occurrence of the emphatic demonstrative and the emphatic possessive or *tŭu* is a noun phrase internal structural constraint. In other words, there appears to be one unique dedicated information-structurally privileged position within the noun phrase. By structure-function mapping, we might expect this to be the specifier of a functional projection, and hence for the tree in (2) or (4) to be appropriate. However, there is no other obvious evidence of a functional projection. There is no article in Babungo; there is what is described as an "anaphoric demonstrative adjective"(Schaub 1985: 97), but its position would not be taken as evidence of it being a projecting D. Babungo has a strict ordering within the noun phrase: Head noun > A > Poss > Nom > Dem > Q > PP > RelC (Schaub 1985: 77), but no evidence of a hierarchical structure.[25] Since freedom of word order is generally taken as one piece of evidence in favour of a flat structure, in Section 2.2 we referred to the possibility of using the criterion conversely, to assume that strict word may indicate a hierarchical structure. However, the interpretation of the Babungo data that we have argued for here indicates that word order can be strict even when there is no other evidence of hierarchical structure. Such non-hierarchical ordering restrictions can be accounted for within LFG by means of LINEAR PRECEDENCE RULES (Dalrymple et al. 2019: 144–145). However, this is not something that has been extensively explored in the LFG literature. Interestingly, in contrast to Babungo, which is head-initial and can be argued to have an initial information-structurally priviliged position, Ingush (Northeast Caucasian) has consistently head-final noun phrases and has an information-structurally privileged post-nominal position (Nichols 2011), so in a sense provides a mirror image of Babungo.

We see evidence, then, that noun phrases in different languages may include positions specifically associated with discourse-function marking. However, such positions need not be specifiers of functional projections, but may instead be specifiers of lexical projections (parallel to Laczkó's DF specifier of VP in Hungarian). Relatively little work has been done on discourse-function marking within the noun phrase, however, and more work is needed to establish the patterns and constraints on this cross-linguistically.[26]

---

[25] The only exceptions involve obligatory possession (inalienable and kinship), which occur between the head noun and the A .

[26] Authors who do consider the dimension of discourse structure within the noun phrase include Charters (2014) and Chisarik & Payne (2001, 2003).

5 Conclusion

In this chapter, we have explored aspects of the analysis of noun phrases in LFG. Relatively little work has been done within LFG on the c-structure of noun phrases, though there are some notable exceptions, to which we have referred in this chapter. Degrees of configurationality at clause level and how to analyse them has, however, been a focus of much LFG work. Therefore, in Section 2, we considered how these analyses could be transferred to noun phrases. We argued that examples can be found of strictly configurational, partly configurational and non-configurational noun phrases, so that the c-structure analyses of the three global levels of configurationality developed at clause level can be carried over to noun phrases. In Section 2.2 we also considered the use of functional categories in the noun phrase in light of the restricted approach generally taken to such categories within LFG.

The role of argument structure and grammatical functions within noun phrases is, on the other hand, well-studied within LFG. However, there is no consensus on which GFs are relevant within noun phrases, or how the arguments of nouns relate to those of verbs. In Section 3, we reviewed and evaluated a number of proposals from the literature. We also considered how principles of endocentric structure-function association (Bresnan et al. 2016: 105, 117) apply to the relation between grammatical functions and structure in noun phrases.

Though noun phrases are unlikely to involve the same range of information structural notions as clauses do, basic notions such as emphasis and contrast do apply. In Section 4, we argued that there are languages that have a position for a basic grammaticalized discourse function within the noun phrase. In the languages we considered, this is a position at the edge of the noun phrase, preceding the head in a head-initial language (Babungo) and following the head in a head-final language (Ingush). However, our consideration has been relatively superficial and the noun phrases of these languages deserve further consideration.

Acknowledgements

Some of this paper formed part of a presentation at LFG 2019 at ANU in Canberra, and Börjars is grateful for comments received there. We are grateful to the three referees whose comments have helped clarify a number of things.

Chapter 13

Pronoun incorporation

Ida Toivonen
Carleton University

In LFG, so-called ‘pro-drop’ is analyzed as pronoun incorporation, where the person and number marking on the head is the pronoun. The morphology on the head thus serves a dual function: it is an agreement marker when an independent noun or pronoun is present in the clause, and it is an incorporated pronoun when no independent nominal element is present. This chapter spells out the basic analysis of the interplay between pronoun incorporation and agreement marking in LFG. The analysis is illustrated with examples from subject, object, and possessive marking in multiple languages. The chapter also discusses cases where the agreement marker displays markedly different characteristics than the homophonous incorporated pronoun.

1 Introduction

In LFG, pro-drop is analyzed as pronoun incorporation. The term pro-drop (from the longer pronoun/pronominal dropping) refers to certain instances where a morphologically independent pronoun is not pronounced even though the sentence involves a pronominal interpretation. The pro-drop example in (1) is from Italian, a language that allows subject pro-drop (the example is from Burzio 1986: 92):

(1) Italian
Ho mangiato bene.
have.1sg eaten well
‘I have eaten well.’

Ida Toivonen. 2023. Pronoun incorporation. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 563–601. Berlin: Language Science Press. DOI: 10.5281/zenodo.10185960

English is not a pro-drop language, and pronouns cannot be left unpronounced like subject pronouns can in Italian. However, possible pronoun omission is not an all-or-nothing phenomenon. Haegeman (1990) and Weir (2008) discuss the restricted omission of subjects which can occur in certain registers in English (especially so-called ‘diary drop’), and Cardinaletti (2014) shows that there is variation within Italian dialects regarding when pronouns can be dropped. The generalization remains that pronouns are omitted quite freely in most languages (e.g., Italian, Arabic, Chicheŵa), although some languages resist it (e.g., English, French).

The Italian example in (1) illustrates what is traditionally called pro-drop, where pronoun omission goes hand-in-hand with rich agreement marking on the verb (see, e.g., Chomsky 1981). The person, number and sometimes gender of the subject is indicated by the morphology on the verb, rendering the independent pronoun in a sense superfluous. This type of pro-drop is analyzed as pronoun incorporation in LFG: the agreement morpheme doubles as an incorporated pronoun.

Section 2 spells out the basics of this incorporation analysis of pro-drop, where the so-called agreement marker is in fact ambiguous between an agreement morpheme and a pronoun. When the independent pronoun is absent (‘dropped’), the morpheme is analyzed as a pronoun whose form is morphologically incorporated into the head. When the independent pronoun is present, the morpheme merely agrees with it.

Section 3 provides examples of pro-drop that illustrate the richness of the phenomenon. The term pro-drop is often used to refer exclusively to the omission of a subject pronoun, as in Italian, but the phenomenon is in fact not limited to subjects of finite verbs: any instance of INDEX agreement (Haug 2023 [this volume], Wechsler & Zlatić 2003) can involve pronoun incorporation.

Section 4 discusses the LFG analysis of pro-drop in light of the standard view of how agreement marking emerges through language change. The section reviews previous work which argues that the standard LFG analysis, positing ambiguity between agreement markers and pronouns, is natural given the grammaticalization path from independent pronoun to bound agreement morpheme.

Section 5 explores ambiguous forms that have grown apart beyond their mere status as pronoun or agreement marker. Many puzzling agreement phenomena from a variety of languages can be explained by the insight that the pronoun/agreement ambiguity assumed in LFG pro-drop analyses can lead to more radical differences between lexical entries that share a form.

Finally, Section 6 turns to a brief discussion of DISCOURSE PRO-DROP and TOPIC DROP. These two types of pro-drop have received less attention in the LFG literature, and, it seems, in the linguistics literature more generally. These types of pro-drop are not tied to rich agreement and therefore tend to be analyzed with different syntactic mechanisms than the Italian-style pro-drop that is the main concern of this chapter.

Reflecting the majority of LFG research concerned with pro-drop, this chapter focuses on the morphosyntactic aspects of pronoun incorporation. However, discourse-pragmatic factors are also highly relevant for a full understanding of the phenomenon. In cases where pro-drop is syntactically optional, the distribution of pronouns is determined by discourse factors. This is illustrated by the Spanish examples in (2) provided by Pešková (2013). In (2a), the independent subject *yo* of the second verb is obligatorily expressed, but in (2b), the inclusion of a subject before the second verb would be infelicitous on the intended interpretation where *Pedro* is the subject of both verbs:

(2) Spanish

a. Juan habla checo, pero yo hablo
John speak.3SG.PRES.IND Czech but I.NOM speak.1SG.PRES.IND
eslovaco.
Slovak
'John speaks Czech, but I speak Slovak.'

b. Pedro canta y toca la guitarra.
Peter sing.3SG.PRES.IND and play.3SG.PRES.IND the guitar
'Peter sings and plays the guitar.'

Example (2a) differs from (2b) in that the subject of the second verb in (2a) is a contrastive topic, and contrastive topics are cross-linguistically often marked by emphatic forms or stress. In Spanish and many other languages, pro-drop only occurs when an appropriate antecedent is readily accessible in the discourse context. However, establishing what counts as an appropriate antecedent is non-trivial and seems to vary across languages and dialects (see Alonso-Ovalle et al. 2002; Holmberg 2010; and references provided in those works).

The pragmatic aspect of pro-drop has been addressed within the LFG literature. For example, Dahlstrom (1991: Chapters 4–5) shows that Plains Cree independent pronouns are only included when they are used contrastively. A few other LFG proposals that address pro-drop at the discourse-pragmatic level are referred to in Section 6. However, unlike the morphosyntax of incorporation-style pro-drop (the Italian, Spanish and Finnish type), there is no unique analysis of the discourse factors that is uniformly adopted across the LFG community, and the important question of exactly when "optional" pronouns are expressed will therefore not be discussed in detail.

2 Pronoun incorporation and agreement in LFG

The standard analysis[1] of pro-drop in LFG posits that the person and number morphology on the head (which is typically a verb) *is* the pronoun. The "agreement" morphology can thus be thought of as an incorporated pronoun when no corresponding independent pronoun or NP is present in the string. This has been the basic analysis of regular pro-drop in LFG since Fassi Fehri (1984, 1988, 1993) and Bresnan & Mchombo (1987). However, the insight predates Fassi Fehri, Bresnan and Mchombo and indeed the LFG framework. The same underlying idea has long been adopted by some traditional grammarians describing languages with prolific pro-drop. It is, for example, implicity assumed by Ashton (1944), who notes in her Swahili grammar "…in a Bantu language function is more important than form, and one affix often has more than one function" (1944: 8).

The formal LFG analysis of pro-drop does not actually involve dropping or deleting a pronoun. There is no phonologically null pronoun present in the phrase structure. There is also no movement involved: the pronominal information is not assumed to have moved into the verbal position in order to be incorporated into the verb.

The separation of constituent structure (c-structure) and functional structure (f-structure) is key to understanding how LFG models pro-drop. C-structure and f-structure concern different aspects of syntactic structure. C-structure is typically modeled using phrase structure trees and displays information about syntactic category (e.g., noun, verb), word order and constituency. F-structure is modeled as feature structures (attribute-value matrices, AVMs) that contain information about formal features such as tense and case. Importantly, LFG also models syntactic functions (e.g., SUBJECT, ADJUNCT) using f-structures.

The basic LFG analysis of pro-drop is described in Haug 2023 [this volume] and will also be illustrated here with the help of example (3) from Finnish (Finno-Ugric):[2]

(3) Finnish

Join	kahvia.
drink.PAST.1SG	coffee.PART

'I drank coffee.'

---

[1] Alternative analyses of pro-drop have been proposed within LFG; see Alsina (2020) for a recent example.

[2] The examples given here are from standard Finnish, which is the variety used in formal settings and in writing. Pro-drop is in fact less common in informal Finnish. Moreover, the discussion here only covers first and second person pronouns; third person pro-drop in Finnish is more constrained (Holmberg forthcoming).

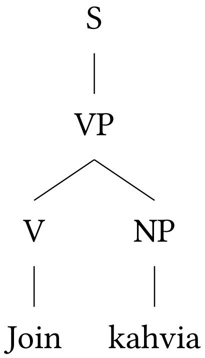
Finnish verbs inflect for three persons and two numbers. The full past tense paradigm for *juoda* 'to drink' is given in (4):

(4) *juoda* 'to drink' (Finnish)

SG	1	*join*
	2	*joit*
	3	*joi*
PL	1	*joimme*
	2	*joitte*
	3	*joivat*

The verb forms provide information about the subject's person and number. In an example like (3), there is no syntactically independent subject. A standard LFG analysis would postulate that the morphological information concerning the subject on the verb *is* the subject. The c-structure and f-structure of (3) are given in (5):

(5) C-structure and f-structure for (3)



$$\left[\begin{array}{ll} \text{PRED} & \text{`DRINK}\langle\text{SUBJ, OBJ}\rangle\text{'} \\ \text{TENSE} & \text{PAST} \\ \text{OBJ} & \left[\begin{array}{ll} \text{PRED} & \text{`COFFEE'} \\ \text{NUM} & \text{SG} \\ \text{PERS} & 3 \\ \text{CASE} & \text{PARTITIVE} \end{array}\right] \\ \text{SUBJ} & \left[\begin{array}{ll} \text{PRED} & \text{`PRO'} \\ \text{NUM} & \text{SG} \\ \text{PERS} & 1 \end{array}\right] \end{array}\right]$$

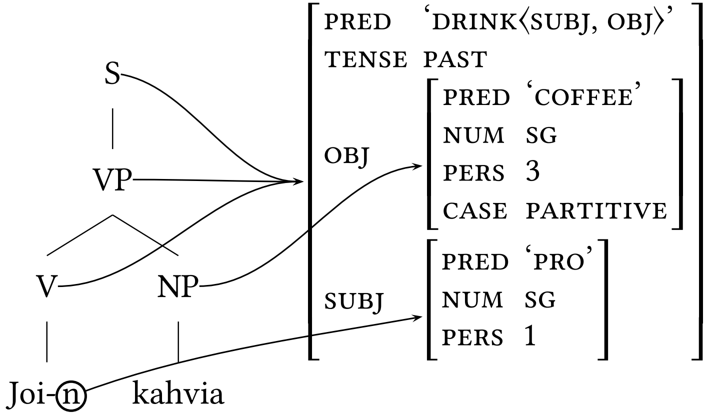
The verb *join* in (3) is not formed in c-structure or f-structure; it is fully formed in the lexicon.[3] The c-structure does not have access to the internal structure of *join*: the terminal nodes in the phrase structure are morphologically complete words.

The mapping between c-structure and f-structure is not necessarily one-to-one; it allows for mismatches. Several f-structures can therefore receive featural information from the same word. In a sentence such as (3), the main f-structure of the sentence (the outer f-structure) and the subject f-structure both receive information from the verb *join*:

---

[3] The modular architecture of LFG is compatible with different theories of morphology (Dalrymple 2015, Dalrymple et al. 2019: Chapter 12; Bond 2016).

(6) Mapping between c-structure and f-structure, example (3)

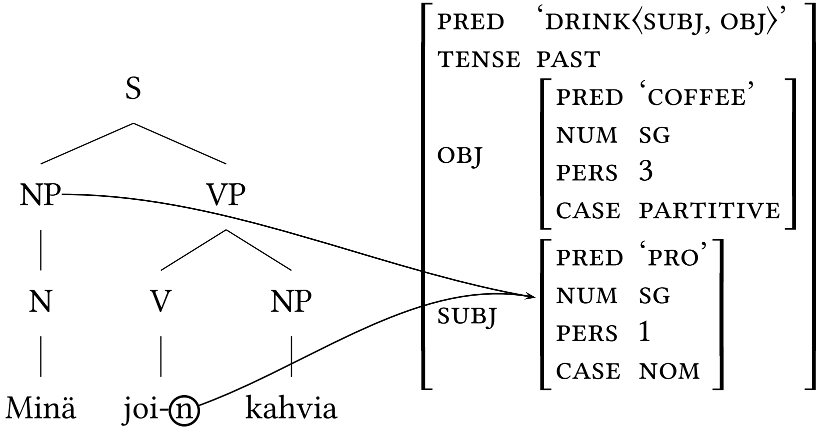


Information from several different words can also map onto the same f-structure. For example, in the Finnish sentence (7), information about the subject comes from both the pronoun *minä* and the agreement morphology on the verb.

(7) Finnish
Minä join kahvia.
I.NOM drink.PAST.1SG coffee.PART
'I drank coffee.'

The c-structure and f-structure for (7) are provided in (8):

(8) Mapping between c-structure and f-structure, example (7)



In sum, in Finnish and other subject pro-drop languages, the pronominal subject information can be provided by the morphology on the verb alone (as in (3)) or from the subject and the verb jointly (as in (7)).

According to the LFG analysis outlined above, the first person singular ending *-n* has a different function in (3) than in (7). In (3), the ending is the pronoun, but in (7) it is a mere agreement marker. In pro-drop languages, the agreement morphology thus doubles as pronominal incorporation. Central to capturing this dual function formally is the PRED feature: pronouns have a PRED feature and agreement markers do not. The PRED feature value is a SEMANTIC FORM and is therefore of a different nature than other feature values:[4] it is an indicator of the semantics of the form and it also contains information about its possible argument structure (Bresnan et al. 2016: Chapter 4), although fuller treatment of these aspects is given at the independent grammatical levels of argument structure and semantic structure.[5] The PRED feature also differs from other features in that its value is unique and can therefore not unify with another PRED feature, even if it is identical. This characteristic is crucial for understanding pro-drop in LFG, as will be illustrated below.

The lexical entry for the Finnish first person singular ending *-n* is provided here:

(9) *-n* (↑ SUBJ NUM) = SG
(↑ SUBJ PERS) = 1
((↑ SUBJ PRED) = 'PRO')

The first two lines of the lexical entry indicate that the subject of the verb hosting the ending *-n* is singular and first person. The third line states that a PRED feature with the value 'pro' (a pronominal referential feature) is optionally contributed to the subject. The parentheses indicate the optionality. The optional feature in effect yields two very similar yet not identical lexical entries, one with a PRED feature and one without:

(10) (a) *-*n_1 (↑ SUBJ NUM) = SG
(↑ SUBJ PERS) = 1
(↑ SUBJ PRED) = 'pro'

(b) *-*n_2 (↑ SUBJ NUM)= SG
(↑ SUBJ PERS) = 1

The ending *-n* maps onto the SUBJ f-structure and cannot combine with an independent subject that is not first person singular, as that would violate the LFG principle of UNIQUENESS. Uniqueness states that every attribute has a unique value. Since LFG allows feature unification, the *-*n_2 ending in (10b) can combine its PERS and NUM values with those of the independent pronoun *minä* where

---

[4] Formal syntactic features such as TENSE and NUM take symbols such as PAST and PLURAL as values. Features can also take feature structures as values. For example, the values of grammatical function attributes (e.g., SUBJ, OBJ) are feature structures. Different types of features are illustrated in the f-structures above.

[5] For more references and discussion of the PRED feature, see Dalrymple et al. (2019: Section 8.2).

there is no feature conflict, but not with those of the pronoun *te* 'you (plural)', for example. The lexical entries for *minä* and *te* are given in (11a) and (11b), respectively:

(11) a. *minä* $(\uparrow \text{PRED}) = \text{`PRO'}$
$(\uparrow \text{NUM}) = \text{SG}$
$(\uparrow \text{PERS}) = 1$
$(\uparrow \text{CASE}) = \text{NOM}$

b. *te* $(\uparrow \text{PRED}) = \text{`PRO'}$
$(\uparrow \text{NUM}) = \text{PL}$
$(\uparrow \text{PERS}) = 2$
$(\uparrow \text{CASE}) = \text{NOM}$

The second person plural pronoun *te* will not co-occur with the first person singular *-n* because of the mismatch in features. The first person singular *minä* does co-occur with *-n* (see (7), for example). There is no mismatch in PERS or NUM, and *minä* can occur with the agreement marking ending in (10b). However, as mentioned above, each PRED value is assumed to be unique, and the pronoun *minä* can therefore not map onto the same f-structure as the pronominal *-n* ending in (10a), which itself contributes a PRED feature. The PRED feature of *minä* would also be 'PRO', but since every PRED feature value is unique, the two cannot combine. The single quotes around the semantic form indicate that it is unique. The uniqueness is sometimes also indicated with a subscript notation.

Again, the agreement marker *-n*$_2$ in (10b) can co-occur with *minä*: *-n*$_2$ has no PRED feature that could clash with the PRED feature of *minä*, the PERS and NUM features match and can unify, and the CASE feature is contributed by *minä* alone. In fact, *-n*$_2$ would have to co-occur with some lexical entry in the string contributing a PRED feature, otherwise the f-structure of the sentence would end up containing a SUBJ feature without a PRED. This is only acceptable for syntactic arguments that are not semantic arguments (e.g., expletives). Each semantic argument needs a PRED feature, by the LFG principle of completeness. The following formulation of completeness is provided by Bresnan et al. (2016: 62):

(12) COMPLETENESS:
i. Every function designated by a PRED must be present in the f-structure by that PRED.
ii. If a designator $(\uparrow \text{GF})$ is associated with a semantic role by the PRED, the f-structure element satisfying the designator must itself contain a semantic feature [PRED v].

The features provided by *minä* will map onto the SUBJ function at f-structure by the regular mapping principles between c-structure and f-structure (Bresnan et al. 2016: Chapter 4), and so will the features provided by -n_1. In terms of feature content, the only difference between *minä* and -n_1 is that *minä* has a nominative CASE feature. The two entries are strikingly different in form: one is an independent word and the other a bound morpheme, and they also differ phonologically. However, the entries are nevertheless almost identical in terms of the feature content they contribute to f-structure. Since both *minä* and -n_1 have a PRED feature 'pro', they both function as pronouns, despite the differences in morphophonological realization. The LFG parallel architecture allows for the possibility that forms look different at c-structure but nevertheless have the same function at f-structure.

LFG also allows for mismatches in the other direction: same form, different function. This is illustrated by the ambiguity of the *-n* form. The optionality of the PRED feature has an important effect on the function of the *-n* morpheme: -n_1, with a PRED 'pro' feature, is a pronoun, and the ending -n_2, without a PRED feature, is an agreement marker.

The examples considered concern subjects. The pronominal possessors in standard Finnish also display pro-drop, as illustrated in (13). The possessive suffix (*-ni* for first person singular) is obligatory but the independent pronoun is optional:[6]

(13) Finnish

a. (Minun) auto-ni on vanha.
my car-1SG.Px is old
'My car is old.'

b. *Minun auto on vanha.
my car is old

Just like subject pro-drop, the analysis of possessor pro-drop relies on the PRED feature of the possessive suffix *-ni*. The suffix contributes a PRED 'pro' feature when it stands alone, and it lacks a PRED feature when it is doubled by the independent pronoun *minun*.

Examples of object pro-drop are also attested cross-linguistically. Object pro-drop is common across the Bantu languages, for example (Bresnan & Mchombo 1987, Hualde 1989, Barrett-Keach 1995, Riedel 2009, a.o.). The examples below,

---

[6] However, there are varieties of Finnish where the example in (13b), without the suffix, is grammatical.

adapted from Hualde (1989), are from the Bantu language KiRimi (also known as Nyaturu):[7]

(14) KiRimi

a. N-a-kU-on-aa (veve).
1-TNS-OM-saw-FV you
'I saw you.'

b. *N-a-on-aa veve.

Parallel to the Finnish subject and possessor examples above, the object markers that agree with independent pronouns in KiRimi are obligatory, while the independent pronouns themselves are optional. The analysis presented above can be applied in this case as well: the prefix *-kU-* has an optional PRED 'pro' feature and contributes its PRED feature only when *veve* is absent.

3 Pronominal marking across languages

This section explores some of the different ways languages make use of morphology on the head to provide information about dependents. The previous section presented the standard LFG analysis of pro-drop, which rests on the insight that the morpheme on the head has a dual function as an agreement marker and an incorporated pronoun. Of course, this does not mean that agreement morphemes *must* be able to double as pronouns. The English third person singular marker on present tense verbs (*-s* in *Mia walks*) functions solely as an agreement marker, for example. Like English, French does not allow pro-drop, even though French verbs display more detailed subject agreement marking than English, especially in the written forms. The paradigm for the verb *finir* 'to end, to finish' in (15) serves as an illustration:

(15) *finir* 'to end, to finish' (French)

SG	1	*finis*
	2	*finis*
	3	*finit*
PL	1	*finissons*
	2	*finissez*
	3	*finissent*

---

[7] FV in the gloss stands for "final vowel". This "final vowel" in Bantu has received some attention in the literature for reasons not relevant here.

In LFG terms, the subject endings on French and English verbs are mere agreement markers that do not have PRED features, not even optional ones. Rich agreement without pro-drop is cross-linguistically very rare (Siewierska 1999).

Conversely, an incorporated pronoun does not necessarily double as an agreement marker. For example, Bresnan & Mchombo (1987) argue that object markers in the Bantu language Chicheŵa are unambiguously incorporated pronouns.[8] Chicheŵa object markers are exemplified by the morpheme *chí* in (16) (Bresnan & Mchombo's example (12)):

(16) Chicheŵa
Fîsi anadyá chímanga. Á-tá-chí-dya, anapítá ku San Francîsco.
hyena ate corn(7) he-SERIAL-it(7)-eat he-went to San Francisco
'The hyena ate the corn. Having eaten it, he went to San Francisco.'

The object marker *chí* is specified as noun class seven,[9] and is naturally interpreted as referring back to 'corn' in (16). It is possible to also include a freestanding pronoun as in (17) (Bresnan & Mchombo's example (13)) below, but the pronoun is then not interpreted as referring back to the 'corn' object from the previous sentence:

(17) Chicheŵa
Fîsi anadyá chímanga. Á-tá-chí-dya icho, anapítá ku San Francîsco.
hyena ate corn(7) he-SERIAL-it(7)-eat it he-went to San Francisco
'The hyena ate the corn. Having eaten it (something other than corn), he went to San Francisco.'

The grammatical object in the second sentence of (17) is the object marker, and the independent pronoun *icho* is a topic anaphorically linked to the object. In Chicheŵa, independent pronouns are used only for introducing new topics or for contrast (Bresnan & Mchombo 1987: 748).

Object markers can also co-occur with NPs headed by non-pronominal nouns:

---

[8] Bresnan & Mchombo (1987) use the term ANAPHORIC AGREEMENT for markers that have a pronominal function and GRAMMATICAL AGREEMENT for markers that have a mere agreement marking function and no referential properties.

[9] Bantu languages are well-known for their rich noun class (gender) system; see Katamba (2003) for an extensive overview. Chicheŵa has 18 noun classes that are listed in Bresnan & Mchombo (1987: Table 1). Agreement markers and pronouns reflect the class of the noun they agree with or refer to.

(18) Chicheŵa
Njâchi zi-ná-wá-lúm-a alenje.
bees SM-PAST-OM-bite-INDIC hunters
'The bees bit them, the hunters.'

In (18) (Bresnan & Mchombo's example (2)), *alenje* is a floating topic linked to the object marker *wá*, which is an incorporated pronoun. However, if the full NP is a regular object with no special discourse status, the object marker does not appear:

(19) Chicheŵa
Njâchi zi-ná-lúm-a alenje.
bees SM-PAST-bite-INDIC hunters
'The bees bit the hunters.'

The object marker cannot co-occur with a regular object as that would result in a 'PRED clash': they would both contribute a PRED feature value and thus violate the uniqueness principle.

Bresnan & Mchombo (1987) provide ample evidence based on word order, intonation, tonal marking and other phenomena showing that the Chicheŵa pronominal object markers differ from subject markers. Chicheŵa subjects display regular pro-drop. The subject markers are obligatory, unlike object markers. A subject marker can be an agreement marker as in (19) above or an incorporated pronoun as in (20):

(20) Chicheŵa
Zi-ná-lúm-a alenje.
SM(10)-PAST-bite-INDIC hunters
'They bit the hunters.'

The Chicheŵa data show that different classes of morphemes (subject markers and object markers) can display different pro-drop characteristics within a single language. While the object marker functions as an incorporated pronoun only, the subject marker has a dual function as an agreement marker and a pronoun.

Agreement marking often shows sensitivity to animacy. Specifically, nouns that refer to entities higher on the animacy scale are more likely to trigger agreement. This effect is observed in many Bantu languages (Riedel 2009), for example Swahili (Barrett-Keach 1995) and KiRimi (Hualde 1989). KiRimi object markers agree with animate but not inanimate objects (Hualde 1989).

KiRimi object pro-drop was illustrated in (14) in Section 2, and is further illustrated in (21). The KiRimi examples in (21–22) and (24) are from Hualde (1989).

(21) KiRimi

a. N-a-**mU**-on-aa Maria.
1-tns-om-saw-fv Maria
'I saw Maria.'

b. N-a-**mU**-on-aa.
1-tns-om-saw-fv
'I saw her.'

Like Chicheŵa subjects, the KiRimi animate object marker has a dual function as an agreement marker (21a) and a pronoun (21b). This is captured here with an optional pred 'pro' in the lexical entries for animate object markers. Inanimate object markers, on the other hand, cannot co-occur with independent objects:

(22) KiRimi

a. N-a-**ki**-on-aa.
1-tns-om-saw-fv

b. *N-a-**ki**-on-aa kItabu.
1-tns-om-saw-fv book
'I saw it.'

Inanimate object markers can function as pronouns (22a), but they cannot agree with an object (22b). KiRimi inanimate object markers thus have an obligatory pred feature, like the object markers in Chicheŵa. The lexical entry for the noun class 7 object marker *-ki-* is given in (23):

(23) *-ki-* (↑ obj pred) = 'pro'
(↑ obj animate) = −
(↑ obj pers) = 3
(↑ obj def) = +

The presence of an agreeing object marker further indicates a definite interpretation of the object. This is shown in (24a) and (24b), where the difference in interpretation is indicated by the translation:

(24) KiRimi

a. N-a-**mU**-on-aa mwalimu.
1-tns-om-saw-fv teacher
'I saw the teacher.'

b. N-a-on-aa mwalimu.
1-TNS-saw-FV teacher
'I saw a teacher.'

The object in example (24a) with the object marker receives a definite interpretation, whereas the object in (24b) without an object marker receives an indefinite interpretation. The lexical entry for the noun class 1 object marker *-mU-* is provided in (25):

(25) *-mU-* ((↑ OBJ PRED) = 'PRO')
(↑ OBJ DEF) = +
(↑ OBJ ANIMATE) = +
(↑ OBJ PERS) = 3

The PRED feature for animate *-mU-* is optional: the feature is present when the object marker is pronominal and absent when the object marker functions as an agreement marker. Both the pronoun and the agreement marker are definite: personal pronouns are in general definite, and the agreement marker ensures a definite interpretation of non-pronominal objects.

The generalizations that KiRimi object markers only double objects that are both definite and animate are captured here with simple lexical specifications and the LFG principle of uniquess. The analysis is straightforward, but it does not explain the fact that the KiRimi facts follow certain cross-linguistic generalizations: dependents that are definite and high in animacy are cross-linguistically more likely to trigger agreement on the head. We will return to this point in Section 4.[10]

Like KiRimi, Irish shows that there can be differences with respect to pronouns and agreement marking within a single paradigm. However, in Irish, the

---

[10] An anonymous reviewer points out that there might be noun classes with both animates and inanimates. Hualde (1989) does not address this possibility, but the description of KiRimi noun classes in Olson (1964) indicates that noun classes 9–10 and possibly 12–13 (diminutives) include both animates and inanimates. This is corroborated by Beletskiy & Diyammi's (2010) notes on noun classes in the closely related dialect/language Isanzu. I have not found a discussion of what the agreement data are in these noun classes. Hualde makes the categorical claim that only definite animates trigger agreement. If this is correct, then each relevant prefix is best represented with two quite different lexical entries and are thus examples of LEXICAL SPLITS (discussed below in Section 5). However, Olson (1964: 171) provides a few examples where inanimate objects from class 9 ('gardens', 'beehive', 'meat') cooccur with an object marker. This would indicate that nouns referring to biological inanimates from class 9 carry a grammatical [+ANIMATE] feature. For other examples of misalignment between biological animacy and grammatical animacy, see Bayanati & Toivonen (2019) and references cited therein.

variation is not governed by definiteness or animacy, the pattern instead seems idiosyncratically determined by form. In Irish, some verb forms (synthetic forms) provide person-number information about the subject that other forms (analytic forms) do not. The following conditional paradigm from Ulster Irish is from McCloskey & Hale (1984):

(26) *cuir* 'to put' (Irish)

sg	1	*chuirfinn*
	2	*chuirfeá*
	3	*chuirfeadh sé* (masc), *chuirfeadh sí* (fem)
pl	1	*chuirfimis*
	2	*chuirfeadh sibh*
	3	*chuirfeadh siad*

The synthetic forms *chuirfinn, chuirfeá* and *chuirfimis* contain information about the pronominal subjects, but *chuirfeadh* does not. The analytic *chuirfeadh* allows the subject to be expressed independently as a pronoun (*sé, sí, sibh,* or *siadh* in (26)) or a full NP. The synthetic forms cannot co-occur with independent pronouns, as evidenced by the ungrammaticality of (27) from McCloskey & Hale (1984):

(27) Irish:
*Chuirfinn mé isteach ar an phost sin.
put.cond.1sg I in on that job
'I would apply for that job.' (intended)

The fact that independent subject pronouns are ruled out indicates that the pronominal pred features in the lexical entries of the synthetic forms *chuirfinn, chuirfeá* and *chuirfimis* are obligatory, unlike the optional subject pred 'pro' features in Finnish and Chicheŵa. The pred features contributed by the synthetic verb forms cannot unify with the pred features of independent pronouns. In second person plural and third person singular and plural, however, the verb form does not contain any information about the subject. This information is instead contributed by independent pronouns. For more examples and discussion of variation within Modern Irish, see McCloskey & Hale (1984). For detailed LFG analyses, see Andrews (1990) and Sulger (2010).

This brief overview provides a sample of the variety of patterns that pro-drop languages put on display cross-linguistically. The cross-linguistic differences are captured lexically in LFG: an incorporated pronoun has a pred 'pro' feature, an agreement marker has no pred feature, and morphemes that lead a double life as pronouns and agreement markers have an optional PRED feature. The data we have examined here illustrate that languages vary with respect to how they employ these possibilities. The data also illustrate that there can be differences within the same language between paradigms and, perhaps surprisingly, also within paradigms.

For more LFG analyses of pro-drop, drawn from a wide variety of languages and also a variety of types of pro-drop, see Dahlstrom (1991: Chapter 5) for Plains Cree subjects and objects, Sadler (1997) for Welsh subject and object clitics, Toivonen (2000, 2001) for Finnish infinitives, Strunk (2004, 2005) for nominal possessive constructions in Low Saxon, Rákosi & Laczkó (2011) for Hungarian spatial particles, Bayram (2013) for Turkish subjects and possessors, Laczkó (2017) for Hungarian possessors, and Dione (2019) for subjects in Wolof.

4 Grammaticalization

A stage where an affix is ambiguous between an agreement marker and a pronoun is unsurprising in light of the typical grammaticalization path of pronoun to agreement marker (Givón 1976, Mithun 1988, Hopper & Traugott 2003, van Gelderen 2011):

(28) independent pronoun > weak pronoun > clitic pronoun > agreement affix > fused agreement marker

The naturalness of pronoun/agreement ambiguities given the grammaticalization cline in (28) has been noted in many previous analyses of pro-drop, including Fassi Fehri (1984), Bresnan & Mchombo (1987), Austin & Bresnan (1996), Toivonen (2001), Morimoto (2002), Butt (2007), Coppock & Wechsler (2010), Barbu & Toivonen (2018) and Haug 2023 [this volume]. These authors and others have pointed out that when pronouns transition into agreement affixes, there can be a stage where the forms are not immediately reanalyzed as wholesale agreement, but instead are agreement markers when they double an NP and pronouns when they do not.

The grammaticalization cline in (28) conflates multiple linguistic dimensions. One such dimension regards the function: Does the marker have pronominal referential capacity or is it a mere agreement marker? This is modeled at f-structure in LFG. Other dimensions concern the morphophonological realization as an independent word, a clitic, a bound agglutinative morpheme, or a fused morpheme. This is modeled at c-structure, m-structure and p(rosodic)-structure in LFG. A lexical entry can in principle be ambiguous between a pronoun and an agreement marker regardless of its morphophonological realization.

The grammaticalization path in (28) therefore conflates common sequences of changes that are often but not always parallel. One sequence concerns c-structural realization:

(29) projecting word > non-projecting word > true clitic > affix > fused affix

A projecting word is a word that projects a phrase and a non-projecting word is a morphologically and phonologically independent word that does not project a phrase. A "true clitic" is here intended to refer to a form that does not project a phrase and is phonologically dependent on a host, but is not a bound morpheme. Projecting words can also be phonologically dependent on a host, which illustrates that prosody has in fact its own relevant dimension which could be separated from (29). Toivonen (2003: 45) provides examples of different types of projecting and non-projecting words and clitics. See also Lowe (2016) for a detailed treatment of clitics in LFG.

Another relevant scale concerns referential capacity:

(30) noun > pronoun > ambiguous pronoun/agreement marker > agreement marker > transitivity marker

The prosodic or phrase-structural realization in (29) is orthogonal to the scale in (30), which is a nominal scale of referential strength. This is modeled here to a large extent with the PRED feature. As seen in the sections above, nouns, pronouns and agreement markers differ in their PRED feature: nouns have a contentful nominal PRED feature, pronouns have the PRED feature 'pro', and agreement markers have no PRED feature at all. A transitivity marker is referentially very weak, as it simply indicates that there *is* an object and does not say anything about what the object refers to.

Changes along the cline in (29) tend to be closely tied to changes along (30). In Siewierska's (1999) survey of 272 languages, most pronouns (forms with obligatory PRED 'pro') are independent words; ambiguous forms (optional PRED) are small words, clitics or affixes; and pure agreement markers are affixes. However, the scales in (29) and (30) are not inherently connected. This disconnect is carefully argued for in van Rijn (2016), who draws on a sample of personal possessors from 39 different languages. She concludes that "loss of referentiality correlates with a loss in form, but in a relative rather than an absolute sense […] function and form evolve in the same direction, but need not evolve at the same pace" (2016: 233).

The insight that function and form can change independently of each other is not difficult to capture within LFG, since the framework models different types of linguistic information at distinct levels such as c-structure, p-structure and f-structure. The changes are also not difficult to formalize, and in fact the directionality of change seems natural within the framework. As explained in Bresnan & Mchombo (1987), the step from pronoun to optional agreement marker is modeled by the PRED feature changing from obligatory to optional. The step from ambiguous pronoun/agreement marker to pure agreement marker is modeled by the loss of the PRED feature. It is important to note, however, that even though this grammaticalization path is naturally modeled formally within LFG, the LFG framework does not dictate the directionality of the change. An explanation for this directionality needs to come from a substantive theory of language change. I will not provide such a theory here, but I will refer to a few insights from the previous literature.

As indicated by the hierarchies above, independent pronouns can be incorporated into the verb. Such a change does not necessarily occur, and it is not predictable exactly when it will occur. However, it is not surprising that such incorporation is common, given the fact that pronouns are typically unstressed and often positioned close to the verb. Pronouns are also often doubled by a full NP or a stressed pronoun, sometimes marked by some special morphology or intonation: *(As for) Carina, I really love her.* It is easy to see how such topic/focus NP + pronoun could come to be reanalyzed as argument NP + agreement marker. For example, recall that Chicheŵa object markers are incorporated pronouns that can double an object that is a discourse topic (Bresnan & Mchombo 1987). The string SUBJECT verb-*pronoun* TOPIC (where the TOPIC and the pronominal OBJECT are co-referential, e.g., (18)) could then in principle easily be reanalyzed as SUBJECT verb-*agreement* OBJECT. Bresnan & Mchombo (1987) indicate that this is precisely what has happened in some other Bantu languages, for example Makua. In light of this, it also makes sense that many agreement markers cross-linguistically agree exclusively with arguments that are high in topicality (Comrie 1981, Woolford 1999, Coppock & Wechsler 2010, Dalrymple & Nikolaeva 2011): it follows from the observation that the pronouns that were reanalyzed as agreement markers originally doubled topics. Since topics tend to be animate (Comrie 1981: 225; Arnold 2013, among others), it is also unsurprising that animates are more likely to agree than inanimates.

Other cross-linguistic observations follow from the very fact that agreement markers used to be pronouns. Agreement marking is often restricted to definite or specific arguments (see, e.g., the discussion of Romanian below). Personal pronouns are in general inherently definite and specific, so it is easy to see how such restrictions could remain when the markers lose their pronominal status.

Several cross-linguistic tendencies thus follow from an understanding of the history of agreement marking: agreement can be restricted to topics and to nominals with animate, definite or specific reference. It is important to note that although these generalizations can be readily captured with the LFG formalism, the formalism itself neither predicts nor dictates these tendencies. In LFG, it would be just as easy to formally specify that only indefinites agree in a given language, for example. However, given what research in historical linguistics and psycholinguistics has shown us, it would be unlikely for such a system to emerge.

One further important cross-linguistic generalization concerns the asymmetry between subjects and objects: object agreement marking is less common than subject agreement. In fact, Siewierska (1999) argues that there is no pure object agreement marking. According to Siewierska, apparent examples of object agreement are actually cases of ambiguous marking: the agreement morphemes double as pronouns. Siewierska (1999) offers some possible explanations for this asymmetry, but stresses that those explanations are tentative. In LFG, it is formally no harder to model object agreement than it is to model subject agreement. The forms would simply lack a PRED feature, like the English and French subject agreement markers mentioned in Section 3. The explanation for Siewierska's generalization thus does not come from the LFG formalism.

In general, I assume that insights about language use and change are largely independent of the formal tools that are used to model grammar. However, it is in principle possible to formulate a substantive theory of language change that is compatible with the LFG framework and that might shed light on attested cross-linguistic generalizations.

Up until now, we have mainly focused on the role of the PRED feature. However, other features are also involved and those features can change and erode as well. Coppock & Wechsler (2010) carefully detail the loss of PRED features alongside changes affecting other features such as PERS, NUM, TOPICALITY and DEFINITENESS in different ways in the Finno-Ugric languages Northern and Eastern Ostyak (Khanty) and Hungarian. Toivonen (2001) similarly traces the change of various features that lead to differences in the possessive systems of different dialects of Finnish and Saami. These works trace historical changes that target features other than PRED features, and such changes can lead to differences that reach beyond the PRED feature when a morpheme is at the ambiguous stage. The next section is devoted to examples where the pronominal morpheme is quite different from the agreement marker, even though they are identical in form.

5 Lexical splits

The LFG approach to pro-drop presented above relies on the insight that a form can have a dual function as an agreement marker and an incorporated pronoun. This duality opens the door to the possibility that the morphemes might grow further apart due to language change: since the morphological form corresponds to two similar but distinct lexical entries (one with and one without a PRED feature), the two entries might develop separately. This is in fact cross-linguistically common, and several examples will be given in this section.

One of the first languages for which the LFG theory of pro-drop was developed was Arabic. Abdelkader Fassi Fehri explored the subject agreement system in Modern Standard Arabic as well as local varieties of Arabic in several talks and papers. Fassi Fehri (1988) shows that some of the affixes are exclusively pronominal (this is the case for the first and second person affixes) and others are ambiguous between pronouns and agreement markers. He further argues that in some cases the pronominal affix is remarkably different from the agreement marking affix, which indicates that their lexical entries differ beyond the PRED feature.

Fassi Fehri's (1988) analysis of feminine subjects in MSA will be reviewed here. Fassi Fehri shows that the affix *-at* (also sometimes *-ati* in Fassi Fehri's examples) is ambiguous. In its pronominal use, it is a third person feminine singular. However, as an agreement marker, the same affix is less restricted. For example, *-at* (here *-ati*) agrees with a plural subject in (31):

(31) Modern Standard Arabic
ja:ʔ-ati l-bana:tu
came-FEM.SG the-girls
'The girls came.'

Fassi Fehri (1988) proposes the lexical entries in (32) for the *-at* affix, indicating that the agreeing affix is only constrained by gender.

(32)

Pronoun:			Agreement:		
(↑ SUBJ PRED)	=	'pro'			
(↑ SUBJ GEND)	=	FEM	(↑ SUBJ GEND)	=	FEM
(↑ SUBJ NUM)	=	SG			
(↑ SUBJ PERS)	=	3			

Fassi Fehri (1988) further proposes that strong forms of pronouns are never directly assigned subcategorized functions in Arabic. Instead, they are always assigned the FOCUS function, which is a grammaticalized discourse function. As such, emphatic pronouns in MSA do not co-occur with the agreement marking version of *-at* even when they are feminine. It would result in a coherence violation: neither the emphatic pronoun nor the agreement marker contributes a PRED feature to the SUBJ.

The *-at* ending can be contrasted with the third person feminine plural affix *-na*, which, unlike *-at*, is a pronoun only and cannot agree:

(33) Modern Standard Arabic

a. ji:ʔ-na
came-FEM.PL.HUM
'They came.'

b. *ji:ʔ-na l-bana:tu
came-FEM.PL.HUM the-girls

The feminine plural pronoun *-na* can only co-occur with independently expressed nouns when they are topics:

(34) Modern Standard Arabic
al-bana:tu ji:ʔ-na
the-girls came-FEM.PL.HUM
'As for the girls, they came.'

In (34), the pronominal affix *-na* is the true subject. The noun *al-bana:tu* is a topic, as evidenced in part by the word order: the unmarked word order in Standard Arabic is VSO. When *al-bana:tu* precedes the verb, *-at* is not felicitous:

(35) Modern Standard Arabic
*al-bana:tu ja:ʔ-at
the-girls came-FEM.SG
(intended) 'As for the girls, they came.'

The pronominal *-at* is singular and cannot refer to the plural *al-bana:tu*. The agreement marking *-at* does not contribute a PRED feature. As the TOPIC, the NP *al-bana:tu* also does not contribute a PRED feature to the SUBJ. The agreement marker cannot alone correspond to the SUBJ function, since the subject needs a PRED feature due to the LFG completeness condition, provided in (12) above. In these specific examples, the verb 'to come' requires a subject with a semantic role, and that subject needs a PRED. In (31), *l-bana:tu* is the subject, and provides the PRED feature. In (33) and (34), the pronominal affix *-na* contributes a pronominal pred feature to the subj f-strucure. In (35), *al-bana:tu* provides a pred feature to the topic function, not the subj function. The agreement marking affix on the verb does not provide a pred feature at all.

Fassi Fehri (1988) introduces further lexical entries and also specific rules to cover the complex pronominal and agreement system in Standard Arabic. Additional examples accompanied by discussions of computational implementations of Arabic agreement are provided by Hoyt (2004) and Attia (2008). Crucial to the point here is that already one of the first treatments of pro-drop in LFG pointed out that an agreement affix can diverge from a homophonous pronominal affix in features other than just the pred feature. The agreement marking *-at* differs from the pronominal version of the same form, and Fassi Fehri captures the differences straightforwardly with the lexical entries.

Next we consider so-called 'clitic doubling' in Romanian. In Romanian, objects can be 'doubled' by a morpheme that agrees in person, number and gender. This morpheme is typically referred to as a clitic, but its morphophonological status is controversial (Dobrovie-Sorin 1994, Monachesi 1998, Popescu 2000, Luís 2004). Romanian clitic doubling is exemplified in (36), where the object *pe băiat* is doubled by the clitic *l-*:

(36) Romanian:
L-am văzut pe băiat.
3sg.m.acc-have.1sg seen acc boy
'I saw the boy.'

In some dialects of Romanian, all definite objects are doubled (Tomić 2006: Chapter 4; Tomić 2008: 84; Hill 2013, Barbu & Toivonen 2018). This is the case in the Aromanian dialect (spoken in Albania, Macedonia, Romania, Bulgaria, Serbia and Croatia) and the Megleno-Romanian dialect (spoken in Greece and Macedonia). Since the relevant pronouns are inherently definite, these dialects can be analyzed in LFG with an optional pred feature in the lexical entry for the clitic, just like most of the pro-drop examples discussed above.

However, in other dialects of Romanian, including the standard variety, doubling is restricted to *pe*-marked, human, definite objects. For example, the nonhuman direct object 'snail' in (37) cannot be doubled by a clitic:

(37) Romanian:

a. Am văzut melcul.
have.1sg seen snail.def
'I saw the snail.'

b. *L-am văzut (pe) melc.
3SG.M-have.1SG seen ACC snail

The clitic can refer to non-humans when it stands alone. For example, the *l-* in (38) can refer back to *melcul*, the snail:

(38) Romanian:
L-am văzut.
3SG.M.ACC-have.1SG seen
'I saw it/him.'

The clitic in (38) could also refer to a human participant.

The restrictions on doubling in this variety of Romanian indicate that the agreement marking clitic and the pronominal clitic differ beyond the presence or absence of the PRED feature. Barbu & Toivonen (2018) spell out the details of such an analysis, and their account is summarized here. They follow the Romanian tradition of treating *pe* as an accusative case marker (e.g., Cornilescu 2000) that is specified for human animacy, and they posit the lexical entries in (39) for the pronominal and agreement-marking clitics.

(39)

Pronoun:			Agreement:		
(↑ PRED)	=	'pro'			
(↑ PERS)	=	α	(↑ PERS)	=	α
(↑ NUM)	=	β	(↑ NUM)	=	β
(↑ GEND)	=	γ	(↑ GEND)	=	γ
(↑ CASE)	=	ACC	(↑ CASE)	$=_c$	ACC
(↑ DEF)	=	+	(↑ DEF)	=	+

The variables α, β and γ simply stand for different PERS, NUM and GEND features that vary according to which form is used: *mă/m-* for first person singular, *te* for second person singular, *îl/l-* for third person singular masculine, etc.

The two entries in (39) only differ very slightly. The pronouns have a PRED 'pro' feature and the agreement markers do not, just like we have seen in several examples above. However, there is one small but important further difference: the *case* is specified as a defining equation for the pronoun and a constraining equation for the agreement marker. The regular defining equation of the pronoun directly contributes a [CASE ACC] feature to the object f-structure. The constraining equation requires a [CASE ACC] feature, but does not itself provide it. If the feature is not provided in some other way, the agreement marker is illicit. The marker *pe* provides the ACC feature that is needed. This explains why the clitic cannot occur without *pe*. When *pe* functions as a case marker (*pe* has an additional function as the preposition 'on'), it is also specified for human animacy, and this indirectly explains why only objects with human reference can be doubled.

Tigău (2010, 2014) reports that some speakers of Romanian allow clitic doubling with indefinites:

(40) Romanian:

Petru	(l-)a	vizitat	pe	un	prieten.
Peter	3SG.M-have.3SG	visited	ACC	a	friend

'Peter visited a friend.'

Even the speakers who allow doubling with indefinite objects allow it only sometimes. Tigău (2010, 2014) argues that doubled indefinite objects get a *specific* interpretation (see also Aoun 1981: Chapter 3).

The difference between the standard variety of Romanian (captured by (39)) and the indefinite-doubling dialect described by Tigău is captured by the lexical entries in (41):

(41)

Pronoun:			Agreement:		
(↑ PRED)	=	'pro'			
(↑ PERS)	=	α	(↑ PERS)	=	α
(↑ NUM)	=	β	(↑ NUM)	=	β
(↑ GEND)	=	γ	(↑ GEND)	=	γ
(↑ CASE)	=	ACC	(↑ CASE)	$=_c$	ACC
(↑ DEF)	=	+	(↑ SPECIFIC)	=	+

In this dialect, the pronoun is the same as in the standard dialect, but the agreement marker is marked for specificity instead of definiteness.

In two of the dialects of Romanian that have been considered here, the difference between the agreement marking clitic and the pronominal clitic goes beyond the PRED feature. Again, this kind of 'split' is not unexpected under the LFG account of pro-drop, since the optional PRED feature in effect means there are two lexical entries: one agreement marker and one pronoun.

Romanian is not the only Romance language in which the agreement marking clitic and pronominal clitic are markedly distinct. Varieties of Spanish display clitic systems very similar to that of Romanian (see, e.g., Mayer 2017). Andrews (1990) and Estigarribia (2013) analyze Rioplatense Spanish within an LFG framework, and they both propose entries for pronominal clitics that differ from the agreement clitics beyond the PRED feature. Estigarribia specifically proposes that the agreement marker has a specificity feature that the pronominal clitic lacks, which would indicate that Rioplatense Spanish clitics are very similar to the Romanian clitics represented in (41).

Finnish possessive suffixes provide yet another example of 'lexical splits'. Pronominal possessors in standard Finnish are marked by an independent pronoun and a suffix on the possessed noun or by a suffix alone (42):

(42) Finnish
Jukka näkee (minun) ystävä-ni.
Jukka sees my friend-1SG
'Jukka sees my friend.'

In first and second person, the independent pronoun is optional, and our basic LFG pro-drop analysis can be employed: first and second person possessive suffixes have an optional PRED 'PRO'.

The optionality of the PRED 'PRO' in Finnish possessive suffixes was already mentioned in Section 2. However, the third person suffix displays a more significant split. When a third person independent pronoun is omitted and possession is marked by just a third person suffix, the possessor is necessarily bound by a subject within the minimal finite clause:

(43) Finnish
Jukka$_i$ näkee ystävä-nsä$_{i/*j}$.
Jukka sees friend-3
'Jukka sees his (own) friend.'

Conversely, when an independent pronoun is present, the possessor *cannot* be bound by a subject:

(44) Finnish
Jukka$_i$ näkee hänen$_{*i/j}$ ystävä-nsä.
Jukka sees his/her friend-3
'Jukka sees his/her friend.'

In Toivonen's (2000) analysis, the suffix in (43) is an anaphoric pronoun with a PRED feature, and the suffix in (44) is an agreement marker without a PRED feature. The entries further differ in that the agreement suffix is restricted to agreement with human personal pronouns (45a–45d), even though the pronominal suffix can be bound by both nouns and pronouns with human or non-human referents (45e):

(45) Finnish

a. Jukka näkee Pekan ystävän.
Jukka sees Pekka's friend.ACC
'Jukka sees Pekka's friend.'

b. *Jukka näkee Pekan ystävä-nsä.
J. sees Pekka's friend-3Px

c. Jukka näkee sen hännän.
Jukka sees its tail.ACC
'Jukka sees its tail.'

d. *Jukka näkee sen häntää-nsä.
Jukka sees its tail-3Px

e. Se/koira$_i$ heiluttaa häntää-nsä$_i$.
It/dog wags tail.PART-3Px
'It/the dog is wagging its tail.'

The Finnish pronominal possession system thus provides a further example where pro-drop involves two homophonous but syntactically quite distinct lexical entries: one agreement marker and one pronoun. In the case of Finnish third person possessive suffixes, the pronoun is anaphorically bound and has no animacy restrictions. The agreement marker agrees only with personal, human pronouns that are not anaphorically bound. For a lexical formalization similar to the analyses of Arabic subject markers and Romanian object clitics outlined above, see Toivonen (1996, 2000). For a different analysis, and also more data and references as well as a critique of the LFG analysis, see Humarniemi & Brattico (2015).

The final language we will consider in this section is Pakin Lukunosh Mortlockese. The Mortlockese data and generalizations come from Odango (2014). Odango argues that the third person singular object marker in this Micronesian language shows a split between incorporated pronoun and transitivity marker. He further shows that other object suffixes (the first and second person suffixes and the third person plural suffix) do not involve a split; they function exclusively as incorporated object pronouns (Odango uses the term 'anaphoric agreement', following Bresnan & Mchombo 1987). Example (46) illustrates the second person singular object suffix, which cannot co-occur with an independent pronoun:

(46) Mortlockese
I=aa wor-o-k (*een).
1sg.sbj-realis see-th-2sg.obj 2sg
‘I see you.’

The third person singular marker is also an incorporated pronoun when there is no independent object:

(47) Mortlockese
anga-i-tou mwo
take-3sg.obj-downward please
‘Please take it down.’

The object marker is translated here as *it*, but it can also be translated as *him* or *her*. The pronominal third person singular marker has a pred feature ‘pro’.

Unlike the other object suffixes, the third person singular suffix can co-occur with an object. When it does, there are no number restrictions on the object. Odango argues that the suffix is a *general transitivity marker* when it co-occurs with an object. In (48), the suffix agrees with a third person plural object:

(48) Mortlockese
Ngaan i=sán mwo shuu-{nge-i/*nge-er}
1sg.emph 1sg.sbj=neg.pot yet meet-th-3sg.obj/th-3pl.obj
mwáán=kewe.
man=dist.pl
‘As for me, I have not yet met those men.’

Note that the third person plural marker is not admissible in (48), because it functions solely as a pronoun with a pred ‘pro’ and can therefore not co-occur with the object *mwáán=kewe*.

According to Odango, the transitivity marking suffix is generally limited to third person for many speakers, but some speakers also accept examples where the transitivity marker co-occurs with a first or second person independent pronoun.[11] He provides the following example, which is accepted by some younger speakers:

---

[11] The independent pronouns only appear with borrowed verbs and a few verbs that cannot be inflected (Odango 2014).

(49) Mortlockese
R-aa wér-e-i kiish.
3pl.subj-realis see-th-3sg.obj 1pl.incl
'They see us (incl.).'

For most speakers, however, it seems that the transitivity marker is restricted to third person. Odango (2014) reports on one further restriction on the use of the transitivity marker: it seems to be restricted either for definiteness or specificity. Odango also points to interesting age and geographical variation regarding the exact use of the marker. The variation details are interesting, but they will nevertheless be set aside here.

The basic generalization that the third person singular object marker has split into a pronominal suffix and a transitivity marker is clear. Odango (2014) ties his discussion to Bresnan & Mchombo (1987), but he does not provide a formal analysis of Mortlockese. However, the generalizations he provides evidence for can be captured by the following lexical entries for the marker *-i*:

(50)

Pronoun:			Transitivity marker:		
(↑ obj pred)	=	'pro'	(↑ obj definite)	=	+
(↑ obj pers)	=	3	(↑ obj pers)	=	3
(↑ obj num)	=	sg			

The lexical entries in (50) are tentative but serve to illustrate the relevant lexical split. The pronominal version of the third person singular suffix is straightforward. Since it provides a pred feature, it cannot co-occur with an independent object. However, the transitivity marker version of the suffix *requires* an independent object. The presence of (↑ obj) features ensures the presence of an obj function in the f-structure corresponding to the verb that the ending is attached to. This object function needs a pred feature because of the completeness condition, and this feature is provided by an appropriate object in the c-structure. The lexical entry for the transitivity marker includes a third person object feature. However, for speakers that allow it to co-occur with first and second person pronouns (see (49)), the lexical entry will not include a pers feature. I assume here that the transitivity marker is specified for definiteness, but Odango hints that it is unclear whether the relevant feature is definiteness or specificity. It is possible that this point is also a matter of speaker variation. In any event, the transitivity marking entry can be modified to include a specificity feature instead of a definiteness feature.

Although the Pakin Lukunosh Mortlockese data involve variations and points to be further investigated, it is clear that the third person singular object marker involves a split. Odango argues that the split is between a pronoun and a transitivity marker. From a historical perspective, the emergence of this split is unsurprising: object markers often grammaticalize into transitivity markers, sometimes via object agreement marking (Lehmann 2002, Mayer 2017, Widmer 2018).

In sum, a pro-drop analysis where an incorporated morpheme is assumed to have a dual function and correspond to both an agreement marker and a pronoun leads to the prediction that the two versions of the morpheme can change independently and grow further apart. This section has considered multiple examples that indicate that such cases do, in fact, occur. The examples we have considered come from Standard Arabic subject marking, Romanian object clitic doubling, Finnish possessive marking, and Mortlockese object marking. In the first three cases, the pronominal version of a morpheme displays different characteristics than the corresponding agreement-marking morpheme. In the Mortlockese case, we adopted Odango's proposal that the non-pronominal version of the third person singular incorporated pronoun is a transitivity marker.

6 Pro-drop without agreement marking

The focus of this chapter has been on cases where information about the dropped arguments is encoded on the head as an incorporated pronoun. However, sometimes pronouns are omitted even though there is no corresponding morphology on the head. This is the case in DISCOURSE PRO-DROP. Some LFG work on this type of pro-drop will be briefly reviewed in this section, even though it does not involve morphological pronoun incorporation.

Chinese and Japanese lack morphological agreement marking but nevertheless allow argument omission. A Cantonese example, originally from Luke et al. (2001), is given in (51):

(51) Cantonese (Talking about dogs)

wui5-m4-wui5	beng6	gaa3
will-not-will	ill	PART

'Would (they = the dogs) get ill?'

This kind of pronoun omission is referred to as DISCOURSE PRO-DROP or RADICAL PRO-DROP. Discourse pro-drop is substantially different from pro-drop linked to agreement (Neeleman & Szendrői 2007, Sigurðsson 2011, Irgens 2017),[12] although

---

[12] Discourse pro-drop has been argued to in fact resemble general nominal ellipsis more than pro-drop (Irgens 2017).

they occur under similar pragmatic conditions, which are also conditions under which omission of weak pronouns occur in the Germanic languages (Sigurðsson 2011, Rosén 1998: and references therein). Focussing on omitted subjects, Luke et al. (2001) analyze Cantonese discourse pro-drop in LFG. They propose specific discourse-pragmatic criteria to explain how empty subjects receive an interpretation. They also posit an empty subject node in the c-structure, which renders their analysis unusual from a mainstream LFG perspective, where empty c-structure material is avoided since it is deemed unnecessary and computationally costly.

Rosén (1998) develops a different LFG analysis for Vietnamese. Vietnamese allows the subject, object and second object (OBJ$_{\theta}$) to be dropped, even though there is no morphology on the head to indicate the characteristics of the omitted element. Two examples from Rosén (1998: 146) are given in (52):

(52) Vietnamese

a. Ăn ít cỏ lắm.
eat few grass very
'(It) eats very little grass.'

b. Ông Ba tặng một bó hoa hồng hôm nọ.
Mr. Ba give one bunch flower pink day other
'Mr. Ba gave (her) a bunch of roses the other day.'

In Rosén's analysis, the dropped pronouns (*it* and *her* in the examples above) are not represented in the c-structure. In the f-structure, they are represented as the relevant grammatical functions. The PRED 'pro' features are contributed by optional equations in the phrase structure rule for S for the SUBJ and the VP rule for OBJ and OBJ$_{\theta}$. The f-structures of Vietnamese examples with pro-drop will thus look quite similar to examples where the c-structure does contain expressed pronouns, and also similar to the f-structures of Italian-style pro-drop languages, where other morphology provides the pronominal information. A difference is that the f-structures for the pro-dropped grammatical functions in Vietnamese do not contain person and number information. The key to understanding how empty pronouns assign reference in Vietnamese lies in semantic structure (s-structure) and discourse structure (d-structure), according to Rosén. Like the f-structure information, the semantic schemata needed for the s-structure of the unpronounced pronoun are contributed by the c-structure rules. These schemata include basic semantic information, such as specifications regarding the argument-function mapping.

Rosén (1998) stresses that the interpretation of the dropped pronouns does not depend on guessing. According to Rosén (1998: Chapter 7), one condition for pronoun omission is referential givenness, meaning the existence of a presupposition of unique reference. Another important condition is relational givenness: the intended referent is clear with relation to the verb in context.[13] This is, for example, the case when the verb is the same as in an immediately preceding context. In this case, the participants of the event referred to by the verb remain the same and can be omitted. For example, if someone asks *Did Sarah cook the meat?* and the response repeats the verb *cooked*, no pronouns are included in Vietnamese as it is clear that the participants remain the same. Another example of relational givenness would be *Sarah bought some meat and (she) cooked (it)*, where in the Vietnamese equivalent both the subject and the object pronoun can be omitted. The use of empty pronouns signals that the speaker is sure that the propositional content makes clear which referents to supply for the arguments (Rosén 1998: 137).

Butt & King (1997) show that pro-drop in Hindi/Urdu is not necessarily tied to agreement, and like Rosén, they argue for a discourse-based account. They argue that pronouns can only be omitted if they are continuing topics or backgrounded information, and they model their analysis on the independent linguistic level of i(nformation)-structure.[14] Butt (2007) extends Butt & King's analysis to Punjabi. The analyses developed by Butt & King (2000), Luke et al. (2001) and Rosén (1998) differ significantly from each other, and this indicates that there is room for more (perhaps cross-linguistic) research on discourse pro-drop within LFG. In general, discourse structure has received less attention in LFG than other levels of linguistic representation, but see King & Zaenen (2004), Dalrymple et al. (2018), and references cited in those works for important proposals.

Yet another type of pronoun omission is topic drop, which is found in several Germanic languages and illustrated in the Swedish example in (53):

(53) Swedish
Kommer kanske att sakna det.
come perhaps to miss it
'[I/We/They...] will perhaps miss it.'

---

[13] According to Rosén's formal analysis of the discourse conditions, empty pronouns must always be part of the tail value at d-structure, where the tail is understood as the s-structure of the sentence minus the value of the link and the focus.

[14] Rosén (1998) uses the label d(iscourse)-structure and Butt & King (1997) use i(nformation)-structure to formalize the same type of phenomena. Zaenen 2023 [this volume] provides a comprehensive overview of LFG research on i-s and d-s in LFG. She reserves the term i-s for sentence-internal information, and d-s for larger units of discourse.

Swedish verbs bear no agreement and the interpretation of the dropped elements is provided by the context. In these two respects, topic drop is similar to discourse pro drop. However, topic drop is more restricted and only elements in the left periphery of the sentence can be dropped (Neeleman & Szendrői 2007, Sigurðsson & Maling 2008, Sigurðsson 2011). Topic drop has not been treated extensively in LFG, but Berman (1996) provides an analysis of the phenomenon in German.

7 Summary

The focus of this chapter has been the LFG theory of pronominal incorporation and the interactions between nouns, independent pronouns, incorporated pronouns, and agreement markers. The analysis of regular pro-drop centers on the person, number and gender marking on the head, which is often ambiguous between an agreement marker and a pronoun. In other words, the marker is an incorporated pronoun, or else it simply agrees with an independent pronoun or noun.

Languages vary with respect to exactly how pronominal information is expressed morphosyntactically, and many different systems have been captured with LFG analyses that take the basic agreement marker-pronoun ambiguity as its starting point. The overview of the literature provided in this chapter illustrates how the typological diversity can be formally understood by appealing to features, feature unification and the mappings between independent linguistic levels.

The LFG theory of pronoun incorporation and pro-drop aligns well with the research on the grammaticalization of pronominal forms and agreement marking. In Section 4 it was argued that although LFG does not technically offer substantive historical explanations, the framework provides formal tools which are suitable for modelling the attested diachronic changes and trends.

Ambiguity between agreement marker and pronoun can give rise to changes that further differentiate between pronominal and agreement morphemes. Such drifts are not uncommon, as illustrated by the examples in Section 5. Many languages have agreement morphemes that differ in clear and significant ways from incorporated pronouns. For example, the Finnish third person possessive suffix is restricted to non-anaphoric human personal pronouns in its agreement use, but it has no animacy restrictions and must be anaphorically bound in its pronominal use.

Finally, Section 6 of this chapter briefly reviewed some LFG accounts of pro-drop that do not involve pronominal incorporation or any morphology indicating the person and number of the omitted discourse participant. These cases are interesting for many reasons. First, they illustrate the importance of discourse-pragmatic principles for pronominal interpretation. Second, these cases pose an interesting challenge for the theory of LFG f-structure. The principle of completeness dictates that a semantic argument needs a PRED feature, and it is not obvious where that feature comes from in cases of discourse pro-drop, where the participant does not have a phonological realization in the linguistic string.

In conclusion, the basic LFG theory of pronominal incorporation and agreement that was first formulated by Fassi Fehri (1984, 1988) and Bresnan & Mchombo (1987) is still adopted today. Over the past four decades, that theory has been used as a tool to gain insight about the details of pro-drop in a large number of languages.

Acknowledgements

I would like to thank three anonymous reviewers for very thorough and insightful comments. I also want to thank Raj Singh, Victoria Rosén, Mary Dalrymple, Roxana-Maria Barbu and Katie Van Luven for their helpful comments on earlier versions of this chapter. The paper has been much improved thanks to the feedback that I have received, but I want to stress that all remaining mistakes and misunderstandings are my own.

Chapter 14

Raising and control

Nigel Vincent
The University of Manchester

Raising and control are classic topics that have had a key role in theoretical debates since the early days of transformational grammar. In this chapter we examine these structural patterns, taking into account cross-linguistic variation and with a particular focus on the way the phenomena in question have been analysed within LFG and the differences between LFG and other theoretical frameworks.

1 The phenomena: raising, control and complementation

The terms RAISING, in reference to the examples in (1), and CONTROL, for those in (2), label different types of relation that may hold between a governing verb and its complement.

(1) a. The teacher seemed to like the students.
b. The students believed the teacher to like them.

(2) a. The teacher tried to help the students.
b. The students persuaded the teacher to help them.

On the surface these look very similar: a verb immediately followed by an infinitival complement in (1a) and (2a), and a verb followed by an NP and an infinitival in (1b) and (2b). However, a moment's inspection is enough to reveal fundamental differences. While (2b) does mean that the students persuaded the teacher, (1b) says nothing about whether the students believed the teacher. At the same time in both (1b) and (2b) the NP *the teacher* responds to standard diagnostics for objecthood such as replacement by the pronoun *her/him* and change of

Nigel Vincent. 2023. Raising and control. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 603–647. Berlin: Language Science Press. DOI: 10.5281/zenodo.10185962

status to subject under passivization: *The teacher was believed to like the students* and *The teacher was persuaded to help the students.*

Considered from a semantic perspective, the essential difference here is that a raising verb like *seem* does not assign a theta-role to its external argument; rather the acceptability of a sentence with *seem* depends on the semantic compatibility of its external argument and the predicate expressed in the following infinitive. Thus, (1a) is good because *like* requires an animate, sentient being as subject and teacher fills that bill; hence by contrast the unacceptability or pragmatic strangeness of *?The blackboard seemed to like the students.* In this respect, items such as *seem* show similarities with an auxiliary or a copula like *be* or *become* and indeed they have sometimes been referred to as semi-auxiliaries or semi-copulas (Pustet 2003: 5–6). This intermediate status between a grammatical and a lexical item is often the product of historical change, a topic to which we will return in Section 13 below. By contrast, the external argument of a control (aka equi) verb such as *persuade* or *try* does identify the source of the persuasion or the effort.

Although, in common with much of the literature, we have referred above to *seem* as a raising verb, it would be more accurate to call it a raising predicate since, as has frequently been observed, a particular lexical item may give expression to more than one predicate, not all of which exhibit the same control/raising status. Thus, *appear* is sometimes synonymous with *seem*, as for instance in (3a) beside (1a), but can also occur in other contexts where *seem* is not an option, hence the contrast in grammaticality between (3b) and (3c) and the fact that (3d) is perfectly acceptable while (3e) is at best tautological:

(3) a. The teacher appeared to like the students.
b. The teacher appeared as if from nowhere.
c. * The teacher seemed as if from nowhere.
d. The teacher seemed to appear from nowhere.
e. ? The teacher appeared to seem to like the students.

In a similar vein, *wants* in (4a) is ambiguous between a reading in which Sally desires to be more diligent and one which expresses her teacher's opinion even if Sally herself has no such wish! The former is a control reading, the latter a raising reading. With a gerundial complement in (4b) only the raising option is available as also in the alternative version in (4c) attested in Scottish and some other varieties of English:

(4) a. Sally wants to work harder.
b. This shirt wants washing.
c. This shirt wants washed.

More generally, rather than a binary split between raising and control verbs, there appears to be a continuum from raising to control with different verbs in different languages ranged along it (Barron 2001: 75–79, who references an earlier discussion by Huddleston 1976). Such evidence in turn implies the importance of taking into consideration both the syntactic and semantic bases of these constructions as well as language-particular lexical idiosyncrasies. The latter, as we will see, also argue in favour of adopting a diachronic as well as a synchronic perspective.

The terms 'raising' and 'control' both go back to the early years of generative grammar and allude in an interestingly complementary way to the different perspectives that scholars have adopted in analysing examples such as those in (1) and (2). Raising implies a movement from a lower to a higher position within a syntactic representation and thus evokes the derivational type of account that LFG has turned its back on. Control by contrast refers to the relation between a dominant element and a subordinate item or position within a range of non-finite — and indeed, as we will see, some finite — contexts, but with no further implication as to how this relation is to be modelled. In other words, it is part of the more general phenomenon of coreference and identifies a relation which can hold both within complement structures, as above, and in broader syntactic contexts as in the examples in (5):

(5) a. Glad to be home again, Sally waved to her neighbours in the garden.
b. Bill called a plumber to fix the drain.
c. Sally came across Bill in the garden crying his eyes out.

In (5a) the argument that *glad* is predicated of can only be Sally and not her neighbours but the relation is determined by the clausal structure and not by any specific lexical item; in (5b) we have an optional purpose clause added to the main clause *Bill called a plumber*; in both (5b) and (5c) the modifying clauses *to fix the drain* and *crying his eyes out* are controlled by the object of the main clause. Cases such as these fall under the heading of adjunct control, a topic which we consider in more detail in Section 12 below.

The literature on these constructions, and possible analyses thereof, is vast (see Davies & Dubinsky 2004 and Landau 2013 for book-length treatments and Polinsky 2013 for a briefer but no less valuable survey), and there is now a very thorough and up-to-date account in LFG terms in Dalrymple et al. (2019: chapter 15). It is natural then to ask what more a chapter such as the present one can bring to the table. Rather than simply serving up yet another overview, we will concentrate instead on three themes, in each case seeking to show the advantages — and in some instances the problems — inherent in adopting an LFG perspective:

1. cross-linguistic and diachronic variation in control/raising structures;
2. proposals that post-date the surveys cited above, in particular the 'two-tier' model put forward in Landau (2015), the analysis of so-called restructuring verbs (Grano 2015), the treatment of partial control (Pearson 2016, Sheehan 2018a,b, Sevdali & Sheehan 2021), and the treatment of adjunct control (Donaldson 2021a,b, Landau 2021);
3. cross-theoretical comparison of LFG with other approaches, in particular on the one hand derivational accounts within versions of Minimalism and on the other the lexical semantic approach of Jackendoff & Culicover (2003) and Culicover & Jackendoff (2006).

That said, some foundations need to be laid. We begin therefore by reviewing a series of dichotomies and sub-types that have served to frame much of the literature to date (Section 2 through Section 5) before moving on to consider our chosen themes and their theoretical implications.

2 Functional vs anaphoric control

Differences of detail and interpretation aside, LFG analyses of these items and constructions all build on the classic distinction between functional and anaphoric control developed in Bresnan (1982a) and other early LFG work on the topic such as Mohanan (1983). Functional control involves identity between a controlling grammatical relation and an open function, xcomp in the case of control induced by lexical items and xadj for adjunct control. Crucially, on Bresnan's account functional control provides a means of modelling both verbs traditionally labelled as raising and equi, as can be seen in the f-structures for *seem* and *try* in (6):

(6) a. *seem* V (↑ pred) = 'seem⟨xcomp⟩subj'
(↑ subj) = (↑ xcomp subj)

b. *try* V (↑ pred) = 'try⟨subj,xcomp⟩'
(↑ subj) = (↑ xcomp subj)

These representations distinguish the raising verb *seem*, where the SUBJ is outside the brackets which enclose the semantically pertinent arguments, from the equi verb *try*, where all the arguments are inside. Otherwise put, *try* assigns a theta-role to its subject while *seem* does not.

The open XCOMP function has also been proposed as a way of modelling some copular and auxiliary constructions (Falk 1984). Thus in Maltese, where there is no copula in the present tense as in (7a) by contrast with the past (7b), one solution is to allow the PRED value ‘BE⟨XCOMP⟩SUBJ’ to be assigned either to the copula or, in its absence, to the predicate nominal. In effect, this treats these constructions as a type of raising.

(7) Maltese

a. Albert tabib
Albert doctor
‘Albert is a doctor.’

b. Albert kien tabib
Albert be.PST.M.SG doctor
‘Albert was a doctor.’

The alternative here, and one perhaps more consistent with traditional accounts of copulas as items that connect subjects and predicates of various grammatical kinds, would involve the closed function PREDLINK and a copula with the PRED value ‘BE⟨SUBJ,PREDLINK⟩’ (for more discussion of these options and the conclusion that no single account will cover all cross-linguistic copular patterns, see Dalrymple et al. (2019: 189–197)).

A further possibility, which we will not discuss here, is to permit control into some object and oblique structures, an account that involves postulating open variants XOBJ and XOBL of the standard closed functions OBJ and OBL (Falk 2005).

In contrast to these lexically determined structures, an example like (5a) requires a statement of the relational equivalence within the relevant PS rule rather than as part of the lexical entry:

(8)
$$\begin{array}{llcc} \text{IP} & \longrightarrow & \text{AP} & \text{IP} \\ & & (\uparrow \text{XADJ})=\downarrow & \uparrow=\downarrow \\ & & (\uparrow \text{SUBJ})=(\downarrow \text{SUBJ}) & \end{array}$$

In this way an adjunct phrase (AP) such as *glad to be home again* is marked as serving the XADJ role within the f-structure of the higher IP and the open subject of the XADJ will be determined at the level of the clause rather than by a specific lexical entry.

The common property in both the XCOMP and XADJ constructions is identity between the controlling and the controlled function, which means not only that the items in question must be coreferential but that they must share all grammatical and semantic features such as case, gender, number and person. They also have in common that in some contexts they may alternate with closed functions. Thus, the examples (9a) and (9b) illustrate a closed COMP *that*-clause subcategorised by verbs like *believe* and *promise*, while in (10a) and (10b) we have instances of closed ADJ as the function to be associated with the constituents *everyone having gone home* and *with Sally away*:

(9) a. The doctor promised Sally that the medicine would work.
b. Sally believed that the doctor was right.

(10) a. Everyone having gone home, Bill could finally relax.
b. With Sally away, the house seemed very quiet.

Examples such as those in (9) and (10) are closed functions with independently defined subjects. However, it is also possible for a closed COMP to have a controlled subject, as in (11) and (12).

(11) a. Losing the race upset Bill.
b. Bill and Sally discussed complaining to the teacher.

(12) a. Bill prefers to leave now.
b. Bill wishes to leave tomorrow

In such a circumstance, in order to establish a link between a controller and a controlled item within a closed function we need anaphoric control. As the name implies, this involves an element, labelled PRO, which behaves like a pronoun in its ability to establish a referential link to an item outside the constituent that it is part of, but, like overt anaphors such as reflexives and unlike pronouns, it does not have the ability to refer independently. Formally, what this involves is the rule in (13) (= (35) in Bresnan 1982a: 326), where G identifies the universal set of semantically unrestricted functions and Δ allows for particular limitations on the available function in any given language:

(13) For all lexical entries L, for all G $\in \Delta$, assign the optional pair of equations $\{((\uparrow \text{G PRED}) = \text{‘PRO’}), (\uparrow \text{FIN}) =_c \alpha\}$ to L.

This general principle allows the PRO-valued function to be assigned to lexical entries while respecting language-particular constraints as to what may constitute the function G and what set of forms it can apply to. Thus, in English G can only be SUBJ and the forms in question must be non-finite but, as we shall see, other languages may vary. This rule is applicable both for predicates with no overt subject such as *losing the race* in (11a) or *complaining to the teacher* in (11b) and for the complements of some verbs, particularly those of wishing and wanting, as in (12). We return to the special issues engendered by the analysis of these verbs in Section 4 below.

The difference between verbs that take functional control and those that take anaphoric control is very clear in Icelandic (Andrews 1982, 1990), a language in which some items display subject properties such as determination of reflexives but where the case marking is not the usual nominative. Thus, in the simple sentence (14a) the subject of *gengur vel* 'do well' is marked with the dative case. When this predicate is embedded under a functional control verb as in (14b) the dative case is maintained but with an anaphoric control verb as in (14c), for many speakers, it is the latter item that determines the nominative case on the subject (examples from Andrews 1990: (39) and (43)):

(14) Icelandic

a. Drengnum gengur vel við vinnuna
boy.DEF.DAT go.PRS.3SG well at work
'The boy is doing well at work.'

b. Drengnum virðist ganga vel við vinnuna
boy.DEF.DAT seem.PRS.3SG go.INF well at work
'The boy seems to be doing well at work.'

c. Drengurinn vonast til að ganga vel við vinnuna
boy.DEF.NOM hope.PRS.3SG C INFL go.INF well at work
'The boy hopes to do well at work.'

To model (14c) requires a lexical entry for *vona* 'hope' as in (15):

(15) *vona* V (↑ PRED) = 'VONA⟨SUBJ,COMP⟩'
(↑ COMP SUBJ PRED) = 'PRO'

Where the presence of PRO is determined by the lexical entry, as here, we have an instance of obligatory anaphoric control. By contrast in (16) we have so-called arbitrary control where the antecedent for PRO depends not on the requirements of the matrix verb but on the broader context.

(16) a. Bill gestured but nobody noticed it.
b. Bill gestured to leave.
c. Bill gestured for everyone to leave.
d. Sally said everyone thought Bill should have gestured (for them/her) to leave.

A verb like *gesture* does not require a complement, as (16a) demonstrates. However, if it is linked to an infinitive, then the external argument of the infinitival verb can either be implicit and dependent on the discourse situation, as in (16b), or be made explicit, as in (16c). Moreover, if there is an overt antecedent it may be two or more clauses earlier as in (16d).

It is important to underscore that while, as we have already said, labels like raising and control verb or construction are commonly used to classify empirical phenomena, the distinction between functional and anaphoric control is a theoretical construct designed to model such data. It is eminently possible, therefore, that within LFG as within other frameworks, there could be different analyses for the same dataset. Thus, for the verb *try* Bresnan's lexical entry in (6b) implies an analysis in terms of functional control, endorsed in Mohanan (1983: 644) and repeated in Börjars et al. (2019: 103). Similarly, Falk (2001: 141–144) argues for a distinction between *try* with functional control and verbs like *agree* with anaphoric control. By contrast, Dalrymple et al. (2019: 561–566), and already Dalrymple (2001: §4.2), prefer to analyse *try* as also requiring obligatory anaphoric control and hence with the PRED value in (17) akin to the one for Icelandic *vona* in (15):

(17) *try* V (↑ PRED) = 'TRY⟨SUBJ,COMP⟩'
(↑ COMP SUBJ PRED) = 'PRO'

This has the benefit of allowing a much closer alignment between the traditional classes and the different analyses, with raising coming under functional control and equi verbs under anaphoric control. It has consequences, too, when we come to consider the semantics of control/raising since a COMP translates naturally into a proposition whereas the obvious semantic correlate of an XCOMP is a property. Moreover, it serves to undermine one of the criticisms of LFG made by Landau (2013: 61–62) following Davies (1988), namely that functional control is not relevant for phenomena which traditionally fall under the heading of control. But this depends on the analysis not the framework. Landau rightly goes on to observe, as others have done, that in this respect the LFG account exhibits parallels with the movement theory of control advanced by Hornstein and colleagues

(Hornstein 1999, Hornstein & Polinsky 2010): they move everything, Bresnan moves nothing! But once again this is a matter for debate within the frameworks in question not one for *a priori* prescription. What is clear is that more than one analytic device is required to encompass the full range of empirical phenomena both within and across languages.

It should also be emphasised that within LFG neither functional nor anaphoric control requires the postulation of anything more than a VP at the level of c-structure in stark contrast to the FinPs, ForcePs, TPs, vPs and the like which populate the syntactic trees assigned to these constructions within derivational/configurational analyses, regardless of the finiteness of the complement.

We return to the question of the relation between finiteness and control/raising in Section 6 and to issues concerning the appropriate semantic analysis in Section 10.

3 Obligatory vs non-obligatory control

The distinction between obligatory (OC) and non-obligatory control (NOC) goes back to Williams (1980); since then there has been considerable discussion about where and how to draw the boundary between them. The crucial differences, as set out by Williams (1980: 208–209), are that in cases of OC the PRO cannot be replaced by an overt lexical item and must have a grammatically determined antecedent. Hence the general agreement that raising constructions fall within the territory defined as OC while the PROs in examples such as those in (18) require NOC.

(18) a. It is not possible [PRO to open the window].
     b. [PRO forgetting his own birthday] is typical of Bill.

Where other types of control are to be placed and how they are to be modelled are by contrast still matters for debate. There is, for example, a close match between Williams's (1980) dichotomy and the distinction between functional and anaphoric control as originally formulated in Bresnan (1982a), although even then the two are not equivalent (*pace* for example Landau 2013: 241). Since that time, however, there has been general agreement that anaphoric control for desiderative verbs for example must fall within OC. In order to get the discussion going, therefore, we need criteria to delimit these empirical domains, and to that end we will adopt what Landau (2013: 29) calls the OC 'signature' and which he defines as in (19) (= his (74)):

(19) In a control construction [... X_i... [$_S$ PRO$_i$...]...], where X controls the PRO subject of the clause S:

  a. The controller(s) X must be (a) co-dependent(s) of S

  b. PRO or part of it must be interpreted as a bound variable.

NOC is then defined as anything which does not meet these criteria. Alternatively, and more positively, NOC covers control into subject and adjoined or extraposed clauses (Landau 2013: 38, (96)) and, if we follow Landau (2020), also for some classes of lexical predicates. We return to the issue of NOC in Section 11 when we discuss Landau's two-tier model.

4 Exhaustive vs partial control

Within the broader domain of OC there is a sub-type that has generated special interest, namely the phenomenon that has come to be called partial control (PC). We have already observed that in one reading of an example like (4a) — repeated here as (20a) — the subject of *want* can be in a control relation to the unexpressed subject of its infinitival complement: Sally is both the source of the desire and the one who will work.

(20) a. Sally wants to work harder.

  b. The chair wanted to meet without me.

  c. Morten wants to leave the European Union.

In (20b), on the other hand, the subject of the infinitive includes, but is not simply coreferential with, the subject of *want*. Rather, the embedded verb *meet* requires a semantically plural subject, as is clear from the ungrammaticality of (21a) but nonetheless can occur as the complement of *want* even when the subject of *want* is singular. Similarly, while (20c) is fine as an expression of Morten's political ambition for the country he belongs to, (21b) describes an odd state of affairs since membership of an organization like the EU is not a matter for individual decisions or efforts.

(21) a. * The chair met.

  b. # Morten tried to leave the European Union.

At the same time, the semantic plurality of the implicit subject does not trigger morphosyntactic plurality for all speakers. Thus, (22a) is fine while the uncontrolled (22b) fails. (22c) is unproblematic because both *Sally* and *herself* are singular whereas American English speakers do not readily accept the plural *by* *themselves*, as in (22d), unless the infinitival clause contains a plural subject as in (22e) (Landau 2013: 161).

(22) a. Sally wanted to work together.
b. * Sally worked together
c. Sally wanted to work by herself.
d. ? Sally wanted to work by themselves.
e. Sally wanted her and Bill to work by themselves.

Given the way the PC effects depend on the choice of governing verb, it follows from the principle in (19) that partial control must be a sub-type of OC. This conclusion is accepted by Asudeh (2005), who proposes an analysis combining f-structure and glue semantics as in (23) for the exhaustive control *try* and (24) for the partial control *want*:

(23) $\lambda x.\lambda P.try(x, P(x)) : (\uparrow \textsc{subj})_\sigma \multimap [(\uparrow \textsc{xcomp subj})_\sigma \multimap (\uparrow \textsc{xcomp})_\sigma] \multimap {\uparrow_\sigma}$

(24) $\lambda x.\lambda P.\exists y.want(x, P(y)) \wedge x \sqsubseteq y) :$
$(\uparrow \textsc{subj})_\sigma \multimap [(\uparrow \textsc{xcomp subj})_\sigma \multimap (\uparrow \textsc{xcomp})_\sigma] \multimap {\uparrow_\sigma}$

Here is not the place to go into the technical details of the glue analysis. The crucial difference is that while the analysis of *try* in (23) maps directly onto the f-structure representation in (6b), the analysis of *want* introduces an additional variable y, which can either be equivalent to x or identify a superset of which x is necessarily a member. In other respects (24) is a straightforward instance of functional control. However, as Haug (2013) notes, this gives the wrong result with quantified examples like (25) (= Haug's (29)):

(25) Everybody wanted to have lunch together.

The most natural reading of this is the collective one in which *everybody* and *together* refer to the same set of individuals, whereas the representation in (24) implies a distributive reading in which for each member of the set identified by *everybody* there is a different, not necessarily overlapping, group of people (s)he wants to lunch with.

In consequence, Haug proposes an alternative analysis involving what he calls 'quasi-obligatory anaphoric control'. Such items are distinguished from contexts of arbitrary control by virtue of a locality constraint imposed by the controlling predicate but, unlike with obligatory control verbs, the constraint is semantic and not syntactic. We will not go here into the formal details of his analysis (for which see also Haug 2014), but note simply that if these proposals are adopted, we end up with a typology of control that allows the four options set out in Table 1. Crucially, such a typology creates a de facto continuum from syntax through to discourse-determined structures rather than reducing all patterns to syntactic configurations.

Similar in spirit, though structurally more wide-ranging, is the LFG-based typology of control proposed in Szűcs (2018b) as in Table 2. The new data that is here incorporated into the typology is what Szűcs calls ‘prolepsis’ as exemplified in Hungarian examples such as (26) (= his 1b):

(26) Hungarian
Janós(-t) mondtad hogy jön a partira
John(-ACC) say.PST.2SG C come.PRS.3SG the party.onto
‘(Of) John, you said that he is coming to the party.’

The fronted argument *Janós* is optionally marked with accusative case. Szűcs takes this as evidence that it is an optional argument of the verb *mond* ‘say’ which therefore has a possible PRED value ⟨(SUBJ)(OBJ)(COMP)⟩. He draws a parallel here with English examples like *I read of Carol that she was awfully shy*, a type of structure that has received little or no attention in the literature to date. The relation of prolepsis to control has been taken up more recently by Landau (2021: §14.4.5) though without any reference to Szűcs’ contribution.

A different strategy for subsuming raising, but not control, within a broader set of constructions is the concept of structure-sharing developed by Alsina (2008, 2010). On this view, what raising shares with long distance dependencies (topics and wh-questions) and parasitic gap constructions is a governing and thematically unrestricted function which is shared with the embedded argument slot. There is not space here to go into the full details of Alsina’s proposals but the overall logic is similar to that of Szűcs, namely that there are shared properties of argument and pronominal constructions that need to be captured in an appropriate formal way, building on functional rather than categorial structure.

Noteworthy, too, is the fact that in a model such as Simpler Syntax, which goes further than LFG in the direction of reducing syntactic operations and structures to a minimum, one area where functions rather than configurations play a key role is precisely raising and control (Culicover & Jackendoff 2019: §3.3).

It is instructive to compare these approaches to syntax-centred ones such as those advanced in recent derivational work. Thus, Sheehan (2014) argues for the presence of a non-overt comitative argument in order to account for the extra participant(s) implicit in examples such as (20b), an analytic strategy akin to

Table 1: Typology of control (Haug 2013: 61)

	f-control	obligatory a-control	quasi-obligatory a-control	arbitrary a-control
locality	syntactic	syntactic	semantic	discourse
identity	+	–	–	–

Table 2: An LFG typology of control (Szűcs 2018b: 359)

CONTROL-TYPE			Example
Thematicity of controller	Nature of identification	Finiteness	
Equi (thematic)	anaphoric identification	finite complement	prolepsis
		non-finite complement	canonical control ("*agree*-type")
	functional identification	finite complement	Turkish object control (?)[a]
		non-finite complement	canonical control ("*try*-type")
Raising (non-thematic)	anaphoric identification	finite complement	not expected
		non-finite complement	not expected
	functional identification	finite complement	copy raising/ hyper-raising[b]
		non-finite complement	canonical raising

---

[a] Turkish is here cited as a further example of control into finite clauses of the kind discussed with reference to a number of other languages in Section 6 below.

[b] The term 'hyper-raising' is taken from Carstens & Diercks (2013) and refers to structures that are in all relevant respects parallel to copy raising (on which see Section 9 below) but where the embedded finite clause has a covert rather than an expletive subject. See Zyman (2023) for further discussion and assessment of analyses within the framework of Minimalism.

that proposed by Asudeh (2005) but with the added variable inserted in the syntax rather than the semantics. This, however, is open to the same objections as raised by Haug and is challenged on its own theoretical terms by Landau (2016). Alternatively, as argued in Sheehan (2018b) and Sevdali & Sheehan (2021), the differences between exhaustive and partial control can be attributed to the syntactic constructs Agree and Case, neither of which are available — or indeed needed — within the theoretically more economical framework of LFG.

5 Split and implicit control

Partial control needs to be distinguished from two further subtypes, namely split control as exemplified in (27) and implicit control as in (28):

(27) John$_i$ discussed with Mary$_j$ [which club PRO$_{i+j}$ to become members of].

(28) a. It was fun to visit the new museum.
b. It was not permitted to cross the track.

In the former the antecedents are divided between the arguments of the verb, so that *members* in (27) must refer back jointly and exhaustively to John and Mary. As Landau notes, this phenomenon does not fall readily under any of the existing approaches and he concludes that at the time of writing 'there is no satisfactory theory for the syntax of split control constructions' (Landau 2013: 174). This may of course be because the pattern is not inherently syntactic but falls within the semantic/discourse domain of Haug's typology. Such a conclusion is reinforced by the fact that it is particularly attested in Japanese and Korean in the context of exhortative marking as in the Korean example (29) (= Landau's 328b):

(29) Korean
Chelsu$_i$-ka Hwun$_j$-eykey [PRO$_{i+j}$ ilbon umsik-ul mek-ca-ko
Chelswu-NOM Hwun-DAT Japan food-ACC eat-EXH-C
mal-ha-yess-ta]
tell-do-PST-DECL
Lit. 'Chelswu said to Hwun to eat Japanese food together.'

This reports a suggestion ('let's eat together') though it is not direct speech but the presence of the exhortative marker *-ca* on the verb licenses the split control. Similarly, the Japanese minimal pair in (30) (adapted from example (38) in Fujii 2010) shows that when the exhortative particle *-(y)oo-* is present there can be split control while with the imperative particle *-e-* the examples are ungrammatical:

(30) Japanese

a. * Taro-wa Hiroshi-ni [PRO otagai-o sonkeesi-a-e-to]
Taro-TOP Hiroshi-DAT each.other-ACC respect-RECP-IMP-C
itta/meireisita
say/order.PST
'Taro said to/ordered Hiroshi that they should respect-IMP each other.'

b. Taro-wa Hiroshi-ni [PRO otagai-o sonkeesi-a-oo-to]
Taro-TOP Hiroshi-DAT each.other-ACC respect-RECP-EXH-C
it-ta/teiansita
say/propose.PST
'Taro said/proposed to Hiroshi that they should respect-EXH each other.'

In other words, it is the nature of the speech act rather than the syntactic configuration that licenses the split control effect.

Implicit control, as in (28), is in a way the direct opposite since there is no overt antecedent for the infinitival complements. In the literature, and following Bresnan (1982a), this has been linked to the so-called Visser's generalization (VG) which states that subject control verbs cannot be passivized and which is claimed to explain the ungrammaticality of examples like (31a,31c) (= 86c,e from Bresnan 1982a):[1]

(31) a. * She was failed (by Max) as a husband.
b. Max failed her as a husband.
c. * Frank was promised to leave (by Mary).
d. Mary promised Frank to leave.

Examples such as these led Bresnan to propose as a general principle that controllers must be overt and occupy a semantically unrestricted grammatical function such as SUBJ or OBJ. However, while this may be true for English, it does not necessarily hold cross-linguistically as the grammaticality of the following Dutch (32) and German (33) examples and the ungrammaticality of their literal English translations — taken from the discussion in Wurmbrand (2021) — attest:[2]

---

[1] In the literature VG is often accompanied by something labelled Bach's generalization (BG) — see for example Dalrymple et al. (2019: 586) — but as Landau (2013: 179–179) notes the empirical basis for BG has been challenged and we will not discuss it further here.

[2] Here and elsewhere in the glosses, to avoid confusion, we use C to label the category complementizer as opposed to the function COMP, although in the general literature and as recommended in the Leipzig conventions COMP is regularly used as a gloss for complementizer.

(32) Dutch
Er werd mij beloofd/aangeboden om me op de hoogte te
There be.pst I.dat promise/offer.pst.ptcp c I.dat on the height to
houden
keep.inf
‘It was promised/offered to keep me informed.’

(33) German
Mir wurde versprochen mir noch heute den Link für das
I.dat become.pst promise.pst.ptcp I.dat still today the link for the
Update zu schicken
update to send.inf
‘It was promised to me to send me the link for the update today.’

In the light of such data, van Urk (2013) proposes what has come to be called (Landau 2013: 182) the restricted VG as in (34):

(34) Implicit subjects cannot control if T agrees with a referential DP.

More recent cross-linguistic investigation of the phenomenon is reported in Pitteroff & Schäfer (2019) and Wurmbrand (2021) offers a formal account within a Minimalist framework. Within LFG, data of this kind can be handled within the framework developed by Haug (2014), as noted by Reed (2020: 13–16) in her discussion of Landau’s two-tier approach, although she herself offers yet another Minimalist account.

6 Control and finiteness

Much, if not most, of the literature dealing with the theory of control has focussed on English but, as we have already seen on more than one occasion, contrasting patterns from other languages shed new light on the phenomena and the way that they can be modelled. The English data that was at the heart of early debates focuses almost exclusively on infinitival constructions, but, as Haspelmath (2013) demonstrates, English is unusual in admitting infinitival clauses both with and without subjects co-referential to the subject of the controlling predicate as in the minimal pair *I want to leave* vs *I want Bill to leave*. In this section we review some of the typological diversity focussing in particular on finite vs non-finite splits (Italian, Danish, Hungarian), control into finite clauses (as in Greek, Romanian, Chinese and Japanese), and the special case of inflected infinitives (as in Portuguese and Sardinian).

We begin then with the finite/non-finite alternation seen in the following Italian examples:

(35) Italian

a. Giorgio vuole partire domani
Giorgio want.PRS.3SG leave.INF tomorrow
'George wants to leave tomorrow.'

b. Giorgio vuole che Paolo parta domani
Giorgio want.PRS.3SG C Paolo leave.PRS.SBJV.3SG tomorrow
'George wants Paul to leave tomorrow.'

The pattern here is clear: infinitival clause when there is co-reference between the subject of the governing verb and the embedded predicate, finite (and subjunctive) clause when the subjects differ. In LFG terms the functional structure of the 'want' verb is constant — 'VOLERE⟨SUBJ,COMP⟩' — but the syntactic realizations differ. Since it is the f-structure that feeds into the semantics there is no need to create parallel c-structures as would be required in frameworks where the configurational syntax drives the semantics.

The Danish examples in (36) work in similar fashion but with an extra dimension of complexity:

(36) Danish

a. Georg vil gerne tage af sted i morgen
Georg want.PRS with-pleasure go.INF from place in morning
'George wants to leave tomorrow.'

b. Georg vil gerne *(have) at Paul tager af sted i morgen
Georg want.PRS with-pleasure have.INF C Paul go.PRS from place in morning
'George wants Paul to leave tomorrow.'

c. Georg vil gerne *(have) æg til morgenmad
Georg want.PRS with-pleasure have.INF egg.PL for breakfast
'George wants eggs for breakfast.'

The translation of 'want' is *vil gerne*, literally 'will with pleasure', and in (36a), parallel to both the Italian (35a) and the English translation, in the coreferential construction it governs an infinitive. In (36b), on the other hand, when there are distinct subjects, the embedded clause is finite but there is an intervening infinitive of the verb *have* ‘have’. This same additional ingredient is required when the ‘want’ verb takes a nominal object as in (36c); both these examples are ungrammatical if *have* is omitted, whereas (36a) is ungrammatical if *have* is inserted.

At first sight the Danish data would appear to support the analysis of the syntax of ‘want’ verbs proposed in Grano (2015: 83), according to which the structures which underlie the various uses of English *want* are as in (37):

(37)
a. John wants [$\varnothing_{have}$ an apple].
b. John wants [$_{\text{VP}}$ to stay].
c. John wants [$_{\text{VP}}$ $\varnothing_{have}$ [$_{\text{vP}}$ Mary to stay].
d. John wants [$_{\text{VP}}$ $\varnothing_{have}$ [$_{\text{vP}}$ PRO to stay].

The key part of this analysis, building on Cinque (2004), is that English *want* is not treated as a full-fledged independent lexical item but rather as an item which occupies a functional head in the modal domain. When it appears to be transitive, as in (37a), it is because it is accompanied by a silent transitive HAVE which licenses the direct object. The same would hold for the equivalent Italian *Giovanni vuole una mela*. Danish then differs from English and Italian simply in virtue of the HAVE item being overt.

It follows, too, that if *want* sits in a functional position, an example like (37b) is monoclausal. This is supported by Italian examples like (38) where the clitic object can either attach to the modal ‘want’ or to the main verb:

(38) Italian
a. Giovanni vuole mangiar=la
Giovanni want.PRS.3SG eat.INF=it
b. Giovanni la=vuole mangiare
Giovanni it=want.PRS.3SG eat.INF
‘Giovanni wants to eat it.’

Strikingly, this so-called clitic climbing, standardly taken as evidence of restructuring from a bi- to a mono-clausal configuration, is for many speakers not permitted in PC contexts like (39):[3]

---

[3] Native speaker judgements here are mixed with some speakers accepting both and some neither! However, for the majority (39a) is acceptable while for (39b) even those who accept it prefer a rephrasing with a finite clause *che ci incontrassimo* ‘that we should meet each other’.

(39) Italian

a. Giovanni vuole incontrar=si domani
Giovanni want.prs.3sg meet.inf=recp tomorrow

b. *? Giovanni si=vuole incontrare domani
Giovanni recp=want.prs.3sg meet.inf tomorrow
'Giovanni wants to meet tomorrow.'

In short, exhaustive control is monoclausal and partial control is biclausal, but with the biclausality in the latter licensed not by the *want* verb but by the silent have, in a structure parallel to that postulated for the English (37d). There are, however, two problems with this analysis. First, precisely in the partial control context Danish does not permit *have*, and second in no other context in English, Danish, Italian and many other languages do *have* verbs license finite clausal complements. Grano seeks to avoid this latter charge by analysing the complement of the silent have as a *v*P rather than the CP that Cinque had proposed but, given that the Italian item *che* in (35b) and the Danish *at* in (36b) are the default complementizers used in a wide range of embedded clauses types, this way out of the dilemma lacks conviction. The best alternative, therefore, would appear to involve a syntax or c-structure based on whatever overt categories are attested in the different languages linked to a more cross-linguistically robust f-structure and a syntax-semantics constructional hierarchy of exactly the kind set out in Table 1 above.

A more radical LFG alternative on the f-structure side, though one still consistent with the Haug hierarchy, would be to collapse comp and obj as proposed for Hungarian *akar* 'want' by Szűcs (2018a):

(40) Hungarian

a. Kati ételt akar
Kati food.acc want.prs.3sg
'Kati wants food.'

b. Kati enni akar
Kati eat.inf want.prs.3sg
'Kati wants to eat.'

c. Kati akarja hogy együnk
Kati want.prs.def.3sg c eat.sbjv.1pl
'Kati wants us to eat, lit. that we eat.'

d. Kati ételt és azzal jóllakni akar
Kati food.ACC and it.with satisfied.become.INF want.PRS.3SG
'Kati wants food and to be satisfied with it.'

This verb displays the same patterns of simple transitivity and an alternation of finite and infinitival complements as Italian and Danish. Given that the nominal and clausal arguments may be co-ordinated as in (40d), Szűcs argues that the most economical account involves a single lexical predicate structure, namely ⟨(SUBJ)(OBJ)⟩. He does not consider the PC option, but there is no reason to believe that this would undermine or alter his argument.

A different type of pattern is found in various languages belonging to the so-called Balkan *Sprachbund* such as Greek and Romanian, in some southern Italian dialects and in Japanese and Korean, where the complements can be finite regardless of whether there is coreference or not. Thus in Greek we have:

(41) Greek
a. thelo na liso to provlima
want.PRS.1SG PRT solve.PRS.1SG the problem
'I want to solve the problem.'
b. O Kostas theli na odhiji
the Kostas want.PRS.3SG PRT drive.PRS.3SG
'Kostas wants (her/him) to drive.'

In (41a) both the controlling verb and the embedded verb are finite first person singular despite the fact that they refer to the same subject. It follows that if both verbs are third person singular as in (41b), they can either co-refer (Kostas wants to be the driver) or have different referents (Kostas wants someone else to drive). A similar ambiguity can be seen in the Korean example (42) (Lee 2009: 112):

(42) Korean
Mina-ke hakkyo-ey ka-nun kes-ul para-yess-ta Wujin-to
M.-NOM school-LOC go-ADN thing-ACC want-PST-DECL W.-also
kuli-ha-yess-ta
SO-do-PST-DECL
'Mina wanted to go to school and so did Wujin.'

This can mean either that Mina wanted to go to school and Wujin also wanted to go to school himself or that Wujin also wanted Mina to go to school.

In all these languages there are restrictions on the tense or mood of the embedded predicate which space prevents us from going into here. However, the general principle is clear: the overt syntax does not map one-to-one onto the semantic ingredients so that either the syntax has to be rendered more semantically transparent via the use of functional and null heads and syntactic movement, or the configurational syntax is held constant and the burden is shifted to other levels. The use of f-structure and s-structure clearly goes down this latter route; see Sells (2007) and Polinsky (2013) for general discussion.

Another difference across languages concerns the realization of the pro item. While this is standardly taken to be a silent category, Satik (2021) argues that in the Anlo dialect of the Niger-Congo language Ewe the pronoun *yè* in the examples in (43) (= his (5a)) exhibits the properties of an overt pro (pot in his gloss stands for 'potential'):

(43) Ewe (Anlo dialect)

Agbei	dzagbagba/ŋlobe/dzina/vɔvɔm/wosusu/dzi/susum	be	yèi-a	dzo
A	try/forget/want/afraid/decide/like/intend	c	yè-pot	leave

'Agbei tried/forgot/wanted/is afraid/decided/likes/intends pro$_i$ to leave.'

Satik goes on to develop a Minimalist-inspired analysis of the Anlo data which we will not discuss in the present context. It suffices for our purposes to note that, as he also argues, the existence of languages with overt pro serves to disconfirm the movement analysis of control alluded to at the end of Section 2, since movement would always leave an empty and not an overt trace. This conclusion is reinforced by languages where the item in the expected pro slot is a full NP, as in the Zapotec example in (44) cited by Polinsky & Potsdam (2006) as an instance of what they call copy control (= their (22a)):

(44) Zapotec

rcààa'z	Gye'eihlly	g-auh	(Gye'eihlly)	bxaady
hab-want	Mike	irr-eat	(Mike)	grasshopper

'Mike wants to eat grasshopper.'

They further note that while the full NP is optional, a pronominal subject in the controlling clause would obligatorily determine an overt matching pronoun in the controlled clause, akin therefore to the Anlo example in (43).

Yet another type of alternation is to be seen in the contrast between bare and inflected infinitives in Portuguese and several other Romance varieties. Thus, consider the examples in (45):[4]

---

[4] It is important to note that the examples in this section are drawn from European Portuguese (EP) since Brazilian and other varieties exhibit significant differences in relation to these constructions (Madeira & Fiéis 2020). There are similar patterns to EP in the closely related Galician (Sheehan et al. 2020).

(45) European Portuguese

a. Serà dificil (eles) aprovar-em a proposta
be.FUT.3SG difficult (they) approve-INF.3PL the proposal
'It will be difficult for them to approve the proposal.'

b. Eu lamento (eles) terem trabalhado pouco
I regret.PRS.1SG (they) have.INF.3PL work.PST.PTCP little
'I regret that they have worked very little; lit. them to have worked.'

In (45a) the embedded infinitival complement *aprovarem* bears the third person plural suffix, as does the perfect auxiliary *terem* in (45b). This same suffix occurs on the finite form *parecem* 'they seem' in the raising context of (46b) but in that context cannot be added to the embedded infinitive, hence the ungrammaticality of (46c).

(46) European Portuguese

a. parece que os organizadores adiaram o congresso
seem.PRS.3SG C the organizer.PL postpone.PST.3PL the conference
'It seems that the organizers have postponed the conference.'

b. Os organizadores parecem ter adiado o
the organizer.PL seem.PRS.3PL have.INF postpone.PST.PTCP the
congresso
conference
'The organizers seem to have postponed the conference.'

c. *Os organizadores parecem terem adiado o
the organizer.PL seem.PRS.3PL have.INF.3PL postpone.PST.PTCP the
congress
conference

With control verbs we find a significant difference between exhaustive and partial control (examples from Madeira & Fiéis 2020: 429):

(47) European Portuguese

a. Prefer-ias chegar(*es) a tempo
prefer-IND.IPFV.2SG arrive.INF (*2SG) on time
'You would prefer to arrive on time.'

b. O João prefer-ia reunir(%em)-se mais tarde
the J. prefer-IND.IPFV.3SG meet(%3PL)-RECP more late
'João would prefer to meet later.'

In the exhaustive control example (47a) the inflection on the infinitive is not permitted just as with raising in (46c). In (47b) on the other hand the notation % implies significant percentage differences in the judgements of native speakers, a conclusion confirmed by the more detailed statistical evidence presented in Sheehan (2018a,b). In this respect they parallel the cross-speaker discrepancies noted with respect to clitic climbing in the Italian PC example (39b). Such a degree of socio-pragmatic variation in turn would seem to support Haug's concept of a control scale moving from pure syntax through to discourse rather than attempts to motivate the differences in terms of core syntactic concepts such as Case and Agree.

All the languages we have considered in this section so far share the property of having morphological realizations of finiteness and the related categories of tense, mood and person. Mandarin Chinese, and Sinitic languages more generally, however do not exhibit such morphology and therefore call into question the relevance of the finiteness criterion in a different way (see Grano 2015: chapter 6 for discussion and a convenient summary of the relevant literature). In his LFG-based discussion of this and related issues, Lam (2022) bases his analysis on the contrast between the f-structure for *shefa* 'try' with xcomp as opposed to comp for the partial control verb *dasuan* 'intend' and with a VP complement for the former beside an IP complement for the latter.

7 Backwards control/raising and subsumption

As we have seen, the treatment of control and raising constructions in LFG relies on f-structure statements of the form (↑ subj) = (↑ xcomp subj), which imply equality between the content of the functional roles but asymmetry in the dominance relations since the thematic argument will of necessity occur in the higher clause. This is the case even if the linear order differs, as in the Hungarian examples (40b) and (40d) where *akar* 'want' follows rather than precedes its infinitival complement. However, an example like (48) from the North Caucasian language Adyghe evidences a different pattern, in which the thematic argument can be situated in the embedded clause (Potsdam & Polinsky 2012: (1), (2)), where the strikethrough items indicate deletion in their notation):

(48) Adyghe

a.

~~axe-r~~	[axe-me	se	saš'e-new]	∅-feže-ʁ-ex
3pl-abs	3pl-erg	1sg.abs	lead-inf	3abs-begin-pst-3pl.abs

b. axe-r [~~axe-me~~ se saš’e-new] ∅-feže-ʁ-ex
3PL-ABS 3PL-ERG 1SG.ABS lead-INF 3ABS-begin-PST-3PL.ABS
‘They began to lead me.’

While (48b) has an overt absolutive subject of the verb *feže* ‘begin’, accompanied by an unrealized subject of the embedded infinitive *saš’enew* ‘lead’, in (48a) the overt item is *axe-me* with the ergative suffix appropriate for the subject of ‘lead’.

The examples in (48) demonstrate a free alternation between forward and backward raising. At the same time, as Perlmutter (1970) demonstrated in a classic paper, verbs meaning ‘begin’ can vary between raising and control uses. An instance of backward control with ‘begin’ can be seen in the Malagasy example (49a). The difference here is both in the theta role — Rabe is the active beginner and the active driver — and in the fact that in Malagasy the forward version (49b) is ungrammatical.

(49) Malagasy
a. m-an-omboka [m-i-tondra ny fiara Rabe]
PRS-ACT-begin PRS-ACT-drive the car Rabe
‘Rabe is beginning to drive the car.’
b. *m-an-omboka Rabe [m-i-tondra ny fiara]
PRS-ACT-begin Rabe PRS-ACT-drive the car

Here only the backward control option is possible, a property which Sells (2006) proposes can be modelled by introducing the subsumption relation, annotated as ⊑, which implies a directionality in the flow of information from controller to controllee but involves no expectation of hierarchy. The difference between the ‘begin’ verbs in Adyghe and Malagasy can then be represented as in (50):

(50) a. Adyghe: *feže* (↑ SUBJ) ⊑ (↑ XCOMP SUBJ)
(↑ XCOMP SUBJ) ⊑ (↑ SUBJ)
b. Malagasy: *omboka* (↑ XCOMP SUBJ) ⊑ (↑ SUBJ)

This kind of cross-linguistic difference is part of a larger typological distribution. Table 3, adapted from Polinsky & Potsdam (2002: 278), shows the various patterns which have been attested to date for verbs meaning ‘begin’, which fall within the larger class of verbs with an aspectual meaning, something which seems to be a key factor here.

The concept of subsumption and its relation to backward control and raising goes back to Zaenen & Kaplan (2002), who propose as a general principle that

Table 3: Typology of backward control with 'begin'

Language	Backward control	Aspectual	Raising/control ambiguity
Tsez (Nakh-Daghestanian)	yes	yes	yes
Malagasy (Austronesian)	yes	yes	no
Tsaxur (Nakh-Daghestanian)	yes	yes	no
English	no	yes	yes

raising verbs involve the equality relation (↑ subj) = (↑ xcomp subj) while control/equi verbs have the subsumption relation (↑ subj) ⊑ (↑ xcomp subj). Sells (2006) goes a step further and proposes to replace equality with subsumption across the board. The debate, however, has not been settled in part because, as we have seen, there are arguments in favour of control as involving comp rather than xcomp and in part because others, notably within LFG (Arka 2014), have argued that both mechanisms can be at work in the same language.

Polinsky & Potsdam (2006) and again Polinsky (2013) argue that backward raising/control supports a movement account, and in particular a copy-and-delete version, with the difference cross-linguistically depending on whether it is the original or the moved copy that is deleted, but as noted above this analysis faces problems when it comes to copy control constructions. At the same time, Polinsky (2013) raises two queries vis-à-vis Sells and subsumption: a) is there a risk of over-generation? and b) how does it connect with other properties such as word order and headedness?

On this last point, Haug (2011, 2017) extends the discussion of backward control to include adjunct clauses as in the Ancient Greek (51) (= example (15) from Haug 2011):

(51) Ancient Greek
[egertheis de Iôsêph apo tou hupnou]
wake.pfv.ptcp.nom but Joseph.nom from def.gen dream.gen
epoiêsen…
do.pst.pfv.3sg
'When he woke up from the dream, Joseph did…'

Here, the subject of the *epoiêsen* 'did' is realised in the adjunct participial clause, which linearly precedes but is structurally subordinate to the main clause. For this reason, as Haug notes, it might be better to refer to ‘upward’ control but either way we have something that is parallel to the kind of pattern we have seen in our earlier examples of backward complement control. However, as he goes on to show, the appropriate analysis here involves functional equivalence and linear precedence rather than subsumption, a conclusion which suggests that subsumption as an operation, if required at all, should be restricted to contexts of complement control and raising, where, as examples like (48) and (49) demonstrate, linearization cannot be the answer.

8 Nominal control and raising

Another logical possibility is that the controlling item is nominal rather than verbal. This is particularly evident in the structure which, following Tsunoda (2020), we will call the Mermaid Construction (MC), as seen in the Japanese examples (52) and (53):

(52) Japanese
Hanako=ga Igirisu=ni ik-u ki=da
Hanako=NOM UK=DAT go-NPST.ADN feeling=COP.NPST.DECL
‘Hanako intends to go to the UK.’ (lit. ‘Hanako is the feeling to go to the UK’ or ‘It is the feeling where Hanako goes to the UK’)

(53) Japanese
Hanako=ga Igirisu=ni ik-u yotei=da
Hanako=NOM UK=DAT go-NPST.ADN plan=COP.NPST.DECL
‘Hanako is going to the UK.’ (lit. ‘Hanako is the plan that goes to the UK’ or ‘It is the plan where Hanako goes to the UK’)

The mermaid label reflects the fact that these are mixed constructions involving a full noun, *ki* ‘feeling’ and *yotei* ‘plan’, and an associated clitic copula *da* ‘be’ which taken together govern a dependent nominalized verb *ik-* ‘go’ and which translate as modal or aspectual markers. Tsunoda (2020) analyses these examples as monoclausal with the sequences *iku kida* and *iku yotei* being treated as complex predicates. Taguchi (2022), however, argues that the structures in question are bi-clausal and hence allow independent negation and adverbials for both predicates:

(54) Japanese
Kinoo Hanako=ga [asita Igirisu=ni ik-u]
yesterday Hanako=nom tomorrow UK=dat go-npst.adn
yotei=datta
plan=cop.pst.decl
'Yesterday Hanako planned to go to the UK tomorrow.'

(55) Japanese
Hanako=ga [Igirisu=ni ik-anai] yotei=dewanai
Hanako=nom UK=dat go-neg.npst.adn plan=neg.cop.pst.decl
'Hanako did not plan not to go to the UK.'

He therefore proposes the following lexical entries, where *ki* involves anaphoric control while *yotei* is treated as a raising verb with functional control:

(56) a. *ki* N (↑ pred) = 'ki⟨subj,comp⟩'
(↑ comp subj pred) = 'pro'

b. *yotei* N (↑ pred) = 'yotei⟨xcomp⟩subj'
(↑ subj) = (↑ xcomp subj)

Examples of the MC are found across a wide range of languages — twenty-six in Asia and one in Africa according to Tsunoda (2020: 1), to which Taguchi adds parallel examples from Scots Gaelic, Tatar and Russian. Here is not the place to compare these in detail and it may well be that, even if Taguchi is right and the monoclausal analysis does not hold for Japanese, this is the correct account for the construction in other languages. What more generally, therefore, this data demonstrates is the fuzzy border between raising/control constructions and complex predicates, and the likelihood that over time the former may develop into the latter (see Butt 2014, Booth & Butt 2023 [this volume] and the discussion in Section 13 below).

9 Copy raising, control and resumption

In addition to the widely discussed examples with an infinitival complement, the English verb *seem* also allows the pattern to be seen in (57) in which the subject of *be sick* appears to have been raised and replaced by the pronoun *he* in the complement clause.

(57) Alfred seems like/as if he's sick.

Structures of this kind have been labelled ‘copy raising’ with the pronoun being treated as ‘resumptive’ (Asudeh & Toivonen 2007, 2012; Asudeh 2012). The last-mentioned work in particular shows how this construction can be naturally accounted for by invoking resource logic and glue semantics, as well as demonstrating the cross-linguistic evidence for similar structures. As Asudeh (2012: chapter 12) shows, the availability of copy raising is lexically determined; it is attested with *seem* and *appear* but not for example with *tend*:

(58) *Alfred tends like he won.

The items in question will therefore have a lexical specification via a local copy name as in (59) together with the usual open function to link the main clause subject and the subject of the embedded predicate *like*:

(59) *seem* V $(\uparrow \textsc{subj})_\sigma$=$(\%\textsc{copy}_\sigma\ \textsc{antecedent})$
$(\uparrow \textsc{subj}) = (\uparrow \textsc{xcomp}\ \textsc{subj})$

(60) *like* P $(\uparrow \textsc{pred})$ = ‘like⟨comp⟩’

The f-structure for *like* needs to include the comp function in order to cope with the fact that the clause following *like* is finite. What has been more open to contention is its categorial status, with some arguing for it as a complementizer but with Asudeh opting for the more traditional assumption that it is a preposition. The latter is more plausible given that it can also take a simple NP as in *Alfred looks like his sister*. This solution would also allow for a transparent analysis of the *as if* alternant in (55) with *as* being a P parallel to *like* and with *if* as the c head of the embedded comp.[5] The prepositional account finds support in the analysis advanced by Camilleri (2018), also within the framework of LFG, of the parallel constructions in Maltese, as in (61) (= her example (32)):

(61) Maltese

qis-ha	bħal(likieku)	ta-w-ha	xebgħa
as.though-3f.sg.acc	as.if	give.3pfv-pl-3f.sg.acc	smacking

‘She’s as though they gave her a smacking.’

We see here a copy raising construction with a null copula (compare the Maltese data in (7) above) and where the optional element *likieku* is indeed a counterfactual complementizer but crucially can only occur in this construction as the complement of the preposition *bħal* ‘like’.

---

[5] Gisborne (2010: chapter 7) also argues for treating *like* as a preposition albeit in the context of a different Word Grammar analysis of the construction as a whole. Landau (2011) by contrast opts for a derivation-based account in which *like* is treated as a complementizer.

Although space here has only allowed us to look at some core examples of this construction, this has sufficed to demonstrate the importance of such data for the analysis of the relation between semantics, syntax and lexis. Further issues concern the relation between these examples and the ones in (62):

(62) a. Alfred seems like Thora hurt him.
b. Alfred seems like Thora's hurt.
c. Alfred sounds/looks like he enjoyed the party.

In (62a) the co-referential argument is an object not a subject and in (62b) there is no overt co-referent but simply a context-derivable assumption that Alfred and Thora are somehow connected. Such an assumption makes clear the route by which the speaker has reached their conclusion, hence the label 'perceptual resemblance verb' (PRV) that has been applied to such items. (Compare too in this connection example (67b) in Section 12 below.) While Asudeh (2012: 351–356) demonstrates how examples like (62) and the dialect variation associated with them can be captured, Toivonen (2021) is an exploration of PRVs and the way they vary between English and Swedish.

This construction with raising verbs has its counterpart in the domain of control verbs as we saw in connection with the so-called 'copy control' construction exemplified in (44), where it is the thematic controller which recurs as a pronoun in the embedded finite clause.

10 The semantics of raising and control

While much of the literature both within and outside LFG seeks to account for control and raising effects in syntactic (i.e. f-structure and/or c-structure) terms, there is an important strand of work which argues that the phenomenon is at heart semantic (for English see Jackendoff & Culicover 2003, Culicover & Jackendoff 2006 and references there, Duffley 2014, and compare Akuzawa & Kubota 2020 for Japanese). In the words of Culicover & Jackendoff (2006: 152): 'Control should be taken out of the hands of the syntax and turned over to the semantics.'

In fact, these debates can be broken down into two separate, though not unconnected, issues. The first concerns the semantics of the governing predicates, which can be divided into a series of lexical sub-classes defined in terms of their semantic content of their predicates and hence their associated thematic roles. Thus, for example, in their treatment of control in Japanese, Akuzawa & Kubota (2020) distinguish the following classes:

(63) Attitudinal, e.g. *try*, *decide*
Commissive, e.g. *declare*
Directive, e.g. *order*
Implicative, e.g. *succeed*
Factive, e.g. *regret*

Such a list is clearly not exhaustive but it goes a good way towards predicting the types of structures and arguments that will be found with the items in the different classes. It is very much in line with the Culicover & Jackendoff way of thinking and with the recent work by Landau discussed below. That said, the fact remains that raising and control exhibit overt syntactic patterns that need to be accounted for. It is striking that the model deployed by Culicover & Jackendoff under the name 'Simpler Syntax' makes crucial use of grammatical relations (GR in their notation) rather than categorial structure in a way that is strikingly similar to the role of f-structure. By contrast a model like Role and Reference Grammar treats raising and control directly in terms of thematic roles without intervening recourse to grammatical functions (see Bentley & Vincent 2023 [this volume]). Within LFG, the role of meaning, and more precisely the relation between a-structure and f-structure, is handled by lexical mapping theory — see the chapter by Findlay et al. 2023 [this volume] — and semantically defined templates (Dalrymple et al. 2019: 230–237).

A separate issue concerns the semantic category to be assigned to the complement: is it to be treated as a proposition, as in Dalrymple (2001) or a predicate, as suggested by Asudeh (2005)? The proposition/predicate debate is one which arises in other frameworks. Thus, Pearson (2016) argues for the property interpretation contra Landau and the use of the contrast in relation to adjunct control in Landau (2021). We return to this issue in Section 11 and Section 12.

11 Predication vs logophoric anchoring

In a substantial contribution to the debate Landau (2015) proposes what he calls a 'two-tiered' theory of control, more precisely a binary division of OC; NOC remains outside this picture. On the one hand, there is logophoric anchoring where the controlling predicate is labelled 'attitudinal'.[6] This contrasts with predicative

---

[6] The concept of logophoricity goes back to Hagège (1974) with specific reference to languages which distinguish between two sets of pronouns according to whether the antecedent is the speaker or not. Sells (1987) offers an early formalization in terms of Kamp's discourse representation structures. Landau's use of the term is rather more general but shares the key idea of reference back to the speaker.

anchoring, which applies to non-attitudinal verbs. The two classes can be further divided into sub-classes:

(64) a. attitudinal: desiderative, propositional, interrogative, factive, e.g. *want, refuse, agree, ask, pretend, plan, imagine*, etc.
  b. non-attitudinal: modal, aspectual, evaluative, implicative, e.g. *dare, see, remember*, etc.

Building on this distinction Landau (2015: 20) states the following generalization:

(65) Nonattitude complements force EC, attitude complements allow PC.

This in turn is worked out in terms of a semantic distinction between what he calls a 'property-denoting projection', which defines predicative control, and a 'propositional projection', which defines logophoric control. Propositional projections involve an extra layer of syntactic structure above the layer containing the property projection and hence they are 'two-tiered'. He sets out the properties of the two types of control in Table 4, and he sums up the resulting empirical contrasts between the two in Table 5.

Table 4: Properties of control constructions (Landau 2015: 83)

	Predicative control	Logophoric control
Semantic type of complement	<d,<e, <s,t>>>	<<e,<κ,e>>,<κ,t>>
Head of complement	transitive $\text{Fin}_{[u\text{D}]}$	transitive $\text{C}_{[u\text{D}]}$
Control and agreement are established via:	predication	predication + variable binding

The diagram from Landau (2015: 85) reproduced in Figure 1 shows his conception of the relations between the two types of control. Two questions then arise: do we need this distinction? And if not, how can the issues it is designed to address be accommodated within a framework like LFG? The answer to the first question is probably not and to the second, they already have been! Thus, as we have noted, Reed (2020) discusses objections to the two-tier account contrasting it with a single-tier approach and citing in this connection Haug (2014). She goes on to develop her own category-based syntactic account but once again we see that elaborating syntactic configurations is an alternative, and less economical, analytical strategy compared to the functional definitions that lie at the heart of LFG, especially once they are combined with a semantics of the Glue type.

Table 5: Empirical diagnostics of control constructions (Landau 2015: 65)

	Predicative control	Logophoric control
Inflected complement	✓	*
[– Human] PRO	✓	*
Implicit control	*	✓
Control shift	*	✓
Partial control	*	✓
Split control	*	✓

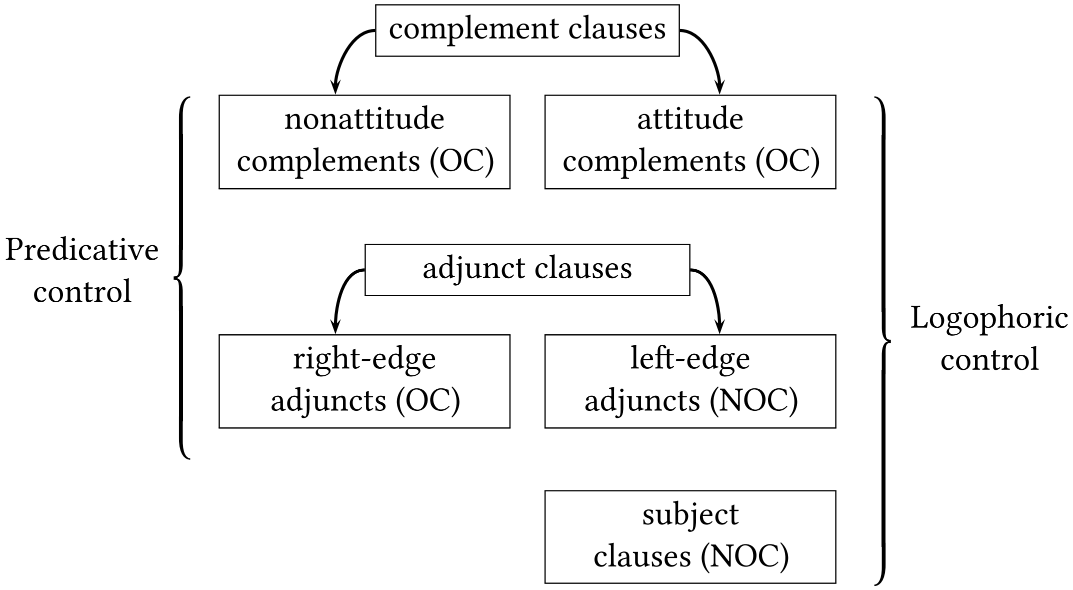

Figure 1: Landau's (2015) two types of control (his Figure 6.1)

12 Adjunct control

In the standard literature, adjunct control, as exemplified in (5) — repeated here in (66) for convenience — has received relatively little attention by comparison with other types of control:

(66) a. Glad to be home again, Sally waved to her neighbours in the garden.
b. Bill called a plumber to fix the drain.
c. Sally came across Bill in the garden crying his eyes out.

Recently, however, there have been some significant contributions which provide interesting contrasts in the way the phenomenon can be modelled. Thus, Green (2019) extends the movement account and challenges an early version of the approach now developed in Landau (2021), where he builds on the two-tier model discussed in the previous section. The LFG account developed in Donaldson (2021a) adopts a similar line of argument, but this is revised in Donaldson (2021b).

Consider the pair of examples cited at the beginning of Donaldson (2021b):

(67) a. Watching him, Thrasher realized that something in his appearance didn't ring true. (Green 1956: *The Last Angry Man*)

b. Watching him, it seemed as if a fibre, very thin but pure, of the enormous energy of the world had been thrust into his frail and diminutive body. (Woolf 1942: *The Death of the Moth*)

In (67a) the missing subject of *watching him* is supplied by the subject of the main clause. By contrast, *his* in *his appearance* is interpreted pragmatically as referring to the same individual as referenced by *him*. If *appearance* was replaced by *memory*, the natural antecedent of *his* would be *Thrasher*. Similarly, it is the context in (67b) which leads the reader to link *him* and *his body*. However, it is also the context that determines the missing subject of *watching him* since there is no argument in the main clause which can fill that role. In short, there is no debate over the fact that structures like (67b) require an extrasentential interpretation of the missing argument, in other words arbitrary anaphoric control and hence in the rightmost box of Haug's Table 1 above.

When it comes to examples like (67a), however, different accounts have been proposed. Donaldson (2021a) follows a line of analysis within LFG going back to Mohanan (1983) and argues that the strict link in interpretation between the missing argument and the subject of the main clause is best treated as an instance of functional control providing the link to the open XADJ clause. However, Donaldson (2021b) notes that a functional control analysis will not generalise to examples like (68) where there is an embedded gerund, but nonetheless the two types of structure pattern similarly in other respects as can be seen in (69).

(68) After a year of complaining, Bill finally left his job.

(69) a. After three days of preparing himself/*herself, Bill spoke to Sue.

b. While preparing himself/*herself, Bill helped Sue.

He therefore proposes an obligatory anaphoric control analysis for both. How then do we distinguish between obligatory and arbitrary anaphoric control in adjuncts?

Adjunct control cross-cuts the opposition between OC and NOC, leading Landau (2021: 21) to propose the following criteria:

(70) a. Locality: an OC controller must be an argument of the clause immediately dominating the adjunct.
  b. Humanness: PRO in NOC, but not in OC, must be [+ human]

A different issue concerns the location of the adjunct clause. As is clear from Figure 1, Landau consider his two-tier theory to apply to both and draws a distinction between right edge adjuncts, which involve OC and are predicative, and left edge adjuncts, which involve NOC and are logophoric (compare already Williams 1992 on logophoricity and adjunct control). Hence by the principle in (70b) left edge adjuncts will be interpreted as holding of a human argument. This conclusion appears to be supported by the examples in (71) cited by Donaldson (2021b):

(71) a. Being made of stainless steel, rust won't be an issue. (after Davies 2018)
  b. * Rust won't be an issue, being made of stainless steel.
  c. The knife resists rusting, being made of stainless steel.

(71a) is acceptable even though the extrasentential controller is necessarily inanimate, while (71b) fails because the adjunct is now left edge and therefore is required to be human unless it can be interpreted as an instance of OC as in (71c).

An alternative account of the difference between OC and NOC adjuncts is advanced by Fischer & Høyem (in preparation, 2022). Instead of a reference to right and left they distinguish the levels of emebedding and hence syntactic scope as the determining factor. OC is limited to arguments within the verbal domain, while proposition modifying adjuncts, which display NOC properties, are interpreted on the basis of pragmatic factors. The common property of all of these accounts is that they involve a scale moving from syntax (whether relationally or categorially defined) through semantics to pragmatics, a scale which we have now seen more than once is best defined in the terms of Haug (2013, 2014) rather than always being reduced to a syntactic configuration. An interesting additional dimension introduced by Donaldson is that of processing, who adduces the psycholinguistically based principle that, in his words, 'language users guess at a controller as soon as it becomes apparent that one is required' (Donaldson 2021b:

100), and hence with differential consequences for initial, medial and final adjuncts. There are also parallels here with the linearization effects noted by Haug (2017) in connection with examples like (51) above.

13 The diachrony of raising and control

Most of the literature on raising and control constructions is synchronic in orientation but there has been some work on the way these patterns may change over time. In this section we will briefly consider some case studies and the contribution made by an LFG-based approach to modelling them.

Our first examples come from the work of Barron (1997, 2001) on the historical development of 'seem' verbs from verbs of perception. One such is Latin *videri*, formally the passive of the verb *videre* 'see' but commonly used in the sense of 'seem' as in (72) contrasted with its literal meaning in (73):

(72) Latin

… ill-orum	beata	mors	vid-et-ur
they-GEN.PL	blessed.NOM.F.SG	death.NOM.F.SG	see-PRS.3SG-PASS

'… their death seems blessed' (Cicero *De amicitia* 23,7)

(73) Latin

ubi	sol	etiam	sex	mensibus	continuis	non
where	sun.NOM.SG	even	six	month.ABL.PL	continual.ABL.PL	NEG
vid-et-ur						
see-PRS.3SG-PASS						

'where the sun is not seen for six months in a row' (Varro *Res rusticae* 1,2,4)

What (72) and (73) share is that the perceiver argument has been suppressed and in consequence the object of perception comes to fill the SUBJ function in virtue of the Subject Condition. However, the verb's inflectional morphology and the syntactic configuration of the clause remain unchanged. In Latin both uses are attested over a long time span, but following the general principle of grammaticalization that concrete meanings develop into abstract ones rather than vice versa, it is reasonable to suppose that the 'be seen' meaning is older than the 'seem' meaning.

The diachronic sequence is not in doubt in Barron's second example, namely the development of French *sembler* and Italian *sembrare*, both meaning only 'seem', from the Latin *simulare* 'pretend'. At the level of function and argument structure the change is parallel. In this case, the ‘pretender’, that is to say the causer of the perception has been lost with the result that the object that has been made to appear takes over the subject role.

While the above examples involve the historical shift into a raising function of items that were already etymologically verbs, our next examples, drawn from Camilleri & Sadler (2019), show how the same verbal function may develop from items that belong to other categories, specifically here a noun *šakl* ‘shape, form’ and a preposition *zēy* ‘like’. Example (74) shows the ‘shape’ word in its nominal use together with a dependent genitive and a predicative adjective that can agree either with the masculine head *šakl* or its possessive feminine dependent *dærah* ‘circle’. (Note here that there is no copula since this is present tense, as with the Maltese example (7a) above.)

(74) Egyptian
šakl id-dærah mdawwar/mdawwar-ah
shape.m.sg def-circle.f.sg round.m.sg/round-f.sg
‘The shape of the circle is round.’

In (75) by contrast *šakl* serves as a raising predicate taking the perfective *rigiʕ* ‘return’ as its complement:

(75) Egyptian
Morsi šakl-u rigiʕ
M. shape-3m.sg.gen return.pfv.3m.sg
‘Morsi seems to have come back.’

In LFG terms the diachronic development here involves a shift from the predicate ‘šakl⟨poss⟩’ to ‘šakl⟨xcomp⟩subj’.

Camilleri & Sadler’s (2019) second case can be seen in the difference between the examples (76) and (77) from two different varieties of Algerian Arabic drawn from studies conducted at different time periods:

(76) Saïda Algerian Arabic, 1908
lābes zēy el-mɣāṛba
wear.act.ptcp.m.sg like def-moroccan.pl
‘He was wearing (i.e. dressed) like Moroccans.’

(77) Djidjelli Algerian Arabic, 1954
zēyu nsā-na
like.m.sg.gen forget.pfv.3m.sg-1pl.acc
‘He seems to have forgotten us.’

In this instance the source is prepositional but the outcome once again is a raising predicate: ‘ZĒY⟨XCOMP⟩SUBJ’. Semantic parallels for this development are to be seen in the use of English like in the copy-raising constructions reviewed in Section 9 and in the origin of Latin *simulare* ‘pretend’ discussed above as a causative built on the same stem as *similis* ‘similar’.

What all these examples taken together demonstrate is that it not the categorial status of the etymon — verb, noun, adposition respectively — that unites them but a common semantic core plus a the transition to the functional structure ⟨XCOMP⟩SUBJ, a shared development that a framework like LFG is ideally equipped to model.

We move now to the development of a control predicate, namely WILL verbs in Germanic. These can all be traced back to the Proto-Indo-European root **wel-*, and are cognate with Latin *velle* ‘want’ which in turn is the source of French *vouloir* and Italian *volere* discussed in Section 6. As Börjars & Vincent (2019) show in detail, comparing items across the family reveals a sequential development from the original ‘want’ meaning through to the future and intentional meanings of modern English. The most conservative languages are Swedish and Icelandic where in the modern languages the verb *vilja* has only ‘want’ meanings and in that respect resembles the Danish pattern set out in (36) above. Modern English *will*, by contrast, has lost these uses though they are attested in Old and Middle English. Danish stands in between in the sense that it has retained the ‘want’ meanings but has also developed the intention and future meanings. Hence an example like (78) is ambiguous:

(78) Danish
Peter vil hjælpe dig
Peter will.PRS help.INF you.ACC
‘Peter will help you.’ OR ‘Peter wants to help you.’

Within grammaticalization studies developments of this kind are typically modelled in terms of informal scales or semantic maps (Bybee et al. 1994, Narrog & van der Auwera 2011) such as the one proposed in Börjars & Vincent (2019: 301):

(79) DESIRE > INTENTION > PREDICTION

We can now offer a more refined version of this development; in effect a diachronic instantiation of Haug’s scale:

(80) QUASI-OBLIGATORY AC > AC > FC > PREDLINK

What we see here, then, is the development from an independent lexical item to control verb to raising verb and ultimately to simple of marker of tense and/or aspect, as is consistent with the cross-linguistic diversity in the etymology of control and raising verbs (Barron 2001, Vincent 2019). One may compare too the diachronic development from control verb to complex predicate discussed in Butt (2014) and in Booth & Butt 2023 [this volume].

14 Conclusion

The general conclusion that emerges from this chapter, in line with the view expressed by Landau (2013: 257–258), is that control and raising do not constitute a unitary phenomenon. Rather such pre-theoretical labels subsume a variety of structural possibilities that vary across languages and which may change over time. However, contrary to Landau (2013, 2015), we argue that these patterns not only can be captured within a framework like LFG but also that a parallel correspondence model of this kind, which does not make all generalizations hinge on syntactic configurationality, has the potential to offer richer insights in both the synchronic and diachronic domains.

Acknowledgments

I am grateful to Nik Gisborne, Louisa Sadler, Peter Szűcs and two anonymous reviewers for their comments and suggestions, and to Mary Dalrymple for her advice, insight and patience.

Abbreviations

Besides the abbreviations from the Leipzig Glossing Conventions, this chapter uses the following abbreviations.

ACT	active	HAB	habitual
ADN	adnominalizer	INFL	head of IP
C	complementizer	POT	potential
EXH	exhortative	PRT	particle

Part III

Grammatical modules and interfaces

Chapter 15

Glue semantics

Ash Asudeh
University of Rochester

Glue Semantics is a general framework for semantic composition and the syntax–semantics interface. It assumes an autonomous syntax and therefore needs to be paired with some syntactic theory. Here the focus is on LFG as the syntactic theory. The Glue logic, a fragment of linear logic, is presented first. This highlights the resource sensitivity of semantic composition in Glue. Second, Glue is presented without reference to LFG or any other syntactic theory. This highlights Glue's property of flexible composition. Third, the syntax–semantics interface is considered. This highlights Glue's autonomy of syntax and serves as a way to compare and constrast Glue with well-known alternatives. Fourth, Glue is paired with LFG (LFG+Glue), which highlights another important property of the theory, syntax/semantics non-isomorphism. Lastly, a number of particular phenomena are briefly reviewed and their analyses sketched: quantifier scope, modification, tense, events, argument structure, multiword expressions, and anaphora.

1 Introduction

The fundamental principle of compositional semantics is the following:

(1) *Principle of Compositionality (PoC)*
The meaning of a whole is a function of the meanings of the parts.
(Partee 1995)

According to the PoC, the meaning of an expression depends on its parts, but also on its syntax. The aspects of syntax that are relevant are standard features like NUM, PERS, TENSE, etc., as well as syntactic predicate-argument relations and local and non-local syntactic dependencies. These are all represented in f(unctional)-structure in LFG, so the relevant syntactic representation for compositional semantics in LFG is f-structure.

Ash Asudeh. 2023. Glue semantics. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 651–697. Berlin: Language Science Press. DOI: 10.5281/zenodo.10185964

But how are compositionally relevant features and relations obtained from f-structure? This is really a question about the mapping between syntax and semantics, or the nature of the *syntax–semantics interface*.[1] There are two fundamental ways in which different levels in LFG's Correspondence Architecture (Kaplan 1987, 1995) can be related: *description by analysis* and *co-description*. Both methods have been applied to the syntax–semantics interface in LFG.

Halvorsen (1983) developed the initial semantics for LFG, in which an f-structure is analyzed for features, including grammatical functions and other relational dependencies, to obtain a description of the compositional semantics. This is an example of *description by analysis* (Halvorsen & Kaplan 1988, Kaplan 1995) and is similar in spirit to Logical Form (LF) semantics (Heim & Kratzer 1998), even though the input syntactic structures are formally quite different. The description-by-analysis approach to LFG semantics effectively makes the same assumption as LF semantics: the semantic interpretation function applies to an entire syntactic structure — a standard non-tangled tree in LF semantics or an f-structure in description-by-analyses semantics for LFG.

Halvorsen & Kaplan (1988) offered a co-description alternative. According to co-description, a lexical item specifies its c-structural category, which captures its syntactic distribution, and also simultaneously specifies its contributions to f-structure, s(emantic)-structure, and any other grammatical modules. The contribution to f-structure, s-structure, etc., is accomplished through a set of constraints and equalities whose solutions determine the lexical item's non-c-structural contributions.[2] Thus, a syntactic formative on this view simultaneously *co-describes* its contributions to compositional semantics.

Glue Semantics (Glue) further develops and logically systematizes the co-description idea of Halvorsen & Kaplan (1988).[3] In contrast to description by analysis, co-descriptive LFG semantics is in the spirit of the syntax–semantics interface tradition that developed out of the *rule-by-rule* approach of Montague (1973), to use the terminology of Bach (1976). This tradition is standardly exemplified by Categorial Grammar (CG; for a basic overview and foundational references, see

---

[1] Unfortunately, this term has been somewhat bleached of meaning through overuse in syntactic theory, where the mapping is often not specified in sufficient detail.

[2] See Asudeh (2012: ch. 3) for a basic introduction to one version of the Correspondence Architecture.

[3] The implementation of Glue that was developed for the Xerox Linguistic Environment (XLE) implementation of LFG (Crouch et al. 2011) used description-by-analysis, but out of necessity rather than by design. The co-descriptive version of Glue would have required changes to the underlying XLE implementation, whereas description-by-analysis Glue did not. Also see Andrews (2008) for a consideration of description-by-analysis versus co-description approaches to Glue.

Wood 1993). In fact, Dalrymple, Gupta, et al. (1999) discuss how Glue is strongly related to Categorial Grammar in the type-logical tradition (for overviews and further references, see e.g., Carpenter 1997, Morrill 1994, 2011, Moortgat 1997).

However, Glue Semantics and Categorial Grammar make distinct assumptions about the relation between the syntax of word order and the syntax of compositional semantics (for discussion and further references on this aspect of CG, see Steedman 2014). LFG's claims about Universal Grammar (Bresnan et al. 2016: ch. 4) serve to highlight the distinction. C-structure, which represents word order, is highly variable cross-linguistically, whereas f-structure, which represents syntactic features and dependencies, is largely invariant cross-linguistically. This is reflected in the fact that although embedding is significant at f-structure, order among features in the same f-structure is not, as shown in (2) and (3):

(2)
$$\begin{bmatrix}\textsc{att1} & \begin{bmatrix}\textsc{att2} & \textsc{val}\end{bmatrix}\end{bmatrix}$$
$$\neq \begin{bmatrix}\textsc{att2} & \textsc{val}\end{bmatrix}$$

(3)
$$\begin{bmatrix}\textsc{att1} & \textsc{val1}\\ \textsc{att2} & \textsc{val2}\end{bmatrix}$$
$$= \begin{bmatrix}\textsc{att2} & \textsc{val2}\\ \textsc{att1} & \textsc{val1}\end{bmatrix}$$

A language with relatively free word order (e.g., Warlpiri) has quite different c-structures from a language with relatively fixed word order (e.g., English). However, the two languages have similar f-structures, which predicts that they are similar with respect to syntactic features and dependencies (Bresnan et al. 2016: ch. 1). It would be antithetical to the theory for compositional semantics to be computed from c-structure, since the cross-linguistically relevant information for semantics is captured in the unordered f-structure. So Glue Semantics uses a commutative logic for composition, which turns out to yield insights beyond those which originally motivated Glue.[4] This will be explored more carefully below, from a higher level perspective.

The first papers in the Glue Semantics (Glue) framework were published in the mid-nineties (Dalrymple et al. 1993, Dalrymple, Lamping, Pereira, et al. 1995, Dalrymple, Gupta, et al. 1997, Dalrymple, Lamping, Pereira, et al. 1997). The initial major publications on Glue, including revised versions of most of these papers, appeared in Dalrymple (1999). These publications all assumed some version of

---

[4] Note that the term *logic* here is intended not merely in the sense of a representational language for meaning, but rather a deductive system for deriving formulae from other formulae, i.e., proving conclusions from premises and previously proven conclusions.

LFG syntax. It should be borne in mind, however, that Glue Semantics (Glue) is a general framework for semantic composition and the syntax–semantics interface and is in that sense independent from LFG per se. The key syntactic assumption that Glue makes is headedness, which is universal across formal syntactic theories, even if specifics vary. Glue thus offers a highly flexible and adaptable approach to semantic composition and the syntax–semantics interface. In addition to LFG, Glue Semantics has been defined for a number of syntactic frameworks, including Lexicalized Tree-Adjoining Grammar (Frank & van Genabith 2001), HPSG (Asudeh & Crouch 2002b), Minimalism (Gotham 2018), and Universal Dependencies (Gotham & Haug 2018).

Asudeh (2022: 324) highlights the following high-level properties of Glue Semantics:[5]

1. *Resource-sensitive composition*
   The logic of composition in Glue is *resource-sensitive*: The underlying logic of composition itself requires that all and only the resources/premises instantiated from the syntax are used in semantic composition.
2. *Flexible composition*
   The logic of composition in Glue is *commutative*. Semantic composition is systematically related to and constrained by syntax, but is not determined by syntactic word order. Semantic composition is tightly restricted by resource-sensitive composition.
3. *Autonomy of syntax*
   The logical assumptions of Glue yield a truly autonomous syntax, as a corollary of flexible composition. Semantic composition is commutative, but syntax is not: Syntax is subject to word order constraints that do not apply to semantic composition.
4. *Syntax/semantics non-isomorphism*
   Grammatical formatives, e.g. lexical items, may contribute multiple Glue terms that are all contributed to the semantic proof or no Glue terms at all, as a corollary of autonomy of syntax. There is no requirement that a formative must make exactly one contribution to interpretation.

In Asudeh (2022), I used these properties as organizing themes for a big-picture discussion that mostly backgrounded the combination of LFG in particular with

---

[5] My thanks to an anonymous reviewer of Asudeh (2022) for suggesting the term *syntax/semantics non-isomorphism.*

Glue (often called LFG+Glue). Here I wish instead to foreground LFG+Glue, but it is nevertheless useful to have these properties in one place, as they will occasionally be referred to below.

I also want to emphasize that these properties are not fully independent, at least as given. The degree of resource sensitivity flows from the particular fragment of *linear logic* (Girard 1987) that one chooses for the Glue logic, but the implicative fragment with universal instantiation is commonly used and this fragment is highly resource sensitive, as explained in the next section. From resource sensitivity flow some automatic constraints on flexible composition such that it's not just 'anything goes.' Flexible composition in turn permits true autonomy of syntax, which fits naturally within LFG's general ethos of allowing mismatches between distinct linguistic modules in the Correspondence Architecture (Kaplan 1987, 1995, Asudeh 2006). Lastly, since syntax is autonomous from semantics, given flexible composition, it does not follow that a compositional analysis is only possible if each formative contributes exactly one meaning to semantic composition. Formatives may contribute nothing to meaning, e.g. expletive subjects or *do*-support *do*, or contribute multiple meanings to semantic composition.

2 The Glue logic: Resource-sensitive composition

The Glue logic is a fragment of *linear logic* (Girard 1987, Crouch & van Genabith 2000). Linear logic can be thought of as a logic of resources: Each premise in a linear logic proof must be used exactly once.[6] This can be usefully understood from the perspective of *substructural logics.* Substructural logics "focus on the behaviour and presence — or more suggestively, the *absence* — of *structural rules.* These are particular rules in a logic which govern the behaviour of collections of information." (Restall 2000: 1–2; emphasis in original). The basic intuition is that the choice of structural rules allows a precise logical characterization of some system of information. Language can be construed as information. For example,

---

[6] Girard (1987) defines two modal operators for linear logic, ! (*Of course!*) and ? (*Why not?*). These operators prefix particular premises (e.g., $!A$ or $?A$). This allows resource accounting to be turned off for the premise. Some early work in Glue used the ! modal in the analysis of coordination (Kehler et al. 1995, 1999). However, Asudeh (2004, 2005a) argued for a stricter notion of resource sensitivity that results from a simpler modality-free fragment of linear logic. Asudeh & Crouch (2002a) present a polymorphic Glue analysis of coordination (Steedman 1985, Emms 1990, 1992). The Asudeh & Crouch (2002a) approach does not require the modality; also see Dalrymple et al. (2019: ch. 16).

Chomsky (1986, 1995) can be understood as characterizing language as information from a cognitive perspective. Another example is the characterization of language as information from a logical perspective, as in van Benthem (1991).

Three structural rules that are particularly relevant to substructural logics for linguistics are *weakening*, *contraction*, and *commutativity*:[7]

(4) *Weakening* Intuition: A premise can be *freely added*

$$\frac{\Gamma \vdash B}{\Gamma, A \vdash B}$$

(5) *Contraction* Intuition: Any additional occurrence of a premise can be *freely discarded*

$$\frac{\Gamma, A, A \vdash B}{\Gamma, A \vdash B}$$

(6) *Commutativity* Intuition: Premises can be *freely reordered*

$$\frac{\Gamma, A, B \vdash C}{\Gamma, B, A \vdash C}$$

If a logic *lacks* the rules of weakening and contraction, then premises in the logic cannot be added or discarded and the logic is therefore a *resource logic*.

However, we can also distinguish logics based on commutativity: A resource logic can be commutative or non-commutative. Linear logic is a commutative resource logic. In contrast, the Lambek logic L (Lambek 1958) is a non-commutative resource logic. L is the fundamental logic of the Lambek calculus, the basis for the type-logical approach to Categorial Grammar (see, e.g., van Benthem 1991, Moortgat 1997). The diagram in Figure 1 shows linear logic in a space of related substructural logics.[8]

The appropriate resource logic for semantics alone is a commutative resource logic. Semantic composition is resource-sensitive but does not show evidence of order-sensitivity in its own right (Asudeh 2012: ch. 5). Consider the general case

---

[7] The notation in these structural rules is understood as follows. Γ denotes a set of terms in the logic, whereas A, B denote particular terms in the logic. The single turnstile denotes a valid derivation/proof from the lefthand side to the righthand side; e.g., $\Gamma \vdash B$ means that B can be proven from Γ. The horizontal line separating the top and bottom of the rule means that the bottom can be derived from the top by the rule in question (i.e., the top *sequent* can be replaced by the bottom one). For example, the weakening rule states that, given $\Gamma \vdash B$, one can conclude $\Gamma, A \vdash B$; i.e., every instance of $\Gamma \vdash B$ can be replaced by $\Gamma, A \vdash B$, given the rule.

[8] Note that the relation between intuitionistic logic and classical logic is characterized by the addition of the law of the excluded middle. However, this law is not strictly a structural rule, hence the dashed rather than solid line in Figure 1.

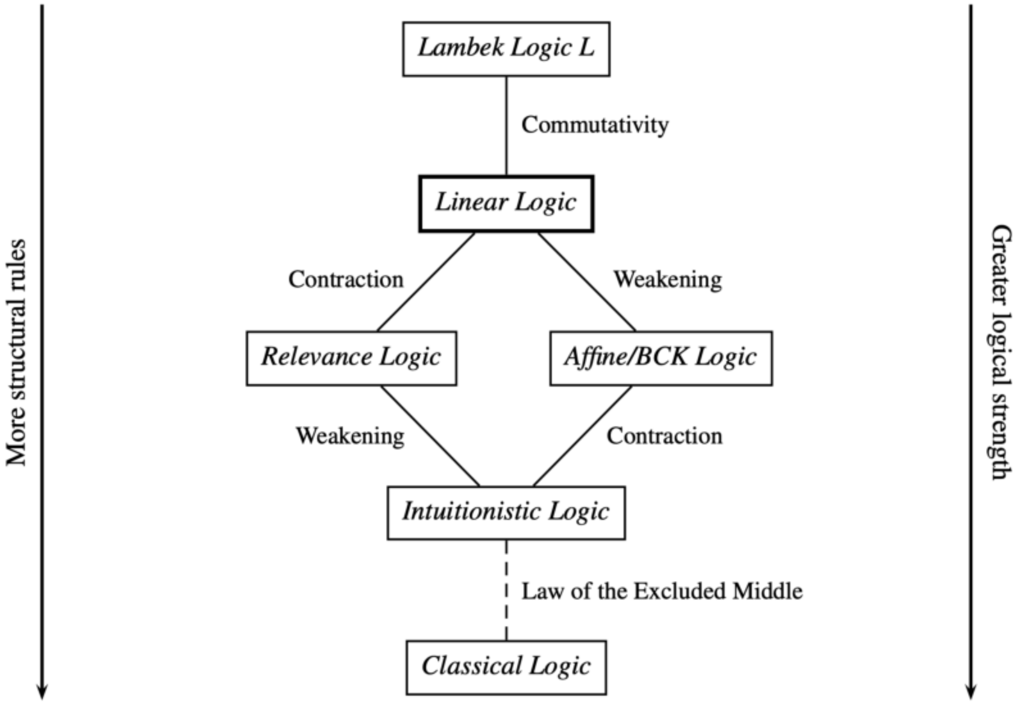

Figure 1: Hierarchy of logics related by structural rules (Asudeh 2012: 103; used with permission)

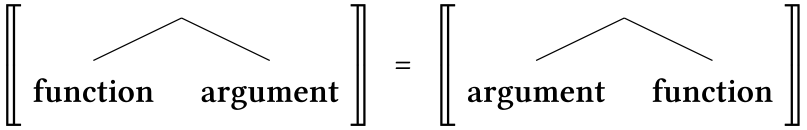
of some binary structure that is to be interpreted. If one branch denotes a function and the other denotes an argument, the function applies to the argument, whether the function is on the left or right:

(7)



For example, in English basic word order, the function that is the denotation of a transitive verb takes its argument to the right, but the resulting function that is the denotation of the VP takes its argument to the left.

It is not the *order* of the function and argument that determines their composition, but rather their semantic types (Klein & Sag 1985). This is saliently exemplified by the rule of functional application in the widely familiar system of Heim & Kratzer (1998: 44, 95). It is also exemplified by the equivalent interpretations of the forward and backward slash rules of Combinatory Categorial Grammar (see, e.g., Steedman 1987: 406 or Steedman & Baldridge 2011: 186).

But how is semantics resource-sensitive? The following quote from Klein & Sag (1985: 172) illustrates:

> Translation rules in Montague semantics have the property that the translation of each component of a complex expression occurs exactly once in the translation of the whole. … That is to say, we do not want the set S [of semantic interpretations of a phrase] to contain all meaningful expressions of IL [Intensional Logic] which can be built up from the elements of S, but only those which use each element exactly once.

In other words, Montague's (1973) translation rules are resource-sensitive. However, this is merely coincidental as far as his translation process is concerned. In their generalization of Montague's system, Klein & Sag (1985: 174) need to define an operation of *bounded closure*. This operation ensures that the meaning of each element of semantic composition is indeed used "exactly once."

We can obtain this result in a more general way, if we adopt a resource logic for semantic composition. This rests on the absence of the structural rules of contraction and weakening. The lack of contraction means that the number of occurrences of a premise matters, so a set of linear logic premises is a *multiset* (sometimes called a *bag*). The lack of weakening means that the bag must be emptied in constructing a valid proof. In other words, it follows directly from the absence of contraction and weakening that "each element" must be used "exactly once". Klein & Sag's (1985) bounded closure is effectively an attempt to capture the logical resource sensitivity of linear logic or L (Asudeh 2012: 110–111).

Logical resource sensitivity in turn forms the basis for linguistic resource sensitivity (Asudeh 2012: ch. 4). This is achieved by placing a linguistically motivated goal condition on the Glue logic proof; for example, we can require that the proof of a sentence terminates in a single meaning constructor of type t (Dalrymple, Gupta, et al. 1999). Asudeh (2012: 110–123) argues that resource-sensitive composition not only directly captures bounded closure, it arguably also captures a diverse set of principles across a variety of frameworks. These include Completeness and Coherence (Kaplan & Bresnan 1982), the Theta Criterion (Chomsky 1981), the Projection Principle (Chomsky 1981, 1982, 1986), No Vacuous Quantification (Chomsky 1982, 1995, Kratzer 1995, Kennedy 1997, Heim & Kratzer 1998, Fox 2000), the Principle of Full Interpretation (Chomsky 1986, 1995), and the Inclusiveness Condition (Chomsky 1995).

In addition, it seems that phonology and syntax can equally be considered resource-sensitive, i.e. lack weakening and contraction from a logical perspective, as outlined in Asudeh (2012: 98–99). This allows a deeper generalization about natural language as computation (Steedman 2007), namely that *natural language is resource-sensitive*. The claim is set out in the *Resource Sensitivity Hypothesis* (Asudeh 2012: 95). Where phonology and syntax contrast with semantics is not with respect to weakening and contraction, but rather with respect to commutativity. Phonology is strictly non-commutative, whereas syntax shows commutativity in some circumstances of free word order. This leaves two options. The partial commutativity of syntax can be captured by separating the syntax of structure from the syntax of composition, treating the syntactic module(s) autonomously, as in Glue Semantics. Alternatively, partial commutativity can be captured by not separating structural and compositional syntax and instead introducing a mechanism to the syntax–semantics interface that relaxes commutativity in what is otherwise a non-commutative system. An example of such a mechanism is the categorial modalities of Baldridge (2002).

3 Glue without LFG: Flexible composition

Linguistic meanings in Glue are encoded in *meaning constructors*. Meaning constructors are pairs of terms from two logics. These terms can be represented as $\mathcal{M}$ and G (where $\mathcal{M}$ is mnemonic for *meaning language* and G is mnemonic for *Glue logic*). These could be written in any conventional way for writing pairs, such as $\langle \mathcal{M}, G \rangle$, but most Glue work of the past couple of decades has written the pair using an uninterpreted colon as a pairing symbol, as in (8):

(8) $\mathcal{M} : G$

The meaning language can be anything that supports the lambda calculus, such as the simply typed lambda calculus that is often used in linguistic semantics. However, more specialized lambda languages can be used, as in van Genabith & Crouch (1999), Bary & Haug (2011), and Lowe (2015), which all use Muskens's (1996) Compositional Discourse Representation Theory (CDRT) or Dalrymple et al. (2019: ch. 14), which uses Haug's (2014) partialized version, Partial Compositional DRT (PCDRT). The glue logic is a fragment of *linear logic* (Girard 1987). The glue logic specifies semantic composition based on a syntactic parse that instantiates the general terms in G to a specific syntactic structure. The meaning constructors thus serve as *premises* in a linear logic *proof* of the compositional semantics.

The linear logic implication connective, $\multimap$,[9] is the basis for the fundamental compositional rule of functional application. Functional application corresponds to linear implication elimination in natural deduction style:

(9) Functional application:
Implication elimination modus ponens

$$\frac{\beta : A \multimap B \qquad \alpha : A}{\beta(\alpha) : B} \multimap_{\mathcal{E}}$$

---

[9] This is the *multimap* symbol, but it is often referred to in Glue discourse as the *lollipop*.

The implication elimination rule is standard modus ponens. The rule is read as follows: given $\beta : A \multimap B$ and given $\alpha : A$, it is valid to conclude $\beta(\alpha) : B$.

The Curry-Howard Isomorphism (CHI; Curry & Feys 1958, Howard 1980) determines the correspondence between the term to the left of the colon — a term from $\mathcal{M}$ — and the term to right of the colon — a term from G. The CHI puts logical formulas in correspondence with computational types. Here linear logic formulas are in correspondence with types in the lambda calculus.[10] The terms A, B in (9) are schematic for possibly complex formulas; α, β may similarly be complex terms.

The rule for linear implication introduction corresponds to functional abstraction.

(10) Functional abstraction:
Implication introduction — hypothetical reasoning

$$\begin{array}{c} [\alpha : A]^{1} \\ \vdots \\ \beta : B \\ \hline \lambda\alpha.\beta : A \multimap B \end{array} \multimap_{\mathcal{I},1}$$

In this schema, a hypothesis is uniquely flagged with a numerical index. The fact that it is a hypothesis — i.e. not a premise encoded by a meaning constructor — is indicated by square brackets. If a conclusion can be derived through some series of proof steps (indicated by the vertical ellipsis), given the hypothesis, then we know that the hypothesis implies the conclusion: the hypothesis is discharged (as the antecedent of an implication with the conclusion as the consequent) and its flag is withdrawn. In the meaning language, this corresponds to abstraction over the variable introduced on the meaning language side of the hypothesis.

Let’s turn to a simple linguistic example:

(11) Blake called Alex.

---

[10] Some early papers in Glue (Dalrymple et al. 1993, Dalrymple, Lamping, Pereira, et al. 1995, 1997, Crouch & van Genabith 1999, van Genabith & Crouch 1999, Fry 1999a, Kehler et al. 1999) used a more ad-hoc method of relating the meaning terms to the Glue logic, but Dalrymple, Gupta, et al. (1997, 1999) introduced the Curry-Howard approach to Glue, which is now standard. Kokkonidis (2008) introduced an alternant called *First-Order Glue* which has also proven influential in subsequent Glue literature (e.g., Bary & Haug 2011, Lowe 2014, Gotham 2018, Gotham & Haug 2018, Findlay 2019; see also Andrews 2010 for a related proposal).

Let us assume the following meaning constructor for the verb *called*, leaving tense aside:[11]

(12) $\lambda y.\lambda x.call(y)(x) : a \multimap b \multimap c$

On the Glue side, *c* is mnemonic for *called*, *a* for *Alex*, and *b* for *Blake*. This meaning constructor would in fact be specified in some general form but instantiated relative to a particular syntactic structure. For now, let us just assume that some instantiation has given us the meaning constructor in (12). In Section 5 below, we'll see how to specify meaning constructors in general terms given LFG's usual f-description language.

Assuming that the lexical entries for *Alex* and *Blake* contribute meaning constructors that are instantiated to $alex : a$ and $blake : b$, we can construct the following proof, given (12); note that $\Rightarrow_\beta$ indicates β-reduction of a lambda term.

(13)
$$\frac{blake : b \qquad \dfrac{\lambda y.\lambda x.call(y)(x) : a \multimap b \multimap c \qquad alex : a}{\lambda x.call(alex)(x) : b \multimap c}\,{\multimap_{\mathcal{E}}, \Rightarrow_\beta}}{call(alex)(blake) : c}\,{\multimap_{\mathcal{E}}, \Rightarrow_\beta}$$

The meaning term in the conclusion is equivalent to $call(blake, alex)$ in the commonly used relational notation (Montague 1973).

Note that proofs are abstract mathematical objects that can be written down in various ways. This is quite apart from whatever convention or notation we choose for writing them down. For example, even holding constant our natural deduction notation, what is shown in (13) is just one of four ways to write down the single abstract normal form proof (Prawitz 1965). Writing the proof down imposes an order,[12] but since the Glue logic is commutative (see Section 2 for further details), all four written representations of the proof are equivalent.

Given the commutativity of the Glue logic, the arguments of the function can be freely reordered (re-curried), as in (14) below, but still yield the appropriate meaning:

(14) $\lambda x.\lambda y.call(y)(x) : b \multimap a \multimap l$

Example (15) below is a schematic demonstration of how this argument reordering works in a proof; the example abstracts away from the particular *call* function. The example also shows the implication introduction rule in action.

---

[11] Note that the lambda term $\lambda y.\lambda x.call(y)(x)$ is equivalent to the function *call* by η-equivalence in the lambda calculus. However, it is useful for the exposition below to present it in non η-reduced form.

[12] The *Alex* meaning constructor/premise must be written either to the right or left of the functional (verb) meaning constructor and similarly for the *Blake* meaning constructor/premise.

(15)
$$\dfrac{\dfrac{\dfrac{\dfrac{\dfrac{\lambda y.\lambda x.f(y)(x) \,:\, a \multimap b \multimap c \qquad [v \,:\, a]^1}{\lambda x.f(v)(x) \,:\, b \multimap c}\multimap_{\mathcal{E}} \qquad [u \,:\, b]^2}{f(v)(u) \,:\, c}\multimap_{\mathcal{E}}}{\lambda v.f(v)(u) \,:\, a \multimap c}\multimap_{\mathcal{I},1}}{\lambda u.\lambda v.f(v)(u) \,:\, b \multimap a \multimap c}\multimap_{\mathcal{I},2}}{\lambda x.\lambda y.f(y)(x) \,:\, b \multimap a \multimap c}\Rightarrow_{\alpha}, \Rightarrow_{\alpha}$$

The result is a reordered form of the original term but without any change in meaning, because the CHI ensures that the function's arguments in the meaning terms are also appropriately reordered. The α-equivalences, in which variables are renamed, are not strictly necessary, but have been added for full transparency. In general, given n arguments in the order $a_1 \ldots a_n$, a reverse order $a_n \ldots a_1$ can be obtained by a series of hypotheses on the arguments that are discharged in the order they were made. More generally, the arguments can be reordered in any order by mixing the order of hypothesis assumption and discharge.

4 The syntax–semantics interface: Autonomy of syntax

Glue rests on two general assumptions about the syntax–semantics interface:

1. The *logical syntax* of semantic composition (Fenstad et al. 1987) is distinct from the *structural syntax*. The syntax of linear logic proofs captures the logical syntax in Glue. Some separate syntactic framework, such as LFG, captures the structural syntax of categorially determined distribution, constituency, features, and local and non-local dependencies (i.e, *syntax* in the standard sense).

2. Logical syntax and structural syntax are systematically related through the instantiation of Glue meaning constructors.

These assumptions distinguish Glue from both *interpretive theories* of semantic composition and *parallel theories* of semantic composition. A well-known example of interpretive theories is Logical Form semantics (e.g., Heim & Kratzer 1998). The *description-by-analysis* semantics for LFG of Halvorsen (1983) is another example of an interpretive theory. Two well-known examples of parallel theories are Combinatory Categorial Grammar (e.g., Steedman & Baldridge 2011) and Type-Logical Categorial Grammar (e.g., Carpenter 1997).[13]

With respect to LF semantics, Glue's assumption of a separate level of structural syntax is similar. However, in its standard co-descriptive guise, Glue is distinct from LF semantics, because Glue does not assume that the syntactic structure in its entirety is the input to semantic interpretation. With respect to Categorial Grammar, we also see similarity and divergence. We see similarity in Glue's assumption of the pairing of functional application (the fundamental compositional operation) with terms that define complex categories implicationally.[14] However, Glue is also distinct from Categorial Grammar, because Glue does not assume that implicational categories are responsible for word order (hence their lack of directionality), but rather that there is a separate syntactic representation. In sum, Glue is a compositional semantic theory of a third kind. From a big picture perspective, Glue synthesizes certain aspects of LF semantics and Categorial Grammar, yet remains distinct from both these theories.

The assumptions, in 1 and 2 above, that began this section derive a strong notion of syntactic autonomy. Categorial Grammar makes the very strong assumption that syntax and semantics are isomorphic. This assumption entails that any semantic distinction must be the reflection of a syntactic distinction. LF semantics similarly assumes that any interpretive/semantic distinction must be due to an underlying syntactic distinction. In an interpretive semantic theory such as LF semantics, the needs of semantics dictate what's in the syntax, even if the things in question are syntactically questionable. The predicate abstraction/numerical nodes in Heim & Kratzer (1998: 186) are an example, since they require the addition of lambda operators to the syntactic tree. This is surprising from the perspective of semantic theory, since this means that *object* languages, i.e. the natural languages undergoing analysis, must in fact contain these logical operators, for which there is no compelling evidence (such as lexicalization in some language or other).

---

[13] Parallel theories are often discussed under the rubric of "rule-by-rule composition" (Bach 1976), but the *rule-by-rule* term is no longer accurate. The term originates in the paired syntactic/semantic rules of Montague (1973), which is now deprecated. This kind of theory is also sometimes referred to as "direct compositionality" (Barker & Jacobson 2007, Jacobson 2014), but this raises a number of issues (Asudeh 2006), so I do not favour that term.

[14] Categorial Grammar's slashes are directed implications. For example, X/Y states that one can conclude a category X conditional on there being a category Y to the right; in other words, X/Y means that Y → X yields X so long as Y is on the right of X.

Quantifier scope ambiguity offers perhaps the most straightforward demonstration of the distinction between Glue on the one hand, and LF semantics and Categorial Grammar, on the other. Consider the following standard example:

(16) Everybody loves somebody.

The Glue logic computes two readings for this sentence, but *without* imputing a syntactic ambiguity, which seems structurally under-motivated; see s 6.1 for further details. This contrasts with both LF semantics and Categorial Grammar; these theories both require the two readings to be syntactically distinguished.

In the next section, I pair Glue with LFG as the syntactic framework in order to render these general points more specific. Although LFG is the natural syntactic framework to choose, given the present venue and the fact that most Glue work has assumed an LFG syntax, see Section 1 above for a list of other syntactic frameworks that have been paired with Glue.

5 Glue with LFG: Syntax/semantics non-isomorphism

Consider the example in Figure 2, which shows the c-structures and f-structure for the sentence *I drank water* in Finnish and English.[15] The distinct c-structures capture the variation in syntactic realization between the two languages. In particular, they capture the fact that Finnish allows null subjects, unlike English. The f-structure shows that these distinct c-structures encode identical syntactic features and dependencies. Figure 3 shows the same structures with the arrows resolved. One way to solve the equations is to label all c-structure nodes that bear a down arrow with an f-structure variable. Instantiation of the metavariables ↑ and ↓ is arbitrary, barring accidental identity, and resolves the equalities (Bresnan et al. 2016: 54–58).

In both the Finnish and English c-structures, the mapping to OBJECT is contributed structurally by the annotation (↑ OBJ) = ↓ on the NP daughter of V′. In the English c-structure, the mapping to SUBJECT is also contributed structurally, by the annotation (↑ SUBJ) = ↓ on the DP in SpecIP. In contrast, the SUBJECT information is contributed morphologically in the Finnish c-structure. This distinction is reflected in the lexical entries in Table 1. Notice that the f-descriptions in these lexical entries not only describe their lexical contributions to f-structure, but also have appropriate Glue meaning constructors that define the mappings

---

[15] I assume LFG's theory of *extended heads*, which allows the Finnish verb to be generated in I (Bresnan et al. 2016: ch. 6–7).

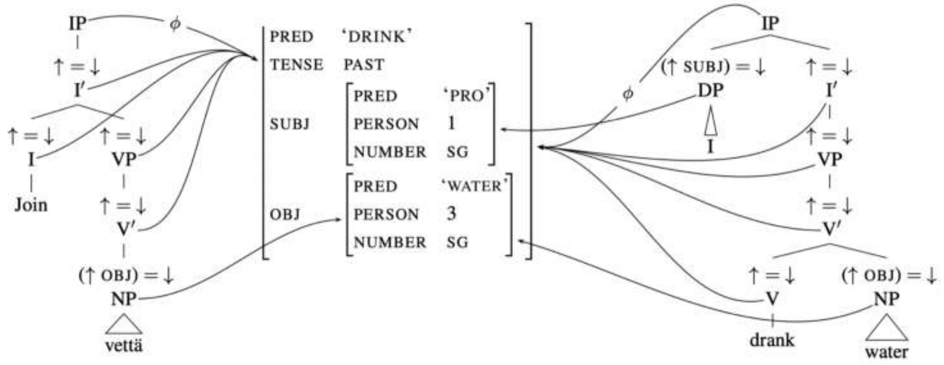


Figure 2: C-structures and f-structure for *I drank water* in Finnish and English (adapted from Asudeh & Toivonen 2015: 27; used with permission)

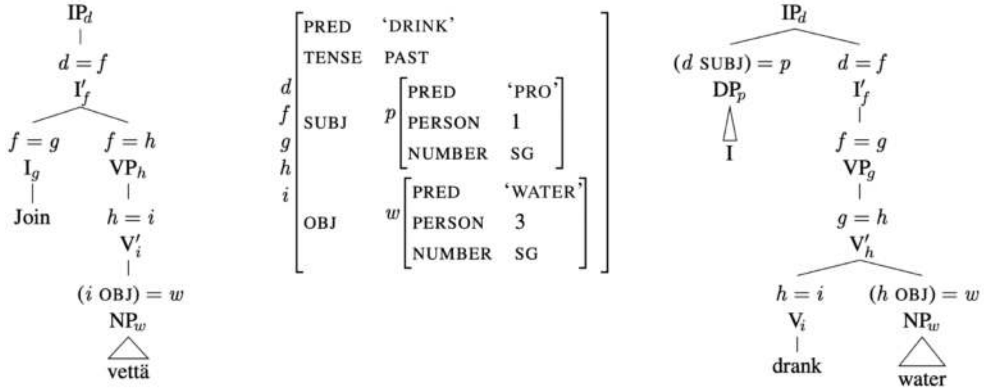

Figure 3: Finnish and English structures with ↑ and ↓ metavariables resolved (Asudeh 2022: 330; used with permission)

to s(emantic)-structure and encode the composition of the head and its dependents as linear implications.[16] I have set tense aside in the semantics, but return to it in Section 6.3 below. The annotation σ on the arrows in the Glue meaning constructors indicates that these are the s-structure correspondents of the relevant f-structures. The σ correspondence function maps from f-structure to s-structure.

The up arrows in Table 1 are instantiated to the f-structure of the relevant pre-terminal node: g (Finnish *join*), w (Finnish *vettä*), p (English *I*), i (English *drank*), and w (English *water*).[17] However, we know from Figure 3 that $g = i = d$.

---

[16] The asterisk in the term for *vettä*/*water* is the cumulativity operator of Link (1983). It states that *water* is a mass term, although this is not important for our present purposes.

[17] In the case of the abbreviated (triangle) structures, there would be intervening nodes. But there would be a chain of ↑=↓ annotations between the word and the phrase it heads, so this is a harmless simplification.

Table 1: Lexicons for *I drank water* in Finnish and English

Finnish			English		
join	I	$(\uparrow \textsc{pred}) = \text{‘}\textsc{drink}\text{’}$ $(\uparrow \textsc{tense}) = \textsc{past}$ $(\uparrow \textsc{subj pred}) = \text{‘}\textsc{pro}\text{’}$ $(\uparrow \textsc{subj pers}) = 1$ $(\uparrow \textsc{subj num}) = \textsc{sg}$ $\mathit{speaker} : (\uparrow \textsc{subj})_\sigma$ $\mathit{drink} :$ $(\uparrow \textsc{obj})_\sigma \multimap (\uparrow \textsc{subj})_\sigma \multimap {\uparrow_\sigma}$	*I*	D	$(\uparrow \textsc{pred}) = \text{‘}\textsc{pro}\text{’}$ $(\uparrow \textsc{pers}) = 1$ $(\uparrow \textsc{num}) = \textsc{sg}$ $\mathit{speaker} : {\uparrow_\sigma}$
vettä	N	$(\uparrow \textsc{pred}) = \text{‘}\textsc{water}\text{’}$ $(\uparrow \textsc{pers}) = 3$ $(\uparrow \textsc{num}) = \textsc{sg}$ ${}^{*}\mathit{water} : {\uparrow_\sigma}$	*drank*	V	$(\uparrow \textsc{pred}) = \text{‘}\textsc{drink}\text{’}$ $(\uparrow \textsc{tense}) = \textsc{past}$ $\mathit{drink} :$ $(\uparrow \textsc{obj})_\sigma \multimap (\uparrow \textsc{subj})_\sigma \multimap {\uparrow_\sigma}$
			water	N	$(\uparrow \textsc{pred}) = \text{‘}\textsc{water}\text{’}$ $(\uparrow \textsc{pers}) = 3$ $(\uparrow \textsc{num}) = \textsc{sg}$ ${}^{*}\mathit{water} : {\uparrow_\sigma}$

So we can just use the mnemonic label d in all relevant cases. We can also take advantage of the equality $(d\ \textsc{subj}) = p$. We obtain the following collection of identical instantiated meaning constructors for each language:

(17) $\{\mathit{speaker} : p_\sigma, \mathit{drink} : w_\sigma \multimap p_\sigma \multimap d_\sigma, {}^{*}\mathit{water} : w_\sigma\}$

This yields a single normal form proof (i.e., minimal proof; Prawitz 1965) for the corresponding Finnish and English sentences, which can be presented in natural deduction format as follows (recall that order of premises on a proof line does not matter, since the Glue logic is commutative):

(18)

$$\dfrac{\mathit{speaker} : p_\sigma \qquad \dfrac{\mathit{drink} : w_\sigma \multimap p_\sigma \multimap d_\sigma \qquad {}^{*}\mathit{water} : w_\sigma}{\mathit{drink}({}^{*}\mathit{water}) : p_\sigma \multimap d_\sigma}\multimap_{\mathcal{E}}}{\mathit{drink}({}^{*}\mathit{water})(\mathit{speaker}) : d_\sigma}\multimap_{\mathcal{E}}$$

6 Some applications of glue semantics

6.1 Quantifier scope

Let us return to the quantifier scope example in (16) above, repeated here as (19).

(19) Everybody loves somebody.

Glue's properties of autonomy of syntax and flexible composition allow (19) to be treated as *syntactically unambiguous* but *semantically ambiguous.*

I will not show the c-structure here, as the relevant syntactic representation is the single f-structure for (19) shown here, with mnemonic labels as usual:

(20)
$$
{}_{l}\left[\begin{array}{ll}
\textsc{pred} & \text{‘}\textsc{love}\text{’} \\
\textsc{tense} & \textsc{pres} \\
\textsc{subj} & {}_{e}\left[\begin{array}{ll} \textsc{pred} & \text{‘}\textsc{everybody}\text{’} \\ \textsc{person} & 3 \\ \textsc{number} & \textsc{sg} \end{array}\right] \\
\textsc{obj} & {}_{s}\left[\begin{array}{ll} \textsc{pred} & \text{‘}\textsc{somebody}\text{’} \\ \textsc{person} & 3 \\ \textsc{number} & \textsc{sg} \end{array}\right]
\end{array}\right]
$$

The Glue meaning constructors in the lexical entries are shown in (21). Tense has again been set aside and it is again most transparent for expository purposes to show the meaning term for *loves* in non-η-reduced form (see footnote 11 on η-reduction).

(21) *everybody* D $\lambda Q.every(person, Q) : \forall S.(\uparrow_{\sigma} \multimap S) \multimap S$
somebody D $\lambda Q.some(person, Q) : \forall S.(\uparrow_{\sigma} \multimap S) \multimap S$
loves V $\lambda y.\lambda x.love(y)(x) : (\uparrow \textsc{obj})_{\sigma} \multimap (\uparrow \textsc{subj})_{\sigma} \multimap \uparrow_{\sigma}$

When we instantiate the meaning constructors in (21) relative to the f-structure in (20), we get:

(22)
$$
\begin{aligned}
\Gamma = \{\, & \lambda y.\lambda x.love(y)(x) : s \multimap e \multimap l, \\
& \lambda Q.every(person, Q) : \forall S.(e \multimap S) \multimap S, \\
& \lambda Q.some(person, Q) : \forall S.(s \multimap S) \multimap S \,\}
\end{aligned}
$$

The functions *every* and *some* are standard quantificational determiners from generalized quantifier theory (Montague 1973, Barwise & Cooper 1981, Keenan & Faltz 1985), with type $\langle\langle e,t\rangle,\langle\langle e,t\rangle,t\rangle\rangle$. The function *every* is defined as $\lambda P.\lambda Q.P \subseteq Q$. The function *some* is defined as $\lambda P.\lambda Q.P \cap Q \neq \emptyset$. In these formulas, P is the set of entities that is the determiner's restriction and Q is the set of entities that is its scope. The quantifier $\lambda Q.every(person, Q)$ thus returns true if the set of people is a subset of its scope set. Similarly, the quantifier $\lambda Q.some(person, Q)$ returns true if the intersection of the set of people and its scope set is non-empty.

A comment is in order about the universal quantification symbol $\forall$ in the Glue terms for the quantifiers. This universal ranges over variables in the Glue logic. It allows the quantifier scope over *any* Glue logic dependency on the semantic correspondent of the quantifier. Asudeh (2005b: 393–394) discusses the interpretation of ∀ in linear logic. The key insight is that, given the resource sensitivity of linear logic, the universal means “any one”, not “all”. The function of the linear universal is to define *scope points* and its interpretation is not related to the quantificational force in the meaning language. Observe that *every* and *some* alike are associated with these linear universal scope terms, even though *some* has existential force.

The meaning constructors in (22) yield exactly two normal form/minimal proofs. These can be represented as in Figure 4 and Figure 5.[18] In other theories, quantifier scope ambiguity requires either a syntactic operation such as Quantifier Raising (QR) in Logical Form semantics (May 1977, 1985, Heim & Kratzer 1998) or a type shifting operation and corresponding categorial modification of some kind, as in Combinatory or Type-Logical Categorial Grammar semantics (Partee & Rooth 1983, Hendriks 1993). Thus, interpretive and parallel theories of composition alike impute a syntactic ambiguity to handle quantifier scope ambiguity.[19]

This contrasts with Glue Semantics. The fact that Glue assumes an independent level of syntax (autonomy of syntax) allows composition to be flexible (flexible composition), which in turn allows the theory to derive the two distinct scope readings without positing a syntactic ambiguity or type shift.

$$
\dfrac{\begin{array}{l}\lambda Q.\mathit{every}(\mathit{person}, Q) :\\ \forall S.(e \multimap S) \multimap S\end{array}
\quad
\dfrac{\dfrac{\begin{array}{l}\lambda Q.\mathit{some}(\mathit{person}, Q) :\\ \forall S.(s \multimap S) \multimap S\end{array}
\quad
\dfrac{\dfrac{\dfrac{\begin{array}{l}\lambda y.\lambda x.\mathit{love}(y)(x) :\\ s \multimap e \multimap l\end{array} \quad [v : s]^1}{\begin{array}{l}\lambda x.\mathit{love}(v)(x) :\\ e \multimap l\end{array}}\multimap_{\mathcal{E}}, \Rightarrow_{\beta} \quad [u : e]^2}{\mathit{love}(v)(u) : l}\multimap_{\mathcal{E}}, \Rightarrow_{\beta}}{\begin{array}{l}\lambda y.\mathit{love}(y)(u) :\\ s \multimap l\end{array}}\multimap_{\mathcal{I},1}, \Rightarrow_{\alpha}}{\mathit{some}(\mathit{person}, \lambda y.\mathit{love}(y)(u)) : l}\multimap_{\mathcal{E}}, \forall_{\mathcal{E}}[l/S], \Rightarrow_{\beta}}{\begin{array}{l}\lambda x.\mathit{some}(\mathit{person}, \lambda y.\mathit{love}(y)(x)) :\\ e \multimap l\end{array}}\multimap_{\mathcal{I},2}, \Rightarrow_{\alpha}}{\mathit{every}(\mathit{person}, \lambda x.\mathit{some}(\mathit{person}, \lambda y.\mathit{love}(y)(x))) : l}\multimap_{\mathcal{E}}, \forall_{\mathcal{E}}[l/S], \Rightarrow_{\beta}
$$

Figure 4: Surface scope interpretation of *Everybody loves somebody*

---

[18] The universal linear instantiation step is trivial, as in classical/intuitionistic logic. I have therefore not shown it explicitly. See Asudeh (2012: 396) for the rule.

[19] Jacobson (2014: ch. 14) offers a textbook comparison of the LF and CG approaches.

$$\dfrac{\begin{array}{c}\lambda Q.\mathit{some}(\mathit{person}, Q) :\\ \forall S.(s \multimap S) \multimap S\end{array} \qquad \dfrac{\dfrac{\begin{array}{c}\lambda Q.\mathit{every}(\mathit{person}, Q) :\\ \forall S.(e \multimap S) \multimap S\end{array} \qquad \dfrac{\begin{array}{c}\lambda y.\lambda x.\mathit{love}(y)(x) :\\ s \multimap e \multimap l\end{array} \qquad [v : s]^1}{\begin{array}{c}\lambda x.\mathit{love}(v)(x) :\\ e \multimap l\end{array}} {\multimap_{\mathcal{E}}, \Rightarrow_{\beta}}}{\mathit{every}(\mathit{person}, \lambda x.\mathit{love}(v)(x)) : l} {\multimap_{\mathcal{E}}, \forall_{\mathcal{E}}[l/S], \Rightarrow_{\beta}}}{\begin{array}{c}\lambda y.\mathit{every}(\mathit{person}, \lambda x.\mathit{love}(y)(x)) :\\ s \multimap l\end{array}} {\multimap_{\mathcal{I},1}, \Rightarrow_{\alpha}}}{\mathit{some}(\mathit{person}, \lambda y.\mathit{every}(\mathit{person}, \lambda x.\mathit{love}(y)(x))) : l} {\multimap_{\mathcal{E}}, \forall_{\mathcal{E}}[l/S], \Rightarrow_{\beta}}$$

Figure 5: Inverse scope interpretation of *Everybody loves somebody*

6.2 Modification

Glue is similar to Categorial Grammar in offering an analysis of semantic *modification* such that modifiers are easily identifiable by their formal shape. For example, the nominal modification category in (23) has its Glue logic analog in (24) (leaving the meaning language aside):

(23) N/N

(24) $A_{\langle e,t\rangle} \multimap A_{\langle e,t\rangle}$

A nominal modifier is a functional category/type that takes a nominal category/type as an input and returns the same category/type as an output. The modificational semantics is captured on the meaning language side.

For example, a Glue meaning constructor for the attributive adjective *Finnish* would look like (25).

(25) $\lambda P \lambda x.P(x) \wedge \mathit{finnish}(x) : (a_e \multimap b_t) \multimap (a_e \multimap b_t)$

Continuing the example, the common noun *city* would provide the ⟨*e,t*⟩ input to the main implication in (25), such that *Finnish city* would correspond to the following (composed) result:

(26) $\lambda x.\mathit{city}(x) \wedge \mathit{finnish}(x) : (a_e \multimap b_t)$

More generally, a modifier of any type corresponds to a meaning constructor with the following form:

(27) $\lambda f.\mathit{mod}(f) : X \multimap X$

The function *mod* is a placeholder for whatever the semantic effect of the modifier is.

The property of syntax-semantics non-isomorphism, which allows a lexical item to contribute multiple meaning constructors, allows a natural and elegant analysis of so-called *recursive modification* (Kasper 1997). In a nominal like the following, the result we want is that it is apparently the case that the city in question is Finnish:

(28) apparently Finnish city

In other words, we somehow want to maintain a consistent semantics for *apparently* as a modifier, while nevertheless allowing it to fulfill this modificational role inside a nominal. This is despite the type clash between the modifier, which expects a proposition-forming type as input, and the adjective *Finnish*, which does not have this type. The adjective instead has the type of a modifier, i.e. a function on the type that the interpretation of *apparently* expects.

The solution in Glue is to associate predicative and attributive adjectives with the property denotation for the adjective, shown in the first line of (29), and to further add a general nominal modification meaning constructor to the lexical entry for the attributive adjective, as in the second line of (29).

(29) *Finnish* $\lambda x.\mathit{finnish}(x) : v \multimap f$
$(\lambda Q \lambda P \lambda x.Q(x) \wedge P(x) : (v \multimap f) \multimap (a \multimap b) \multimap (a \multimap b))$

The reader can verify that the combination of these two meaning constructors yields the meaning constructor in (25) above (with types omitted). The second meaning constructor is treated as optional to ensure that predicative uses of the adjective work as expected. Resource-sensitive composition ensures that a predicative occurrence of the adjective cannot use the second meaning constructor whereas an attributive occurence must use it.

The revised analysis allows recursive modification by a modifier like *apparently*, assuming that we have a meaning constructor like the following associated with *apparently*, suitably instantiated to an f-structure where *apparently* is in the ADJ set of *finnish*:

(30) *apparently* $\lambda P \lambda x.\mathit{apparently}(P(x)) : (v \multimap f) \multimap (v \multimap f)$

The combination of this meaning constructor for *apparently* and the first meaning constructor in (29) then yields the following:

(31) $\lambda x.\mathit{apparently}(\mathit{finnish}(x)) : v \multimap f$

This is sufficient for a predicative occurrence, as in *Marimekko is apparently Finnish.*

For attributive occurrences, (31) then combines with the second meaning constructor in (29), which yields the desired result:

(32) $\lambda P \lambda x.\mathit{apparently}(\mathit{finnish}(x)) \land P(x) \,:\, (a \multimap b) \multimap (a \multimap b)$

This would then combine with the interpretation of *city* to yield the correct interpretation for, e.g., *The apparently Finnish city is nice.*

I leave aside here the natural extension that is necessary to fully capture recursive modification in examples like the following:

(33) apparently obviously Finnish

The extension just involves having two separate meaning constructors for the adverbial modifier *obviously* (and *apparently*, etc.), in order to make the system fully general, much as we have for the adjective *Finnish* in (29).

The first proposal for the extended modificational semantics presented here was in Dalrymple (2001: 255–274), to my knowledge. The most recent version of the LFG+Glue approach to modification, including recursive modification, is the subject matter of Dalrymple et al. (2019: ch. 13).

6.3 Tense

The basic approach to modification that was sketched at the beginning of Section 6.2 supports a simple account of tense as a modifier on a basic verb meaning, provided that we add a tense coordinate to verb meanings (for a review of approaches to tense in compositional semantics, see Grønn & von Stechow 2016).

Let us assume that a basic meaning constructor for a verb now looks like this:

(34) *sigh* $\lambda x \lambda t.\mathit{sigh}(t, x) \,:\, \mathit{subj} \multimap \mathit{tense} \multimap \mathit{verb}$

Let's also assume, following Haug 2008, that u stands for utterance time (what Grønn & von Stechow 2016 denote as s^*, for speech time). Then we can capture simple present, past and future tense as follows, with the Glue logic instantiated suitably per the terms in (34):[20]

(35) a. PAST $\lambda P \lambda t.P(t) \land t \prec u \,:\, (\mathit{tense} \multimap \mathit{verb}) \multimap (\mathit{tense} \multimap \mathit{verb})$
b. PRESENT $\lambda P \lambda t.P(t) \land t = u \,:\, (\mathit{tense} \multimap \mathit{verb}) \multimap (\mathit{tense} \multimap \mathit{verb})$
c. FUTURE $\lambda P \lambda t.P(t) \land u \prec t \,:\, (\mathit{tense} \multimap \mathit{verb}) \multimap (\mathit{tense} \multimap \mathit{verb})$

This sort of account is obviously too simple, but it illustrates tense as a modifier. Note that I've presented the tenses "on their own" for maximal perspicuity, but

---

[20] These sorts of meanings assume a model of time as consisting of points, but it may well be preferable to think of time as consisting of intervals (Dowty 1979). An interval-based semantics poses no problem for tense in Glue Semantics per se, but I've chosen to keep things simple here.

in a lexicalist framework such as LFG, one would normally assume that tense-inflected forms are inserted in the syntax as words, formed morpholexically. That would just mean that, for example, the inflected form *sighed* would contribute both the meaning constructor in (34) and the one in (35a). Note also that I assume some kind of suitable eventual existential closure of the temporal variable.

One could also incorporate grammatical (as opposed to lexical) aspect in a similar, modificational manner. For analyses of tense and grammatical aspect in Glue Semantics, see Haug (2008), Bary & Haug (2011), and Lowe (2014, 2015).[21]

6.4 Events

The first Glue analysis to incorporate event semantics (Davidson 1967, Parsons 1990, Champollion 2017) was never published (Fry 1999b, 2005). To my knowledge, the first major publications to use event semantics were Asudeh & Toivonen (2012) and Asudeh et al. (2013). Much like the analysis of tense sketched above, event semantics for Glue involves adding a dependency on an event variable. Moreover, work in event semantics in Glue has generally taken the Neo-Davidsonian approach of Parsons (1990), in which verbs (and other predicates that take event-arguments) denote functions from events to truth values, such that the arguments of the verb are actually modifiers of the event variable. For example, the sentences in (36) would receive an interpretation like (37), whereas the sentence in (38) would receive an interpretation like (39).[22]

(36) a. Sam hugged Max.
  b. Max was hugged by Sam.

(37) $\exists e.hug(e) \wedge agent(e) = sam \wedge patient(e) = max$

(38) Max was hugged.

(39) $\exists e \exists x.hug(e) \wedge agent(e) = x \wedge patient(e) = max$

It can be observed from (37) and (39) that the event variable is eventually existentially closed. This is a standard assumption in event semantics.

Event semantics is a natural meaning language for Glue Semantics, because the event variable permits a highly factorized semantics, using LFG's *template* language (Dalrymple et al. 2004), which is designed to allow generalizations to be

---

[21] Some of this work assumes some version of event semantics (sketched in Section 6.4). However, event semantics is not necessary for a basic treatment of tense, as I've illustrated here.

[22] It is also possible to treat verbs as generalized quantifiers over events (Champollion 2017, Coppock & Champollion 2020), but I'm not aware of any Glue work thus far that has taken this tack and it wouldn't make a difference to the sorts of simple cases sketched here.

captured across grammatical elements, including meaning constructors. This in turn maximizes the analytic leverage offered by flexible composition and syntax/semantics non-isomorphism.

For example, the lexical entry for the verb *hugged* (again leaving tense aside) can capture its underlying semantic bivalence by encoding a dependency on a SUBJECT and OBJECT (as well as the event variable):[23]

(40) *hugged* $\lambda y \lambda x \lambda e.hug(e) \wedge agent(e) = x \wedge patient(e) = y \;:\; obj \multimap subj \multimap event \multimap verb$

We can take advantage of pervasive syncretism in the English passive participle here and assume that the meaning constructor in (40) is associated with the past tense and passive participle alike.

We can then treat the passive voice as contributing a modificational meaning constructor that remaps the arguments, as in (41). I again associate this with an abstract formative to gloss over details of lexicalization (for a related proposal, see Findlay 2019: 185–186).[24]

(41) PASSIVE $\lambda P \lambda x \lambda y.P(x)(y) \;:\; (obj \multimap subj \multimap verb) \multimap subj \multimap obl \multimap verb$

Note that this entry requires implication elimination on the *event* term in the verb's meaning constructor and then reintroduction of the term (for eventual existential binding of the corresponding variable) after the passive modifier has composed with the verb's meaning constructor. We will shortly add a second meaning constructor to the entry for PASSIVE, but this one suffices to capture the truth-conditional equivalence of (36a–b) (which is not to say that they are information-structurally equivalent).

The result of combining the meaning constructor in (41) with the one in (40) is passive *hugged*:

(42) *hugged*+PASSIVE $\lambda x \lambda y \lambda e.hug(e) \wedge agent(e) = y \wedge patient(e) = x \;:\; subj \multimap obl \multimap event \multimap verb$

In other words, the passive voice modifies the meaning of *hugged* such that the passive subject corresponds to the logical object (the patient in this case) and

---

[23] It has been common in Glue work on event semantics to use e, e', e'', etc., as variables over events, but a common convention in event semantics more generally is to use v, v', v'', etc. (e.g., Champollion 2017, Coppock & Champollion 2020).

[24] Note that the treatment sketched here uses mnemonics for f-structure grammatical functions, like *subj*, in the Glue terms. However, actual Glue work in this vein uses Glue terms defined with respect to argument structure, as sketched in the next section. See Asudeh & Giorgolo (2012: 75–76) and Asudeh et al. (2014: 77ff.) for further details.

passive *by*-phrase corresponds to the logical subject (the agent in this case).[25] Figure 6 shows the proof for (36b). The reader can verify that the result is the same interpretation as that of (36a). The interpretation for (36a,b) is shown in (37) above.

But what of the short passive in (38)? Here we can leverage optionality and the properties of resource-sensitive composition and syntax/semantics non-isomorphism to naturally extend the analysis. We simply add an optional meaning constructor to (41), such that the revised lexical entry is as follows:

(43) PASSIVE $\lambda P \lambda y \lambda x.P(x)(y) : (obj \multimap subj \multimap verb) \multimap subj \multimap obl \multimap verb)$
$(\lambda P \exists x.P(x) : (obl \multimap verb) \multimap verb)$

The optional entry allows the passive to also contribute a second meaning constructor that existentially binds the subject argument. If there is an actual subject resource, though, as in the long passive in (36b), resource sensitivity ensures that the optional meaning constructor cannot be used, because then the actual subject resource would go unused. Figure 7 shows the proof for (36b). The reader can verify that the result is the same interpretation as that of (38), shown in (39) above.

The use of event semantics in LFG+Glue has become especially common in a thread of work on argument structure, the topic that we turn to next.

6.5 Argument structure

There is a prominent strand of work in Glue Semantics on argument structure and mapping theory (i.e., the realization of underlying arguments in the syntax). Representative work in this vein includes Arnold & Sadler (2013), Asudeh & Giorgolo (2012), Asudeh et al. (2014), Asudeh (2021), Findlay (2014, 2016, 2020), Lowe (2016, 2019), Lowe & Birahimani (2019), Przepiórkowski (2017), and Lovestrand (2020).

However, before turning to the Glue approach to argument structure, it is worth presenting some of the background that led to it, because it highlights another issue in Glue Semantics that has concerned some researchers. The substance of the worry can be straightforwardly summarized: What are the identity conditions for empty semantic structures? In other words, if a semantic structure is an attribute value matrix of some kind, as assumed from quite early on

---

[25] I have implicitly assumed in my choice of mnemonic, *obl*, that the *by*-phrase is an OBLIQUE, but nothing hinges on this. The same term works if it is treated as an ADJUNCT, although its mnemonic function is obscured.

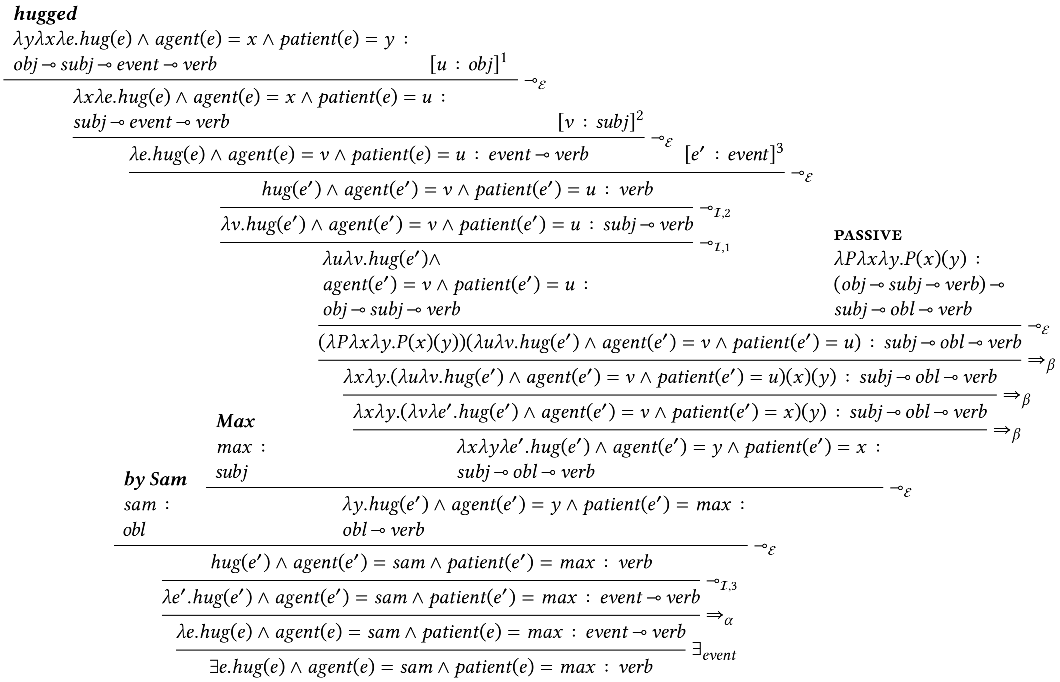

Figure 6: Proof for passive (36b), *Max was hugged by Sam*

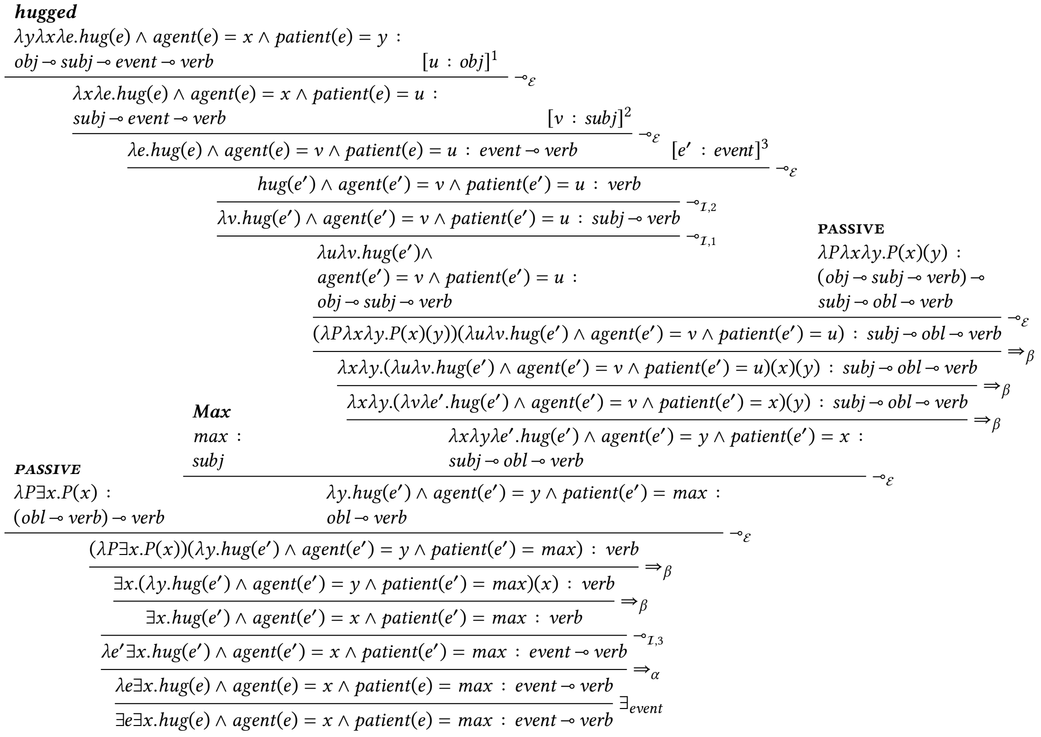

Figure 7: Proof for short passive (38), *Max was hugged*

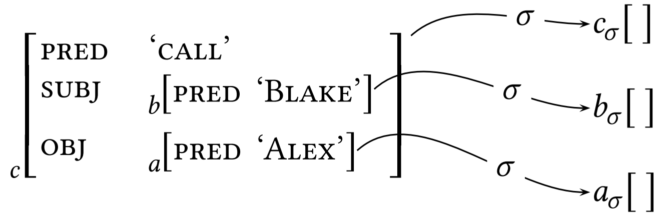
in the development of Glue Semantics (Dalrymple, Gupta, et al. 1999, Dalrymple 2001), how can there be *distinct* empty s-structures, since an empty AVM seems to correspond to the empty set, which is unique (Kokkonidis 2008, Findlay 2021)?

(44)



One possible solution to the empty s-structure problem is to make the labelling part of the definition of the structure. In other words, if a standard attribute-value matrix is a finite set of attribute-value pairs (see, e.g., Bresnan et al. 2016: 44), then let us define an s-structure as a finite set of pairs, where the first member of each pair is a string (a unique label) and the second member of each pair is a (possibly empty) AVM. In that case, it's clear that the s-structure $\{\langle a_\sigma, \varnothing\rangle\}$ does not equal the s-structure $\{\langle b_\sigma, \varnothing\rangle\}$, even if both of them have the empty AVM as their second coordinate.

However, another issue with the sort of s-structure in (44) is that it's really not a structure at all, since the parts are not connected. In other words, what we have in (44) is really *three* s-structures, not a single one. This does not make a substantive difference to the kinds of proofs one can do in Glue Semantics, but it is a bit strange from a general LFG-theoretic perspective, as we would expect all the modules in the Correspondence Architecture to be structures and all of the ones that have been proposed, aside from the version of s-structure above, indeed are structures.

Asudeh & Giorgolo (2012) solve this last problem by offering a connected s-structure that also fulfills the role of a(rgument)-structure (Butt et al. 1997) in the Correspondence Architecture. Not only does this eliminate the need for a-structure as a separate module in the architecture, it also relates argument structure and mapping theory more strongly to compositional semantics, as the locus for both is now s-structure. Figure 8 shows the Asudeh & Giorgolo (2012) analysis for (45).

(45) Kim ate at noon.

The verb *ate* is semantically bivalent, since it entails that there is something that has been eaten, but it can nevertheless be syntactically intransitive (Asudeh & Giorgolo 2012: 71). This is reflected in the analysis in Figure 8. There is no OBJECT in the f-structure, but there are two arguments in the connected s-structure, which also serves as a representation of argument structure.

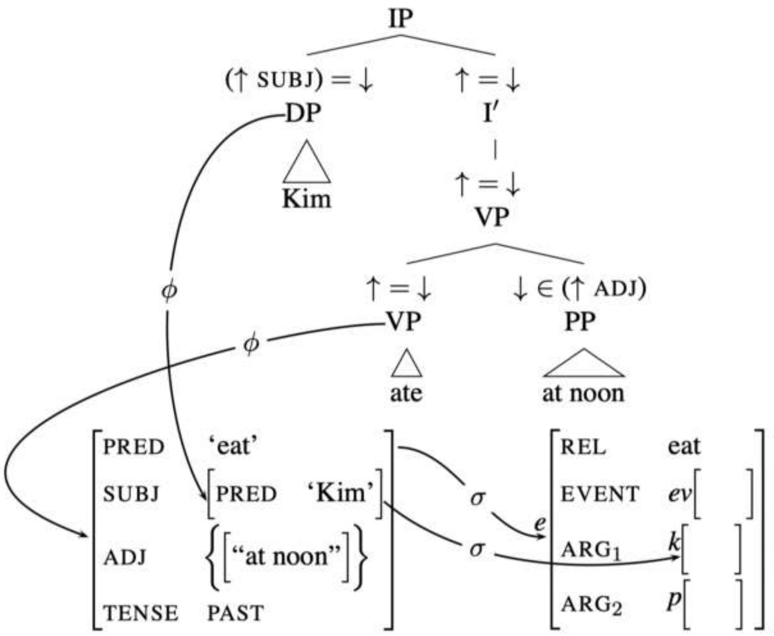


Figure 8: *Kim ate at noon* (Asudeh & Giorgolo 2012: 72; used with permission)

The solution to the syntax/semantics mismatch for the verb *ate* is to allow the verb itself to contribute an optional second meaning constructor that existentially closes the dependency on the second argument:[26]

(46) *ate* $\lambda y \lambda x \lambda e.eat(e) \wedge agent(e) = x \wedge patient(e) = y \;:$
$obj \multimap subj \multimap event \multimap verb$
$(\;\lambda P \exists x.P(x) \;:\; (obj \multimap verb) \multimap verb\;)$

This treatment is similar to the one for the passive in (43). Note that this is a simplification of the actual approach in Asudeh & Giorgolo (2012) and Asudeh et al. (2014), because in those approaches the Glue logic terms are defined using ARG features at s-structure, which allows the analysis to more naturally interact properly with argument alternations.

6.6 Multiword expressions

Multiword expressions (MWEs) are a challenge to a lexicalist theory like LFG, because they show a mixture of idiomaticity and productivity in both their syntax

---

[26] Intransitive uses of semantically bivalent verbs also trigger presuppositions about the implicit argument (Fillmore 1986); e.g., *Kim ate at noon* presupposes that what Kim ate is food (for Kim). I do not attempt to model this here, but see Asudeh & Giorgolo (2012) and Asudeh (2021) for some further discussion.

and semantics (Findlay 2019: ch. 1). On the one hand, we find expressions like *by and large* which are idiosyncratic in both their syntax (apparently a coordination of a preposition and an adjective) and semantics (the expression means something similar to the adverb *mostly*, but this can't be compositionally obtained from the usual meanings of its parts). On the other hand, we find expressions like *spill the beans*, which are syntactically unexceptional and possibly yield to a kind of transpositional semantic analysis in which $[\![spill]\!] = [\![reveal]\!]$ and $[\![the\ beans]\!] = [\![the\ secret]\!]$. Nevertheless, even with this MWE we see evidence of particular syntactic and semantic restrictions. For example, the object is necessarily the definite plural *beans* and other forms are either excluded entirely (e.g., #*a bean* or #*the peas*) or else seem at best like metalinguistic word-play (e.g., *the legumes*).

In short, MWEs are challenging because they are like words in the sense that they seem to be lexically stored expressions but are like phrases in having syntactic parts and, in some cases, these parts seem to be visible to syntactic operations. For example, in *It's too late: the beans have already been spilled*, the MWE has been passivized and one part is modified by an adverbial. For a lexicalist theory, simultaneously capturing these lexical and non-lexical properties of MWEs is difficult. Indeed, in order to account for this mixture of lexical and syntactic properties, Findlay (2019) replaces the c-structural part of standard LFG with Tree-Adjoining Grammar (TAG; Joshi et al. 1975, Abeillé & Rambow 2000), which allows expressions to be associated with trees in the lexicon, rather than with a simple category. TAG allows these trees to then be inserted or adjoined in the phrasal syntax. Findlay (2019) calls the resulting theory *Lexicalised LFG*, in a nod to Lexicalized TAG (Schabes et al. 1988), because it allows lexicalization of syntactic structures as TAG trees while maintaining LFG's standard separate level of f-structure and a mapping between the TAG-based c-structures and the f-structures.

No matter how one captures the syntax of MWEs, the syntax/semantics non-isomorphism of Glue Semantics naturally captures their syntax/semantics mismatches and idiomaticity. For example, Figure 9 shows Findlay's (2019) *lexical* entry for *by and large*. It is an adjunct tree, since this is a modifier. The meaning of *by-and-large* is captured by the call to a template, @By-And-Large-Meaning, but we can simplify things as in (47).

(47) *by and large* $\lambda P \lambda x.mostly(P(x)) : (subj \multimap verb) \multimap (subj \multimap verb)$

This is a relatively straightforward example. For more complex examples, see Findlay (2019).

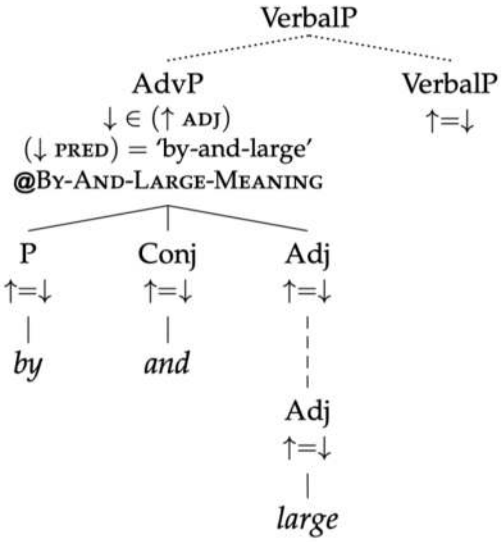

Figure 9: Lexical entry for *by and large* (Findlay 2019: 265; used with permission)

In more recent work, Findlay (2021) has adopted a different formalization of Glue in order to account for MWEs that show form flexibility as long as some kind of core meaning is maintained, like in the following:

(48) a kick up the bum/backside/bottom/buttocks/ass/heinie/keister/booty/…

In this MWE, any word that denotes ⟦*bum*⟧ would seem to do, no matter its form, but anything that doesn't denote ⟦*bum*⟧ doesn't seem to have the idiomatic 'motivational' reading (e.g., #*crotch*).

6.7 Anaphora

Anaphora has been a topic of long-standing interest in Glue Semantics. A recent LFG+Glue treatment and overview of previous literature is given in Dalrymple et al. (2019: ch. 14). Their treatment is a fairly sophisticated one that builds on recent work by Haug (2014) and Dalrymple et al. (2018). Here I present a simpler overview that summarizes the approach in Dalrymple, Lamping, Pereira, et al. (1997) and Asudeh (2004, 2012).

The property of flexible composition means that Glue can provide a variable-free treatment of anaphora, but without requiring that the anaphoric dependency be passed through all intervening material between the anaphor and its antecedent (in the intra-sentential case), as in non-commutative Categorial Grammar approaches (Jacobson 1999 et seq.). The simplest way to capture this would be through an implicational meaning constructor as in (49). I again associate the meaning constructor with an abstract formative to leave aside other aspects of particular personal pronouns, such as person, number, gender.

(49) ANAPHOR $\lambda y.y : antecedent \multimap anaphor$

However, there is a problem with a treatment this simple, because of resource-sensitive composition. If the anaphor consumes the antecedent resource, then the antecedent would no longer be available for composition. This means that whatever function takes the antecedent's denotation as an actual argument can no longer have its resource-sensitive compositional requirements satisfied. There would be no valid proof.

In order to remedy this, a simple solution is to slightly expand the fragment of linear logic that serves as the Glue logic. We add the *multiplicative conjunction* operator, ⊗, which does tensor/pair formation. The meaning constructor in (49) is then revised as follows:

(50) ANAPHOR $\lambda y.y \times y : antecedent \multimap (antecedent \otimes anaphor)$

The anaphor is still a function on its antecedent, but it now returns both its own resource and the antecedent resource.

On this sort of approach to anaphora, the multiplicative conjunction ⊗ is only ever introduced lexically (much as is the linear logic universal for scope points; see above). Therefore we just need to add the elimination rule for this connective, which is the following:

(51) Structured functional application:
Multiplicative conjunction elimination pairwise substitution

$$\dfrac{\begin{array}{c}\vdots\\ \alpha : A \otimes B\end{array} \qquad \begin{array}{c}[\beta : A]^1 \qquad [\gamma : B]^2\\ \vdots \qquad\qquad \vdots\\ \delta : C\end{array}}{\text{let } \alpha \text{ be } \beta \times \gamma \text{ in } \delta : C} \otimes_{\mathcal{E},1,2}$$

The *let* type constructor performs pairwise substitution for the variables x, y in the result.

This is still quite abstract, so it is probably helpful to look at example (52) and its accompanying proof in Figure 10, both from Asudeh (2012: 84).[27]

---

[27] Note that I have left out the $\multimap_{\mathcal{E}}$ annotations in the proof to reduce clutter. Also, the following mnemonic Glue terms are used: t for the term contributed by *Thora* (which is both the antecedent of the pronoun and the subject of the sentence), p for pronoun, g for *giggle*, and s for *said*.

(52) Thora said she giggled.

$$\dfrac{\dfrac{\dfrac{\begin{array}{l}\boldsymbol{Thora}\\ thora :\\ t\end{array} \quad \begin{array}{l}\boldsymbol{she}\\ \lambda z.z\times z :\\ t\multimap(t\otimes p)\end{array}}{thora\times thora : t\otimes p}\multimap_{\mathcal{E}} \quad \dfrac{\dfrac{[x : t]^1 \quad \begin{array}{l}\boldsymbol{said}\\ \lambda u\lambda q.say(u,q) :\\ t\multimap g\multimap s\end{array}}{\lambda q.say(x,q) : g\multimap s}\multimap_{\mathcal{E}} \quad \dfrac{[y : p]^2 \quad \begin{array}{l}\boldsymbol{giggled}\\ \lambda x.giggle(x) :\\ p\multimap g\end{array}}{giggle(y) : g}\multimap_{\mathcal{E}}}{say(x,giggle(y)) : s}\multimap_{\mathcal{E}}}{\text{let } thora\times thora \text{ be } x\times y \text{ in } say(x,giggle(y)) : s}\otimes_{\mathcal{E},1,2}}{say(thora,giggle(thora)) : s}\Rightarrow_{\beta}$$

Figure 10: Proof for intra-sentential anaphoric reading of (52), *Thora said she giggled*

For a fuller treatment of anaphora that extends to inter-sentential cases, see Haug & Dalrymple (2020) and Dalrymple & Haug (2022).

7 Conclusion

Glue Semantics is a general framework for semantic composition and the syntax–semantics interface. The focus here has been on Glue for LFG, typically known as LFG+Glue. Four key properties of Glue Semantics are resource-sensitive composition, flexible composition, autonomy of syntax, and syntax/semantics non-isomorphism (Asudeh 2022: 324). Analyses in Glue Semantics are highly constrained by the resource logic *linear logic*, a fragment of which serves as the Glue logic for semantic composition. Although resource-sensitive composition constrains semantic composition, it allows composition to be commutative. This yields the property of flexible composition: The logical syntax of composition is not identical to the structural syntax. From this we can derive the property of autonomy of syntax: Syntax and semantics are separate levels. From this we lastly derive the property of syntax/semantics non-isomorphism: Whatever the basic elements of structural syntax are taken to be (words in the case of standard LFG), these elements may make multiple or no contributions to semantic composition. The best source for further details about Glue analyses of particular phenomena and further Glue references is Dalrymple et al. (2019). However, I've listed a representative sample of Glue work by topic in the appendix.

Acknowledgements

Many thanks to Mary Dalrymple for editing this volume, but also for many useful discussions about Glue Semantics over the last more than two decades. Similarly,

thank you to Avery Andrews, Doug Arnold, Dick Crouch, Jamie Findlay, Gianluca Giorgolo, Matthew Gotham, Dag Haug, Miltos Kokkonidis, John Lowe, Agnieszka Patejuk, Adam Przepiórkowski, Louisa Sadler, and Vijay Saraswat. Last but not least, a big thank you to the three anonymous reviewers. All remaining errors and misconceptions are my own.

List of Glue work by topic

Here is a representative sample of work in Glue Semantics, organized alphabetically by topic:[28]

- Anaphora
  Dalrymple, Lamping, Pereira, et al. (1997), Asudeh (2004, 2005b, 2012), Bary & Haug (2011), Belyaev & Haug (2014), Dalrymple et al. (2019: ch. 14), Haug & Dalrymple (2020), Dalrymple & Haug (2022)

- Argument structure and argument realization
  Asudeh & Giorgolo (2012), Asudeh et al. (2014), Asudeh (2021), Arnold & Sadler (2013), Findlay (2014, 2016, 2020), Lowe (2016, 2019), Lowe & Birahimani (2019), Przepiórkowski (2017), Lovestrand (2020)

- Category theory for natural language semantics
  Giorgolo & Asudeh (2012a,b), Giorgolo & Asudeh (2014a,b), Asudeh & Giorgolo (2016, 2020)

- Complex predicates
  Andrews (2007, 2018), Lowe (2016, 2019), Lowe & Birahimani (2019), Lovestrand (2020)

- Computational applications and tools (open source)[29]
  Crouch et al. (1986), Lev (2007), Meßmer & Zymla (2018), Dalrymple et al. (2020), Zymla (2021a,b,c)

- Concomitance
  Haug (2009)

- Constructions
  Asudeh et al. (2008, 2013), Asudeh & Toivonen (2014)

---

[28] My apologies to anyone whose work I have inadvertently omitted.

[29] Zymla's (2021c) tool goes with the XLE tools for computational implementation and testing of LFG grammars (Crouch, Dalrymple, Kaplan, King, Maxwell & Newman 2011).

- Control/equi and raising
  Asudeh (2005a), Haug (2013), Dalrymple et al. (2019: ch. 15)

- Conventional implicature
  Asudeh (2004: ch. 4), Potts (2005), Arnold & Sadler (2010, 2011), Giorgolo & Asudeh (2012a)

- Coordination
  Kehler et al. (1999), Asudeh & Crouch (2002a), Dalrymple et al. (2019: ch. 16)

- Copy raising
  Asudeh (2004, 2012), Asudeh & Toivonen (2007, 2012)

- Distance distributivity
  Przepiórkowski (2014a,b, 2015)

- Dynamic semantics
  Crouch & van Genabith (1999), van Genabith & Crouch (1999), Dalrymple et al. (2019: ch. 14)

- Event semantics
  Fry (2005), Asudeh & Giorgolo (2012), Asudeh & Toivonen (2012), Asudeh et al. (2013), Asudeh et al. (2014)

- Evidentiality
  Asudeh & Toivonen (2017)

- Formal foundations
  Dalrymple, Gupta, et al. (1999), Dalrymple, Lamping, Pereira, et al. (1999), Dalrymple, Lamping, Pereira, et al. (1997); Asudeh (2004, 2012: ch. 5) Kokkonidis (2008), Andrews (2008, 2010), Findlay (2021))

- Fragments
  Asudeh (2012: ch. 11)

- Idioms and multiword expressions
  Findlay (2019, 2021)

- Incorporation
  Asudeh (2007), Baker et al. (2010)

- Information structure
  Dalrymple & Nikolaeva (2011), Mycock (2006), Morrison (2017)

- Intensionality
  Dalrymple, Lamping, Pereira, et al. (1997), Asudeh & Toivonen (2012)
- Modification
  Dalrymple et al. (1993), Dalrymple, Lamping, Pereira, et al. (1999), Dalrymple (2001), Asudeh & Crouch (2002b), Andrews (2018), Dalrymple et al. (2019: ch. 13)
- Negative polarity items
  Fry (1999a)
- Perception verbs
  Asudeh & Toivonen (2007, 2012), Asudeh (2012), Camilleri et al. (2014)
- Predication
  Dalrymple (2001), Asudeh & Crouch (2002b), Dalrymple et al. (2019: ch. 13)
- Quantification and scope
  Dalrymple, Lamping, Pereira, et al. (1997), Dalrymple et al. (2019: ch. 8)
- Relational nouns
  Asudeh (2005b)
- Resumptive pronouns
  Asudeh (2004, 2005b, 2011, 2012), Camilleri & Sadler (2011)
- Split nominals
  Kuhn (2001)
- Tense and aspect
  Haug (2008), Bary & Haug (2011), Lowe (2014, 2015), Belyaev (2020)
- Unbounded dependencies
  Asudeh (2012), Dalrymple et al. (2019: ch. 17)

Chapter 16

Argument structure and mapping theory

Jamie Y. Findlay
University of Oslo

Roxanne Taylor
University of Huddersfield

Anna Kibort
Trinity College Library

This chapter presents the LFG view of two closely related areas of inquiry: argument structure, a level of structure which represents the syntactically realisable arguments of a predicate, and mapping theory, the theory of how those arguments are linked to grammatical functions at f-structure, as well as of alternations in this linking brought about by processes like passivisation. After introducing some preliminary concepts, the chapter explores various approaches within LFG: the earliest work using lexical rules to explain argument alternations, the "classical" version of Lexical Mapping Theory (LMT) developed in the late '80s and early '90s, and various subsequent modifications, extensions, and reimaginings of LMT, including contemporary work focussing on the formal status of argument structure and mapping theory, and their connection to the rest of the grammar.

1 Introduction

Predicates have both syntactic and semantic arguments, and the two are not always aligned. For instance, expletives, as shown in (1), are syntactic but not semantic arguments of their verbal governors:

(1) a. *It* is snowing.
b. *There* seems to be a problem.

Jamie Y. Findlay, Roxanne Taylor & Anna Kibort. 2023. Argument structure and mapping theory. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 699–778. Berlin: Language Science Press. DOI: 10.5281/zenodo.10185966

On the other hand, there are verbs like *saddle*: conceptually, a saddling event involves three entities, the saddler, the saddled (usually a horse), and the saddle itself, but only the first two are expressible in the syntax (cf. Bresnan 1980). Similarly, there are clear patterns regarding which kinds of semantic arguments are realised by which kinds of grammatical functions – in general, more Agent-like arguments are more likely to be subjects than more Patient-like arguments, which are more likely to be objects – but there are also exceptions. There are, for example, verbs which seem to express the same type of event but to realise the semantic participants differently in the syntax (Rappaport 2006 [1983]: 132):

(2) a. Fred fears the prospect of failure.
    b. The prospect of failure frightens Fred.

(3) a. I like a job well done.
    b. A job well done pleases me.

Due to these kinds of mismatches, neither syntactic nor semantic arguments can be reduced to the other, and instead we need some intervening level of representation that can mediate the relationship between them. This is what is known as ARGUMENT STRUCTURE, and in LFG is often taken to constitute a separate module of the grammar called a-structure. Although it sits between syntax and (lexical) semantics, argument structure itself is often taken to be a specifically syntactic level of representation (Alsina 2001),[1] whose primary purpose is to explain a predicate's syntactic valency patterns – while acknowledging that at least some of these explanations are to be found in lexical semantic properties. The arguments represented at argument structure are therefore those which can or must be realised syntactically.

Explaining how exactly these arguments are realised is the purview of MAPPING THEORY. Such a theory seeks generalisations in the mapping between argument structure and syntax proper, and to explain any alternations which are possible (such as passivisation, causativisation, detransitivisation, etc.). In LFG, this means determining what GRAMMATICAL FUNCTION (GF) the argument will instantiate – overt phrasal realisation is then handled by the language-specific phrase-structure rules or case-marking system which determines how particular GFs surface (see Belyaev 2023a,b [this volume] for more on LFG's view of grammatical functions and their relation to phrasal syntax).

---

[1] Indeed, in the Minimalist tradition, argument structure is often represented in the phrasal syntax itself – see Harley (2011) and references therein for an overview.

As part of this LFG handbook, the present chapter focusses on providing a survey of work on argument structure and mapping theory which takes a Lexical-Functional approach.[2] The structure of the chapter is as follows: we begin, in Section 2, with a brief high-level introduction to some of the questions and phenomena which we will return to throughout the chapter. Section 3 then looks at the earliest work on these problems in LFG, which used LEXICAL RULES to account for argument alternations. Section 4, the largest of the chapter, presents the still-canonical theory of argument structure and mapping developed in the late 1980s and early 1990s, known as LEXICAL MAPPING THEORY (LMT). Section 5 examines a different version of LMT, that of Kibort (2007, *i.a.*) which, among other things, is designed to extend the empirical coverage of the mapping theory to so-called morphosemantic alternations. Section 6 delves more deeply into some formal issues and alternative proposals, before Section 7 concludes.

2 Background and basic concepts

2.1 From semantics to syntax

There are regularities in the ways that semantic participants of predicates are realised syntactically. For example, in a nominative-accusative language like English, when a verb describes an event that has a volitional Agent and a Theme or Patient affected by the event, the Agent will be realised as the active voice subject and the Theme/Patient as the object:

(4) a. Your dog is chasing my rabbit!
(cf. # My rabbit is chasing your dog![3])
b. The engineers will build the bridge there.
(cf. # The bridge will build the engineers there.)
c. The teacher opened the cupboard.
(cf. # The cupboard opened the teacher.)

---

[2] For general introductions as well as critical overviews of work in other traditions, the reader is directed to Grimshaw (1990), Comrie (1993), Levin & Rappaport Hovav (2005), Ramchand (2014), Williams (2015). For a different perspective on the LFG literature, see Dalrymple et al. (2019: ch. 9).

[3] The point of these anomalous alternatives is to illustrate that the (prototypical) situations presented are expressed via the (a) encodings, where the Agent is a subject and the Theme/Patient an object, rather than the *a priori* equally plausible (b) encodings, where the pairings of semantic and syntactic roles are reversed. The (b) sentences are of course perfectly grammatical strings of English, but they describe situations which are at odds with our real-world knowledge or expectations, precisely because the subjects in each case are interpreted as Agents.

Similarly, if the sentence expresses an Instrument used to perform the action described, along with the Theme/Patient, then the Instrument is the subject and the Theme/Patient the object:

(5) a. The key opened the cupboard.
(cf. # The cupboard opened the key.)

But if the Agent is also included, then *it* is the subject:

(6) The teacher opened the cupboard with the key.

This generalisation goes back to Fillmore (1968: 33), who expresses it as follows:

(7) If there is an A [= Agent], it becomes the subject; otherwise, if there is an I [= Instrument], it becomes the subject; otherwise, the subject is the O [= objective, i.e. Theme/Patient].

This is a productive rule (at least in English), as can be seen from the fact that invented words will also follow the same pattern. Alsina (1996: 5–6), for instance, imagines a verb *obliquate*, meaning 'build or place in an oblique position or direction', and notes the clear intuition that, if such a verb existed, we would say things like (8a), but not like (8b):

(8) a. Jim obliquated the door of the closet.
b. # The door of the closet obliquated Jim.

All this goes to illustrate a key explanandum: the semantic relationship which an argument bears to its verb is also implicated in determining its syntactic relationship, but in what way precisely? Mapping theory is interested in discovering the nature of this connection, and in finding generalisations over the links between semantic and syntactic relationships.

The observation in (7) induces a ranking of semantic/thematic roles,[4] where the highest available argument becomes the subject:

(9) A > I > O

This can be seen as a precursor to the well-known THEMATIC HIERARCHY (Jackendoff 1972: 43), of which there have been many versions. The one which has been most influential in LFG comes from Bresnan & Kanerva (1989: 23), and is shown in (10):

---

[4] We will use these two terms interchangeably in this chapter, drawing no theoretical distinction between them.

(10) *The Thematic Hierarchy:*
Agent > Beneficiary > Recipient/Experiencer
> Instrument > Theme/Patient > Location

Arguments which are more thematically “prominent” on this hierarchy tend to be realised by more grammatically “prominent” GFs, e.g. as defined by the Keenan-Comrie hierarchy (Keenan & Comrie 1977; see also Belyaev 2023b [this volume]) – in particular, the SUBJ function is usually taken by the the argument highest on the thematic hierarchy (Grimshaw 1990, Speas 1990). This insight is often at the core of mapping theories, and so the thematic hierarchy figures centrally in the standard version of Lexical Mapping Theory, which we explore in Section 4, as well as in other approaches discussed below.

The use of thematic hierarchies has also been challenged, however. For one thing, a consistent list of roles and definitions has proved elusive, and classification of arguments can therefore be problematic and open to disagreement (Gawron 1983, Dowty 1991, Ackerman & Moore 2001, Davis 2011). For another, even when a set of roles is agreed on, the question of their relative ordering has not been settled, and different hierarchies have been proposed for different phenomena, or even for the same phenomenon (Newmeyer 2002: 65ff. Levin & Rappaport Hovav 2005: ch. 6; Rappaport Hovav & Levin 2007). While it is clearly possible that different orderings could be relevant for different things, the extent of the variability in the literature, even with respect to one and the same phenomenon, stands in stark contrast to the putative appeal of a unifying thematic hierarchy where a fixed set of roles is used in order to abstract away from predicate-specific semantic entailments. Because of these concerns, some recent work in LFG’s mapping theory, most notably that of Kibort (2007, *i.a.*), has attempted to do without thematic roles altogether. We discuss Kibort’s work in Section 5.

Some questions of mapping depend not on the semantic relationship between an argument and its verb, but rather on lexical semantic properties of the verb itself. For example, *break* and *hit* both take Agent and Patient arguments, but *break* has an intransitive alternant, where the Patient appears as the subject, which is impossible with *hit*:

(11) a. The teacher broke the ruler.
b. The ruler broke.

(12) a. The teacher hit the ruler.
b. * The ruler hit.

Fillmore (1970) observes that this contrast is not a lexical idiosyncrasy of these two verbs, but actually applies to two large classes of semantically-related verbs, as shown in (13–14):

(13) a. The teacher {bent / folded / shattered / cracked / …} the ruler.
b. The ruler {bent / folded / shattered / cracked / …}.

(14) a. The teacher {slapped / struck / bumped / stroked / …} the ruler.
b. * The ruler {slapped / struck / bumped / stroked / …}.

Once again, we can see that this is a productive generalisation if we examine our intuitions about invented forms. For example, let us imagine a verb *jellate*, meaning 'to turn to jelly'. It is clear that this verb could appear in the same constructions as *break*.

(15) a. The wizard jellated the box.
b. The box jellated.

But if we invent a word like *coude*, meaning 'to touch with one's elbow', it is just as clear that it will pattern with *hit*:

(16) a. I couded the wall.
b. * The wall couded.

We do not want to simply stipulate the possibilities for each new verb, since then we fail to capture the regularity and productivity of our intuitions.

A mapping theory ought to give an account of these patterns. To do this, it must have access to detailed lexical semantic information, such as event structure. For example, a hitting event does not necessarily result in a change of state in the affected entity, whereas a breaking event does; that is, the structure of a hitting event does not contain a result state, in Ramchand's (2008) terms. Now, this may be expressed in the semantic role assigned to the affected entity – in some theories, the difference between Patient and Theme is that the former undergoes a change of state while the latter does not. But often such nuances are not captured by a simple semantic role analysis – for example, the thematic hierarchy in (10) collapses Theme and Patient into a single position – and it is certainly not apparent that there are any principled limits on what kinds of lexical semantic information can be relevant for questions of mapping, so it is quite possible that mapping theory needs access to a very rich representation of lexical semantics. In general, argument structure proposals in LFG have not taken up this challenge, instead treating this level of representation as relatively informationally impoverished (it is often no more than a list of arguments and their associated thematic roles). Nevertheless, there have been, and continue to be a growing number of, exceptions, which we examine in Section 6.1.

2.2 Argument alternations

Accounting for the syntactic realisation of semantic arguments means also addressing the fact that a single predicate may permit multiple ways of expressing its arguments (including not expressing some of them at all) – that is, the existence of ARGUMENT ALTERNATIONS, such as that between the transitive and the inchoative illustrated in (11), above. Perhaps the most famous and well-studied of these is the active-passive alternation, a typologically common pattern whereby a transitive verb alternates with an intransitive in which the subject argument of the transitive form is either unexpressed or expressed as a non-core, oblique grammatical function instead:

(17) a. *Active:*
The dog chased the rabbit.

b. *Passive:*
The rabbit was chased (by the dog).

One important property of the active-passive alternation is that it does not involve any change in lexical semantics. That is, the situations described by (17a) and (the long version of) (17b) are truth-conditionally equivalent, and so this alternation is described as MEANING-PRESERVING (cf. Sadler & Spencer 1998). This label is slightly infelicitous, however, since once we look beyond mere truth conditions there are of course changes to other aspects of "meaning", writ large: for instance, the information-structural Topic is the dog in (17a) but the rabbit in (17b). This is not at all surprising, since language abhors true synonymy (Cruse 1986, Goldberg 2019), and variation of whatever kind is inevitably operationalised for communicative purposes (Clark 1987, Eckert 2018) – but it does mean that the term "meaning-preserving" must be understood in a suitably narrow sense.

Such meaning-preserving alternations are known as MORPHOSYNTACTIC, since they are morphological operations which alter the syntactic alignment of participants; this is in contradistinction to MORPHOSEMANTIC alternations, which involve changes in (truth-conditional) lexical meaning. Another example of a morphosyntactic alternation is locative inversion, illustrated in (18) for Chicheŵa (Bresnan & Kanerva 1989: 2). In this alternation (also found in English, as indicated by the translations below – see Bresnan 1994), a locative phrase which normally appears as an oblique can surface as a subject, demoting the subject of the non-inverted form to object:[5]

(18) a. Chi-tsîme chi-li ku-mu-dzi.
7-well 7-be 17-3-village
'The well is in the village.'

b. Ku-mu-dzi ku-li chi-tsîme.
17-3-village 17-be 7-well
'In the village is a well.'

Once again, this affects certain properties of a sentence's information structure, for instance changing what is available for contrastive focus (Bresnan & Kanerva 1989: 35, Bresnan 1994: 86–87), but it does not alter the truth-conditional meaning.

Morphosemantic alternations, on the other hand, change the lexical meaning of a predicate – a change which may then have syntactic effects, though these are in a sense only incidental, merely following as automatic consequences of the lexical semantic changes (Kibort 2004: 374). Examples include many of the alternations listed in Levin (1993), such as the *spray/load* alternation shown in (19) or the dative shift alternation shown in (20):

(19) a. Carly loaded the wagon with barrels.
b. Carly loaded barrels onto the wagon.

(20) a. Julian brought Elim the message.
b. Julian brought the message to Elim.

In (19a), the Goal/Location *the wagon* is realised as the object, and in this case there is a "holistic" interpretation (Levin 1993: 50), whereby the Goal/Location is understood to be fully affected by the action (i.e. the wagon is filled up with barrels). This entailment is absent from the sentence in (19b), where the Theme is realised as the object instead. Similarly, in (20a), there is an entailment that the dative-shifted Goal object is animate (Goldberg 1995: 146–147), but this same constraint does not hold of the Goal argument in the prepositional variant (20b), as illustrated by the following contrast:

(21) a. # Julian brought Elim's study the message.
b. Julian brought the message to Elim's study.

---

[5] Numbers indicate noun classes: this is in part how we can tell that the locative is the subject in (18b), since the verb now agrees with it in this respect.

Both of these alternations involve differing syntactic realisations of the same arguments, but unlike the morphosyntactic alternations shown above, they also change certain properties of the truth-conditional meanings expressed by their governing verbs. Other morphosemantic alternations, such as the causative, also introduce *new* arguments, rather than simply rearranging existing arguments. The causative introduces a new Causer argument, which brings about the event described by the predicate. Here is a classic example from Turkish (Comrie 1974: 5):

(22) a. Hasan öl-dü.
Hasan die-PST
'Hasan died.'

b. Ali Hasan-ı öl-dür-dü.
Ali Hasan-OBJ die-CAUS-PST
'Ali killed Hasan.' (lit. 'Ali made Hasan die.')

As can be seen, this also has syntactic effects, since causativisation increases the valency of the predicate. Here an intransitive becomes a transitive, and the previous subject is demoted to object.

The world's languages are replete with a wide and varied selection of argument alternations, both meaning-preserving as well as meaning-altering, many of which are highly productive. Any mapping theory must therefore be capable of giving an account of such alternations in general, and this has been a major focus of research, as we will see below.

3 Lexical rules

Argument alternations have been at the heart of work in LFG since the very beginning. The seeds of LFG as a framework can be found in Bresnan's (1978) work on the psychological plausibility of transformational grammars, illustrating how the passive can be profitably viewed as an operation on lexical representations, rather than on phrase-level syntactic structures. Bresnan (1980) presents this analysis in a more recognisably LFG-like form, and extends the approach to the formation of intransitives and middles in English. In this and much other early work in LFG, argument alternations are treated as involving LEXICAL RULES, which systematically relate the different alternants of the same verb (e.g. active and passive). In this section, we give a brief overview of this approach, and highlight some of the reasons why it has fallen out of favour in recent work.

In Bresnan (1980), lexical items are assumed to possess abstract predicate-argument structures, which characterise “those arguments of a semantic predicate that are open to grammatical interpretation” (Bresnan 1980: 100). Such argument positions are then associated with grammatical functions by various (undiscussed) lexical processes, with the result being a lexical form – recognisable as what would become in LFG the semantic form value of a pred attribute (Belyaev 2023a [this volume]). For example, the lexical form for transitive *read*, as in *John read my letter*, is given in (23) (Bresnan 1980: 116):

(23) *read* ⟨ (subj) (obj) ⟩

Here the first argument, corresponding to the reader, is linked to subj, and the second argument, the thing read, is linked to obj. The exact nature of this initial linking of arguments to GFs is not spelled out explicitly, and is generally taken to follow from some intrinsic pairings of roles and syntactic functions. What is more, in this early work, the specific role of each argument is not labelled in the representation, and must be inferred from the combination of their ordering and lexical idiosyncrasies of meaning. In other work (e.g. Baker 2006 [1983]), lexical forms are shown with semantic roles alongside their associated GFs, thus highlighting both sides of the linking question explicitly in the representation. For the sake of clarity, we will follow this convention for the rest of this section; thus instead of (23), we will write (24) for the lexical form of *read*:

(24) *read* ⟨ Agent Theme ⟩
(subj) (obj)

However such structures are represented, once the links between arguments and GFs are in place, other rules can then apply to manipulate them, capturing the effect of various argument alternations. For example, intransitivisation is achieved by the following lexical rule (Bresnan 1980: 116):

(25) *Intransitivisation:*
(obj) ↦ ∅

Here the argument previously linked to obj is instead assigned the special null GF ∅, which indicates that the argument is existentially bound in the semantics, and is not expressed overtly in the syntax. The application of (25) to (24) results in the lexical form in (26), corresponding to the intransitive form of *read*, as in *John read all night.*

(26) *read* ⟨ Agent Theme ⟩
(subj) ∅

It is clear to see how this approach can be extended to other, more complex alternations. Bresnan (1982), for instance, proposes the following lexical rule for passivisation:[6]

(27) *Passivisation:*
$(\textsc{subj}) \mapsto \varnothing/(\textsc{obl}_{\textsc{agent}})$
$(\textsc{obj}) \mapsto (\textsc{subj})$

This demotes the subject to either the unexpressed null GF (as in the English short, Agent-less passive), or an oblique (as in the English long, *by*-passive), and promotes the object to subject.

One important strength of such lexical rules is that they manipulate grammatical functions, rather than surface constituent structures; that is, (27) promotes the obj, rather than, say, moving the post-verbal NP to the specifier position of IP. This means that the same rule can be used across the languages of the world, with language-specific variations falling out from the rules for c- to f-structure mapping in those languages (Belyaev 2023a [this volume]).[7] Such an approach is a corollary of the claim that argument alternations operate at the level of argument structure, and not directly on the phrasal syntax.

Lexical rules in LFG are taken to be redundancy rules (Bresnan 1990: 638): they are not applied on-line in the process of parsing, but instead describe regular relations between items in the lexicon. In other words, the existence of a lexical form like (28a) implies the existence of a corresponding passive form like (28b), because of the existence of rule (27):[8]

(28)	a.	*read*	⟨	Agent	Theme	⟩
				(subj)	(obj)	
	b.	*read*	⟨	Agent	Theme	⟩
				$(\textsc{obl}_{\textsc{agent}})$	(subj)	

Such a restriction follows from Bresnan's (1980: 118) claim that "structures which are analyzed by lexical rules must be lexical structures, and cannot be syntactically derived". Bresnan (1982: 6) goes further, and proposes that alterations of

---

[6] Bresnan (1982) is in fact the *locus classicus* of the lexicalist approach to the passive in general. In the paper, Bresnan makes a compelling case against the prevailing wisdom that passivisation should be treated as a transformation, i.e. something that takes places in the phrasal syntax. Instead, she shows that it must be treated as a process occurring inside the lexicon. Bresnan et al. (2016: ch. 3) provide a contemporary presentation of the relevant arguments.

[7] This insight originates from work in Relational Grammar (e.g. Perlmutter & Postal 1977).

[8] Bresnan (1980, 1982) presents such rules as directional, so that the active maps to the passive, but they can also be seen as bidirectional, so that the existence of either kind of entry implies the other – this is how it is presented in Bresnan (1990), for example.

argument-to-GF assignments can *only* take place in the lexicon, via lexical rules, and cannot be effected on-line by syntactic rules – she refers to this as the principle of DIRECT SYNTACTIC ENCODING. Although contemporary LFG makes much less (or no) use of lexical rules, it continues to maintain the first part of this principle, and treats all argument alternations as applying in the lexicon, not in the syntax.

While lexical forms, which appear at f-structure as the value of PRED attributes, are obtained by augmenting a predicate-argument structure with linkings to GFs, at this stage in the development of LFG the formal status of the predicate-argument structures themselves is not made explicit. They are certainly not a separate level of representation, akin to c- and f-structure (i.e. there is no a-structure). Indeed, it is not until Butt et al. (1997) that the formal position of argument structure in the LFG architecture is tackled head on – we will have more to say about this in Section 6.1.

A more urgent shortcoming of the early lexical rule approach is that there is no account of how the original assignment of GFs to arguments is accomplished – that is, as Falk (2001b: 96) observes, early LFG has a theory of *re*mapping, via lexical rules, but no theory of the initial mapping. Bresnan (1980: 112) briefly suggests some principles for default assignments, but this is not developed more fully. Since, as we observed in Section 2.1, the initial mapping is also amenable to systematic study, and exhibits a number of clear generalisations, this lacuna is therefore a significant one.

There is also the question of appropriately constraining lexical rules. Clearly the rule of intransitivisation given in (25) cannot apply freely to any verb with an object, otherwise we would expect examples like (29b) to be grammatical, contrary to fact:

(29) a. Naomi told the story to Jim.
b. * Naomi told to Jim.

Lexical rules must be assigned syntactic, semantic, and morphological conditions in order to constrain their application. Even then, it remains a fact that lexical rules are very powerful formal devices: there are no in-principle constraints on what kinds of alternations can be described, which means that any remapping can be represented, including some which are most unnatural in the world's languages (Bresnan 1980: 639ff.).[9]

---

[9] Of course, we may not expect formalism to constrain theory in this way (cf. Pollard 1997), and in that case this objection is of less concern.

The unconstrained expressive power of lexical rules arises from the fact that they are not MONOTONIC (Bresnan 1990): since such rules *overwrite* the original assignments of GFs to arguments, they are are not information-preserving.[10] Aside from the possibility of expressing unnatural alternations, another reason why non-monotonicity may be problematic has to do with processing. Arbitrary rewrite rules render a system intractable (cf. Peters & Ritchie 1973), and this is at odds with the LFG desideratum of psychological plausibility (Kaplan & Bresnan 1982: 173–174). However, this objection only carries weight insofar as the rules are applied during on-line processing; if they only apply in the lexicon, their computational power is irrelevant, since lexical entries are stored in memory. The discovery that complex predicates necessitate an analysis whereby argument structures can be assembled in the syntax (Butt 1995, Alsina 1996; Section 4.2.4 below) challenges this solution, however. Another way to neutralise the processing objection is by formally implementing lexical rules in such a way as to make them tractable, such as by treating two lexical entries related by lexical rule as a single lexical entry containing disjunctive specifications (cf. fn. 10). This might result in quite a gap between theoretical LFG and computational implementations (which again runs counter to the Competence Hypothesis of Kaplan & Bresnan 1982), but it does at least avoid intractability.

Although none of these objections may be insurmountable, lexical rules have nevertheless fallen out of favour in LFG. Lexical Mapping Theory has offered a fruitful alternative that avoids the formal and conceptual issues of lexical rules, and also goes further, by providing an account of the initial linking of arguments and GFs. Lexical rules have not entirely disappeared, however, and are still sometimes invoked to capture certain generalisations over the lexicon – see e.g. Bresnan et al.'s (2016: 315–319) analysis of possessors and gerundives. However, such generalisations can also be captured by using TEMPLATES (Dalrymple et al. 2004, Asudeh et al. 2013, Belyaev 2023a [this volume]), providing the possibility of doing away with lexical rules altogether.

---

[10] Note that this is not an inherent property of lexical rules *per se*; as a reviewer notes, in XLE (the computational implementation of LFG – Kaplan & Newman 1997, Crouch et al. 2011), lexical rules are implemented as disjunctions of functional descriptions, thereby restoring monotonicity. This approach has also been taken in some theoretical work in LFG, starting with Butt et al. (1997) – see Section 6.2 below. HPSG takes a different approach to lexical rules again, treating them as unary-branching rules in the type hierarchy (see e.g. Davis & Koenig 2021: 155ff.).

4 Classical LMT

Lexical Mapping Theory (LMT) arose in part as a result of dissatisfaction with the shortcomings and unconstrained nature of lexical rules (Bresnan 1990). LMT therefore attempts to offer a more principled and constrained theory of both argument alternations and initial argument-GF mappings. Since the foundational work in LMT (Levin 1986, Bresnan & Kanerva 1989, Bresnan & Zaenen 1990), the theory has undergone many alterations and extensions; some of these build on one other, some offer competing perspectives, and some are simply different ways of saying the same thing. In addition, some are mere extensions or minor tweaks, while others involve rebuilding the theory from the ground up. We feel it would be both convoluted and unilluminating to trace every divergent strand of research in the LMT tradition, and so in this section we try to present a single coherent version of the theory, which we call Classical LMT. In order to maintain this coherence, we will adapt and update analyses where necessary, provided this does not detract from the main goals of the work in question.

Classical LMT represents what many take to be the "canonical" version of mapping theory in LFG, and is the variety which often appears in textbook presentations of the framework (as in e.g. Dalrymple 2001: 202ff. Falk 2001b: ch. 4, Bresnan 2001: ch. 14, Bresnan et al. 2016: ch. 14, and Börjars et al. 2019: ch. 8; see also Butt 2006: pp. 117ff.). However, it has long since been recognised that the name "*Lexical* Mapping Theory" is inappropriate, since "the theory cannot apply exclusively to individual words" (Dalrymple 2001: 212): for example, complex predicates which are formed analytically nonetheless contribute a single (complex) argument structure, despite the fact they contain multiple lexemes (Mohanan 1994, Butt 1995, Alsina 1996; Section 4.2.4 below). For this reason, alternative names have been proposed for the theory, including Mapping Theory *tout court* (as in e.g. Kibort & Maling 2015), Functional Mapping Theory (Alsina 1996), and Linking Theory (Butt et al. 1997). We use "Classical LMT" as a cover term, and for consistency with the large body of literature that uses the moniker "LMT", but we do not thereby intend to deny the importance of the work on complex predicates which shows that LMT cannot apply exclusively in the lexicon.

Our presentation of Classical LMT in this section has two parts: in Section 4.1, we present the basic formal tools and theoretical assumptions which characterise Classical LMT, while in Section 4.2 we discuss several case studies which illustrate the application of the theory to some empirical challenges, some of which necessitate (minor) changes to the theory.

Table 1: Feature decomposition of grammatical functions

	$-r$	$+r$
$-o$	SUBJ	OBL$_\theta$
$+o$	OBJ	OBJ$_\theta$

4.1 The framework

In this section, we present the theoretical and formal tools which are used in Classical LMT. We begin in Section 4.1.1 by introducing the idea of decomposing grammatical functions by means of binary features, which underpins the LMT approach to mapping. In Section 4.1.2, we address the question of the initial (unmarked) mapping of arguments to GFs, something that was ignored in the lexical rule approach. Lastly, Section 4.1.3 discusses the Classical LMT approach to argument alternations.

4.1.1 Feature decomposition

In the theoretical world described above in Section 3, arguments are associated with GFs in the lexicon. If those arguments are realised by different GFs as the result of some alternation, like the passive, the original assignments have to be overwritten. As discussed, this means that argument alternations involve non-monotonic re-writing rules. The key innovation of Classical LMT allowing it to avoid this unhappy conclusion is to underspecify the mappings between arguments and GFs, by grouping GFs into natural classes. Each argument can then be associated with one of these natural classes, rather than a specific GF, thereby constraining but not totally determining its ultimate realisation. And since the groupings of GFs are supposed to be natural, this also answers the complaint of unconstrainedness levelled at the lexical rule approach: no longer can we replace a GF with any other; instead, the choice of GFs available to an argument is limited to a natural class.

To achieve this cross-classification, Classical LMT decomposes the GFs using two binary-valued features, [±*r*] and [±*o*] (Bresnan & Kanerva 1989: 24–25). The first, [±*r*], refers to whether a GF is thematically restricted or not: OBJ$_\theta$ and OBL$_\theta$ are; SUBJ and OBJ are not. The second, [±*o*], refers to whether a GF is objective or not: OBJ and OBJ$_\theta$ are; SUBJ and OBL$_\theta$ are not. This is illustrated in Table 1. Grammatical functions can now be described in terms of two features: SUBJ is [−*r*, −*o*], OBJ is [−*r*, +*o*], OBL_θ is [+*r*, −*o*], and OBJ_θ is [+*r*, +*o*].[11] Each individual feature can also be used to describe a pair of GFs, as seen in each of the two rows and two columns of Table 1. This is what enables the association of an argument with a limited natural class of GFs: in Classical LMT, arguments are linked to a single feature (by means to be explored in the next section), and thereby made compatible with two GFs. This is more permissive than the original LFG approach, where an argument is linked to a specific GF, but still limited: argument alternations can only map the argument to the *other* GF, not to any arbitrarily different GF.

Bresnan & Kanerva (1989: 25) claim that the pairings induced by the feature decomposition just described are natural classes. This is a large part of the explanatory appeal of Classical LMT, so it is worth dwelling on momentarily. In fact, this is an area where Classical LMT has received some criticism. Alsina (1996), for example, observes that the standard feature decomposition fails in both directions: it describes an unnatural class and also fails to capture an important natural one. The pair of GFs described by [+*r*], namely OBJ_θ and OBL_θ, does not seem to form a natural class, in that there are no instances where arguments alternate between them. At the same time, the division between terms/direct GFs and nonterms/obliques has a number of linguistic reflexes (Dalrymple et al. 2019: 15–17), yet no single feature can pick out the terms, i.e. SUBJ, OBJ, and OBJ_θ, or the nonterms, i.e. OBL_θ (Alsina 1996: 29, fn. 9). For this reason, Alsina (1996: 19–20) suggests a different decomposition, according to the features [±subj] and [±obl].

On a related note, Findlay (2020: 130) and Asudeh (2021: 32) object to the "suspiciously circular" (*ibid.*) definition of [±*o*]. While it might be relatively clear what independent content [±*r*] could have (being semantically restricted makes sense outside of the context of grammatical functions), it is much less clear what independent content [±*o*] could possess: it identifies a GF as belonging or not to the set {OBJ, OBJ_θ}, but by virtue of no other property than membership of that set.

Despite these qualms, the cleavages induced by the [*r*] and [*o*] features remain in common usage, even if their interpretation is reimagined (e.g. Kibort 2014: 266 views [+*o*] as picking out the complements from the non-complements, and [−*r*] as picking out the core arguments from the non-core – see Section 5). The most

---

[11] If we take this feature decomposition literally, then grammatical functions are no longer primitives in the theory; instead, the features are. Butt (1995: 31) makes this claim explicitly. However, it is also possible to avoid this conclusion, and retain the primitive status of grammatical functions in LFG, by viewing such feature decomposition as merely descriptive, so that it cross-classifies the GFs but does not formally break them down (Butt et al. 1997, Findlay 2016: 298ff.; see Section 6.2 below).

significant reason for this is ultimately their success: the cross-classification in Table 1 has proved incredibly useful in describing a variety of argument structure phenomena in a diverse selection of languages – we will see some examples of this later in this section and especially in Section 4.2.

One potential immediate issue is that using two binary-valued features enables us to describe a four-way classification, but LFG's inventory of grammatical functions has more than four members. Of course, it is no problem that we omit ADJ and XADJ from consideration, since adjuncts are not involved directly in argument structure and mapping, being unable (by definition) to be selected by a predicate.[12] However, the two clausal GFs COMP and XCOMP, both argument GFs, are also missing from Table 1. In fact, and despite some countervailing voices (Dalrymple & Lødrup 2000, Lødrup 2012), many researchers have advocated for eliminating these GFs by assimilating them to one or more of the other complement GFs, *viz.* OBJ, OBJ_θ, and OBL_θ (Zaenen & Engdahl 1994: 197–198, Alsina 1996, Alsina et al. 2005, Forst 2006, Berman 2007, Patejuk & Przepiórkowski 2016, Szűcs 2018). In that case, the omission of COMP and XCOMP from Table 1 is not a problem. Even if the clausal GFs are not eliminated entirely, it seems possible that the distinction between them and the other complement GFs could still be neutralised at the level of specificity required of mapping theory. We can therefore continue to assume that the four GFs in Table 1 are the only ones relevant for mapping.

Besides dividing up the GFs, the $[r]$ and $[o]$ features can also be used to order them. Bresnan & Zaenen (1990: 49) claim that the features indicate markedness of GFs, so that those which possess more negative-valued features are less marked than those which possess more positive-valued ones. This leads to the partial ordering known as the MARKEDNESS HIERARCHY:

(30) *The Markedness Hierarchy:*
$\text{SUBJ} > \text{OBJ}, \text{OBL}_\theta > \text{OBJ}_\theta$

---

[12] In fact, it has been argued that there are such things as "obligatory adjuncts", given the existence of contrasts like the following, where the omission of the parenthetical material leads to ungrammaticality on the intended reading of the verb:

(i) a. Cat behaves *(badly).
b. Lister lives *(in space).
c. This book reads *(well).

See Przepiórkowski (2016: 262–263) and references therein for further discussion and exemplification.

subj, bearing a negative value for both features, is the least marked GF, at the top of the hierarchy; obj$_\theta$, with two positive values, is the most highly marked, at the bottom. Since obj and obl$_\theta$ both have one negative- and one positive-valued feature, they sit in the middle, and are not ordered with respect to one another.[13] This hierarchy of GFs is important for the principles which Classical LMT uses to determine the ultimate mapping of arguments to GFs, to which we now turn.

4.1.2 Initial classification and mapping of arguments

Just as in Section 3, we assume that predicates are equipped with an argument structure that lists their syntactically-realisable arguments. (31) shows a simple example for *kick*:

(31) *kick* ⟨ Agent Patient ⟩

Although Classical LMT still offers no formal consensus on its status or position in the architecture of LFG, such a list now starts to be referred to as a-structure, as if it were a separate level of the parallel projection architecture (see Falk 2001b: 97–106 for some discussion). Arguments within a-structure are ordered according to their thematic role, following the thematic hierarchy introduced in (10), and repeated in (32) (Bresnan & Kanerva 1989: 23):

(32) *The Thematic Hierarchy:*
Agent > Beneficiary > Recipient/Experiencer
> Instrument > Theme/Patient > Location

The most important function of this ranking in Classical LMT is simply to identify the most highly ranked argument, which we refer to as $\hat{\theta}$.[14] This is because of the observation that the most "prominent" thematic role often aligns with the

---

[13] Note that the order of GFs in this hierarchy differs from the typologically-motivated Functional Hierarchy, which Dalrymple et al. (2019: 11) present as the standard in LFG (based on the Accessibility Hierarchy of Keenan & Comrie 1977):

(i) *The Functional Hierarchy:*
subj > obj > obj$_\theta$ (> xcomp, comp) > obl$_\theta$ (> xadj, adj)

Notably, obj$_\theta$ outranks obl$_\theta$ in (i), while the opposite is true in (30).

[14] This is also sometimes called the thematic subject or a-structure subject, and has also been equated with the concept of logical subject. Such a notion of "most thematically prominent argument" has been shown to play a role outside of mapping theory as well, such as in determining the antecedent of a reflexive (Dalrymple 1993, Joshi 1993, Mohanan 1994, Manning & Sag 1999).

most “prominent” GF, i.e. subj (Fillmore 1968, Grimshaw 1990, Speas 1990). We will see how this is cashed out in Classical LMT below.

Whereas arguments were previously associated with a specific GF in the lexicon, in Classical LMT they are associated with a single $[\pm o/r]$ feature instead (i.e. with a *pair* of GFs). In early versions of LMT, such as Bresnan & Kanerva (1989: 25–26) or Bresnan & Moshi (1990), this is achieved by intrinsic connections between specific named thematic roles and features, as in (33), from Bresnan & Moshi (1990: 168):

(33) *Intrinsic classifications:*

Agent	Theme/Patient	Location
$[-o]$	$[-r]$	$[-o]$

This is based on typological observations about common realisations of various thematic roles across languages: cross-linguistically, for instance, Themes/ Patients canonically alternate between the unrestricted GFs, i.e. subject and object, while other roles like Agent and Location canonically alternate between the non-object functions, i.e. subject and oblique (Bresnan & Kanerva 1989: 26). There is no principled limit on which roles might receive intrinsic classifications like this.

In subsequent work in Classical LMT, this open-endedness is rejected, and the initial classification principles are reduced to three (Bresnan & Zaenen 1990: 49; cf. also Her 2003, 2013; and see Bresnan et al. 2016: 331 for a contemporary textbook presentation), claimed to be general across languages:[15]

(34) *Intrinsic classifications (general):*

patientlike roles:	secondary patientlike roles:	other roles:
θ	θ	θ
$[-r]$	$[+o]$	$[-o]$

While this is an improvement in terms of theoretical parsimony, there is a cost in terms of explicitness. Asudeh (2021: 32), for instance, complains that the notion of being “patientlike” is “obscure”, noting that “it’s not clear what the conditions are for meeting the criterion of being ‘like’ a patient”.

Let us assume, however, that it is clear enough when a role is patientlike or not. What of the secondary patientlike roles? Where verbs have more than one patientlike argument, as in ditransitives, one of the two may be “secondary” in

---

[15] “θ” is used to stand for any thematic role, since these principles no longer refer to specific roles.

the sense of Dryer (1986), and this argument will be marked as [+*o*]. Such languages are called asymmetrical object languages, in contrast with symmetrical object languages, which permit multiple patientlike roles to be marked [−*r*] (see Bresnan & Moshi 1990 and Section 4.2.3 below). Even within asymmetrical object languages, there is variation in which of the two arguments counts as primary or secondary – indeed, a single language can permit both possibilities (see discussion of English *give* below).

Given these basic assignments, the a-structure of our simple transitive verb *kick* will be as follows:

(35)
$$\textit{kick}\quad \langle\quad \underset{[-o]}{\text{Agent}}\quad \underset{[-r]}{\text{Patient}}\quad \rangle$$

There is one patientlike role, namely the Patient itself, so this is marked [−*r*]; the one other role is marked [−*o*], according to the third, "elsewhere" principle in (34).

To resolve these single features to fully-specified GFs, Classical LMT makes use of two Mapping Principles:[16]

(36) *Mapping Principles*:

a. Subject roles:

i. $\underset{[-o]}{\hat{\theta}}$ is mapped onto subj when initial in the a-structure;

otherwise:

ii. $\underset{[-r]}{\theta}$ is mapped onto subj.

b. Other roles are mapped onto the lowest featurally compatible function on the Markedness Hierarchy in (30).

As mentioned, the most thematically prominent argument, $\hat{\theta}$, is strongly associated with the subj position; Mapping Principle (a-i) captures this, and requires that a non-patientlike $\hat{\theta}$ maps to subj where possible. The constraint that $\hat{\theta}$ be leftmost in the a-structure is to account for the presence of non-thematic arguments which might take precedence in mapping to subj. For example, the a-structure of a raising verb like *seem* is as shown in (37) (Zaenen & Engdahl 1994: 200):

(37)
$$\textit{seem}\quad \underset{[-r]}{\_\_}\quad \langle\quad \underset{[-o]}{\text{Proposition}}\quad \rangle$$

---

[16] We follow the formulation of Bresnan et al. (2016: 334); for the first appearance of these principles, see Bresnan & Zaenen (1990: 51).

Although *seem* only takes a single semantic argument, the Proposition it embeds, this argument cannot surface as the subject, and the verb instead takes a non-thematic, expletive subject:[17]

(38) a. * That Kira smiled seemed.
 b. It seemed that Kira smiled.

For this reason, (37) contains two argument slots, although one is devoid of semantic content and is therefore marked as $[-r]$, since a non-thematic argument, by definition, cannot be semantically restricted. The highest thematic role, $\hat{\theta}$, is still the Proposition, and it is marked $[-o]$, but because it is no longer initial in the a-structure, it is not mapped to SUBJ by Mapping Principle (a-i), leaving the expletive argument available to map to SUBJ by Principle (a-ii).

In addition to the Mapping Principles in (36), there are two other well-formedness conditions on mapping, FUNCTION-ARGUMENT BIUNIQUENESS (Bresnan 1980: 112), and the SUBJECT CONDITION (Baker 2006 [1983], Bresnan & Kanerva 1989: 28):[18]

(39) *Function-Argument Biuniqueness:*
Each a-structure role must be associated with a unique function, and vice versa.

(40) *The Subject Condition:*
Every predicator must have a subject.

The first condition ensures that a predicate cannot select for multiple of the same GF, and that a single argument cannot be realised by multiple GFs of the same predicate.[19] The second represents a supposed language universal, that all predicates possess subjects – even when these are not overtly expressed. There have been some doubts about the universality of this claim (see e.g. Bresnan & Kanerva 1989: 28, fn. 37, Bresnan et al. 2016: 334, fn. 9, Kibort 2006, and references therein), so it may be more appropriate to see this as a parameter which varies by language.[20]

---

[17] Of course, there is also the "raised" alternative *Kira seemed to smile*. See Zaenen & Engdahl (1994) and Dalrymple et al. (2019: ch. 15) for the treatment of raising in LFG.

[18] Once again, we take the specific wording from Bresnan et al. (2016: 334).

[19] The first part of this is already barred by the f-structure well-formedness condition called Consistency (Dalrymple et al. 2019: 53–54), which follows from the functional nature of f-structure: each attribute at f-structure, such as a GF like SUBJ or OBJ, can only have a single value.

[20] Kibort (2004: 358–359) reworks the Classical LMT Mapping Principles in such a way that she can do without the Subject Condition altogether – see Section 5 for more details.

Note that these well-formedness conditions are more important in early LMT work, such as Bresnan & Kanerva (1989), since this version of the theory does not include explicit Mapping Principles like (36). Instead, through a richer theory of intrinsic and default assignment of features to arguments, a number of mappings are made possible, which are then filtered down to the unique solution by Function-Argument Biuniqueness and the Subject Condition (Bresnan & Kanerva 1989: 28ff.). In the sense that this involves positing fewer rules, it is a simpler theory – but the rules it does include are more specific (i.e. referring to particular thematic roles by name), making it less general overall.

Let us return now to the example of a simple transitive predicate like *kick* and see how the Mapping Principles apply in practice. Since Agent outranks Patient on the Thematic Hierarchy, the Agent is identified as $\hat{\theta}$; since this argument is also initial in the a-structure, it is therefore mapped to SUBJ. The remaining argument, the $[-r]$ Patient, then maps to the lowest compatible GF on the Markedness Hierarchy: the lowest $[-r]$ GF is OBJ. This correctly gives us the active voice mapping whereby the Agent is realised as the subject, and the Patient as the object:

$$\begin{array}{llcccc} (41) & \textit{kick} & \langle & \text{Agent} & \text{Patient} & \rangle \\ & & & [-o] & [-r] & \\ & & & | & | & \\ & & & \text{SUBJ} & \text{OBJ} & \end{array}$$

What of other predicate types?[21] Intransitives should have their single argument mapped to SUBJ. The initial feature assignment to this argument will depend on whether the predicate is unaccusative or unergative (Perlmutter 1978):

---

[21] We consider only verbal predicates in this chapter. This footnote offers a selection of references for the reader interested in learning more about argument structure and mapping phenomena within the nominal domain. The most prominent idea, proposed by Rappaport (2006 [1983]), is that nominals derived from verbs inherit that verb's argument structure, but that the possibilities for mapping are more constrained within the noun phrase – for example, the functions SUBJ and OBJ are not available to the dependents of nouns (cf. *Luke destroyed the Death Star* and *Luke's destruction of the Death Star*). This perspective remains the dominant one – see e.g. Laczkó (2000, 2003, 2007), Kelling (2003), Chisarik & Payne (2001, 2003) – but some have instead argued that nominals either don't have argument structures, or that, where they do, they can differ from the corresponding verbal ones (Ramchand 1997, Lowe 2017, Taylor 2023). Börjars & Lowe (2023) [this volume] provide a useful contemporary summary of the issues.

A wide range of languages have been studied in LFG with respect to nominal argument structures and their mapping possibilities: see Saiki (1987) on Japanese, Markantonatou (1995) on Modern Greek, Laczkó (2000, 2003, 2004, 2010) on Hungarian, Falk (2001a) on Modern Hebrew, Kelling (2003) on French, Sulger (2013) on Hindi-Urdu, Lowe (2017) on Sanskrit and other early Indo-Aryan languages, and Taylor (2023) on Old English.

since the single argument of an unaccusative is patientlike, it will be assigned [−*r*]; unergatives, on the other hand, have more agentlike arguments, which will therefore be assigned [−*o*]. However, in both cases this will result in the correct mapping (in the simple, active case): for the unaccusative verb, (42), Mapping Principle (a-ii) applies, while for the unergative (43), Principle (a-i) does the job.

$$\begin{array}{llccc} (42) & \textit{fall} & \langle & \text{Patient} & \rangle \\ & & & [-r] & \\ & & & | & \\ & & & \text{SUBJ} & \end{array}$$

$$\begin{array}{llccc} (43) & \textit{run} & \langle & \text{Agent} & \rangle \\ & & & [-o] & \\ & & & | & \\ & & & \text{SUBJ} & \end{array}$$

Ditransitives like *give* are slightly more complicated. They of course have three arguments in their a-structure:

$$\begin{array}{llccccc} (44) & \textit{give} & \langle & \text{Agent} & \text{Beneficiary/Recipient} & \text{Theme} & \rangle \end{array}$$

Following the usual initial classifications, the Theme, as a patientlike argument, is linked to [−*r*], and the Beneficiary/Recipient and Agent both receive the "elsewhere" [−*o*] feature. As per the Mapping Principles, the Agent, an a-structure-initial, [−*o*]-valued, $\hat{\theta}$ argument, is mapped to SUBJ. The Beneficiary/Recipient maps to the lowest [−*o*] GF, which is OBL_{θ}, while the Theme maps to the lowest [−*r*] GF, OBJ. This gives us one correct mapping for *give*, illustrated in a sentence like *Peter gave a present to Harriet.*

$$\begin{array}{llccccc} (45) & \textit{give} & \langle & \text{Agent} & \text{Beneficiary/Recipient} & \text{Theme} & \rangle \\ & & & [-o] & [-o] & [-r] & \\ & & & | & | & | & \\ & & & \text{SUBJ} & \text{OBL}_{\theta} & \text{OBJ} & \end{array}$$

But of course there is another way of realising the arguments of a ditransitive like *give*: the dative-shifted version, illustrated in *Peter gave Harriet a present.* Since this involves the same thematic roles, this alternation cannot be derived in Classical LMT without some further stipulation (Kibort 2008: 314). It seems that we can choose to view the Beneficiary/Recipient as patientlike (cf. Toivonen 2013), in which case it is assigned [−*r*] by the intrinsic classification rules

(Bresnan 2003: 14–15; cf. also Bresnan et al. 2016: 337–340). Now, English is an asymmetrical object language, which means it does not permit the presence of two [−*r*] arguments at a-structure (see Section 4.2.3), and so the (lower-ranked) Theme must instead be marked [+*o*], as a secondary patientlike argument, per (34). The Agent receives the “elsewhere” [−*o*] specification as usual, giving us the following a-structure and GF-mapping:

(46)
$$\begin{array}{lccccc} \textit{give} & \langle & \text{Agent} & \text{Beneficiary/Recipient} & \text{Theme} & \rangle \\ & & [-o] & [-r] & [+o] & \\ & & | & | & | & \\ & & \textsc{subj} & \textsc{obj} & \textsc{obj}_{\theta} & \end{array}$$

This is the double object version of *give*: the Agent is mapped to SUBJ as usual, then the other arguments are mapped to the lowest compatible GFs, in this case OBJ for the Beneficiary/Recipient (the lowest [−*r*] GF) and $\textsc{obj}_{\theta}$ for the Theme (the lowest [+*o*] GF). So, Classical LMT can account for the dative shift alternation, but only with the initial stipulation that the Beneficiary/Recipient can be viewed as patientlike, and hence assigned [−*r*] at a-structure. Indeed, morphosemantic alternations in general are problematic for Classical LMT, a shortcoming which Kibort (2007, 2014) attempts to rectify, and which we will examine in more detail in Section 5. For now, though, we consider the well-developed Classical LMT account of (morphosyntactic) alternations.

4.1.3 Argument alternations

Argument alternations in Classical LMT are handled by adding extra specifications to arguments – in this way information is only added, not removed, meaning that “the computational requirement of monotonicity can be met even in the domain of relation changes” (Bresnan 1990: 650).

One common mechanism is that of SUPPRESSION, illustrated schematically in (47):

(47)
$$\begin{array}{c} \theta \\ | \\ \varnothing \end{array}$$

This prevents an argument from being mapped to a GF at f-structure, and existentially quantifies over the argument in the semantics (though it does allow the possibility of the argument being realised by an adjunct, like the English *by*-phrase which can express the Agent of a passive, so this quantification only applies if the argument remains unexpressed). Suppression is restricted to unmarked arguments, i.e. those pre-specified with a negatively-valued feature at a-structure (Alsina 1999; see also Bresnan et al. 2016: 338–340 for a relevant example), a principle known as Recoverability of Suppresion (Bresnan et al. 2016: 333).

Lexical rules involving deletion can be recast in terms of suppression. For example, instead of deleting an obj, as in (25), intransitivisation involves suppression of a Theme/Patient argument:

(48) Intransitivisation: $\begin{array}{c}\text{Theme/Patient}\\ | \\ \emptyset\end{array}$

And rather than deleting or re-writing the subj and changing an obj to a subj, as in (27), passivisation simply involves a single process, *viz.* the suppression of the highest thematic role:

(49) Passivisation: $\begin{array}{c}\hat{\theta}\\ | \\ \emptyset\end{array}$

This simplified analysis of passivisation works because of the general system of mapping assumed in Classical LMT. In a standard two-place predicate like *kick*, the highest, Agent argument will be [−*o*], while the next, Patient argument will be [−*r*]. If the Agent argument is suppressed, Mapping Principle (a-i) will not apply, and instead Principle (a-ii), which maps a [−*r*] argument to subj, will step in, correctly promoting the Patient argument, without any need for further stipulation:[22]

---

[22] The way the Mapping Principles are written, it seems to us that argument suppression should lead to a contradiction. Assuming the Principles are intended to be declarative rather than procedural, then (50) would seem to violate Mapping Principle (a-i), since it is not true that a [−*o*], a-structure-initial $\hat{\theta}$ is mapped onto subj: instead, it is not mapped to anything; and the same goes for intransitivisation: the suppressed Theme/Patient argument in a transitive will not be mapped to the lowest featurally compatible function on the Markedness Hierarchy, contrary to Principle (b). Perhaps suppression removes an argument from consideration at a-structure altogether, but in that case it would not be monotonic. One solution would simply be to add the rider "unless suppressed" to each of the Mapping Principles, but this seems far from parsimonious.

$$\begin{array}{llcccc} (50) & \textit{kicked}_{\text{PASSIVE}} & \langle & \text{Agent} & \text{Patient} & \rangle \\ & & & [-o] & [-r] & \\ & & & \mid & \mid & \\ & & & \varnothing & \text{SUBJ} & \end{array}$$

Passivisation also correctly applies to ditransitives in both their a-structure realisations. For example, suppressing the Agent in the non-shifted version, repeated in (51), results in the Theme being promoted to SUBJ, by Mapping Principle (a-ii), since it is a $[-r]$ argument.

$$\begin{array}{llccccc} (51) & \textit{give} & \langle & \text{Agent} & \text{Beneficiary/Recipient} & \text{Theme} & \rangle \\ & & & [-o] & [-o] & [-r] & \\ & & & \mid & \mid & \mid & \\ & & & \varnothing & \text{OBL}_{\theta} & \text{SUBJ} & \end{array}$$

This gives us the correct alternation, illustrated in (52), where the Beneficiary/Recipient remains an OBL_{θ} (since this is still the most marked $[-o]$ GF):

(52) a. Peter gave a present to Harriet.

b. A present was given to Harriet (by Peter).

On the other hand, when the Agent is suppressed in the dative-shifted version, the Beneficiary/Recipient is promoted instead, since it is now the $[-r]$ argument, while the Theme remains an OBJ_{θ} (since this is still the most marked $[+o]$ GF):

$$\begin{array}{llccccc} (53) & \textit{give} & \langle & \text{Agent} & \text{Beneficiary/Recipient} & \text{Theme} & \rangle \\ & & & [-o] & [-r] & [+o] & \\ & & & \mid & \mid & \mid & \\ & & & \varnothing & \text{SUBJ} & \text{OBJ}_{\theta} & \end{array}$$

This again accords with the facts:[23]

(54) Peter gave Harriet a present.

(55) Harriet was given a present (by Peter).

---

[23] For those dialects where *%A present was given Harriet (by Peter)* is grammatical, something more needs to be said, of course. It is possible the Asymmetrical Object Parameter (Bresnan & Moshi 1990) is not in force in these varieties of English (see Section 4.2.3 for more on the AOP).

Notice that because Mapping Principle (b) requires that an argument be mapped to the *lowest* compatible GF on the hierarchy, the [+*o*] argument of such double object verbs remains an obj$_\theta$ in the passive, and is not, for example, "promoted" to obj. That this is the correct result is not at all obvious from English data alone: the usual test for obj-hood is the possibility of promotion through passivisation, but we cannot passivise a passive. In the absence of any morphological marking of the distinction between obj and obj$_\theta$, there is no obvious way to tell which of these two GFs *a present* bears in example (55).

Data from other languages, however, such as the Bantu language Chicheŵa, support the Classical LMT analysis. Ditransitive verbs can be formed in Chicheŵa by applicativisation, and when the applied argument is a Beneficiary, it is assigned a [−*r*] classification at a-structure, while the Theme is assigned [+*o*], exactly as in the English double object construction, and resulting in the same GF assignments as we saw above (Alsina & Mchombo 1993: 28). In such Chicheŵa applicatives, only the obj (the Beneficiary) can be indexed by an object marker on the verb, while the obj$_\theta$ (the Theme) cannot (Bresnan & Moshi 1990; Alsina & Mchombo 1993: 22):[24]

(56) a. Chi-tsîru chi-na-wá-gúl-ir-á m-phâtso (a-tsíkāna).
7-fool 7s-pst-2o-buy-appl-fv 9-gift 2-girls
'The fool bought a gift for them (the girls).'

b. * Chi-tsîru chi-na-í-gúl-ir-á a-tsíkāna (m-phâtso).
7-fool 7s-pst-9o-buy-appl-fv 2-girls 9-gift

Now, given the a-structure assignments, we also observe the same passivisation pattern for Chicheŵa applicatives as for the English double object construction, with the Beneficiary obj being promoted to subj (Alsina & Mchombo 1993: 29):

(57) Atsíkāna a-na-phík-ír-idw-á nyêmba.
2-girls 2s-pst-cook-appl-pass-fv 10-beans
'The girls were cooked beans.'

Crucially, we now have a diagnostic to identify the GF of the remaining Theme argument: if it is promoted to obj, it should be compatible with the presence of an agreeing object marker on the verb; if it remains an obj$_\theta$, then the use of the object marker will not be possible. In fact, use of the object marker in this construction is ungrammatical (Alsina & Mchombo 1993: 30):

---

[24] Object NPs indexed on the verb can be omitted, indicated here by parentheses. Numbers signify noun classes; s = subject marker; o = object marker; fv = final vowel.

(58) * Atsíkāna a-na-zí-phík-ír-idw-á (nyêmba).
2-girls 2s-pst-10o-cook-appl-pass-fv 10-beans
'The girls were cooked beans.'

This incompatibility shows that the Beneficiary argument here must still be an obj$_{\theta}$, not an obj, and this therefore motivates Mapping Principle (b), where arguments are linked to the *most* marked compatible GF (though the empirical landscape may not be quite so straightforward as this single data point would suggest: see Kibort 2008 for some discussion of the complexities).

Along with suppression, argument alternations can involve adding new arguments to an a-structure, as in the Bantu applicative (Bresnan & Moshi 1990), or the English benefactive (Toivonen 2013). For example, Toivonen (2013: 514) gives the rule in (60) for the benefactive in English, which takes a transitive verb into a ditransitive, as in (59):

(59) a. I'll pack some sandwiches.
b. I'll pack the children some sandwiches.

(60)
$$\text{English benefactive:} \quad \left\langle \begin{array}{ccc} & \overset{\varnothing}{\downarrow} & \\ \hat{\theta} & \text{Beneficiary/Recipient} & \text{Theme} \\ [-o] & [-r] & [+o] \end{array} \right\rangle$$

Note that the symbol ∅ is used differently here from above, where it represented argument suppression. Here it captures the fact that the Beneficiary/Recipient is added to an a-structure which otherwise contains only a Theme and a $\hat{\theta}$, whatever role that may play; i.e. (60) adds the Beneficiary/Recipient where previously there was no argument.

As well as adding or suppressing arguments, alternations can also involve constraining the mapping possibilities of arguments. This is what happens in locative inversion, for example. The relevant examples from Chicheŵa are repeated in (61):

(61) a. Chi-tsîme chi-li ku-mu-dzi.
7-well 7-be 17-3-village
'The well is in the village.'

b. Ku-mu-dzi ku-li chi-tsîme.
17-3-village 17-be 7-well
'In the village is a well.'

Bresnan & Kanerva (1989: 27) analyse the relevant process in the following terms:

(62)

$$\begin{array}{lccccc} \text{Locative inversion:} & \langle & \text{Theme} & \ldots & \text{Location} & \rangle \\ & & & & [-r] & \end{array}$$

That is, when a Location appears in the same a-structure as a Theme, assign it the specification [−*r*] in addition to whatever its intrinsic feature assignment is. Let us see how this provides the contrast in (61).

In the relevant sense, the verb *-li* 'be' takes a Theme and a Location argument; as per the intrinsic specifications of (34), the patientlike Theme is assigned [−*r*] and the other role is assigned [−*o*]. All things being equal, this will provide the mapping instantiated by (61a), where the Theme maps to SUBJ, by Mapping Principle (a-ii), and the Location maps to $\textsc{obl}_\theta$, the lowest [−*o*] GF.

(63)

$$\begin{array}{lcccc} \textit{-li} & \langle & \text{Theme} & \text{Location} & \rangle \\ & & [-r] & [-o] & \\ & & | & | & \\ & & \textsc{subj} & \textsc{obl}_\theta & \end{array}$$

When we apply the additional assignment in (62), however, things change:

(64)

$$\begin{array}{lcccc} \textit{-li} & \langle & \text{Theme} & \text{Location} & \rangle \\ & & [-r] & [-o] & \\ & & | & [-r] & \\ & & | & | & \\ & & \textsc{obj} & \textsc{subj} & \end{array}$$

Here, the Location argument is fully specified as a SUBJ, meaning that the Theme is prevented from also being mapped to SUBJ, owing to Function-Argument Biuniqueness. Instead, it must map to the lowest available GF on the Markedness Hierarchy, namely OBJ. This gives us the mapping instantiated by (61b).

This section has served to provide a sampling of the different approaches to argument alternations in Classical LMT. By suppressing, adding, or further specifying arguments, the theory can give succinct accounts of a variety of different phenomena. To the extent that these simple descriptions make the correct predictions in conjunction with the underlying theory, this also serves as a vindication of the latter. Of course, we have hardly been able to do justice to such a rich literature in a handful of pages, but we hope to have illustrated the key technical points. In the following section, we provide a few more case studies, further showcasing areas where Classical LMT has provided elegant and illuminating analyses.

4.2 Case studies and extensions

The framework of Classical LMT has been shown to offer an elegant solution to many thorny empirical issues, but it has also sometimes been necessary to expand or modify the theory in the face of empirical deficiencies or theoretical shortcomings. In this section, we discuss various topics which showcase the workings of Classical LMT.

4.2.1 Resultatives

As first observed by Simpson (2006 [1983]), resultative predicates in English can be applied to the objects of transitives or to the subjects of their corresponding passives, as shown in (65), and to the subjects of unaccusative intransitives but not of unergatives, as shown in (66) (examples from Bresnan & Zaenen 1990: 46):

(65) a. We pounded the metal flat.
b. The metal was pounded flat.

(66) a. The river froze solid.
b. * The dog barked hoarse.

The question then arises: how should we characterise all and only the arguments which can have resultatives predicated of them?

The generalisation cannot be based on surface grammatical function. For one thing, the data above show that both subjects and objects can take resultative predicates. What is more, only some subjects are implicated: (66b) is ungrammatical, and (65a) would be too if it were intended to mean that we pounded the metal until *we* were flat.

Given the contrast between unaccusative and unergative predicates, we might think instead to appeal to the thematic role of the arguments in question: perhaps resultatives can be applied to Themes, and not to Agents? This would account for the data in (65–66), but unfortunately there are other data which invalidate such a generalisation. Resultatives can also be applied to non-thematic arguments such as "fake reflexives", illustrated in (67), or "non-subcategorised objects" which do not stand in a direct semantic relation to the main verb, illustrated in (68) (examples from Bresnan & Zaenen 1990: 47):

(67) a. The dog barked itself hoarse.
b. We ran ourselves ragged.

(68) a. The dog barked us awake.
b. We ran the soles right off our shoes.

The tools of Classical LMT offer a straightforward solution to this descriptive challenge: the arguments in question are simply those which are assigned [−*r*] as their initial feature value at a-structure. For the Themes in (65–66), this follows from their being patientlike, while for the problematic arguments in (67–68) this follows from their being non-thematic (and so by definition semantically unrestricted). The more agentive subjects of transitive and unergative verbs will instead by classified as [−*o*] by the "elsewhere" condition, which sets them apart.

4.2.2 Proto-roles and unaccusativity

Another area where intrinsic classification of argument positions at a-structure has proved a more useful discriminator than other notions is in Zaenen's (1993) analysis of unaccusativity in Dutch. Before we consider the data, however, we first introduce Zaenen's innovative approach to intrinsic feature specification.

Rather than having to decide impressionistically whether an argument is "patientlike" or not, in order to decide whether it should be assigned [−*r*] or [−*o*] as its initial feature specification at a-structure, Zaenen (1993: 146–154) proposes to operationalise Dowty's (1991) notion of semantic PROTO-ROLE.

Dowty (1991: 571–575) envisages semantic roles as prototypes: arguments can possess a number of both proto-agent and proto-patient properties, with their behaviour depending on the balance between the two groups. This allows a fuzzier notion of semantic role, and avoids some of the definitional challenges of using named roles. Proto-agentivity and proto-patientivity are determined by a number of lexical entailments, including volition, change of state, and movement, which describe aspects of the relationship between participant and event (Dowty 1991: 572):

(69) *Proto-agent entailments:*

- volitional involvement in the event or state
- sentience (and/or perception)
- causing an event or change of state in another participant
- movement (relative to the position of another participant)
- exists independently of the event named by the verb

(70) *Proto-patient entailments:*

- undergoes change of state
- incremental theme[25]
- causally affected by another participant
- stationary relative to movement of another participant
- does not exist independently of the event, or not at all

Dowty (1991: 576) uses these proto-properties to determine the assignment of the subject and object GFs to arguments (the argument with more proto-agent properties becomes the subject, while the argument with more proto-agent properties becomes the object), but Zaenen (1993: 149) instead uses them to determine the intrinsic feature specification of an argument at a-structure: those that have more proto-agent properties will be classified as [−*o*], while those that have more proto-patient properties will be classified as [−*r*]. This therefore captures the same general intuition as the Classical LMT intrinsic assignment principles in (34), namely that patientlike arguments are [−*r*] and others are [−*o*], but does so in a way which makes it more explicit what criteria an argument has to satisfy to count as patientlike. (Of course, determining whether an argument satisfies the proto-properties can also sometimes be rather impressionistic, but many are clear-cut enough to at least afford one an analytical toehold.)

A problem arises when an argument possesses an equal number of proto-agent and proto-patient properties (including zero). Dowty (1991: 576) proposes that in this situation both mappings are available. Zaenen (1993: 150) instead assumes that in such a case the argument is assigned [−*r*]. This is somewhat self-serving in that it gives her the correct results for Dutch (see below), but, as she observes, it does not seem unreasonable that it is precisely in areas such as this, where the distinctions are less clear-cut, that languages vary, and so perhaps a degree of arbitrariness is unavoidable.

Let us now turn to the Dutch data which Zaenen (1993) uses these tools to analyse. Intransitive verbs in Dutch take different auxiliaries in the compound past tense depending on whether they are unaccusative or unergative. The unergatives take *hebben* 'have' and the unaccusatives take *zijn* 'be':

---

[25] Dowty (1991: 588) defines an incremental theme as "an NP that can determine the aspect of the sentence […]; the event is 'complete' only if all parts of the NP referent are affected (or effected)". For example, in *Chrisjen ate a pistachio*, the eating event is only complete once all (edible) parts of the pistachio are eaten.

(71) **Unergative verbs:**

a. Hij heeft/*is gelopen.
he has/is run
‘He has run.’

b. Ze heeft/*is getelefoneerd.
she has/is telephoned
‘She has telephoned.’

(72) **Unaccusative verbs:**

a. Ze is/*heeft overleden.
she is/has died
‘She has died.’

b. Hij is/*heeft gevallen.
he is/has fallen
‘He has fallen.’

This also correlates with another contrast: the possibility of using the past participle as a pre-nominal modifier. This is impossible with the unergative, *hebben*-taking verbs, but perfectly productive with the unaccusative, *zijn*-taking verbs:

(73) a. * de gelopen/getelefoneerd man
the run/telephoned man

b. de overleden/gevallen vrouw
the deceased/fallen woman
‘the deceased/fallen woman’

Now, if the intransitives were the only verbs we had to consider here, then a semantic explanation would be possible. For one thing, the single argument of an unaccusative is generally Theme/Patient-like. Zaenen (1993: 132–136) also discusses other semantic criteria which distinguish the two classes of verbs. However, a class of transitive verbs (those with an experiencer argument) also exhibit the same syntactic split, despite having different semantics. Firstly, some take *hebben* and some take *zijn* in the compound past tense:

(74) a. Dat is/*heeft me jarenlang goed bevallen.
that is/has me for.years well pleased
‘That has pleased me well for years.’

b. Hij heeft/*is me jarenlang geïrriteerd.
he has/is me for.years irritated
'He has irritated me for years.'

And this distinction once again maps onto a difference in the use of the past participle as a pre-nominal modifier. When the past participles of those verbs that take *zijn* are used pre-nominally, their head noun can be understood as the equivalent of their active voice subject, whereas this is not the case for those that take *hebben*:

(75) het hem goed bevallen boek
the him well pleased book
'the book that pleased him well'

(76) a. de geïrriteerde jongen
the irritated boy
'the irritated boy'

b. # de geïrriteerde fouten
the irritated mistakes
'the mistakes that were irritated', not 'the mistakes that caused irritation'

But here the semantic explanation is not available: the subject of a verb like *bevallen* 'please/suit' is not a Theme/Patient, but rather a Stimulus or equivalent. And Zaenen (1993: 144) notes that "if there are any semantic properties that distinguish the two classes of experiencer verbs under consideration, they are not the same as the ones distinguishing the two classes of intransitives".

In fact, once again the solution is to look at intrinsic assignment of features at a-structure. The subjects of verbs like *bevallen* do not, in Zaenen's (1993: 149) view, possess any proto-agent or proto-patient entailments; in the event of a tie, Zaenen (1993: 150) assumes that the argument is assigned [−*r*], and so these arguments are treated as being patientlike. We now have an explanation for the shared unaccusative/unergative split across intransitives and transitives. Just as with resultatives, the presence of a [−*r*] argument is the significant factor: verbs in which the intrinsically [−*r*]-marked argument becomes subject take the auxiliary *zijn* (otherwise verbs take *hebben*), and the head noun of the pre-nominal participle corresponds to the [−*r*] argument – this makes such participial uses simply impossible for unergative intransitives, which have no [−*r*] argument, and means that the head noun corresponds to the "logical object" of transitives.

4.2.3 Double object constructions

The world's languages are divided in how they treat ditransitive predicates. For some, both objects of a ditransitive are treated equally: for example, either can be promoted to subject by passivisation, flagged by object marking on the verb, etc. As mentioned above, these languages are called symmetrical object languages. Other languages, called asymmetrical object languages, exhibit strong differences between "primary" and "secondary" objects, whereby only one object is eligible for promotion by passivisation, flagging by object marking on the verb, etc. This distinction was first drawn as a result of work on the Bantu languages (e.g. Gary & Keenan 1977, Kisseberth & Abasheikh 1977, Baker 1988), where the divide is particularly clear: since these languages have a productive process of applicativisation, ditransitive predicates are very frequent, and a number of grammatical features are sensitive to objecthood.

To illustrate the contrast between symmetrical and asymmetrical object languages, we consider two languages from the Bantu family: Kichaga and Chicheŵa. Kichaga is a symmetrical object language, and so either of the post-verbal arguments in the active can be promoted to subject by passivisation (Bresnan & Moshi 1990: 150):

(77) a. N-a̋-i̋-lyì-í-à m̀-kà k-élyà
FOC-1S-PRS-eat-APPL-FV 1-wife 7-food
'He is eating food for/on his wife.'

b. M̀-kà n-a̋-i̋-lyì-í-ò k-élyâ
1-wife FOC-1S-PRS-eat-APPL-PASS 7-food
'The wife is being eaten food for/on.'
(i.e. 'The wife is being benefitted/adversely affected by someone eating food.')

c. K-élyà k-i̋-lyì-í-ò m̀-kà
7-food 7S-PRS-eat-APPL-PASS 1-wife
'The food is being eaten for/on the wife.'

Chicheŵa, on the other hand, is an asymmetrical object language. Here, only the immediately post-verbal argument in the active can be promoted to subject in the passive (Baker 1988: 248):

(78) a. Kalulu a-na-gul-ir-a mbidzi nsapato.
hare S-PST-buy-APPL-ASP zebras shoes
'The hare bought shoes for the zebras.'

b. Mbidzi zi-na-gul-ir-idw-a nsapato (ndi kalulu).
zebras S-PST-buy-APPL-PASS-ASP shoes by hare
'The zebras were bought shoes (by the hare).'

c. * Nsapato zi-na-gul-ir-idw-a mbidzi (ndi kalulu).
shoes S-PST-buy-APPL-PASS-ASP zebras by hare
'Shoes were bought for the zebras (by the hare).'

There are a number of other properties which correlate with the passivisation facts (Bresnan & Moshi 1990: 150–153). Either or both post-verbal arguments in Kichaga can be omitted if they are encoded on the verb by an object marker, for instance, while in Chichewâ, only the immediately post-verbal Beneficiary argument can be encoded/omitted this way; Kichaga allows unspecified object deletion of the Patient in a ditransitive where Chichewâ does not; Kichaga allows the Patient argument to be eliminated by reciprocal marking on the verb in the presence of any applied object, while this is not the case in Chichewâ; and all of these properties can interact in different ways.

These patterns receive an elegant explanation in Classical LMT, by way of the Asymmetrical Object Parameter (AOP; Alsina & Mchombo 1990, Bresnan & Moshi 1990: 172). This is a well-formedness constraint on a-structures, parametrised so that some languages apply it (i.e. asymmetrical object languages) and others do not (i.e. symmetrical object languages).

(79) *Asymmetrical Object Parameter*

$$* \begin{array}{ccc} \theta & \dots & \theta \\ | & & | \\ [-r] & & [-r] \end{array}$$

The AOP prohibits the presence of two intrinsically classified $[-r]$ arguments in the same a-structure: when it is in force, secondary patientlike arguments are assigned $[+o]$ by the intrinsic linking principles introduced in Section 4.1.2; when it is not, we permit multiple patientlike arguments to be assigned $[-r]$ instead. Let us consider how this can explain the passivisation facts shown in (77) and (78).

Chichewâ is an asymmetrical object language, so the AOP is active. The a-structure for an applicative verb like we see in (78a) is therefore as follows:

(80)	*gulira* ‘buy-for’	⟨	Agent	Beneficiary	Theme	⟩
			[−*o*]	[−*r*]	[+*o*]	
			│	│	│	
			SUBJ	OBJ	OBJ_θ	

Just as with the English ditransitive above, we interpret the Beneficiary as patientlike, and so assign it the intrinsic feature [−*r*]. By the AOP, the second patientlike argument cannot also be marked [−*r*], so it is instead classified as [+*o*]. This leads to the (correct) mapping shown in (80).

In the passive, only the Beneficiary is eligible for promotion to SUBJ when the Agent is suppressed, since the [+*o*] Theme is featurally incompatible. This explains the contrast between (78b) and (78c).

(81)	*guliridwa* ‘buy-for$_{\text{PASSIVE}}$’	⟨	Agent	Beneficiary	Theme	⟩
			[−*o*]	[−*r*]	[+*o*]	
			│	│	│	
			∅	SUBJ	OBJ_θ	

Now consider Kichaga. Since it is a symmetrical object language, we are free to ignore the AOP ban on having two intrinsically [−*r*]-marked arguments. However, if we do, then we run into trouble in the active:

(82)	*lyìíà* ‘eat-for’	⟨	Agent	Beneficiary	Patient	⟩
			[−*o*]	[−*r*]	[−*r*]	
			│	│	│	
			SUBJ	OBJ	*	

Since the Agent will be mapped to SUBJ, we are left with only one remaining [−*r*] GF to share between two arguments. So here Kichaga must take the same option as Chichewâ of assigning the non-Beneficiary argument [+*o*] instead:

(83)	*lyìíà* ‘eat-for’	⟨	Agent	Beneficiary	Patient	⟩
			[−*o*]	[−*r*]	[+*o*]	
			│	│	│	
			SUBJ	OBJ	OBJ_θ	

However, in the passive, things are different. Now that the Agent is not mapped to any GF, there are still two [−*r*] GFs available. This means the unrestricted intrinsic mapping of two arguments to [−*r*] is possible, and will in fact lead to two possible final mappings:

(84)	*lyìíò* ‘eat-for$_{\text{PASSIVE}}$’	⟨	Agent	Beneficiary	Patient	⟩
			[−*o*]	[−*r*]	[−*r*]	
			│	│	│	
			∅	SUBJ/OBJ	OBJ/SUBJ	

This is exactly the right prediction, since both (77b) and (77c) are grammatical.

The other properties can also be made to follow from the possibility of having multiple [−*r*] arguments or not. Recall that the argument structure operation of suppression is limited to unmarked arguments (those that possess negatively-valued intrinsic features) – it then follows that e.g. unspecified object deletion applies more freely in symmetrical object languages, which can have more arguments with negatively-valued features than asymmetrical object languages.

4.2.4 Complex predicates

Complex predicates are predicates which syntactically head single clauses, but whose meanings incorporate multiple semantic heads and which therefore have complex argument structures. They have been at the centre of LFG work on argument structure and mapping theory since the earliest days, and have consistently drawn a great deal of attention in the literature (e.g. Ishikawa 1985, Alsina 1992, 1996, Butt 1995, 2014, Mohanan 1994, Matsumoto 1992, 1996, Andrews & Manning 1999, Lowe 2016, Lovestrand 2020, among many, many others; see also Dalrymple et al. 2019: 351–352 for an overview of the range of cross-linguistic work on complex predicates carried out in LFG).[26] As one might expect, therefore, this work has also led to various innovations and extensions of Classical LMT. In this section, we discuss two of these: the idea that one a-structure can be embedded inside another, with appropriate fusion of overlapping arguments, and the claim that this a-structure composition can take place in the syntax proper, not just in the lexicon, thus putting paid to the “lexical” aspect of Lexical Mapping Theory.

The first of these points can be seen by considering causatives in Chicheŵa (Alsina 1992). Verbs containing the causative suffix *-íts* add an additional Causer argument which, in the active, surfaces as the subject, with the previous subject being demoted, either to object or oblique status (Alsina 1992: 518):

---

[26] There has also been extensive work on computational grammars for LFG that can handle complex predicates, with a particular focus on Hindi-Urdu: see Butt et al. (2003, 2012), Butt & King (2007), Bögel et al. (2009), Sulger (2013).

Another strand of research worth highlighting studies the consequences of complex predicates for the syntax-semantics interface: see Dalrymple, Hinrichs, et al. (1993), Kaplan & Wedekind (1993), Andrews & Manning (1999), Andrews (2007), Homola & Coler (2013), Lowe (2015).

(85) Nǔngu i-na-phík-íts-a kadzidzi maûngu.
9.porcupine 9s-pst-cook-caus-fv 1a.owl 6.pumpkins
'The porcupine made the owl cook the pumpkins.'

(86) Nǔngu i-na-phík-íts-a maûngu (kwá kádzīdzi).
9.porcupine 9s-pst-cook-caus-fv 6.pumpkins to 1a.owl
'The porcupine had the pumpkins cooked by the owl.'

Now, we might imagine that such causative forms have a simple a-structure, containing three argument positions for the Causer, Causee, and original Patient (here *maûngu*, 'pumpkins'). Instead, Alsina (1992: 521) suggests they have a complex argument structure, formed by embedding the base verb's a-structure into the a-structure of the cause predicate, whose Patient is then merged with one of the arguments of the base predicate:

(87) $$\textsc{cause}\ \langle\ \text{Agent}\quad \text{Patient}\quad \underbrace{\textsc{pred}\ \langle \ldots \theta \ldots \rangle}_{\text{caused event}}\ \rangle$$

Where the base predicate has more than one argument, this means there are multiple possibilities for this argument fusion: for instance, the causative's Patient argument may fuse with either the Agent or Patient of *phīka* 'cook'. Alsina (1992: 523–524) claims that this is precisely the difference between the two realisations in (85) and (86). In (85), the causative Patient is combined with the embedded verb's Agent, meaning the Causer's goal was to make the owl carry out the cooking; this sentence, but not (86), is therefore a possible answer to the question "What did the porcupine do to the owl?". In (86), however, the causative Patient is fused with the embedded verb's Patient, meaning the Causer merely intended for the pumpkins to get cooked, but did not especially care whether the owl did it; this sentence, but not (85), is therefore a possible answer to the question "What did the porcupine do to the pumpkins?".

The fact that an argument of the base predicate is the Patient of the causative morpheme itself has a number of effects. For instance, although the verb *phīka* 'cook' normally allows deletion of its object, in its causative form this is not possible, showing that in this respect the object behaves like an argument of the causative morpheme, rather than of the base predicate (Alsina 1992: 524–525):

(88) Kadzīdzi a-na-phík-a (maûngu).
1a.owl 1s-pst-cook-fv 6.pumpkins
'The owl cooked (the pumpkins).'

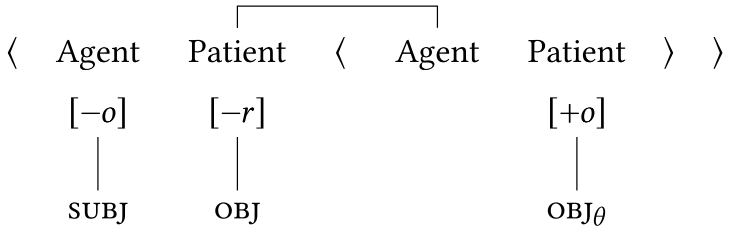
(89) Nǔngu	i-na-phík-îts-a	*(maûngu)	(kwá	kádzīdzi).
9.porcupine	9S-PST-cook-CAUS-FV	6.pumpkins	to	1a.owl

‘The porcupine had the pumpkins/something cooked (by the owl).’

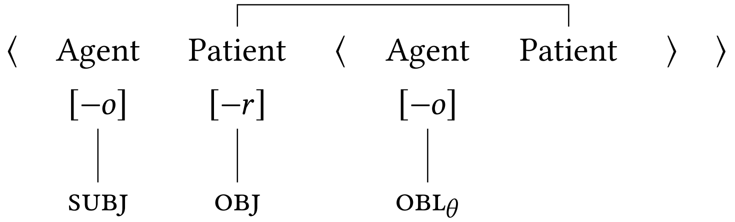
At the same time, the fused argument is also sensitive to its thematic role within the embedded predicate – for example, if it is an Agent in the base predicate it cannot be extracted (e.g. by relativisation), whereas if it is a Patient then it can (Alsina 1992: 529–530). This mixed behaviour motivates the idea that two argument positions are fused in the a-structure of these complex predicates.

The assumption of argument fusion also allows a straightforward Classical LMT account of the mapping possibilities open to causatives in Chichewa̐. The alternation between (85) and (86), for example, follows naturally if we assume that when two arguments fuse it is only the higher one which receives its intrinsic feature assignment:[27]

(90) a. *phikītsa* ‘cause to cook’



b. *phikītsa* ‘cause to cook’



When the causative Patient is fused with the embedded Agent, the embedded Patient is marked [+*o*] as a secondary patientlike argument (the higher Patient taking priority owing to its ranking in the a-structure). When it is fused with the embedded Patient instead, the embedded Agent now receives a [−*o*] specification, but since the higher Agent is leftmost in the a-structure, it will map to SUBJ, leaving this lower Agent to map to OBL$_\theta$ instead.

We can also see why the causatives of intransitives do not exhibit this same alternation – their Causee can only surface as an OBJ, never as an OBL$_\theta$:

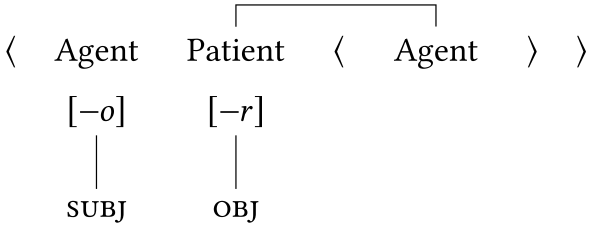
---

[27] We diverge somewhat from Alsina’s (1992) proposal here – albeit only in detail and not in spirit – in order to harmonise with the approach to mapping we introduced earlier.

(91) Chatsalĭra a-ku-nám-íts-á (* kwá) mwắina.
1.Chatsalira 1s-prs-lie-caus-fv to 1.child
‘Chatsalira is making the child tell lies.’

This follows naturally from the argument structure facts: since the embedded predicate only has a single argument, that will necessarily be the argument that fuses with the causative Patient, and so it is mapped to obj, not to obl$_\theta$:

(92) *namĭtsa* ‘cause to lie’



Chichewâ forms causatives morphologically, and so the processes of a-structure composition and argument fusion can be thought of as taking place in the lexicon. However, some complex predicates are made up of multiple words, and so their argument structures must be built in the syntax rather than in the lexicon. Butt (1995), studying Hindi-Urdu permissive and aspectual constructions, and Alsina (1996), studying Romance causatives, were among the first to make this observation. We will illustrate the phenomenon with Hindi-Urdu data.

In Hindi-Urdu, complex predicates can be formed from a combination of a main verb and a light verb. In the case of so-called permissive complex predicates, the light verb in question is *de* ‘let’, homophonous with the lexical verb meaning ‘give’ (Butt 1995: 35). As with the causative morpheme, the light verb contributes its own arguments, which are added to and overlap with the arguments of the main predicate. For example, in (93), *saddaf=ko* is at once the “lettee” argument of the light verb *diyaa* and the “maker” argument of *banaane* ‘make’ (other arguments belong to only one verb: *anjum=ne* is only an argument of *diyaa* – she is the the one giving permission – and *haar* ‘necklace’ is only an argument of *banaane* – it is the thing being made).

(93) anjum=ne saddaf=ko haar banaa-ne
Anjum.f=erg Saddaf.f=dat necklace.m.nom make-inf.obl
di-yaa.
give-perf.m.sg
‘Anjum let Saddaf make a necklace.’

The light verb and main predicate do not have to be adjacent or form a constituent at c-structure, so there is no sense in which they can be analysed as a single, morphologically complex word (Butt 1995: 46):

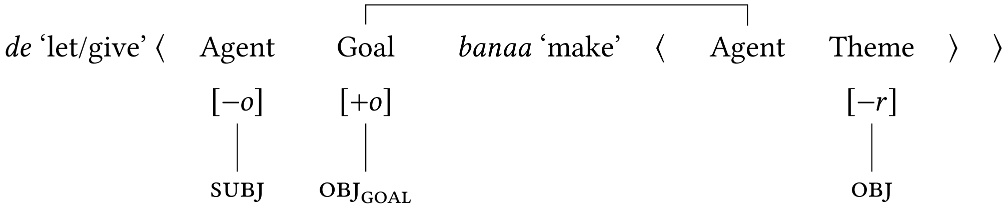
(94) a. anjum=ne saddaf=ko haar [**banaa-ne di-yaa**].
b. anjum=ne **di-yaa** saddaf=ko [haar **banaa-ne**].
c. anjum=ne [haar **banaa-ne**] saddaf=ko **di-yaa**.

Nevertheless, these sentences do not involve clausal embedding: with respect to agreement, anaphora, and control, they behave monoclausally (see Butt 1995: 36–43 for detailed evidence of this). That is, they have a flat f-structure, shown in (95):[28]

(95)
$$\begin{bmatrix} \textsc{pred} & \text{‘}\textsc{let-make}\langle\textsc{subj},\textsc{obj},\textsc{obj}_{\textsc{goal}}\rangle\text{’} \\ \textsc{subj} & \begin{bmatrix}\textsc{pred} & \text{‘Anjum’}\end{bmatrix} \\ \textsc{obj}_{\textsc{goal}} & \begin{bmatrix}\textsc{pred} & \text{‘Saddaf’}\end{bmatrix} \\ \textsc{obj} & \begin{bmatrix}\textsc{pred} & \text{‘}\textsc{necklace}\text{’}\end{bmatrix} \end{bmatrix}$$

This means the complex predicate must also have a single, composite a-structure:

(96)



But this a-structure cannot be the property of any one word in the lexicon, since it combines information from two words, and the light verb can freely combine with various predicates. What is more, complex predicates can be recursively embedded – Butt et al. (2010) give an example involving four levels of embedding, for instance:

(97) taaraa-ne amu-ko (bacce-se) haathii pinc kar-vaa
Tara-ERG Amu-DAT child.OBL-INS elephant.M.SG.NOM pinch do-CAUS
le-ne dii-yaa.
take-INF.OBL give-PRF.M.SG
‘Tara let Amu have the elephant pinched (by the child) (completely).’

---

[28] The question of how the composite PRED value emerges here is an unanswered one – see Lowe (2016: sec. 2) for a sceptical review, and see Asudeh & Rad (2023: sec. 4) for a technical solution.

The core meaning here is the noun-verb complex predicate made up of *pinc* ‘pinch’ and *kar* ‘do’. This is then embedded under a causative predicate, which is hosted morphologically on this same light verb. Then we have a “completive” light verb *le* (with the lexical meaning ‘take’). Finally, this whole complex is embedded under the permissive light verb *de*, which we saw above.

The conclusion such data must lead us to is that complex predicate formation is a productive, syntactic process, which means that we need to be able to combine a-structures on-line, outside of the lexicon. Apart from anything else, this means that the name “Lexical Mapping Theory” is a misnomer, since the theory must not apply only to individual words, but also to complex predicate-argument structures built up syntactically.

5 Kibort MT: incorporating morphosemantic alternations

We’ve now seen a sampling of the successes of and challenges for Classical LMT. In this section, we turn to a rather different view of LMT, that developed by Kibort over a series of papers (Kibort 2001, 2007, 2008, 2009, 2013, 2014, Kibort & Maling 2015), which purports to improve on Classical LMT in a number of respects, not least of which being its ability to handle morphosemantic alternations. We will refer to this theory as Kibort MT.

As we saw in Section 4.1.2, the dative shift alternation poses a challenge for Classical LMT, in that the theory must assume two distinct initial assignments of features to arguments in order to be able to derive the two alternants. Other morphosemantic alternations are even more challenging. Consider again the *spray/load* alternation (Levin 1993: 50–51), illustrated in (98):

(98) a. Adam sprayed the paint on the wall.
 b. Adam sprayed the wall with the paint.

This is morphosemantic insofar as the entailments of the alternants differ: in each case, the participant corresponding to the obj is completely affected – i.e. in (98a) the paint is fully used up, while in (98b) the wall is totally covered. Once again, both alternants involve the same thematic roles, and so the basic Classical LMT a-structure will be the same for both:

(99) *spray* ⟨ Agent Goal Theme ⟩

We would expect the Theme, being patientlike, to be assigned [$-r$], and the other arguments to receive the default [$-o$] assignment; this correctly produces the alternant in (98a), where the Theme surfaces as obj, and the Goal as an obl$_\theta$:

(100)	*spray*	⟨	Agent	Goal	Theme	⟩
			[−*o*]	[−*o*]	[−*r*]	
			SUBJ	OBL$_\theta$	OBJ	

Producing the other alternant, in (98b), is much more difficult, however. Compared to (98a), we need the Goal and Theme to switch GFs: the former now surfaces as an OBJ, and the latter as an OBL$_\theta$. We could try the same trick as we did for ditransitive *give*, and say that the Goal argument counts as patientlike: this will allow us to classify it as [−*r*], so that it can map to OBJ. But now the Theme will receive a [+*o*] assignment as a secondary patientlike argument, which is incompatible with the [−*o*] GF OBL$_\theta$. Indeed, patientlike arguments can only be classified as [−*r*] or [+*o*] by the intrinsic assignments in (34), which is precisely the opposite of what is needed to be compatible with the [+*r*, −*o*] specification of OBL$_\theta$.

In Kibort's view, the problem arises because Classical LMT conflates syntactic arguments and semantic participants, representing both simultaneously in the list of arguments-*cum*-thematic roles. She proposes therefore to expand the domain of a-structure and mapping theory to include not only ARGUMENT-FUNCTION MAPPING, i.e. what we have been considering as the domain of mapping theory up to now, but also ARGUMENT-PARTICIPANT MAPPING.[29] This is illustrated in Figure 1, representing the typical active voice realisation of the Polish double object verb *dać* 'give' (cf. Kibort 2014: 265).[30]

semantic participants	Agent	Theme	Recipient	SEMANTIC VALENCY
arguments of the predicate	⟨ arg$_1$	arg$_2$	arg$_3$ ⟩	LEXICAL VALENCY
grammatical functions	SUBJ	OBJ	OBJ$_\theta$	FUNCTIONAL SUBCATEGORISATION

Figure 1: The separation of levels in Kibort MT

Before providing the Kibort MT solution to the *spray/load* puzzle, we first introduce the theory in more detail.

---

[29] In other works by Kibort, these are referred to as "argument-**to**-function/participant mapping", but since the connections are intended to be bidirectional, we omit the preposition here to minimise the procedural implications.

[30] As Kibort (2007: 252) points out, separating argument positions from semantic participants in fact goes back to early LFG work (such as Bresnan 1982), and has been argued for by others such as Grimshaw (1988: 1), Mohanan (1990), Ackerman (1991: 12, 1992: 57ff), Mohanan (1994: 15ff), Joshi (1993), Alsina (1996: 37), Falk (2001b: 105), and Ackerman & Moore (2013: 40ff).

Kibort retains the Classical LMT mapping features [±*r*] and [±*o*], but, in keeping with the separation of syntax and semantics shown in Figure 1, she reinterprets them in purely syntactic terms, according to two traditional classifications of verbal dependents (Kibort 2014: 266):[31]

(101)	[−*o*]	non-complements	(the "external" argument and oblique arguments)
	[+*o*]	complements	("internal arguments" of the predicate)
	[−*r*]	core arguments	(subject and object only)
	[+*r*]	non-core arguments	(all arguments except subject and object)

These features are associated with positions in a universally available lexical valency frame, from which predicates select a subset of argument positions:

(102)
$$\langle \begin{array}{cccccc} \text{arg}_1 & \text{arg}_2 & \text{arg}_3 & \ldots & \text{arg}_4 & \ldots \\ [-o]/[-r] & [-r] & [+o] & [+o] & [-o] & [-o] \end{array} \rangle$$

The ordering and feature assignment in (102) is based on the standard LFG Functional Hierarchy, repeated in (103):

(103) *The Functional Hierarchy:*
SUBJ > OBJ > OBJ$_\theta$ (> XCOMP, COMP) > OBL$_\theta$ (> XADJ, ADJ) .

The first position in (102), called mnemonically arg$_1$, corresponds to the canonical subject, and is associated with one of the two features which describe the SUBJ function (it is marked [−*o*] in unergative predicates, emphasising its non-complement status, and [−*r*] in unaccusative ones, emphasising its core status).[32] The second position, arg$_2$, corresponds to the canonical direct object, and is marked [−*r*] (core). The next position, arg$_3$, corresponds to the restricted object, and is marked [+*o*] (complement). Lastly, arg$_4$, corresponds to a canonical oblique argument, and is marked [−*o*] (non-complement). Predicates can select any number of arguments from this frame, but, as indicated, they can only choose one arg$_1$ and arg$_2$, though they can select multiple arg$_3$s and arg$_4$s – this corresponds to the fact that a predicate can subcategorise for only a single SUBJ and

---

[31] At least two other LFG linguists have proposed LMT feature sets which make no reference to semantic/thematic restrictions: Alsina (1996) and Hemmings (2012).

[32] Although the unergative/unaccusative distinction was originally applied only to intransitive predicates (Perlmutter 1978), subsequent work has extended it to predicates of all valencies: see Kibort (2004: 74–75) for discussion, and cf. the Dutch experiencer verbs discussed in Section 4.2.2, which exhibited the same syntactic split as intransitive unergatives/unaccusatives.

obj, whereas multiple obj_θs and obl_θs are permitted, being individuated by their subscripts (e.g. $\text{obj}_{\text{THEME}}$ vs. obj_{BEN}).[33]

What we have considered as mapping so far in this chapter corresponds to "argument-function mapping" in Kibort MT, i.e. the linking of argument positions and GFs. As in Classical LMT, arguments in Kibort MT are associated with a feature specification that makes them compatible with two different GFs, and mapping therefore consists in determining which of the two (if either) will realise the argument syntactically. Kibort MT diverges from Classical LMT, however, in only having a single Mapping Principle (Kibort 2014: 267; cf. Her 2013):

(104) *Mapping Principle (Kibort MT):*
The ordered arguments are mapped in turn onto the highest (i.e. *least* marked) compatible grammatical function on the Markedness Hierarchy.

This inverts Mapping Principle (b) of Classical LMT, which maps arguments to the lowest, i.e. *most* marked, compatible GF, and in so doing removes the need for Mapping Principle (a), along with the Subject Condition, as we shall see. This is clearly a huge gain in parsimony, though it is not without cost, as we discuss below.

By way of illustration, consider again the simple transitive (and unergative) verb *kick*. This has the following Kibort MT a-structure:

(105) $\textit{kick} \; \langle \begin{array}{cc} \text{arg}_1 & \text{arg}_2 \\ [-o] & [-r] \end{array} \rangle$

By the Mapping Principle, we first map the highest argument, arg_1, onto the highest compatible GF: in this case, the highest $[-o]$ GF is subj, so this is what we choose. Next, arg_2 is mapped onto the highest $[-r]$ GF available: since subj is already taken, this is obj.[34] Note that despite the procedural talk here and in the Mapping Principle itself (arguments are mapped "in turn"), this process is intended to be understood declaratively. It can be seen as optimising the alignment between two hierarchies: are the highest arguments linked to the highest

---

[33] While these functions are often indexed by thematic roles, this can be understood purely for distinctiveness, having no semantic content: instead of $\text{obj}_{\text{THEME}}$ and obj_{BEN} we could use other mnemonic labels such as cases (e.g. obj_{ACC} vs. obj_{DAT}, etc.) or preposition names (e.g. obl_{TO} vs. obl_{ON}, etc.), or purely arbitrary labels such as obj_1 and obj_2. Thus, the retention of the GFs obj_θ and obl_θ does not diminish the syntactically-motivated characterisation of GFs in Kibort MT.

[34] Function-Argument Biuniqueness still applies in Kibort MT, although it may not be necessary to stipulate it as a separate principle – see fn. 19.

GFs? This can then be solved using various constraint-based tools such as those of Optimality Theory (Prince & Smolensky 1993, 2004; cf. also Asudeh 2001 for an application of OT to mapping in an LFG context).

Morphosyntactic argument alternations interfere with the default argument-function mapping. As in Classical LMT, this is achieved monotonically, by further specifying the mapping possibility of an argument. However, Kibort MT goes even further in this respect, eschewing the use of suppression altogether, and thus sidestepping the issues mentioned in fn. 22. For instance, Kibort (2001: 170) treats passivisation as a further specification of arg$_1$ as [+*r*], illustrated in (106) for passive *kicked* (cf. (50) above):

(106)

$$\textit{kicked}_{\text{PASSIVE}} \quad \langle \begin{array}{ll} \text{arg}_1 & \text{arg}_2 \\ [-o] & [-r] \\ [+r] & \end{array} \rangle$$

The argument which by default would map to SUBJ is instead fully specified as an OBL$_\theta$, and, as a result, the arg$_2$, if there is one, becomes the SUBJ. Note that this gives the correct result for the English long passive, where the Agent is expressed as an oblique *by*-phrase, but in the short passive the Agent is not expressed grammatically at all. Kibort (e.g. 2004: 29) refers to such obliques as "optional", but it is not clear what determines this – it cannot be the case that OBL$_\theta$s are always optional, for instance, since there are certainly cases of obligatory obliques, as in *I gave the book *(to my friend).*

In general, morphosyntactic operations are assumed to involve making arguments more marked, by adding additional +-valued specifications:

(107)
a. adding the [+*r*] specification to a [−*o*] argument
(e.g. passivisation)
b. adding the [+*r*] specification to a [+*o*] argument
(e.g. secondary object preservation – Kibort 2007: 268)
c. adding the [+*o*] specification to a [−*r*] argument
(e.g. locative inversion – Kibort 2004: 364–367)

One thing to note about argument-function mapping in Kibort MT is that the Subject Condition of Classical LMT is absent. The motivation for this is that genuinely subjectless predicates are quite common in the world's languages (see Kibort 2006 and Lowe et al. 2021 for discussion). For instance, Polish intransitives can be passivised, resulting in a subjectless sentence (Kibort 2006: 304–307):

(108) Było codziennie sprzątane (przez firmę).
was.3SG.N every-day clean.PART.SG.N (by company)
'There was cleaning every day (by a company).'

This follows quite naturally in Kibort MT, where the verb will have the following a-structure, resulting in the first and only argument being mapped to OBL$_\theta$, rather than SUBJ:

(109)
$$\textit{sprzątać}_{\text{PASSIVE}} \quad \langle \begin{array}{c} \text{arg}_1 \\ [-o] \\ [+r] \end{array} \rangle$$

The strong cross-linguistic preference for subjects is captured in the Mapping Principle: since arguments are mapped to the highest available GF on the Markedness Hierarchy, and since SUBJ is at the top of that hierarchy, SUBJ will always be the most preferred GF, meaning *something* will usually map to it. But by making this a strong preference rather than a principle of the grammar, Kibort MT also allows for the possibility of subjectless predicates in marked circumstances – such as the passivisation of an intransitive.

One negative side effect of this choice, however, is that Kibort MT apparently makes the wrong predictions about the passive of double object verbs. As mentioned above in Section 4.1.3, when a double object verb is passivised, and so the primary object is promoted to SUBJ, it is apparently *not* the case that the secondary object is promoted to primary object – but this is exactly what Kibort MT predicts should happen, since the [+*o*]-valued arg$_3$ of a secondary object argument is compatible with OBJ, and OBJ is less marked than OBJ$_\theta$ (though see Kibort 2008).

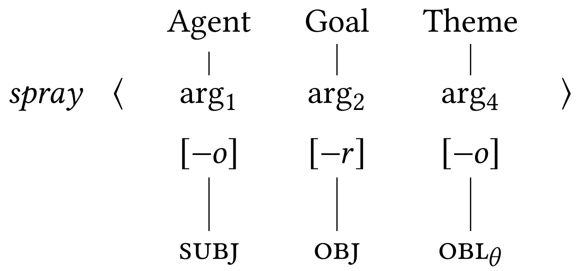
The Kibort MT approach to argument-function mapping offers a different perspective from Classical LMT, and perhaps represents an advancement in certain areas, in particular with respect to theoretical parsimony. However, the real advantage of the theory is in the fact that argument-*participant* mapping can interact in interesting ways with argument-function mapping. Let us return now to the question of the *spray/load* alternation. The verb *spray* in this sense will have the following a-structure and argument-function mappings:

(110)
$$\textit{spray} \quad \langle \begin{array}{ccc} \text{arg}_1 & \text{arg}_2 & \text{arg}_4 \\ [-o] & [-r] & [-o] \\ | & | & | \\ \text{SUBJ} & \text{OBJ} & \text{OBL}_\theta \end{array} \rangle$$

In fact, these GFs are the same ones which appear in both alternants – the only difference is which participants map to which GFs. Because Kibort MT posits a separate level of semantic participants, the mapping between those participants and the argument positions – and so, indirectly, the GFs – can be allowed to vary.

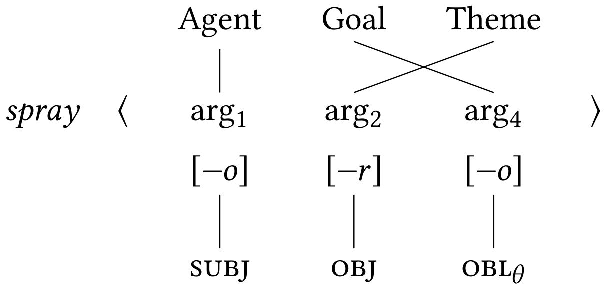
(111) a. Adam sprayed the wall with the paint.

b.



(112) a. Adam sprayed the paint on the wall.

b.



Although for a human reader it may be easier to track the re-aligned participants in diagrams like (111b) and (112b) if they are represented by thematic role labels, Kibort MT takes the criticisms of thematic roles mentioned in Section 2.1 to heart, and so they play no role in the theory. Furthermore, Kibort (2014) argues that neither Dowty-style proto-roles nor feature decomposition attempts are adequate either. In the absence of an adequate and complete representation of lexical knowledge, Kibort MT instead adopts a very minimal representation of semantic participants. In this system, semantic participants are labelled by numbers which identify which arg positions they can map to (Kibort 2014: 275ff.). For example, the a-structure of *spray* would be augmented as follows:

(113)
$$\begin{array}{lccccc} & & 1 & 24_{\text{TH}} & 24_{\text{GO}} & \\ \textit{spray} & \langle & \text{arg}_1 & \text{arg}_2 & \text{arg}_4 & \rangle \\ & & [-o] & [-r] & [-o] & \end{array}$$

The first semantic participant is labelled 1 since it can only be linked to the arg_1 position, but the other two are labelled 24 since they can be linked to either the arg_2 or the arg_4 position. The subscripts on the semantic participants are purely for distinctness, to individuate the two participants with identical labels, and have no semantic content.

Argument-participant mapping has no principles beyond stating that participants with label *n* can be linked to argument $\arg_n$; arguments whose labels contain multiple numbers, like the Theme and Goal in (113), are assumed to bear multiple labels, i.e. each of the Theme and Goal in (113) simultaneously has the label 2 and the label 4. In cases where multiple mappings are possible, Kibort MT predicts that neither is more basic than the other, since there is no preference ranking encoded in the argument-participant mapping. This is certainly right for the *spray/load* alternation, since there does not seem any reason to assume that one alternant is derived from the other or that one is more basic than the other, especially given that this alternation is unmarked in English (i.e. there is no morphological or syntactic marker in either version).[35]

Kibort MT thus draws a clear formal distinction between morphosyntactic (meaning-preserving) and morphosemantic (meaning-altering) alternations: the former affect the argument-function mapping, using techniques very similar to those of Classical LMT; the latter affect the argument-participant mapping, something made possible by separating out these two levels of representation.

In sum, Kibort MT offers a mapping theory that on the one hand simplifies, and on the other hand elaborates on Classical LMT. It is simpler in that there is a universal valency frame, a single Mapping Principle, and no mention of thematic roles, but it is more complex in that it separates out the notion of argument from semantic participant. This does, however, offer the possibility of straightforwardly representing the effects of meaning-altering, morphosemantic alternations, something that was not always possible in Classical LMT.

6 Formal issues and recent developments

Aside from Kibort's focus on expanding the empirical coverage of LMT, another major thread in contemporary work on argument structure and mapping theory has been an increased interest in questions of formalisation. In this section, we address three areas in this vein: the formal status of a-structure, the nature of mapping, and the integration of mapping theory and compositional semantics.

---

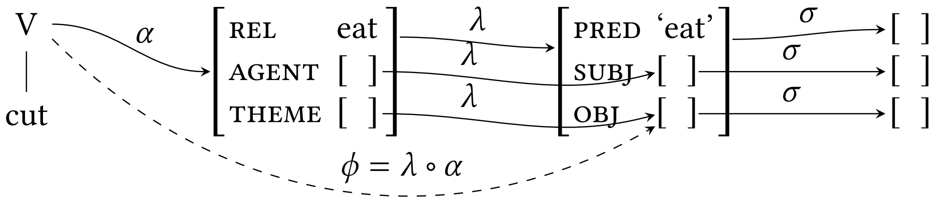
[35] It may be possible to argue that one of the variants is more basic on non-linguistic grounds, e.g. by reference to the relative prominence of cognitive concepts like Figure and Ground (Talmy 1978; see also Schätzle 2018 for an implementation of these concepts within LFG's mapping theory), but a strength of Kibort MT is that such a move is not *necessary*, even if it may sometimes be independently motivated.

6.1 The position and nature of a-structure

In Kibort MT, Classical LMT, and earlier work, the position of argument structure in the architecture of the grammar is left vague or unmentioned. Sometimes, it is (implicitly) assumed to be situated inside f-structure, as (part of) the value of PRED, but otherwise the question does not arise.

Butt et al. (1997: 1) are the first to address this formal deficiency head on, and propose that argument structure forms its own level of representation, a-structure, situated in the LFG projection architecture between c-structure and f-structure:

(114)



(Butt et al. 1997: 1, their ex. (1))

This positioning is motivated by the complex predicate facts discussed in Section 4.2.4. Since complex a-structures can correspond to simplex (monoclausal) f-structures, and since the projection functions, as functions, can be many-to-one but not one-to-many, a-structure must be mapped to f-structure, and not vice versa. On the other hand, since complex a-structures can be built from discontinuous pieces in the syntax, and are not necessarily generated in the lexicon, a-structure must be positioned after c-structure, so that information can be passed from the latter to the former.

One immediate effect of this positioning is to break up the traditional ϕ mapping from c- to f-structure: it is now the composition of two functions, the α function from c- to a-structure, and the λ function from a- to f-structure, i.e. $\lambda \circ \alpha$.[36] Some have seen this as undesirable: for example, Asudeh & Giorgolo (2012) propose a change to the architecture (to be discussed shortly), one of the effects of which is to restore ϕ to its atomic status, and they claim this as an advantage of their proposal (Asudeh & Giorgolo 2012: 71) – but if this is an advantage, we do not see how it can be anything other than an aesthetic one.

Unlike in most earlier approaches, for Butt et al. (1997), a-structures are not simply lists of arguments, but are instead AVMs. This allows for a richer internal structure: for example, complex predicates have nested a-structures (Butt et al.

---

[36] Butt et al. (1997: 1) identify ϕ with $\alpha \circ \lambda$ (rather than $\lambda \circ \alpha$), but this must be an error, since α has to be applied before λ, given their architecture.

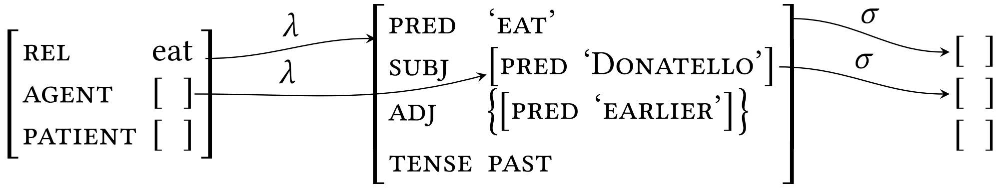
1997: 12). Each a-structure contains a REL attribute that names the semantic relation it encodes, and attributes labelled with thematic role names corresponding to argument positions. Nothing further is said about the value of these attributes, and they are represented as empty AVMs in Butt et al. (1997). These must be shorthand for more complete structures, however, since otherwise, under a standard set-theoretic interpretation of AVMs, all the "empty" AVMs would in fact be one and the same.[37]

Asudeh & Giorgolo (2012) criticise Butt et al.'s (1997) architecture and propose an alternative which has since proven influential. They do so on the basis of verbs which take optional objects, like *eat* in English:

(115) a. Donatello ate a pizza earlier.
b. Donatello ate earlier.

Although the Patient argument does not need to be expressed in the syntax, it must still be present in the a-structure, since it remains part of the core relation expressed by the verb (eating events involve something being eaten), and must also be represented at s-structure, since it is interpreted semantically: the truth of *Donatello ate* implies the truth of *Donatello ate something*. This poses a problem for the Butt et al. (1997) architecture, since there is no route through the projection architecture from the a-structure PATIENT to its corresponding s-structure without going via its f-structure representation, and it appears not to have one:

(116)



One might therefore be tempted to posit an unpronounced OBJ attribute at f-structure corresponding to the Patient, but there is empirical evidence against this (Asudeh & Giorgolo 2012: 71). For example, this putative null pronoun cannot antecede another, subsequent pronoun:

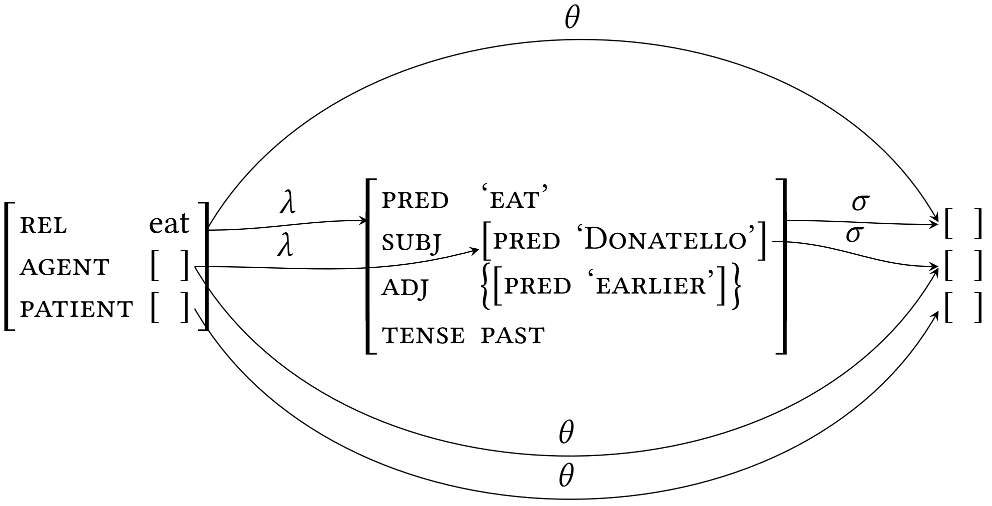
(117) a. Donatello ate a pizza, but it turned out to be Raphael's.
b. * Donatello ate, but it turned out to be Raphael's.

---

[37] For discussion of a similar problem, this time with regard to s-structure, see Findlay (2021: 348–353).

Given this, we are forced to propose a new function which projects directly from a-structure to s-structure (i.e. it is not simply the composition of σ and λ); Asudeh & Giorgolo (2012: 70) call this the θ projection. (118) shows this new situation.

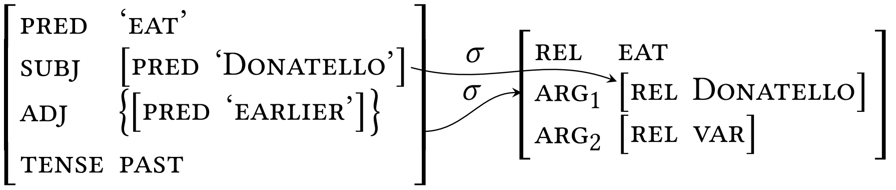
(118)



This move adds formal complexity to the grammar (a whole new projection function) and also adds indeterminacy: when an element of a-structure *is* expressed at f-structure, there are now two ways of reaching its s-structure – one via $\sigma \circ \lambda$ and one via θ directly. Even if this solves the problem of unexpressed arguments, it is a formally unhappy scenario to be forced into.

Asudeh & Giorgolo's (2012) solution is to do away with a-structure as a separate level of representation, and to replace it with a new, connected version of s-structure – that is, rather than the s-structures for the arguments being separate from the s-structure for the clause (and from each other), they are instead embedded inside it. This makes this new conception of s-structure very similar to Butt et al.'s (1997) a-structures. An example is shown in (119):

(119)



Ultimately, it is a fairly arbitrary choice whether we call this new connected structure s-structure or a-structure. Asudeh & Giorgolo (2012) call it s-structure since they continue to use it as part of the linear logic component of Glue Semantics meaning constructors, but it has a lot in common with Butt et al.'s (1997) a-structure as well, being internally structured/connected and expressing the predicate-argument structure of the clause. What is more, later developments have sought to imbue this new structure with additional information about tense, aspect, and event structure (see e.g. Lowe 2014, Lovestrand 2018, 2020, Findlay 2021), thereby incorporating some information which is also present in Butt's (1995) "elaborated" a-structures (on which see below). For consistency with other work, however, we will continue to call these s-structures here.

The exact content of these s-structures is subject to ongoing research, but they are assumed to at least include a REL attribute identifying the semantic relation expressed (cf. Asudeh et al. 2013: 24), and potentially several numbered ARG attributes, e.g. ARG_1, ARG_2, for each of that relation's arguments. Asudeh & Giorgolo (2012) use REL only for predicates, and leave argument s-structures as "empty" AVMs, just like Butt et al. (1997). Lovestrand (2018: ch. 8.3) and Findlay (2020: 135f.), however, generalise the presence of REL to argument as well as predicate s-structures, and Findlay (2020: 144) proposes to use "var" as the REL value for unexpressed/suppressed arguments.

The numbered ARG attributes are used instead of Butt et al.'s (1997) thematic role labels in part because Asudeh & Giorgolo (2012) make use of a neo-Davidsonian meaning language (Parsons 1990) such that thematic role information is expressed directly in the semantics – i.e. instead of (120a), the meaning of *eat* is expressed by (120b) – and so it would be redundant to also encode this information in s-structure.

(120) a. $\lambda x \lambda y \lambda e.\mathbf{eat}(e, x, y)$
b. $\lambda x \lambda y \lambda e.\mathbf{eat}(e) \wedge \mathbf{agent}(e, x) \wedge \mathbf{theme}(e, y)$

This has the additional benefit of relegating thematic roles to the meaning language rather than making them part of the meta-language of the grammar itself. There they can be treated as abbreviations for whatever sets of semantic entailments we take them to encode (*à la* Dowty 1991), with whatever level of granularity is required, leaving the grammar itself free of the nebulous notion of thematic role.

The significance, or lack thereof, of the ARG labels has been the subject of disagreement, however. They were originally intended as arbitrary labels merely to achieve distinctness at s-structure, but Findlay (2016) imbues them with meaning, identifying them with the numbered arg positions of Kibort MT (see Section 5), as part of an implementation of that theory within the new architecture. This view has been adopted by others (e.g. Asudeh et al. 2014, Lowe 2016, Lovestrand 2018, 2020), but Findlay (2020) argues for a return to the *status quo ante*, where these labels have no significance in and of themselves, and shows that the same implementation of Kibort MT can be achieved while avoiding reifying the s-structure attribute names.

The title of Findlay (2016) is "Mapping theory without argument structure", but this is in many respects a mischaracterisation of the research programme inspired by Asudeh & Giorgolo's (2012) architectural proposal. Rather than doing away with argument structure, this work has served more as a rationalisation of the LFG architecture: instead of having two levels, a-structure and s-structure, the latter of which is rather informationally impoverished, we have a single level of representation which shares properties of both.[38]

As mentioned above, some researchers have imbued this new structure with additional information about lexical semantics and event structure (e.g. Lowe 2014, Lovestrand 2018). But suggestions to add this kind of information to a-structure are not new. Butt (1995) develops what she calls an ELABORATED A-STRUCTURE (Butt 1995: 133), which includes much more structure and much more semantic information than Classical LMT's minimalist a-structures. This elaborated a-structure is based on Jackendoff's (1990) LEXICAL CONCEPTUAL STRUCTURES (LCSs), but only includes the concepts relevant to linking and semantic case marking (Butt 1995: 143). An example of the elaborated a-structure for the Urdu main verb *de* 'give' is shown in (121):

(121)
$$\left[\begin{array}{l} \text{de `give'} \\ \left[\begin{array}{l} \text{CS}([\alpha], \text{GO}_{Poss}([\ \ ], \text{TO}[\ \ ])) \\ \text{AFF}([\ \ ]^{\alpha}, \ ) \\ \text{ASP}(\_\ \_\ \_) \end{array}\right]_{E} \end{array}\right]$$

The inner box is the actual a-structure, and contains three levels. The first two are borrowed from Jackendoff's LCSs: the THEMATIC TIER and the ACTION TIER.

---

[38] The observant reader may be entertaining an architectural concern at this point: earlier, we motivated the Butt et al. (1997) architecture by drawing on the facts of complex predicates: a complex a-structure can correspond to a simplex (monoclausal) f-structure, and so we need the former to precede the latter in the projection architecture in order to retain the functional nature of the projection relations. However, in the new architecture, the connected s-structure which represents predicate-argument structure comes after f-structure, so we appear to be in trouble. Two solutions to this puzzle have been proposed. Lowe (2016) gives the first analysis of complex predicates in this new framework, and argues that they should be given a flat s-structure (in contrast to the articulated a-structures usually assumed), representing their complexity in the meaning language instead. This avoids any problems arising from having a flat f-structure, since it is no longer required to subsequently project a more articulated s-structure. Alternatively, Lovestrand (2020) proposes to give complex predicates articulated f-structures after all, which means a complex s-structure is also possible without losing the functional nature of σ. There are empirical shortcomings with both of these approaches, but they fare no worse than existing, alternative approaches, and serve to illustrate how the apparent monoclausality of complex predicates does not force us to assume an articulated a-structure which precedes f-structure in the projection architecture.

The former, the Thematic Tier, describes the lexical meaning of the verb in decompositional terms – here that one entity *causes* (CS) *possession* of another to *go* (GO_{Poss}) *to* a third entity (TO). The latter, the Action Tier, describes the relationship between Actor, Patient, and Beneficiary roles – in other words those roles which usually receive structural case. As Butt (1995: 137) points out, it can also be thought of as encoding an analogue of Dowty's (1991) proto-roles. Here the argument labelled α, i.e. the "giver" (the one causing the transfer of possession) is indicated to be *affecting* (AFF) something else. The second slot of the function AFF is left empty, indicating that there is no true Patient or Beneficiary here (Butt treats the recipient as a simple Goal instead of a Beneficiary). There are also subtypes of the AFF function which provide information about volitionality or conscious choice.

The final tier is the Aspect Tier. This is not borrowed from Jackendovian LCSs, but is an innovation by Butt. It represents aspectual information: specifically, whether a verb is positively or negatively specified for inception, duration, and/or completion (Butt 1995: 142). The function ASP contains three slots, one for each of these properties, and each can be specified positively, with a '1', negatively, with a '0', or left unspecified, indicated by a '_'. In (121), all three slots are empty, showing that this verb is unspecified for this aspectual information.

Clearly, this conception of argument structure is far more complex than the ordered lists used in Classical LMT, and more informationally rich than either of the structures discussed already in this section.[39] Butt argues that this complexity is motivated by its capacity to offer an elegant account of complex predicates. For one thing, the elaborated a-structures expose more lexical semantic content to the grammar, enabling appropriately fine-grained constraints to be placed on complex predicate formation (see e.g. Butt 1995: 147–155 for examples). For another, they add articulation and structure, and, as we saw in Section 4.2.4, the proper treatment of complex predicates necessitates assuming a more articulated a-structure than is standard in Classical LMT – at least one capable of recursive embedding.

On Butt's (1995) approach, the light verbs which are used in complex predicates have a-structures which themselves have argument slots for *other a-struc-*

---

[39] Indeed, one reviewer suggests that the level of representation proposed by Butt (1995) is not argument structure at all, but rather some kind of "event structure" or "semantic structure". To the extent that the additional information is necessary to handle argument structure phenomena like complex predicate formation, and given that these structures also do everything else we would want from an argument structure (see e.g. Butt 1995: ch. 6 on mapping), it is hard to know what to make of this complaint. Perhaps a more minimal a-structure would in fact be sufficient, but if so that is a matter to be demonstrated empirically, rather than settled by definitional fiat.

tures, labelled as transparent events (E_T), since the light verbs that host them can "see into" their internal structure. This visibility allows different kinds of argument fusion to take place, whereby participants of the embedded event are identified with participants of the event described by the light verb (as discussed in Section 4.2.4). We omit the full details here – see Butt (1995: ch. 5) for more information. By way of illustration, the a-structure for the Urdu permissive light verb *de-* 'let' is given in (122) (Butt 1995: 156):

(122)
$$\left[\begin{array}{l} \text{de- `let'} \\ \left[\begin{array}{l} \text{CS}([\alpha], \text{GO}_{Poss}(\{\ \ \}_{E_T}, \text{TO}[\ \ ])) \\ \text{AFF}([\ \ ]^{\alpha},\ ) \\ \text{ASP}(\_\ \_\ \_) \end{array}\right]_{E} \end{array}\right]$$

This is very similar to the a-structure in (121), the only difference being that the first argument of GO_{Poss} has been replaced by a transparent event (indicated by the curly braces and subscript E_T). The "letting" event expressed by this light verb is viewed metaphorically as a transfer event, where the thing transferred is the permitted event. This gives some explanation to the fact that both verbs share the same form in Urdu, for example, and shows how the embedded verb contributes to the overall interpretation of the complex predicate. It also allows for the recursive construction of complex predicates which are embedded under more than one light verb.[40]

A more contemporary approach to expanding the coverage of a-structure, but without assuming the Asudeh & Giorgolo (2012) architecture, is that of Schätzle (2018: ch. 6). She assumes a richly multidimensional version of Kibort MT's a-structure, where each argument can be annotated with a variety of non-standard semantic information, such as whether it is a Figure or Ground (Talmy 1978), and which kind of event participant it is in the typology of Ramchand's (2008) first-phase syntax. This, Schätzle (2018: 202) claims, enables a more "semantically realistic" account of mapping and of argument alternations, a goal shared by other recent work – see Section 6.3.

---

[40] Other work on complex predicates and LMT, including Butt's own later work, has tended to eschew these more complex a-structures in favour of the simpler, ordered list representations of Classical MT (e.g. Alsina 1996, 1997, Butt 2014). But this leads to enormous difficulty in appropriately formalising the process of predicate fusion: see Lowe (2016: sec. 2) for critical discussion.

6.2 Mapping as co-description

The relationship between different levels of structure, such as a-structure and f-structure, has been approached in two different ways in LFG: CO-DESCRIPTION and DESCRIPTION BY ANALYSIS (Kaplan 1995, Dalrymple et al. 2019: 267–270). In co-description, multiple levels of structure are described simultaneously – for example, LFG's annotated phrase-structure rules simultaneously describe both c-structure and f-structure. This is the most commonly used approach in LFG. The alternative, description by analysis, involves determining the description of one structure by inspecting and analysing another. This was used in early LFG proposals for semantic analysis (e.g. Halvorsen 1983). Findlay (2021: 344–345) discusses various shortcomings of the description by analysis approach: notably, it ignores the possibility of mismatches between levels, and fails to meet the desideratum of constraint-based grammars laid down by Pollard & Sag (1994: 13) that they be "process neutral": description by analysis inevitably introduces directionality into parsing, which co-description does not. Co-description therefore "most directly captures the spirit of the constraint-based approach to linguistic analysis" (Findlay 2021: 344), which may explain why it has come to dominate in LFG analyses – indeed, while description by analysis was prominent in early accounts of semantics in LFG, those approaches have since been replaced by Glue Semantics (Dalrymple, Lamping & Saraswat 1993, Dalrymple 1999, Asudeh 2022), which employs co-description.

Classical LMT, though, is very much in the spirit of description by analysis: GF assignments at f-structure are determined by inspecting a-structure, and by analysing it using the Mapping Principle(s). This state of affairs meant that LFG work on argument structure and mapping was out of sync with the theoretical mainstream, where co-description was the norm. Once again, Butt et al. (1997: 6) were the first to tackle this formal issue, treating mapping as co-description of both a- and f-structure.

For example, to say that a predicate's Agent argument is expressed as its SUBJ GF, we could include the following piece of functional description in its lexical entry (where $*$ refers to the c-structure node bearing the annotation, and $\hat{*}$ to its mother node):

(123) $(\hat{*}_{\alpha}\ \textsc{agent})_{\lambda} = (\hat{*}_{\alpha\lambda}\ \textsc{subj})$

The expression $\hat{*}_{\alpha}$ refers to the lexical item's a-structure, via the α projection from c- to a-structure, while the expression $\hat{*}_{\alpha\lambda}$ refers to the lexical item's f-structure (the equivalent of the more familiar ↑). This constraint therefore picks out the f-structure corresponding to the a-structure AGENT, and identifies it with the verb's f-structure SUBJ.

But, of course, we generally don't want to associate an argument with only a single GF. Instead, Classical LMT associates it with a feature which describes a *pair* of GFs. Butt et al. (1997: 6) make this disjunctive meaning of the features explicit: instead of associating an argument with a feature, a disjunction of mapping equations like (123) is given, as in (124) or (125):

(124) *AGENT links to* $[-o]$*:*
$(\hat{*}_{\alpha}\ \textsc{agent})_{\lambda} = (\hat{*}_{\alpha\lambda}\ \textsc{subj}) \vee$
$(\hat{*}_{\alpha}\ \textsc{agent})_{\lambda} = (\hat{*}_{\alpha\lambda}\ \textsc{obl}_{\textsc{agent}})$

(125) *THEME links to* $[-r] \vee [+o]$*:*
$(\hat{*}_{\alpha}\ \textsc{theme})_{\lambda} = (\hat{*}_{\alpha\lambda}\ \textsc{subj}) \vee$
$(\hat{*}_{\alpha}\ \textsc{theme})_{\lambda} = (\hat{*}_{\alpha\lambda}\ \textsc{obj}) \vee$
$(\hat{*}_{\alpha}\ \textsc{theme})_{\lambda} = (\hat{*}_{\alpha\lambda}\ \textsc{obj}_{\textsc{theme}})$

Butt et al. (1997: 6) suggest that these intrinsic specifications can be universal, like (124) for AGENTS and (125) for THEMES, or they can be parameterised on a language-by-language basis, as is the case for other roles like LOCATION, GOAL, or INSTRUMENT.

Of course, these specifications alone do not determine the final mapping. In fact, Butt et al. (1997: 6) propose an important theoretical break from Classical LMT in this respect:

> Our approach departs most radically from the LMT literature in that we do not assume that a-structure roles are deterministically and uniquely linked to grammatical functions via a set of default principles. Instead, we propose a set of preference constraints which impose an ordering on the available linking possibilities; the most preferred possibility or possibilities are chosen.

In essence, their approach rejects the mechanistic, rule-driven approach of Classical LMT, and instead proposes that there is a hierarchy of GFs, and that those mappings which realise more highly ranked GFs are preferred. The hierarchy they propose is as follows:[41]

(126) $\textsc{subj} > \textsc{obj} > \textsc{obl}_\theta, \textsc{obj}_\theta$

That is, SUBJ outranks OBJ, which in turn outranks $\textsc{obl}_\theta$ and $\textsc{obj}_\theta$, which have the same rank as each other. This means, for each argument, that it is preferable for it to be realised as a SUBJ, or, failing that, as an OBJ, or, lastly, as either an $\textsc{obl}_\theta$ or an $\textsc{obj}_\theta$. The argument will therefore be linked to the highest GF on this hierarchy with which it is compatible, given the disjunctive specifications provided in its intrinsic classification.[42] This gives us a much more dynamic system than in Classical LMT: there are no explicit Mapping Principles, and arguments simply compete for the highest available GFs. In a nod to Mapping Principle (a-i) of Classical LMT (see Section 4.1.2), Butt et al. (1997: 6) do include a preference for the SUBJ to be linked to the highest available argument on the thematic hierarchy, but crucially this is just a preference, and so is not inviolable.

The final mapping chosen is the one deemed "optimal" in terms of realising the highest number of the most highly ranked GFs, and in terms of satisfying any other preference constraints, such as the subject preference just mentioned (as well as not violating Function-Argument Biuniqueness or the Subject Condition). Butt et al. (1997: 7) use a numerical system to express the relative weightings of

---

[41] Butt et al. (1997: 7) claim that the hierarchy in (126) can be recast as a preference for negative-valued features in the classic $[\pm o/r]$ schema:

(i) a. $[-r] > [+r]$
    b. $[-o] > [+o]$

But the expressions in (i), which is their (15), do not match the authors' prose description, which only applies (i-b) within the $[-r]$ GFs. If we simply take (i) as expressing two independent preference rankings, we get the Markedness Hierarchy of Classical LMT (see Section 4.1.1):

(ii) $\textsc{subj} > \textsc{obj}, \textsc{obl}_\theta > \textsc{obj}_\theta$

Alternatively, if we see (i-a) as taking precedence over (i-b), then we obtain another ranking, this time a total ordering:

(iii) $\textsc{subj} > \textsc{obj} > \textsc{obl}_\theta > \textsc{obj}_\theta$

It is of course an empirical matter which of these rankings (if any) is correct.

[42] Just like Kibort MT's Mapping Principle (see Section 5), this reverses the Classical LMT mapping principle where GFs *lower* down the hierarchy are preferred. This means that Butt et al.'s (1997) proposal shares the weakness of Kibort MT that it makes the wrong prediction about the passives of ditransitives – see Section 4.1.3.

different GFs and of other constraints, but this is not a crucial component of the theory, and any appropriate means of ranking different solutions in terms of a set of preferences could be used – for example, the authors speculate (p. 7) that the proposal could be reformulated in terms of Optimality Theory (Prince & Smolensky 1993, 2004, *et seq.*).

By way of illustration, consider a simple transitive like *kick* again. For every argument, the most preferred GF is subj. But is each compatible with subj? According to the disjunctions in (124) and (125), assuming that the intrinsic classification for Theme also applies to Patients, subj is a possible realisation of both arguments. But we cannot map both to subj, or we fall foul of Function-Argument Biuniqueness, so we must decide which one to map to subj, and which to map to the next most highly ranked compatible GF. Since, following the thematic hierarchy, the Agent argument of *kick* outranks its Patient argument, the subject preference will be satisfied if we map the Agent to subj but not if we map the Patient to subj, so the former mapping is preferred; the next highest GF compatible with the Patient intrinsic specification is obj, and so we end up with the correct outcome whereby the Agent is linked to subj and the Patient to obj.

The theoretically most interesting consequence of the Butt et al. (1997) approach to mapping is that certain constructions may have more than one optimal linking. Butt et al. (1997: 8ff.) argue that this in fact characterises alternations which are motivated by semantic/pragmatic constraints (such as the dative shift) and not by morphosyntactic ones (such as the passive).[43] This offers a more natural account of the dative shift alternation than the Classical LMT analysis, which requires two different initial assignments of features to the arguments. In the Butt et al. (1997) framework, both realisations of the dative shift alternation in English are made available automatically, since they have equivalent preference rankings:

(127) [Garak] gave [the datarod] [to Sisko].
subj obj obl$_{\text{goal}}$

(128) [Garak] gave [Sisko] [the datarod].
subj obj obj$_{\text{theme}}$

---

[43] However, their distinction does not seem to perfectly match that between meaning-preserving (morphosyntactic) and meaning-altering (morphosemantic) alternations, since they consider the locative inversion to be grouped with the dative shift (as being explained by the presence of more than one optimal linking) and distinct from the passive, when the locative inversion is no more meaning altering than the passive (neither alternation affects truth-conditional semantics, but only alters the information structural prominence of its arguments).

Both involve a SUBJ (linked to the highest argument) and an OBJ, and since OBJ_θ and OBL_θ are equally ranked, the different realisations of the third argument make no odds when it comes to the relative weightings of the two mappings. Therefore both mappings are made available by the grammar, and the choice between them must be determined by other factors, such as lexical preference (the shifted variant is impossible with verbs of Latinate origin, for example) or semantic/pragmatic considerations (see Bresnan 2007 and Bresnan et al. 2007 for usage-based/probabilistic accounts of the alternation, and Goldberg 1995: ch. 6 on the special meanings associated with the double object construction in English).

Work which assumes the Asudeh & Giorgolo (2012) architecture also makes use of co-description to express mapping possibilities, although here the directionality is changed: we are mapping from f-structure to s-structure, rather than from a-structure to f-structure. The equivalent of (123), assuming ARG_1 corresponds to the Agent (see Section 6.3), is (129):

(129) $(\uparrow \text{SUBJ})_\sigma = (\uparrow_\sigma \text{ARG}_1)$

As in Butt et al. (1997), feature decomposition is replaced by explicit disjunctions over GFs. Findlay (2016: 299) uses abbreviations to describe the (supposedly) natural classes captured by the traditional features:

(130) a. $\text{MINUSO} \equiv \{\text{SUBJ}|\text{OBL}_\theta\}$
b. $\text{PLUSO} \equiv \{\text{OBJ}|\text{OBJ}_\theta\}$
c. $\text{MINUSR} \equiv \{\text{SUBJ}|\text{OBJ}\}$
d. $\text{PLUSR} \equiv \{\text{OBL}_\theta|\text{OBJ}_\theta\}$

This gives us (131) as the equivalent of (124):

(131) $(\uparrow \text{MINUSO})_\sigma = (\uparrow_\sigma \text{ARG}_1)$

In fact, since arguments may not be realised by any GF – for example, the Agent argument of a short passive – we also need a description which says that the argument in question does not correspond to any GF at f-structure. We achieve this by stating that the inverse of the σ mapping from f- to s-structure is empty when applied to that argument, as in (132):

(132) $(\uparrow_\sigma \text{ARG}_1)_{\sigma^{-1}} = \varnothing$

This says that the s-structure ARG_1 has no f-structure correspondent, i.e. that this argument is not realised syntactically.

Findlay (2016: 319, 321) proposes to use templates to abbreviate these mapping equations and make them more readable:[44]

(133) Map(D, A) $\equiv$ $(\uparrow \mathrm{D})_\sigma = (\uparrow_\sigma \mathrm{A})$

(134) NoMap(A) $\equiv$ $(\uparrow_\sigma \mathrm{A})_{\sigma^{-1}} = \varnothing$

The first of these, (133), says that the GF or disjunction of GFs D is mapped to the s-structure argument A, while (134) says that the s-structure argument A has no GF correspondent at f-structure.[45] These templates can then be combined, so that e.g. the correct expression to capture the mapping possibilities of an Agent assigned to ARG_1 is the following:

(135) $\{$@Map(minuso, ARG_1) | @NoMap(ARG_1)$\}$

That is, either this argument is mapped to one of the two minuso GFs (subj or OBL_θ), or it is not expressed syntactically at all.

Using disjunctions over GFs like minuso or plusr instead of assuming features like $[-o]$ and $[+r]$ sidesteps any formal issues arising from seeing GFs as decomposable into features (as discussed in Section 4.1.1), and simply represents the most significant empirical claim of the feature-based approach – that GFs can be grouped into natural classes (whether the $[\pm o/r]$ classification is the correct way of grouping them is orthogonal). It has been objected that this use of disjunctions makes the approach somehow more arbitrary or less well motivated than earlier incarnations of LMT, since we could just as easily have written a different set of disjunctions in (130). Such an objection is misplaced for two important reasons. Firstly, it purports to contrast the arbitrariness of the disjunctive approach with the theoretical motivation of the feature-decomposition approach. But this is only true to the extent that the features used in the latter have independent motivations. While a case could be made for $[\pm r]$ on these grounds (one could imagine an independent criterion for determining semantic restrictedness), as we mentioned in Section 4.1.1, this seems not to be the case for $[\pm o]$, which has no content other than identifying the two object functions obj and OBJ_θ, and whose definition is therefore circular. Given this situation, we take the use of the explicitly "arbitrary" mechanism of disjunction to in fact be an advantage

---

[44] On templates, see Dalrymple et al. (2004), Crouch et al. (2011), Asudeh et al. (2013) and Belyaev (2023a: §5.1 [this volume]).

[45] One problem with the NoMap template is that in the event an argument is not expressed syntactically, nothing will ensure its presence at s-structure. Findlay (2020: 135–136) argues therefore that existential constraints must accompany the introduction of each argument.

over the classical approach, since it wears its arbitrariness on its sleeve rather than concealing it behind a veneer of theoretical motivation.

Secondly, and much more significantly, such an objection misses the crucial distinction between formalism and theory. The formalism *itself* need not be expected to say anything about what natural groupings of GFs occur in the world's languages. Rather, the formalism gives us tools for making explicit claims about such things – and it is those claims which constitute the theory. As Pollard (1997: 9) puts it, "it is the theory that imposes the constraints, not the language in which the theory is expressed". So, although we could've written different disjunctions in (130), it is precisely in writing one set of expressions rather than another that we make a theoretical claim. This claim may turn out to be true or false, but if it is false, we would prefer to be able to use the same familiar tools to express a different, revised hypothesis, rather than have to throw away our tools entirely because they have been over-engineered to fit one particular view of reality. Once again, therefore, we see this property as being an advantage of the disjunctive approach. As an example, consider the objection by Alsina (1996: 29, fn. 9), noted in Section 4.1.1, that the traditional $[\pm o/r]$ features cannot be used to describe the natural class of terms, or direct GFs, i.e. SUBJ, OBJ, and OBJ$_\theta$. He instead proposes a different classification using the features [±subj/obl], where [−obl] describes the terms (Alsina 1996: 27–30). In the traditional view, this approach and the Classical LMT approach are simply incommensurable: they represent two different formalisms which contain different primitive elements. But in the view we are considering, both can be expresed in the *same* terms – compare (130) and (136) – thereby highlighting their status as competing theoretical claims rather than totally distinct formal approaches.

(136) a. MINUSSUBJ ≡ {OBJ|OBJ$_\theta$|OBL$_\theta$}
b. PLUSSUBJ ≡ SUBJ
c. MINUSOBL ≡ {SUBJ|OBJ|OBJ$_\theta$}
d. PLUSOBL ≡ OBL$_\theta$

It is an empirical matter which of these analyses is correct, and we should not generally expect the formalism to adjudicate on empirical matters. Rather, the theory which we develop in using that formalism is what we expect to align with the facts.

6.3 Connection to semantics

While the most influential research in Classical LMT was being conducted, there was no canonical theory of the syntax-semantics interface in LFG to appeal to. With the acceptance of Glue Semantics (Glue) into the LFG mainstream around the turn of the millennium, this changed.[46] One of the most important goals of recent work on mapping theory has therefore been to integrate the theory into a Glue-based analysis of the syntax-semantics interface. In particular, this strand of research assumes that Glue's concept of resource sensitivity (Asudeh 2012: ch. 5) subsumes the traditional LFG principles of Completeness and Coherence, so that pred features at f-structure no longer contain an argument list. That is, instead of (137a), we have (137b):[47]

(137) a. $\left[\textsc{pred}\ \text{`}\textsc{eat}\langle\textsc{subj}, \textsc{obj}\rangle\text{'}\right]$
b. $\left[\textsc{pred}\ \text{`}\textsc{eat}\text{'}\right]$

This creates greater flexibility when it comes to argument realisation, since one and the same pred value can correspond to different syntactic realisations of its arguments. In the previous conception, each argument array required a separate pred value (and therefore a separate lexical entry), since pred values cannot be manipulated in the syntax (cf. the principle of Direct Syntactic Encoding introduced in Section 3, and discussed further in Kaplan & Bresnan 1982, Bresnan et al. 2016: sec. 5.2, and Dalrymple et al. 2019: 329).

---

[46] Although Glue first appeared in the early '90s (Dalrymple, Lamping & Saraswat 1993), it was still not well established in the LFG community by the time much of the the work discussed in the earlier sections of this chapter was carried out. The first major collection of Glue work connected to LFG was Dalrymple (1999), and the theory later appeared in Dalrymple's (2001) handbook-style presentation of LFG, as well as the latest reference guide to LFG, Dalrymple et al. (2019: ch, 8.5). We cannot include an introduction to Glue Semantics in this chapter for reasons of space, but see the references just cited, along with Asudeh (2022) and Asudeh (2023) [this volume] for further information.

[47] The idea of using linear logic's resource sensitivity to account for Completeness and Coherence goes back to the very first Glue paper (Dalrymple, Lamping & Saraswat 1993), and was noted again by Dalrymple et al. (1999), Kuhn (2001), and Asudeh (2012: 112ff.), though it didn't find its way into more mainstream LFG work until the research programme initiated by Asudeh & Giorgolo (2012).

One oft-noted (potential) problem with viewing Completeness and Coherence as reducible to semantic resource sensitivity is expletive arguments, i.e. syntactic arguments which do not correspond to semantic ones. Since, by hypothesis, they make no semantic contribution, they will not be required by constraints of semantic resource sensitivity, even though they *are* required for grammaticality. As Asudeh (2012: 113) points out, however, this is far from an insurmountable problem, and there are a number of potential solutions (including rejecting the idea that expletive arguments are semantically empty in the first place – see Bolinger 1977).

A typical lexical entry in this strand of work is given in (138):

(138) *kick* V $(\uparrow\ \textsc{pred}) = \text{‘kick’}$
$(\uparrow_{\sigma}\ \textsc{rel}) = \text{kick}$

$\big\{@\textsc{Map}(\textsc{minuso}, \textsc{arg}_1) \mid @\textsc{NoMap}(\textsc{arg}_1)\big\}$
$\big\{@\textsc{Map}(\textsc{minusr}, \textsc{arg}_2) \mid @\textsc{NoMap}(\textsc{arg}_2)\big\}$

$\lambda x \lambda y \lambda e.\mathbf{kick}(e) \wedge \mathbf{agent}(e, x) \wedge \mathbf{patient}(e, y)\ :$
$(\uparrow_{\sigma}\ \textsc{arg}_1) \multimap (\uparrow_{\sigma}\ \textsc{arg}_2) \multimap (\uparrow_{\sigma}\ \textsc{event}) \multimap \uparrow_{\sigma}$

The first two lines provide the pred value along with a value for rel at s-structure.[48] The next two lines provide the mapping information, using the technique explained in the previous section: either the arguments map to one of a pair of GFs, or they are not realised syntactically. This corresponds to argument-function mapping in Kibort MT (see Section 5). The crucial advantage of incorporating a theory of the syntax-semantics interface is that we can also express the equivalent of Kibort MT's argument-participant mapping, via the meaning constructor in the final line. Here the variable x is identified as the Agent of the kicking event, and connected via the linear logic term to $\textsc{arg}_1$ at s-structure; similarly, y is identified as the Patient, and connected to $\textsc{arg}_2$. That is, the link between GFs and semantic participants, a key part of any mapping theory, is mediated by the intervening level of s-structure, here playing the same role as Kibort MT's lexical valency frame. And just like in Kibort MT, this setup allows for the realignment of participants to argument positions – see Findlay (2016: 328–332) for an example of this with the English benefactive.

By bringing together information about mapping and about semantics, which are just the same kind of object in this approach, *viz.* pieces of functional description, it becomes far easier to express semantic constraints on, and semantic consequences of, argument alternations and other argument structure operations (cf. also the discussion of Butt's 1995 enhanced a-structures above). Asudeh (2021: 32–39) shows the potential of this approach in his analysis of the English "non-agentive dynamic intransitive", and contrasts it with what he calls the "low resolution" of Classical LMT, which only has access to very spartan semantic information (usually just the thematic roles of arguments).

---

[48] The current status of pred and rel in LFG is not settled: many if not all of the important functions of pred have been taken over by Glue Semantics (Andrews 2008), and rel really has no substantive role in the theory (Lovestrand 2018: 169ff. although see Lowe 2014). They also seem to both express the same information in (138), which adds a degree of redundancy to the grammar. Nevertheless, they at least serve to help distinguish different f- and s-structures, as well as making the representations more readable.

One promising area of research made possible by this “joined up” approach to mapping is the idea of incrementally bundling up semantic and mapping information into more and more complex valency templates (as employed in e.g. Asudeh & Giorgolo 2012, Asudeh et al. 2014, Findlay 2020), which, coupled with the notion of an inclusion hierarchy between templates (see especially Asudeh et al. 2013: 17–20), could lead to a mapping theory based purely on a richly structured and hierarchical lexicon, along the lines of Davis & Koenig (2000). This potential has yet to be fully explored, though Przepiórkowski (2017) has pointed the way.

7 Conclusion

New approaches to argument structure and mapping theory phenomena were at the heart of what gave rise to LFG as a separate approach to linguistic theory in the first place: Bresnan’s (1980, 1982) observations about the lexical character of argument alternations and the benefits afforded by separating out lexical predicate-argument structures from surface syntactic structures were what laid the foundations for LFG’s lexicalist, modular view of the grammar. The advent of Lexical Mapping Theory (LMT) helped to constrain the theory of argument alternations, and also offered new explanatory tools which proved successful in characterising a number of linguistic phenomena across a fairly typologically diverse range of languages. Recent developments in both theory and formalism show that the field is ripe for a renaissance, and that while great strides have been made, many important questions still remain unanswered. This chapter has attempted to give a broad and expository overview of the status quo, along with a little of how we got here, with the hope that by drawing together different theoretical perspectives we can both encourage dialogue among experienced researchers, and bring new scholars up to speed, so that both can be in the best position to contribute to a field which remains full of untapped potential.

Acknowledgements

We would like to thank in the strongest possible terms the four anonymous reviewers whose extremely detailed comments have vastly improved the quality of this chapter. Jamie Findlay also gratefully acknowledges the financial support of Research Council of Norway grant number 300495, “Universal Natural Language Understanding”.

Chapter 17

Prosody and its interfaces

Tina Bögel
University of Konstanz

LFG has always had a strong focus on syntax and semantics, but the last two decades have seen significant progress with regard to the integration of p(honological)-structure into LFG. This chapter first briefly introduces important concepts for the analysis of prosody and gives an overview of widely adopted approaches to the syntax–prosody interface. The second part surveys the different proposals for the integration of p-structure and its interfaces into LFG, with a particular focus on the architectural assumptions behind each approach and the resulting implications for the architecture of grammar.

1 Introduction

LFG has always had a strong focus on syntax and semantics. However, with the realisation that prosodic information can significantly contribute to linguistic analyses and is often crucial for the correct interpretation of meaning (e.g., in form of prosodic disambiguation of syntactically ambiguous structures or for the correct interpretation of information structure), the last two decades have seen significant progress with regard to the integration of prosodic structure into LFG.

LFG assumes that different aspects of grammar (i.e., syntax, semantics, etc.) are represented by unique modules (also called ‘projections’), each guided by its own principles and constraints, and with representations well-suited to their unique functions (cf. Dalrymple 2001, Sadock 1991, see also Belyaev 2023b [this volume]). The syntactic component, for example, is represented by c(onstituent)- and f(unctional)-structure and is concerned with constituency (via phrase structure rules) and the encoding of grammatical functions and morphosyntactic features, while phonology (including prosody) is represented by p(honological)-

Tina Bögel. 2023. Prosody and its interfaces. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 779–821. Berlin: Language Science Press.
DOI: 10.5281/zenodo.10185970

structure and is concerned with phonological and prosodic properties like prosodic phrasing, rhythmic constraints, and intonation.[1]

Communication between the different modules is handled by LFG's correspondence architecture, which allows for relevant information to be made available at the respective interfaces. The establishment of these interfaces necessarily presumes a specific grammar architecture; that is, it presupposes an explicit positioning of modules with respect to each other. Discussing the architectural assumptions made in each p-structure proposal is thus essential for the understanding of the (in parts fundamental) differences in the representation of prosody and the communication at the interfaces.

This chapter provides an overview of the different approaches to prosody and its interfaces in LFG, and places these with respect to proposals made in the wider literature. It furthermore discusses the architectural assumptions made in each proposal and offers insights into a more general view of grammar. The chapter is structured as follows: Section 2 provides a general introduction into two major aspects of prosody (phrasing and intonation) and discusses current approaches to prosody and its interfaces in the wider literature. A discussion of the LFG grammar architecture and the placement of the phonological module (including prosody) is provided in Section 3. This section also establishes a fundamental difference between the proposals with respect to how grammar is viewed in general. Section 4 provides a chronological overview of the different approaches to prosody and its interfaces in LFG, in particular with respect to the architectural assumptions made in each proposal. Section 5 concludes the chapter.

2 Prosody and its interfaces

The LFG approaches to prosody discussed in Section 4 draw on a number of notions and theories established in the wider literature. This section first gives an overview on the general features that are particularly relevant with respect to the analysis of prosody at the interfaces and then describes the major approaches to the interface between syntax and prosody.

---

[1] In most of the approaches discussed in Section 4 the 'p' in p-structure represents p(rosodic)-structure, as prosodic features ususally contain relevant information for analyses at the interfaces to syntax, semantics, and information structure. However, prosody is only one part of the larger field of phonology and some phenomena that are not part of prosody (e.g., postlexical sandhi phenomena) can be closely interlaced with prosody in that they can indicate a specific prosodic domain. This chapter will thus use the term p(honological)-structure, of which prosody is part, but which does not, per se, restrict p-structure to represent prosody alone.

2.1 What is prosody?

Prosody is a term used to describe suprasegmental phonology. It goes beyond the phonemic level of segmental phonology and is concerned with larger units in spoken language, including prosodic grouping, intonation and/or tones, rhythm, and stress patterns. Prosody can be used to express a number of properties and functions, among these clause type, clause structure, semantic scope, concepts of information structure such as topic and focus, but also speaker emotion, irony, or sarcasm. A detailed description of prosody goes far beyond the aim of this chapter and this section will only focus on some basic notions of prosody deemed fundamental for the current state of the art in LFG, namely prosodic phrasing, intonation, and the relationship between prosody and other modules of grammar.

Traditionally, it is assumed that spoken language is grouped into hierarchically structured **prosodic domains** (e.g., Selkirk 1978, Nespor & Vogel 1986, Hayes 1989). Example (1) shows the most widely used proposal for the prosodic hierarchy originally made in Selkirk (1978) (building on an earlier proposal by McCawley 1968; see also Frota 2012 for different suggestions).

(1) The Prosodic Hierarchy (Selkirk 1978)

Prosodic hierarchy

U utterance (Ut)
|
ι intonational phrase (IntP)
|
φ phonological phrase (PhP)
|
ω prosodic word (PW)
|
Σ foot (Ft)
|
σ syllable (Syll)

In addition, the constraints in (2) are assumed to apply to the prosodic hierarchy.[2]

---

[2] These constraints have been challenged and are now mostly considered to be ‘soft’ constraints, see, e.g., Bennett & Elfner (2019).

(2) **Constraints on Prosodic Domination (Selkirk 1995: ex. 4)**
(where C^n = some prosodic category)
   (i) *Layeredness:* No C^i dominates a C^j, j > i,
      e.g. “No syllable dominates a foot.”
   (ii) *Headedness:* Any C^i must dominate a C^{i-1} (except if C^i = syllable),
      e.g. “A prosodic word must dominate a foot.”
   (iii) *Exhaustivity:* No C^i immediately dominates a constituent C^j, j < i-1,
      e.g. “No prosodic word immediately dominates a syllable.”
   (iv) *Nonrecursivity:* No C^i dominates C^j, j=i,
      e.g. “No foot dominates a foot.”

The identification of a prosodic unit is based on various types of evidence and can vary greatly across languages. Among these types of evidence are sandhi processes (e.g., linking and intrusive /r/ in English (Wells 1970)), tonal events (e.g., Beckman & Pierrehumbert 1986, Pierrehumbert & Beckman 1988), and rhythmic patterns (e.g., Liberman 1975, Nespor & Vogel 1989). A phonological phrase in English, for example, is assumed to be intonationally represented by a pitch accent and a phrase accent, and to show phrase-final lengthening, where the last syllable is significantly longer compared to the other syllables of the phonological phrase (Lehiste et al. 1976, Frota 2012).

Tonal events like accents and boundary tones can contribute significantly to the meaning of a clause. These events are often described in terms of High and Low tones and tone combinations following the ToBI annotation conventions.[3] The first set of conventions was developed for American English in 1992 (Silverman et al. 1992); others have followed with specific adaptations to other languages (e.g., German GToBI (Grice & Baumann 2002)). The ToBI conventions distinguish between three tonal events:

- Pitch accents (L* and H*, and combinations like L+H* and L*+H) are usually found on the words that are most important for an interpretation. In a neutrally pronounced sentence like *Amra went to the playground to meet her friends*, ‘Amra’, ‘playground’ and ‘friends’ would usually carry pitch accents. Pitch patterns can reflect information structure (Zaenen 2023 [this volume]): Contrastive focus in Germanic languages, for example, can be indicated by the use of an accent with a notably larger pitch span compared to the other accents of the clause (see, e.g., Féry 2020).

---

[3] The Autosegmental-Metrical/Tone and Break Indices framework (AM/ToBI) (Pierrehumbert 1980, Silverman et al. 1992, Beckman et al. 2005) is a generally adopted set of conventions to describe tonal events in the intonational contour. Break indices, which indicate the strength of a break between words, are not further discussed in this chapter.

- Boundary tones (H% and L%) are only associated with phrase edges of larger prosodic units, most often the intonational phrase boundary. They can, for example, signal the difference between a question and a statement with identical linear word order by means of rising or falling final phrase boundary tones.

- Phrase accents (H- and L-) are situated between a pitch accent and a boundary tone. They are often related to the edge of a prosodic domain below the intonational phrase, but there is some variation (see the discussion in Grice et al. 2000). They can significantly contribute to the disambiguation of syntactically ambiguous structures.

While these conventions are adopted by the vast majority of the field, proposals with a more fine-grained understanding of tonal events in combination with, for example, a distinct level of prominence (which is essential for the interpretation of focus type), have recently been developed (e.g., DIMA: Kügler et al. 2019). Whether these proposals allow for a more thorough interpretation of prosody and meaning is subject to future research.

Both areas, prosodic constituency and intonation, are deeply intertwined with each other, and are also closely associated with **segmental phonology**, in that phonological processes (e.g., resyllabification) may be constrained to a particular prosodic domain (e.g., the phonological phrase), or the quality of a vowel may change if it is associated with a pitch accent. Segmental and suprasegmental prosody both are part of lexical and postlexical phonology. Prosodic constituency and (lexical) stress are also part of a word's lexical entry, as is the knowledge about prosodically deficient clitics, while segmental phenomena frequently also occur between two words and hence are not restricted to the lexicon. As a consequence, p-structure should not only represent prosodic structure, but should rather include lexical and postlexical segmental and suprasegmental phonology (cf. fn 1).

Phonetics can be viewed as the physical translation of phonology into a concrete speech signal (and vice versa), which is reflected in the close relationship between prosodic terms like pitch, length, or loudness, and phonetic terms like fundamental frequency, duration, and intensity (see Kingston 2019 for a detailed discussion). Phonetics has not been in the focus of the proposals made in LFG, although initial approaches towards its integration have been undertaken (see Butt et al. 2020, Bögel 2020; also Section 4.5).

It is clear that prosodic structure is governed by p-structure internal principles and constraints, and that, for example, rhythm and the prosodic status of words (prosodic words vs. prosodically deficient clitics) can determine the formation of prosodic domains. It is, however, equally assumed that prosody is influenced by syntactic structure and discourse-related aspects like the differentiation between new and given information and the expression of different focus-types (Zaenen 2023 [this volume]). Furthermore, 'extralinguistic' factors such as speaking rate or frequency effects can affect p-structure.[4] The exact influence of these and other factors on prosody is far from being fully explored. As the vast majority of research (within and outside of LFG) has focussed on the exploration of the relationship between syntax and prosody, the major approaches to this interface are briefly introduced here, before turning to the role of p-structure and the different proposals to prosody and its interfaces in LFG.

2.2 Theories of the prosody-syntax interface

The literature on how the syntactic and the prosodic modules interact can be roughly divided into two major camps: **direct reference** and **indirect reference** (see Bennett & Elfner 2019 for a detailed discussion of each approach). The direct reference approach proposes that phonological rules and groupings can directly be conditioned on syntactic relations or properties, e.g., on c-command, sister relations, or 'head' status, without the intervention of a separate prosodic structure (e.g., Kaisse 1985; see Elordieta 2008 for an overview). As LFG assumes a modular view of grammar and none of the LFG approaches propose the (non-modular) direct reference approach, this chapter will not further discuss this particular approach to the interface.

The other school of thought pursues the indirect reference approach, which assumes that syntactic structure is first mapped to prosodic domains as shown in (1). Phonological rules are then conditioned based on these prosodic domains (e.g., Hayes & Lahiri 1991). Prominent proposals include the **end-based** approach (Selkirk 1986, Chen 1987) which assumes that the mapping algorithm is restricted to the edges of syntactic heads and maximal projections. In the abstract example in Figure 1, each syntactic head receives a prosodic word boundary and each XP receives a phonological phrase boundary at its right edge. As all XPs align at their right edge, only one phonological phrase boundary is included.[5] Function words ('fw') are excluded from the mapping algorithm.

---

[4] See Shattuck-Hufnagel & Turk (1996) for a thorough discussion of different constraints on prosody.

[5] Whether the right or the left edge is aligned seems to be subject to language-specific constraints.

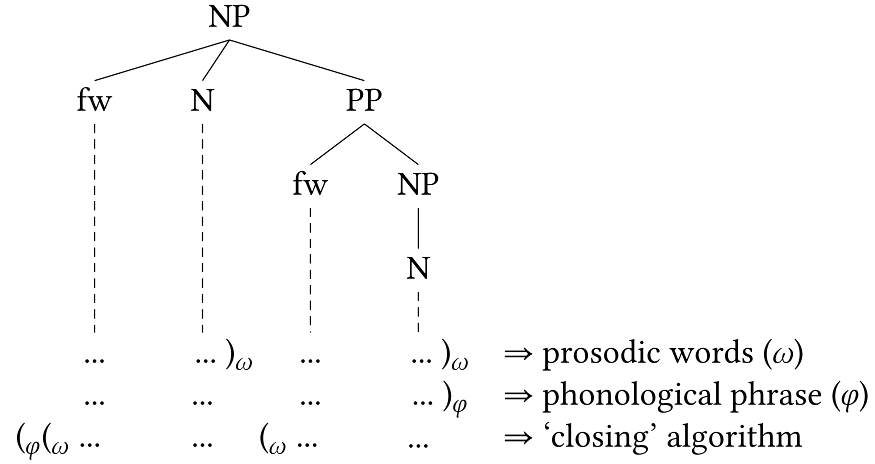

Figure 1: The end-based approach (Selkirk 1986: 387, shortened and modified)

All prosodic domains in this example are 'closed' by assuming an automatic insertion of a left boundary with the neighbouring right boundaries or at the edges of the whole construction. This effectively groups all function words together with their corresponding syntactic heads into prosodic words and places both prosodic words within the phonological phrase: $(_{\varphi}(_{\omega}\text{fw N})_{\omega}(_{\omega}\text{fw N})_{\omega})_{\varphi}$.

The end-based approach has been reformulated as a generalized alignment constraint in Optimality Theory (OT; McCarthy & Prince 1993, Prince & Smolensky 2004) and is generally represented in this format, for example as Align-XP-R(ight): Align (XP, R; φ, R)[6] (Selkirk 1995).

In later work, Selkirk (2009, 2011) introduced **match theory** (which has ancestors in, e.g., Ladd 1986). In contrast to the previous end-based approach, match theory assumes that both edges of a syntactic constituent are simultaneously matched to a prosodic constituent.

- match-clause: A clause in syntactic constituent structure must be matched by a corresponding intonational phrase (ι) in prosodic constituent structure: match (clause, ι)
- match-phrase: A phrase in syntactic constituent structure must be matched by a corresponding phonological phrase (φ) in prosodic constituent structure: match (xp, φ)

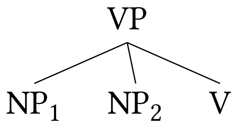
---

[6] Read as: "Align the right edge of an XP with the right edge of a phonological phrase/φ".

- match-word: A (lexical) word in syntactic constituent structure must be matched by a corresponding prosodic word (ω) in prosodic constituent structure: match (lex-word, ω) (Selkirk 2011: 439, modified)

Match theory reflects the syntactic structure in much more detail; in particular (and in contrast to the end-based approach) it predicts recursion, as syntactically nested XPs will be phrased as recursive structures in prosodic constituency. The (modified) example in (3) from Selkirk (2011) illustrates this point for a transitive verb phrase.

(3) Different mapping approaches for a transitive verb phrase



Align-L(eft): $(\mathrm{NP}_1)_\varphi\ (\mathrm{NP}_2\ \mathrm{V})_\varphi$
Match-phrase: $((\mathrm{NP}_1)_\varphi(\mathrm{NP}_2)_\varphi\ \mathrm{V})_\varphi$

In (3), each VP/NP receives a preceding left phonological phrase boundary in the end-based approach (Align-L). The φ-boundary for NP_1 is identical with the boundary for the VP. The right boundary for NP_1 is placed (‘closed’) before NP_2, and the second right φ-boundary is placed after V, which does not receive any boundaries by itself. The first phonological phrase thus contains NP_1 and the second phonological phrase groups the verb together with NP_2. In contrast, the match algorithm maps each XP (NP_1, NP_2, and VP) into a phonological phrase, thus creating a recursive structure.

Besides these two major schools of direct and indirect reference, a third proposal with regard to the formation of prosodic structure has been adopted into the LFG community as well (most prominently in Dalrymple & Mycock 2011, Mycock & Lowe 2013, and subsequent work), which will be called the **parallel approach** in this chapter. The main motivation for the parallel approach is the frequently observed non-isomorphism between syntactic and prosodic constituency as illustrated in example (4).

(4) Syntactic Phrasing: [Drink [[a pint] [of milk]] [a day]]
Phonological Phrasing: (Drink a) (pint a) (milk a) (day)
(Lahiri & Plank 2010: 376, modified)

This frequent mismatch seemingly rules out any approaches which map syntactic constituents to prosodic domains, but suggests that prosodic structure is built up on prosodic principles alone. Based on observations of rhythmic patterns (e.g., Sweet 1904), Lahiri & Plank (2010) assume the trochaic foot (X –) to be the determining element for the creation of prosodic structure in English, with the stressed syllable as the initial element of each prosodic chunk. Lahiri and Plank discuss this approach to prosodic phrasing with respect to a number of diachronic and synchronic examples which support the assumption that function words are frequently grouped together with preceding strong syllables (as in example 4) and not necessarily with the following syntactic head (as suggested in Figure 1).

However, while the parallel approach provides a suggestion for the creation of the lower prosodic domains (foot and prosodic word structure), no suggestion is made for the formation of the higher domains (phonological phrase and intonational phrase); nor do Lahiri and Plank explicitly exclude the influence from other modules of grammar. Furthermore, it has long been part of the indirect reference tradition that it is "crucially [...] not the case that all syntactic boundaries of a certain type must correspond to prosodic boundaries of a given type and vice versa" (Frota 2012: 256). Most researchers assume "prosodic restructuring" (Nespor & Vogel 1986: 172) based on, for example, the type of word (function word vs. lexical word), the size of the phonological phrase, or the amount of recursive nesting.[7] The indirect reference approaches thus do not take prosodic constituency to be a simple derivative of syntax, but assume that prosodic structure is also formed by means of syntax-independent constraints, among them the rhythmic constraints proposed by the parallel approach.

The difference between these two approaches to prosody and its interfaces necessarily reflects two distinct views of grammar in general. As both directions have been pursued in the proposals made in LFG, the following section briefly discusses how prosodic structure is integrated into the overall grammar architecture and how the indirect reference approach and the parallel approach differ with respect to the communication at the interfaces.

3 Prosody in LFG's grammar architecture

Several proposals have been made with respect to LFG's grammar architecture (see also Belyaev 2023b [this volume]) and a closer discussion of the different approaches to prosody and its interfaces presented in this chapter provides interesting insights into the positioning of the different modules on the one hand, and a general understanding of grammar on the other hand.

Prosodic structure is especially interesting as it is usually taken to represent FORM and is thus placed at one 'end' of the FORM-MEANING relationship as, for

---

[7] For prosodic restructuring mechanisms/'prosodic markedness constraints' as expressed in Optimality Theory, see Selkirk (2011: 468ff) for an overview.

example, discussed in Kaplan (1987: 362). In Kaplan's original proposal, shown in Figure 2, p-structure was not yet part of the grammar architecture; instead, the (word) string was taken to be the external form of the sentence. This is also reflected in Asudeh (2009: 110), where the string is understood as a 'representation of linear phonology' and as the center of the syntax–phonology interface, a proposal that has concretely been pursued in the approaches of Bögel et al. (2009, 2010), Dalrymple & Mycock (2011), and Mycock & Lowe (2013) (see Section 4).

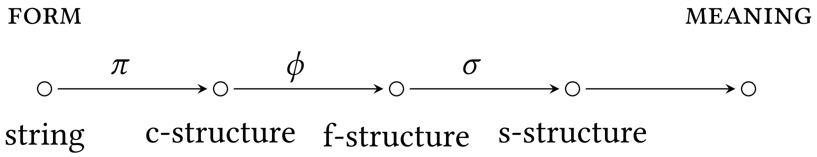


Figure 2: (Simplified) FORM-MEANING relationship in Kaplan (1987: 362)

Proposals in the wider literature have assumed a slightly more complex representation of FORM. Very early, Selkirk (1984) proposed that syntactic structure is first mapped to a phonological (including prosodic) representation, which is then further processed by means of phonological rules and constraints before being mapped to a phonetic representation. In this model the string is not placed between the syntactic and the phonological module, but is the output of the phonological and the phonetic modules. Such a model is very much in line with psycholinguistic models of speech production and comprehension, e.g., as found in Levelt (1999) and in Jackendoff's (2002) work on Parallel Grammar; see Varaschin 2023 [this volume].

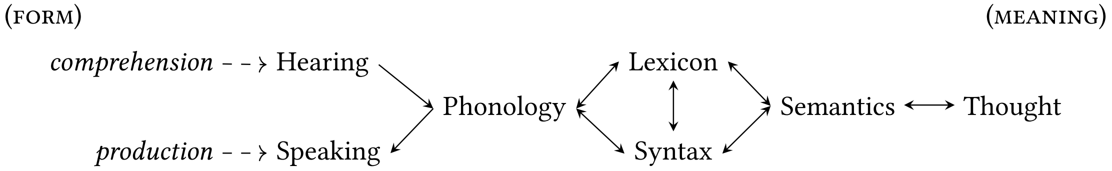

Figure 3: The language processor (cf. Jackendoff 2002: 197, modified)

The model in Figure 3 states clearly what is only implicitly expressed in theoretical LFG:[8] The different modules, placed between FORM and MEANING, assume a certain directionality, generally termed as 'comprehension' (parsing) and 'production' (generation) in the wider literature. This is seemingly in conflict with

---

[8] For example, in Figure 2 by means of arrows, and more explicitly in the pipeline architectures of the numerous computational LFG grammar implementations (see Forst & King 2023 [this volume]).

the assumption that the different modules exist in ‘parallel’ in LFG (Dalrymple et al. 2019: 265); however, as Jackendoff explicitly remarks, this is not necessarily a hindrance:

> P[arallel] A[rchitecture] is nondirectional, but its constraints can be implemented in any order suited to particular processing tasks. (Jackendoff 2009: 589)

‘Parallel’ under this approach refers to the general understanding that each module is subject to its own principles and constraints (= modularity). It does not mean that each component builds a completely isolated structure which then has to be aligned to the output of other modules. Instead, the individual constraints should be adjusted to the processing task at hand (which is either from FORM to MEANING (comprehension/parsing) or from MEANING to FORM (production/generation)).

While this distinction might not carry much weight if a linguistic analysis is provided within one module of grammar (e.g., a syntactic phenomenon), it is crucial when modelling constraints at an interface, as the involvement of two (or more) modules always involves a ‘direction’. The assumptions made by Selkirk above, for example, are made from the perspective of production, while the architecture proposed by Kaplan in Figure 2 (and in general the vast majority of LFG-related linguistic analyses) is made from the comprehension perspective. The acknowledgement of this bidirectionality as made explicit in Figure 3 is fundamental for the discussion of any interfaces between different modules, and thus essential for the proposals on the integration of prosody and its interfaces into LFG.

Models which follow the parallel approach to prosody and its interfaces as detailed in Section 2.2 by assuming that modules are built up independently of each other and that their output is matched for the best alignment at each interface might seemingly be in line with the concept of modules existing in parallel. However, such models are not built to reflect the processing of a given speech signal to understand its meaning (→ comprehension), or the production of a signal expressing a specific thought (→ production).

4 LFG approaches to prosody and its interfaces

With respect to prosody and its interfaces, both the indirect reference and the parallel approach have been explored within the LFG community, mostly with a directional perspective. As these proposals frequently influence each other and furthermore represent very different views of grammar, the following section provides a chronological overview of the different approaches with a specific focus on the architectural assumptions behind each proposal.

4.1 From c-structure to p-structure: Butt & King (1998)

Butt & King (1998) were the first to introduce a discussion of the syntax-prosody interface and p-structure to LFG. They assumed a mutually constraining model where d(iscourse)- and p-structure are projected off c-structure (in parallel to f-structure), as shown in Figure 4.

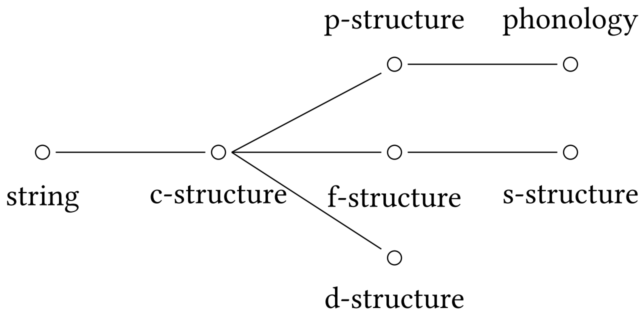

Figure 4: Grammar architecture according to Butt & King (1998: modified)

Under this approach, c-structure is a pivot point between d- and p-structure.[9] P(rosdic)-structure is viewed as an intermediate between c-structure and the phonological component itself which also contains postlexical phonological rules.

Based on work by Hayes & Lahiri (1991), Butt and King focus on syntactically ambiguous sentences in Bengali, such as example (5).

(5) ami bHut dekH-l-am
I ghost see-PST-1SG
a. 'I was startled' (idiomatic)
b. 'I saw a ghost.' (transitive)

Following findings discussed in Hayes and Lahiri, Butt and King assume that prosody can be applied to differentiate between the idiomatic and the transitive interpretation. For Bengali, the assumption for the syntactic-prosodic constituent mapping is that every clause is mapped to an Intonational Phrase (ι, IntP),

---

[9] In contrast to this chapter which takes prosody to be part of phonology (see footnote 1), Butt and King differentiate between a p(rosodic)-structure and a phonological component.

every NP to a Phonological Phrase (φ, PhP), and every main V or complex predicate is phrased separately. Figure 5 shows the c-structures for (5) and the phrasing possibilities for *bHut dekHlam* which consist of separate phonological phrases in the transitive, and a single phonological phrase in the idiomatic reading.

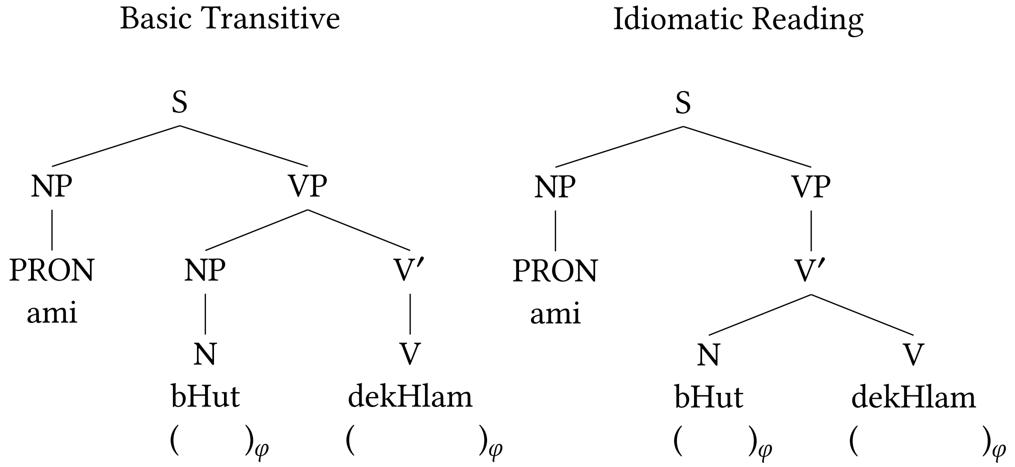

Figure 5: Two c-structure analyses for example (5), Butt and King (1998, modified)

Butt & King (1998) represent p-structure as an AVM structure based on the prosodic hierarchy as shown in (1) above. The AVM structure allows for the inclusion of more detailed information beyond the prosodic domain and the p(honological)-form, such as pitch accents or boundary tones. Butt and King also discuss the linearity issue given with any AVM approach. In order to apply phonological and phonetic processes, it is necessary to preserve the linear order of the string. For a possible solution to this issue, Butt and King point towards projection precedence (Zaenen & Kaplan 1995), which arranges the attributes in p-structure similarly to the string.

Figure 6 shows the prosodic structure of the idiomatic reading in (5), where *bHut* and *dekHlam* are phrased into one phonological phrase (DOM(AIN): P-PHRASE).

The AVM includes all the information in the tree structure and the additional information known about the tones in the language, for example, that in a neutral (non-phonological) focus construction, a high tone is associated with the left p-word in the rightmost p-phrase and the whole clause receives a low boundary tone. This information is stored in the AVM (TONE HIGH), but the final association of the hight tone with the correct p-form (and the correct syllable in this p-form) is left to the phonological component itself. The reason is that the final p-phrase can only be identified once prosodic phrasing is complete and that the placement

$$\left[\begin{array}{ll}
\textsc{dom} & \textsc{intonational-phrase}\\
 & \left\{\left[\begin{array}{ll}\textsc{dom} & \textsc{p-phrase}\\ & \left\{\left[\begin{array}{ll}\textsc{dom} & \textsc{p-word}\\ \textsc{p-form} & \text{ami}\end{array}\right]\right\}\end{array}\right]\right\}\\
 & \left\{\left[\begin{array}{ll}\textsc{dom} & \textsc{p-phrase}\\ & \left\{\begin{array}{l}\left[\begin{array}{ll}\textsc{dom} & \textsc{p-word}\\ \textsc{p-form} & \text{bHut}\end{array}\right]\\ \left[\begin{array}{ll}\textsc{dom} & \textsc{p-word}\\ \textsc{p-form} & \text{dekHlam}\end{array}\right]\end{array}\right\}\end{array}\right]\right\}\\
\textsc{tone} & \textsc{high}\\
\textsc{bnd-tone} & \textsc{low}
\end{array}\right]$$

Figure 6: Prosodic structure relating to the idiomatic reading in example (5), neutral focus

of the pitch accent on the correct syllable is solely depending on the phonological structure of the word itself.

Contrastive focus, on the other hand, is indicated by a low pitch accent and a high (intermediate) boundary tone at the level of the phonological phrase, as shown in Figure 7. As the target of the contrastive focus is determined by grammar (here d(iscourse)-structure), the associated pitch accent and boundary tone can be mapped to p-structure together with their domain.

$$\left[\begin{array}{ll}
\textsc{dom} & \textsc{intonational-phrase}\\
 & \left\{\left[\begin{array}{ll}\textsc{dom} & \textsc{p-phrase}\\ & \left\{\left[\begin{array}{ll}\textsc{dom} & \textsc{p-word}\\ \textsc{p-form} & \text{ami}\end{array}\right]\right\}\end{array}\right]\right\}\\
 & \left\{\left[\begin{array}{ll}\textsc{dom} & \textsc{p-phrase}\\ \textsc{tone} & \textsc{high}\\ & \left\{\begin{array}{l}\left[\begin{array}{ll}\textsc{dom} & \textsc{p-word}\\ \textsc{tone} & \textsc{low}\\ \textsc{p-form} & \text{bHut}\end{array}\right]\\ \left[\begin{array}{ll}\textsc{dom} & \textsc{p-word}\\ \textsc{p-form} & \text{dekHlam}\end{array}\right]\end{array}\right\}\end{array}\right]\right\}\\
\textsc{bnd-tone} & \textsc{low}
\end{array}\right]$$

Figure 7: Prosodic structure relating to the idiomatic reading in example (5), contrastive focus

Butt and King determine the tone distribution by using c-structure as a pivot between d-structure and p-structure, as shown in (6).[10]

(6) ($\downarrow_d$ FOCUS-TYPE) $=_c$ CONTRASTIVE
($\uparrow_p$ TONE) = HIGH → phrasal high
($\downarrow_p$ TONE) = LOW → local low

The approach proposed by Butt & King (1998) was later taken up in Bögel et al. (2008) in their analysis of Urdu *ezafe*. In the *ezafe* construction in (7), the *ezafe* clitic is syntactically grouped with the following modifying noun, but is prosodically attached to the previous head noun.

(7) sher=e panjAb
lion=Ez Punjab
'a/the lion of Punjab'

Syntactic Phrasing: [[sher] **[e** panjAb]]
Prosodic Phrasing: ((sher **e)** panjAb)

Example (7) shows a typical mismatch between syntactic and prosodic structure, which is difficult to account for if prosodic constituency is directly based on syntactic constituency. The solution proposed in Bögel et al. (2008) integrates the *ezafe* clitic (CL-FORM) into the phonological phrase using a number of bookkeeping features to make sure an *ezafe* clitic is present, as shown in Figure 8.

NPez′ ⟶ N: ($\uparrow_p$ DOM) = P-WORD
($\downarrow_p$ P-FORM) = sher
($\downarrow_p$ CL-FORM) = ezafe
($\uparrow$ CHECK EZAFE) $=_c$ +

ezafe: ($\uparrow$ CHECK EZAFE) = +

$$\left[\begin{array}{ll} \text{DOM} & \text{P-PHRASE} \\ & \left\{\left[\begin{array}{ll}\text{DOM} & \text{P-WORD}\\ & \left\{\left[\begin{array}{ll}\text{P-FORM} & \text{sher}\\ \text{CL-FORM} & \text{EZAFE}\end{array}\right]\right\}\end{array}\right]\right\} \\ & \left\{\left[\begin{array}{ll}\text{DOM} & \text{P-WORD}\\ & \left\{\left[\begin{array}{ll}\text{P-FORM} & \text{panjAb}\end{array}\right]\right\}\end{array}\right]\right\}\end{array}\right]$$

Figure 8: (Reduced) *ezafe* rule and the resulting p-structure in Bögel et al. (2008)

This approach is not entirely satisfactory. For one, in this approach it is actually the noun which is 'checking' for a following clitic, instead of the clitic 'asking' to be grouped with a preceding prosodic host. Furthermore, this approach does not allow for a language-specific expression of prosodic principles, e.g.,

---

[10] For the interested reader: Focus in Bengali can also be signalled by the clitic *-o*. Following Lahiri & Fitzpatrick-Cole (1999), Butt and King assume a lexical high tone which is introduced onto the prosodic word with the clitic's lexical specifications.

the general integration of *en*clitics into the preceding prosodic domain, and of *pro*clitics into the following prosodic domain. Instead, individual specifications have to be created for each clitic. This is not only unintuitive, but also does not allow for any predictions to be made about prosodic structure in general.

Summing up, Butt and King make a first proposal to include prosodic information into LFG and show how this can interact with d- and c-structure. In contrast to Hayes & Lahiri's (1991) original approach (and in contrast to the claim made in Dalrymple et al. 2019), their model does not permit the direct reference of phonological restructuring rules to relations internal to syntactic structure (e.g., to 'right sister' or modifier-head-constructions), but provides an indirect, modular approach to the interface.

Butt and King distinguish between two structures: p-structure and the phonological component. P-structure only includes the information that is pre-determined by other modules of grammar, e.g., pitch patterns introduced by different sentence types and focus, and prosodic constituency based on syntactic constituency. This information serves as input to the phonological component (not further defined in their paper) and its inherent rules and constraints, which include prosodic restructuring, or the placement of pitch accents on the correct syllables within the right domains. This directional analysis from c-structure to p-structure to phonology reflects part of the production process in Figure 3. However, Butt and King's model (as shown in Figure 4) is generally not in line with the architectural assumptions made in Figure 2 and Figure 3 in that the string is not the representative of FORM: neither is the string equal to the phonological output nor is it closely associated with the phonological module. Without this connection, it is unclear how the string could be realised in terms of a (physical) speech signal.

4.2 Prosody and i-structure: O'Connor (2005)

In his thesis, O'Connor (2005) discusses the interface between prosody and information structure. O'Connor (2005) assumes a bidirectional approach, which distinguishes between a 'hearer-based' and a 'speaker-based' approach. He explicitly focusses only on the hearer-based direction (from p- to d-structure → comprehension) and leaves the speaker-based direction (from d- to p-structure → production) to further research.

O'Connor's approach is based on the AM/ToBI framework (see Section 2.1), but the description of accents is restricted to High and Low tones only.[11] He is

---

[11] O'Connor does not distinguish between different types of pitch accents and how these may relate to specific i-structure categories, e.g., the distinction between broad and narrow focus based on different pitch patterns (a.o., Baumann et al. 2007).

mostly concerned with utterances where a difference in meaning is expressed solely by means of prosodic emphasis (expressed by capital letters in example (8)).

(8) a. He rode [a green DRAGON]$_{foc}$.
b. He rode a [GREEN]$_{foc}$ dragon.

The two propositions have a different information structure. Example (8a) can be the answer for a question with a broad focus (e.g., *Did he ride a green dragon or a thestral?*), while example (8b) is more likely to be the (contrastive) answer to a question like *Did he ride a green dragon or a blue dragon?*

In his proposal, O'Connor assigns a central role to i-structure. As the AM/ToBI system is not concerned with the influence of syntactic structure on prosody, O'Connor assumes that prosody and i-structure can be related to each other without syntactic mediation, as shown in Figure 9.[12]

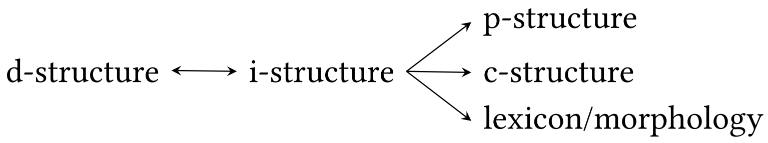

Figure 9: Architecture proposed in O'Connor (2005: Fig 6.3, 142, modified)

Following the general idea behind autosegmental approaches (Goldsmith 1976), O'Connor pursues the idea of a representation of tonal information independent from the segmental/phonemic representation. He proposes that p-structure should be represented by a hierarchical constituent structure (thus paralleling c-structure). Via so-called 'tune structure rules' like the ones in (9), a tree-like structure is created to represent intonation where the terminal nodes correspond to underspecified tonal events: t^* represents a pitch accent, t^- a phrase accent, and t% a boundary tone.

(9) $n \geq 1$
a. $\textsc{Tune}_{IP} \rightarrow \text{tune}_{ip}^{n}\ \ t\%$
b. $\text{tune}_{ip} \rightarrow t^{*n}\ \ t^{-}$

---

[12] O'Connor does not completely exclude the influence of c-structure on prosody, but only acknowledges a relevance of the linear and hierarchical syntactic structure of the clause for the length of the transition between tonal events and the alignment of the pitch in general.

As a result, each prosodic tree constructed on the basis of these rules has four obligatory nodes: the prosodic ‘intermediate phrase’ (tune$_{ip}$) consists of a nuclear accent t^* and a phrase accent t^- while the prosodic ‘intonational phrase’ (TUNE$_{IP}$) consists of at least one intermediate phrase and a boundary accent t%. For example (5) (see also Figure 5, basic transitive) from Butt & King (1998), O’Connor proposes the p-structure in Figure 10.

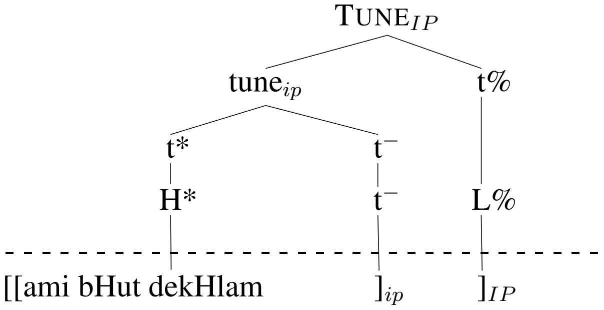

Figure 10: O’Connor’s p-structure as applied to example (5) from Butt & King (1998)

The tree representation is mainly concerned with the organisation of tonal events; the material below the dashed line includes the orthographic tier and the prosodic domain information in the form of bracketing.[13]

O’Connor emphasises the point that under his approach, the association of the High tone is not left to a further phonological component as proposed in Butt & King (1998) and discussed above in Section 4.1. It is however not quite clear how the High tone is associated with the correct string sequence in O’Connor’s approach, as no formal alignment of string and pitch (i.e., c-structure and p-structure) is established in his thesis. Indeed, in the data provided by Butt and King, the High tone should be assigned to the ‘leftmost’ prosodic word in the ‘rightmost’ phonological phrase. As O’Connor collapses all three phonological phrases proposed by Butt and King under one tune$_{ip}$, it is not clear how the association of the High tone with the correct word can be ensured.

With respect to i-structure, O’Connor assumes that categories like FOCUS and TOPIC are organised linearly in an utterance, and assigns each to one tune$_{ip}$, as shown in (10). If there are not enough tunes, then the assumption is that there is no topic correspondent.

---

[13] As O’Connor’s (2005) main focus is on the relation between intonation and discourse functions, the encoding of further prosodic/phonological information, e.g., syllable structure, or lexical stress, is not further discussed in his thesis.

(10) $$\textsc{Tune}_{IP} \longrightarrow \begin{array}{c} \text{tune}_{ip} \\ \downarrow \in \{\uparrow_d \textsc{topic}\} \end{array} \quad \begin{array}{c} \text{tune}_{ip} \\ \downarrow \in \{\uparrow_d \textsc{focus}\} \end{array} \quad \text{t\%}$$

As O'Connor notes, there are a number of cases where the proposed association of i-structure categories and tunes does not work. Sentences like *'It broke.'* will only have one tune, indicating a FOCUS. However, in i-structural terms, *It* is a TOPIC. This mismatch between tunes and i-structure roles is discussed (O'Connor 2005: 161), but not resolved.

In conclusion, O'Connor's indirect, directional approach to the relationship between prosody and i-structure suggests an alternative to the syntactocentric view proposed in Butt & King (1998). However, there are a number of outstanding questions. Besides the incomplete association of i-structure categories to tune-structure rules just discussed, there is also the fundamentally important question as to how tonal events can be associated with their targets without reference to the morphosyntactic string, or how common phenomena, e.g., the (syntactic) scope of a prosodically expressed focus, can be determined without reference to syntactic constituency. The missing association of p-structure, string, and c-structure, and other unresolved questions thus only allow for an analysis of a more descriptive nature.

4.3 The string as an interface between c- and p-structure: Bögel et al. (2009, 2010)

Based on the realisation that the frequent misalignment of prosodic and syntactic constituents would seriously complicate previously established prosody-syntax mapping algorithms, Bögel et al. (2009) pick up on the notion of the parallel approach discussed in Section 2.2. The underlying assumption is that the prosodic component operates independently of syntax and that the two components are not related via LFG's projection architecture. To account for the cases where syntax is influenced by prosody, Bögel et al. (2009) assume a directional 'pipeline' architecture (from the comprehension perspective): First, an independent prosodic component interprets various phonological properties thus establishing the boundaries of prosodic units. This information on prosodic constituency is then made available to syntax by inserting prosodic bracketing features into the terminal string of c-structure.[14]

Bögel et al. (2009) discuss a number of different phenomena, among them Urdu *ezafe* (Bögel et al. 2008: see Section 4.1). They extend the c-structure rules by

---

[14] Under this approach, the string has a central role as it includes information from both the syntactic and the prosodic component (similar to the understanding of the string in Asudeh 2009: 110 as a 'linear representation of phonology').

adding left and right prosodic brackets ('lexical categories' RB and LB) which reflect prosodic constituency.

(11) a. EzP ⟶ EZ RB N
b. NPez′ ⟶ LB [...] N

The inclusion of brackets greatly simplifies the rule originally used in Bögel et al. (2008: Figure 10) where a number of CHECK-features were applied to control for an *ezafe* clitic following the head noun. The resulting c-structure representation, shown in Figure 11, allows for the depiction of the misalignment between syntactic and prosodic structure.

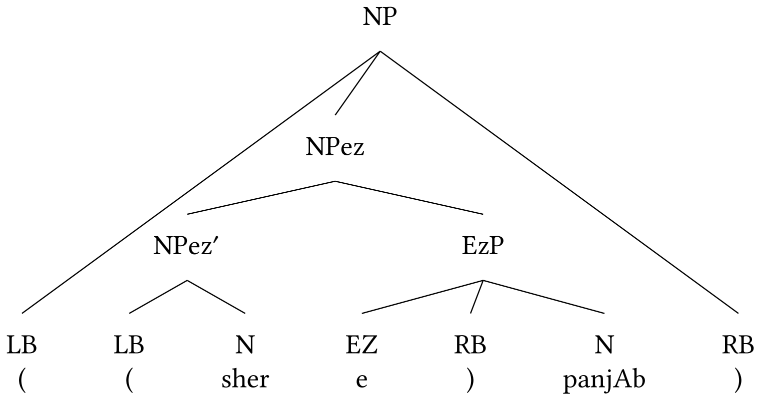

Figure 11: Urdu *ezafe* analysis as proposed in Bögel et al. (2009)

Another aspect discussed in Bögel et al. (2009) is the prosodic resolution of syntactically ambiguous structures. Consider the following example, where *old* can either modify only the first noun ((12a)) or scope over the whole coordination ((12b)). Each possibility is accompanied by a distinct prosodic grouping.

(12) a. [old men] and [women]
(old men) and (women)

b. [old [men and women]]
(old (men and women))

The paper postulates a 'Principle of Prosodic Preference', according to which the syntactic component disprefers syntactic structures whose constituent boundaries do not coincide with prosodic boundaries. For the implementation, Bögel et al. (2009) use a metarule, which systematically transforms the rules of the syntactic component. In the following metarule, CAT is a nonterminal category, and RHS denotes the regular language over categories which are annotated with co-describing constraints.

(13) CAT ⟶ RHS

In Bögel et al.'s metarule in (14), the top part of the rule will match a (recursive) sequence of CAT surrounded by prosodic brackets (LB and RB). The bottom part will match the RHS regular expression if all occurrences of LB or RB are ignored, thus preventing the inserted prosodic brackets from ruling out a valid syntactic analysis.[15]

(14) CAT → LB CAT RB
| RHS / [LB | RB]
Disprefer

The Principle of Prosodic Preference is enforced via the 'Disprefer' optimality mark,[16] which assigns a dispreference mark to the construction every time the bottom part of the metarule in (14) is applied. In the case of several possible syntactic analyses (as in (12)), this extension effectively ranks the analyses: The top half of the rule only applies if the prosodic brackets match the syntactic structure, while the syntactic analyses with no matching prosodic brackets will be parsed by the bottom half of the rule, but will receive a 'Disprefer' mark. This allows for constructions with matching prosodic and syntactic brackets to be preferred, while constructions with non-matching brackets will only be valid if a preferred solution (with matching brackets) is not available.

This first approach to the interface was extended in Bögel et al. (2010) which discusses second position (2P) clitics in Russian and Serbian/Croation/Bosnian (SCB). It is concerned with examples like (15), where a clitic cluster (CCL) disrupts the NP *Taj čovek*.

(15) [Taj *joj* *ga* *je* čovek] poklonio.
that her it AUX man presented
'That man presented her with it.' (Schütze 1994)

These clitics appear in the second position after a first prosodic word without regard to syntactic requirements ((16)).

---

[15] The 'Ignore operator' / was first introduced in Kaplan & Kay (1994).

[16] See Forst & King 2023: section 1.5 [this volume] for a description of optimality marks and relevant references.

(16) (((Taj)$_{\omega}$ (*joj ga je*)$_{cl}$)$_{\omega}$ (čovek)$_{\omega}$)$_{\varphi}$ (poklonio)$_{\varphi}$
That her it AUX man presented
'That man presented her with it.'

Such a structure is problematic for traditional LFG accounts, because it is difficult to account for the clitics' appearance within an NP and to furthermore retrieve the clitics' functional contribution to the clausal f-structure. With a purely syntactic account, this information is locked into the NP's f-structure.

Bögel et al. (2010) resolve this issue by assuming a shared responsibility between the syntactic and the prosodic component: While the syntactic component ensures the availability of the functional information by placing the clitic in the (linear) first position, the prosodic component ensures the correct position of the clitics within the clause and places the clitics following the first prosodic word. This prosodic repair mechanism has been shown to apply crosslinguistically and was dubbed 'prosodic inversion' by Halpern (1995).[17]

In order for the clitic to appear in the correct syntactic position, Bögel et al. (2010) define the rule in (17), where RHS$_S$ denotes the possible expansion of the clausal S node with left and right brackets (as discussed above). LB$_S$ is a preterminal node that marks the left edge of a clause and allows syntactic/prosodic constraints to be aligned with respect to clause boundaries. CCL can optionally appear as a prefix to the S expansion; the ↑=↓ annotation ensures the processing of the clitics' clause-level functional information.

(17) $\mathrm{S} \longrightarrow \mathrm{LB}_S \quad \underset{\uparrow=\downarrow}{(\mathrm{CCL})} \quad \mathrm{RHS}_S$

To account for the prosodic placement, Bögel et al. (2010) distinguish between a prosodic and a syntactic (c-structure terminal) string which includes the lexical formatives discussed above. The interface between these (usually aligned) strings is a regular relation, where the syntactic string is the 'upper language' and the prosodic string is represented by the 'lower language'. In the simplified illustration in (18), the upper language/syntactic string clitic sequence (CS:0) immediately following the clause boundary ($(_S$ is placed after the first prosodic word ω in the prosodic string in the lower language/prosodic string (0:CS).

(18)

s(yntactic)-string ('upper'):	$(_S$	CS	ω	0
p(rosodic)-string ('lower'):	$(_S$	0	ω	CS

---

[17] For further work in LFG, see an account of prosodically determined second position clitics in Vafsi in Bögel et al. (2018).

The regular relation has the effect that strings with syntactically clause-initial clitic sequences are related to strings where those clusters appear on the other side of an adjacent prosodic word. The sentence-initial position allows for the functional information to be made available to syntax, but violates the prosodically dependent clitic's need for a preceding host. The second position in the prosodic string satisfies this prosodic constraint in that the clitic is placed following a valid prosodic host.

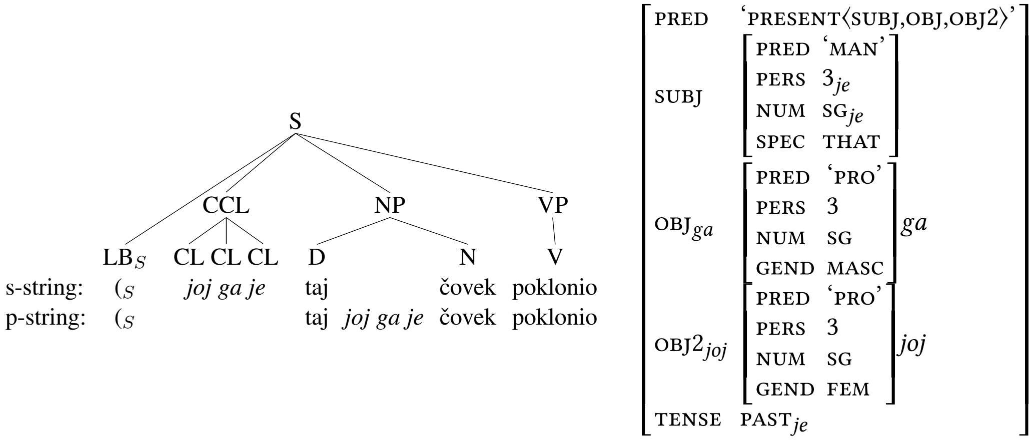

Figure 12: 2P clitics and the syntax-prosody interface (Bögel et al. 2010: 13)

In conclusion, Bögel et al. (2009) set up a directional architecture where they assume an independent prosodic component to process information related to prosody. Information on prosodic constituency is only entered into the terminal syntactic string in the form of lexical formatives, that is, the approach pursues a softer version of the parallel approach discussed above in Section 2.2. This allows for an account of general prosody-syntax misalignment, but also for a prosodic resolution of syntactically ambiguous structures. The approach was furthermore extended to account for second position clitics as well.

There are also several problems with this approach. For one, no further prosodic information can be transmitted via the string. However, information on pitch patterns, accent types or other prosodic features can be crucial for a correct interpretation of meaning.

Another factor is the relatively coarse-grained representation of prosody. Prosodic units can be relevant down to the syllable, a granularity that becomes difficult to represent by interspersing brackets with the terminal c-structure string. And finally, integrating the prosodic structures into the c-structure analysis makes the representation not only difficult to process, but is also questionable in terms of modularity.

4.4 A stricly parallel approach: Dalrymple & Mycock (2011), Mycock & Lowe (2013)

Dalrymple, Mycock, and Lowe base their approaches[18] on the assumption that the prosodic and the syntactic component are parallel but separate components, which goes beyond the distinction between direct and indirect approaches to prosody and its interfaces as briefly discussed in Section 2.2. In the parallel approach, syntactic structure has no influence on the formation of prosodic structure (and vice versa).[19] Instead, each structure is built up independently: syntactic structure as traditionally assumed, and prosodic structure based on rhythmic principles, more specifically, the trochaic foot. In constrast, the indirect reference approach assumes that rhythmic structure is only one factor among many which contribute to the formation of prosodic structure.

The approach represents prosodic constituency in a tree-like structure, assuming the constituents proposed by Selkirk (1995) (see Section 2.1). Similar to the proposal made in Bögel et al. (2010), the interface between the syntactic and prosodic components is the interface between a s(yntactic)-string and a p(honological)-string. The "linguistic signal" (Dalrymple et al. (2019: 407), the nature of which is not further defined) is parsed into minimal syntactic units in the s-string, and into minimal prosodic units (i.e., syllables) in the p-string. A (very simplified) representation of the example sentence *Anna was studying at the university* is shown in Figure 13 (see Figure 15 for a complete picture).

Figure 13 displays the syntactic component (s-string and c-structure) in the top part. The bottom part represents p-structure: the p-string and the prosodic tree. The p-string is parsed into syllables (but see below for further specifications) which are grouped into prosodic words. Following Lahiri & Plank (2010), prosodic structure is built based on rhythmic principles, specifically on the trochaic foot (see Section 2.2). The representation omits the foot structure, but the underlying formation algorithm is still visible in the fact that the left edge of each prosodic word is placed with the syllable carrying primary stress in a lexical, (syntactic) word; e.g., u.ni.(VER.si.ty)$_{\omega}$. Function words and feet built on secondary stress (e.g., (ˌu.ni)$_{ft}$) seem to generally be phrased with the preceding

---

[18] The approach to the interface described in this section was developed in a number of works, namely Mycock (2006), Dalrymple & Mycock (2011), Mycock & Lowe (2013) (see also Lowe 2016 and Jones 2016 for further discussion); the version described here is part of the prosody chapter in Dalrymple et al. 2019.

[19] Dalrymple et al. (2019: 398) classify their approach as indirect reference. However, all indirect reference approaches include syntactic structure as a main factor for building up prosodic structure (mostly from the perspective of production). This is not the case here.

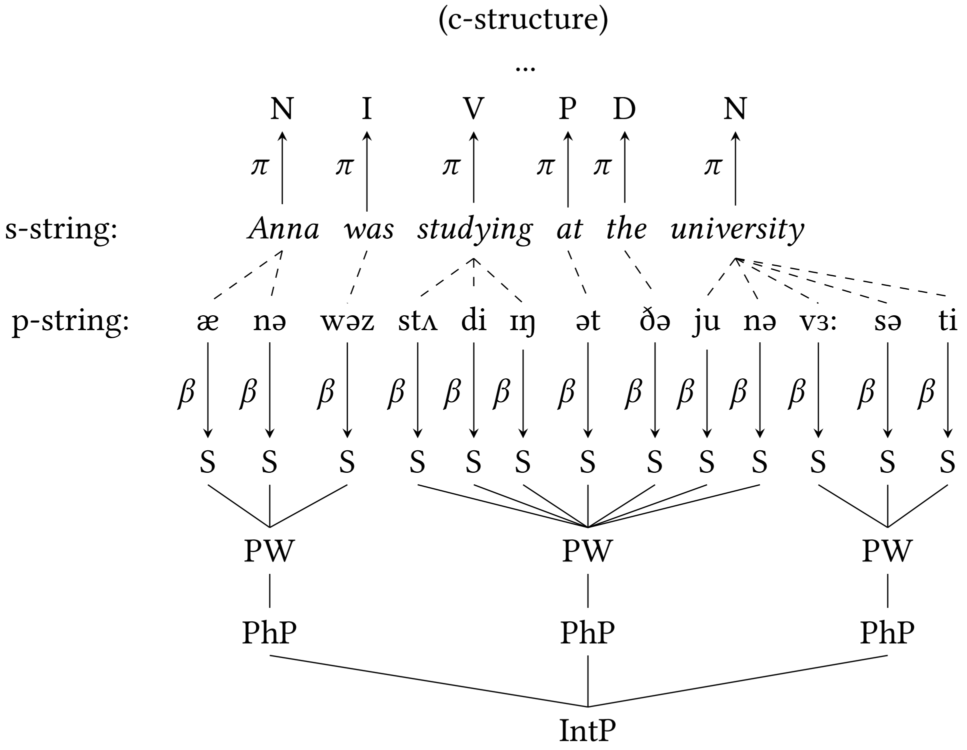

Figure 13: Simplified interface for *Anna was studying at the university* (Dalrymple et al. 2019: 408, showing only c-structure terminal nodes)

prosodic word.[20] The following example shows the prosodic phrasing according to a trochaic foot structure, with primarily stressed syllables in capital letters.

(19) (Anna was) (STUdying at the uni) (VERsity)

The formation of prosodic words based on rhythmic principles naturally leads to regular mismatches between syntactic and prosodic units. However, the approach raises the question whether these units are indeed prosodic words or whether they should rather be defined as phonological phrases. If these units are prosodic words, then the question arises how phonological phrases are defined under this approach. In Figure 13, each phonological phrase is identical with a prosodic word, which is a crosslinguistically very unusual 1-1 relationship.[21]

---

[20] It would be interesting to see how this approach can be applied to cases where the first syllable of a prosodic unit is unstressed as in a modified version of example (19), *Anna or Ravi and Karla* ... (Anna ∨ (Ravi ∧ Karla)), where the prosodic boundary is realised directly after *Anna* (Wagner 2010), while the rhythmic approach would predict the prosodic boundary to occur after *or*.

[21] See, for example, the family of BinMin-constraints, which require for a higher prosodic domain to contain more than one unit of a lower prosodic domain (a.o., Ghini 1993, Inkelas & Zec 1995).

Mycock & Lowe (2013) extend the string interface by assuming that the string-units are not atomic but should rather be seen as feature bundles, represented as AVMs. The relation between the two strings and their units is regulated through information stored in the lexicon. While the lexical s(yntactic)-form contains the traditional morphosyntactic information, the p(honological)-form contains information on segments and syllable structure as well as the feature SYLLSTRESS which indicates the primary lexical stress position.

In addition to the lexical information, the feature structures at the interface also include information on the edges of constituents in the respective modules. These 'edge features' are necessary to allow for the matching of prosodic and syntactic constituents, e.g., in order to prosodically disambiguate syntactically ambiguous structures. Mycock and Lowe define a number of mechanisms to make the edges available to the strings: ⇙ and ⇘ for the left and right edges of syntactic nodes, and ↙ and ↘ for the left and right edges of prosodic nodes.[22] Figure 14 shows the AVMs for the first syntactic and the first prosodic unit of example (19), where the values of L(eft) and R(ight) consist of a set of syntactic and prosodic nodes whose edges are represented by this particular form.

$$
\begin{array}{cc}
\text{s-string unit } \textit{Anna} & \text{p-string unit } \textit{æ} \\
\begin{bmatrix} \textsc{fm} & \textsc{Anna} \\ \text{L} & \{\text{IP, NP, N}\} \\ \text{R} & \{\text{NP, N}\} \end{bmatrix}
&
\begin{bmatrix} \textsc{fm} & \text{æ} \\ \textsc{syllstress} & \text{P} \\ \text{L} & \{\text{I}\textsc{nt}\text{P, P}\textsc{h}\text{P, PW}\} \\ \text{R} & \{\} \end{bmatrix}
\end{array}
$$

Figure 14: Feature structure for first unit of the p-string and the s-string (Dalrymple et al. 2019: 412)

At the interface, a "Principle of Interface Harmony" ensures that the best-matching parses between the p-string and the s-string are preferred. Note, however, that the approach does not explain how this preference is implemented.[23]

Furthermore, the question of which syntactic and prosodic constituent edges should be matched, that is, which prosodic boundary type is important to syntax and vice versa, is left for future research (Dalrymple et al. 2019: 419). This is surprising, given the extensive existing literature on the topic, but in a sense it is a necessary consequence of assuming strictly parallel modules as has been discussed in Section 2.2.

---

[22] See Dalrymple et al. (2019) for the exact definitions.

[23] Lowe (2016) presents a possible implementation of the Principle of Interface Harmony using additional formal power in form of OT contraints (see also Lowe & Belyaev 2015). A critical discussion of this approach can be found in Bögel (2015: Ch.6).

Apart from the interface to syntax, the string interface also serves as an interface between prosody and semantics and i-structure.[24] The semantics-prosody interface is demonstrated by means of declaratives, where the intonational contour distinguishes between declarative statements and questions. In order to make the semantic information available at the string interface, the c-structure receives a "label" PolarIntSem along with the meaning constructor [PolarInt]. Similar to the edge values, this label is handed down to the s-string where it is placed in the rightmost AVM.

For the prosodic interpretation of a declarative question, information on pitch is required. This information is included in the form of H and L pitch accents and boundary tones.

Dalrymple et al. (2019) assume that in English declarative questions, a nuclear L tone is associated with the stressed syllable of the first prosodic word in the last phonological phrase, and an H boundary tone at the right edge of the Intonational Phrase.[25] Similar to O'Connor (2005) above (Section 4.2), they annotate prosodic structure by means of prosodic phrase structure rules. In addition, a label *PolarInt* appears at the rightmost AVM of the p-string. The rule in (20) can then be read as follows: In this phonological phrase, assign a nuclear tone L to the leftmost syllable with primary stress ($\swarrow^{s}$) and a right boundary tone to the rightmost unit;[26] if these constraints are satisfied, create a label *PolarInt* which appears as a set member of the rightmost unit's right edge.

(20)
$$\begin{array}{llll} \text{IntP} & \longrightarrow & \text{PhP}^{*} & \text{PhP} \\ & & & ((\swarrow^{s}\ \textsc{n\_tone}) = \text{L}) \\ & & & (\searrow\ \textsc{rb\_tone}) = \text{H} \Rightarrow \\ & & & \textit{PolarInt} \in (\searrow\ \textsc{r}) \end{array}$$

Figure 15 shows part of the full analysis for example (19), the PP *at the university*. In addition to the edge features, both labels, PolarIntSem and *PolarInt* appear at the right edge of the string interface. The Principle of Interface Harmony requires both labels to co-occur for the overall structure to be grammatical, but the matching process is not further detailed here.

---

[24] As the description of the interface to i-structure is similar to the one provided for the prosody-semantics interface, the interested reader is referred to Dalrymple et al. (2019) for details.

[25] The prosodic expression of declarative questions in English shows much more variability than assumed here, see, e.g., Gunlogson (2003) for discussion of different contours.

[26] The assignment of a right boundary tone here does not distinguish between 'boundary tones', e.g. H%, which appear as boundary tones of intonational phrases, and 'phrase accents', e.g., H⁻, which appear at the edges of phonological phrases. If both edges fall together, these tones form combinations, e.g. H-H%, which can be crucial for an interpretation. The use of a boundary tone with a phonological phrase unfortunately collapses this distinction.

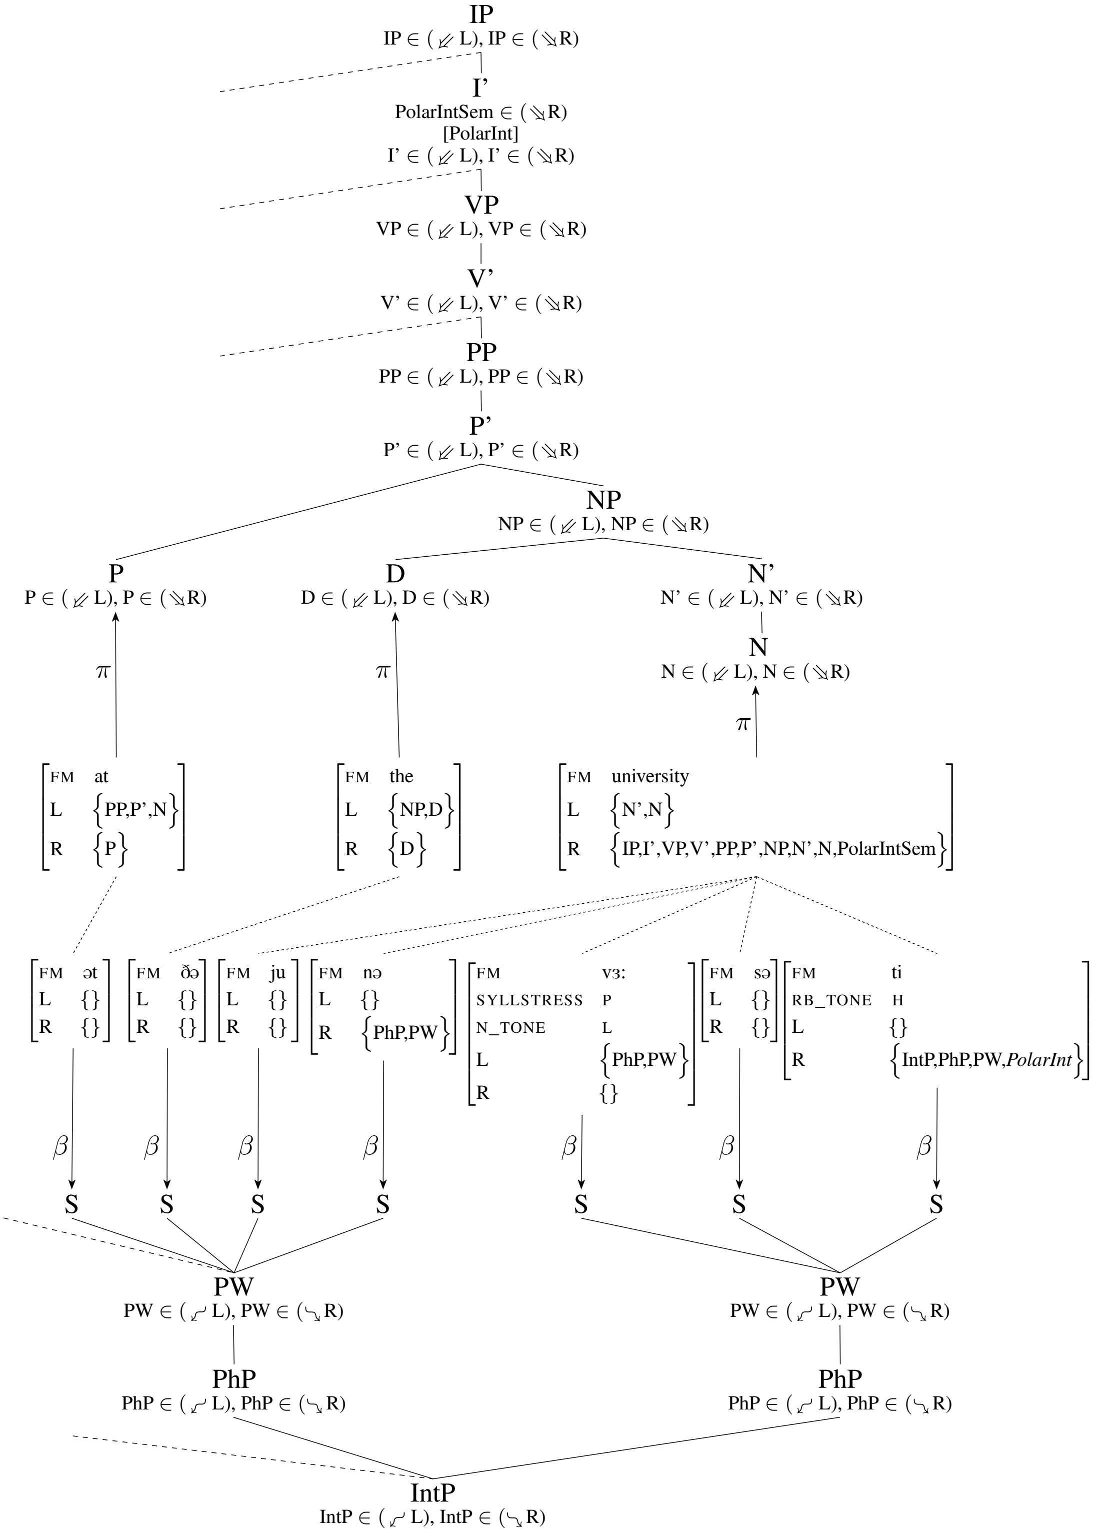

Figure 15: Analysis of the PP in the declarative question *Anna was studying at the university?*

In conclusion, the non-directional model proposed by Dalrymple et al. (2019) pursues the idea of modularity in the extreme: the syntactic and the prosodic component are taken to be completely independent structures which do not allow for any co-description mechanisms as commonly found in LFG (see Belyaev 2023a [this volume]). Instead, information about (at least) syntactic and prosodic constituency, semantics, i-structure, and intonational contours is handed to the respective strings. The interface between the syntactic and the prosodic component is then situated between the s-string and the p-string, where matching edges and 'labels' are preferred according to the Principle of Interface Harmony.

Apart from initial suggestions involving OT-constraints in Lowe (2016) and Lowe & Belyaev (2015), the formal implementation of the Principle of Interface Harmony is not further detailed. Given that there are numerous combinatorial possibilities of prosodic constituents, pitch accents, phrase accents, and boundary tones, and hardly any of them can be mapped to one particular interpretation, but are always co-dependent on other modules of the grammar, the matching of labels at the string interface will most likely prove to be difficult. The introduction of these labels and the mingling of information from different modules is, however, a necessary consequence of the parallel approach. The reduction of the interface to the strings implies that *all* potentially relevant information from other modules has to be duplicated and appear as part of the string where it might or might not be matched against the material in the parallel string. As it was the case in Bögel et al. (2009, 2010) (Section 4.3), this is also problematic with respect to modularity.

The extensive duplication and blending of structures can be avoided by assuming a more traditional co-descriptive approach, while at the same time acknowledging modularity in that each module only processes information related (i.e., 'native') to its module. This indirect reference approach was first pursued in Butt & King (1998), and was further developed in Bögel (2015) and subsequent work as discussed in the next section.

4.5 Production and comprehension: Bögel (2015)

Starting with her dissertation in 2015, Bögel developed a directional indirect reference model of the prosody-syntax interface that enables the integration of a speech signal into LFG and can account for a vast variety of phenomena from both perspectives, production and comprehension. In this approach, illustrated in Figure 16, the interface between c-structure and p-structure is regulated via two transfer processes, the 'transfer of vocabulary' (ρ), which exchanges phonological and morphosyntactic information of lexical elements via the multidimensional lexicon, and the 'transfer of structure' (♮), which exchanges information on syntactic and prosodic phrasing, and on intonation.

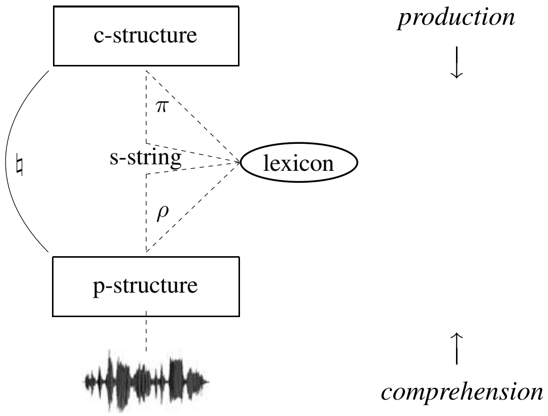

Figure 16: Abstract overview of the prosody-syntax interface (Bögel 2015)

The transfer of vocabulary requires a lexical entry to contain detailed information on (at least) the morphosyntactic as well as the phonological form (s-form and p-form, Dalrymple & Mycock 2011). Following Levelt et al. (1999), Bögel (2015) develops a multidimensional lexicon where the s-form encodes the traditional morphosyntactic information, and the p-form contains information on segments, the metrical frame and prosodic word status.[27] Figure 17 shows the (shortened) lexical entries for *čovek* ('man'), *taj* ('that'), and *joj* ('her') from example (15) (repeated in (21)) from SCB, where the clitic cluster (*joj ga je*) is placed in the prosodic second position, syntactically 'interrupting' the NP *taj čovek*.

(21) [Taj *joj* *ga je* čovek] poklonio.
that her it AUX man presented
'That man presented her with it.' (Schütze 1994)

The lexical p-form entries of *čovek* and *taj* are both marked as full prosodic words (ω). In contrast, the p-form of *joj* is marked as a prosodically deficient enclitic (=σ), that is, it is prosodically dependent on a preceding host. Following the concept of modularity, each dimension can only be accessed by the related module: c-structure can access the s-form and p-structure the p-form. However, during the transfer of vocabulary, the lexicon also assumes a 'transducer function' between s-form and p-form: If a particular dimension is accessed (e.g., s-form from

---

[27] A third dimension, 'concept', which includes semantic information is assumed as well, but not discussed further here.

s(yntactic)-form				**p(honological)-form**	
čovek	N	(↑ PRED)	= ‘čovek’	P-FORM	[tʃovek]
		(↑ PERS)	= 3	SEGMENTS	/tʃ o ʋ e k/
		…		METR. FRAME	$(ˈ\sigma\sigma)_{\omega}$
taj	PRON	(↑ PRED)	= ‘pro’	P-FORM	[taj]
		(↑ PRON-TYPE)	= demon	SEGMENTS	/t a j/
		…		METR. FRAME	$(ˈ\sigma)_{\omega}$
joj	PRON	(↑ PRED)	= ‘pro’	P-FORM	[joj]
		(↑ PRON-TYPE)	= pers	SEGMENTS	/j o j/
		…		METR. FRAME	$=\sigma$

Figure 17: Lexical entries for SCB *čovek* ‘man’, *taj* ‘that’, and *joj* ‘her’

c-structure), the associated dimensions become available as well and the information stored in them is projected to their respective structures (e.g., p-form information becomes available to p-structure).

P-structure itself is represented by the p-diagram, a compact linear representation of the utterance. The p-diagram is structured syllablewise, where each syllable is part of a vector (V(ECTOR) INDEX) which associates the syllable with relevant segmental and suprasegmental phonological information.[28] During the transfer of vocabulary, the information stored with each lexical item’s p-form is stored in the p-diagram. Figure 18 illustrates this process for example (21).

PHRASING	$=\sigma$	$=\sigma$	$=\sigma$	$(\sigma)_{\omega}$	$(\sigma$	$\sigma)_{\omega}$	…
LEX.STRESS	–	–	–	prim	prim	–	…
SEGMENTS	/joj/	/ga/	/je/	/taj/	/tʃo/	/ʋek/	…
V. INDEX	S_1	S_2	S_3	S_4	S_5	S_6	…

Figure 18: The p-diagram with material from the transfer of vocabulary from example (21) (production)

The p-diagram’s content in Figure 18 is identical with the lexical p-form information in Figure 17: *tʃovek*, for example, consists of two syllables, each of which contains a number of segments. The first syllable has primary stress and the complete word forms a prosodic word. These attributes and their values are stored

---

[28] The choice of the underlying prosodic or phonological unit and of the different attributes is up to the researcher.

for each syllable, thus creating a linear representation of the phonological string, with a vertical representation of the different values associated with each part of the phonological string.

In addition to the lexical information, p-structure receives information on syntactic constituency through the transfer of structure. This approach assumes match theory[29] (see Section 2.2), where each syntactic clause is mapped to an intonational phrase and each XP is mapped to a phonological phrase. The c-structure annotation in (22) models this approach to the mapping between syntactic and prosodic constituents for the clausal node S.

(22) S

$(\natural(T(*))\ \mathrm{S}_{min}\ \textsc{phrasing}) = {}_{\iota}($

$(\natural(T(*))\ \mathrm{S}_{max}\ \textsc{phrasing}) =)_{\iota}$

This annotation can be read as follows: Take all terminal nodes (T) of the current node (*, here S), for the attribute PHRASING assign a left IntP boundary (${}_{\iota}($) to the leftmost syllable (S_{min}) and a right IntP boundary to the rightmost syllable (S_{max}) in p-structure. The transfer of structure thus encodes information on larger prosodic domains in p-structure. Taken together, the transfer of vocabulary and the transfer of structure thus provide an initial input to p-structure based on lexical phonological information on the one hand, and on syntactic constituency in form of larger prosodic domains on the other hand (see Figure 19).

As discussed above in Section 4.3, the syntactic analysis of example (21) positions the clitic cluster in the sentence-initial position: *[joj ga je]*$_{CCL}$ *[taj čovek]*$_{NP}$ *[poklonio]*$_{VP}$. As information is accumulated, a prosodic constraint violation becomes apparent (which, in line with modularity, syntax neither recognized nor cared about): The clitics are placed in the initial position of the intonational phrase ι, where they cannot attach to a preceding prosodic host: ${}_{\iota}(=\sigma$. This issue is resolved by positing that p-structure is organised according to its own principles and constraints. One of these constraints is prosodic inversion (Halpern 1995), which allows for the clitics to be placed after the first valid prosodic host – in this case (/taj/)$_{\omega}$. As a consequence, the initial linear order of the phonological string as depicted in Figure 19 will be adjusted to satisfy the prosodic constraints. The result is the (final) p-string (taj)$_{\omega}$ =joj =ga =je (t͜ʃoʋek)$_{\omega}$ … which in turn forms the basis for the phonetic representation.

This approach to the interface allows for a clear separation of syntactic and prosodic analyses and can account for a number of other phenomena as well,

---

[29] Which approach is chosen for the mapping between syntactic and prosodic constituency is up to the researcher. In this case, the end-based approach would not lead to a different outcome with respect to the clitic placement.

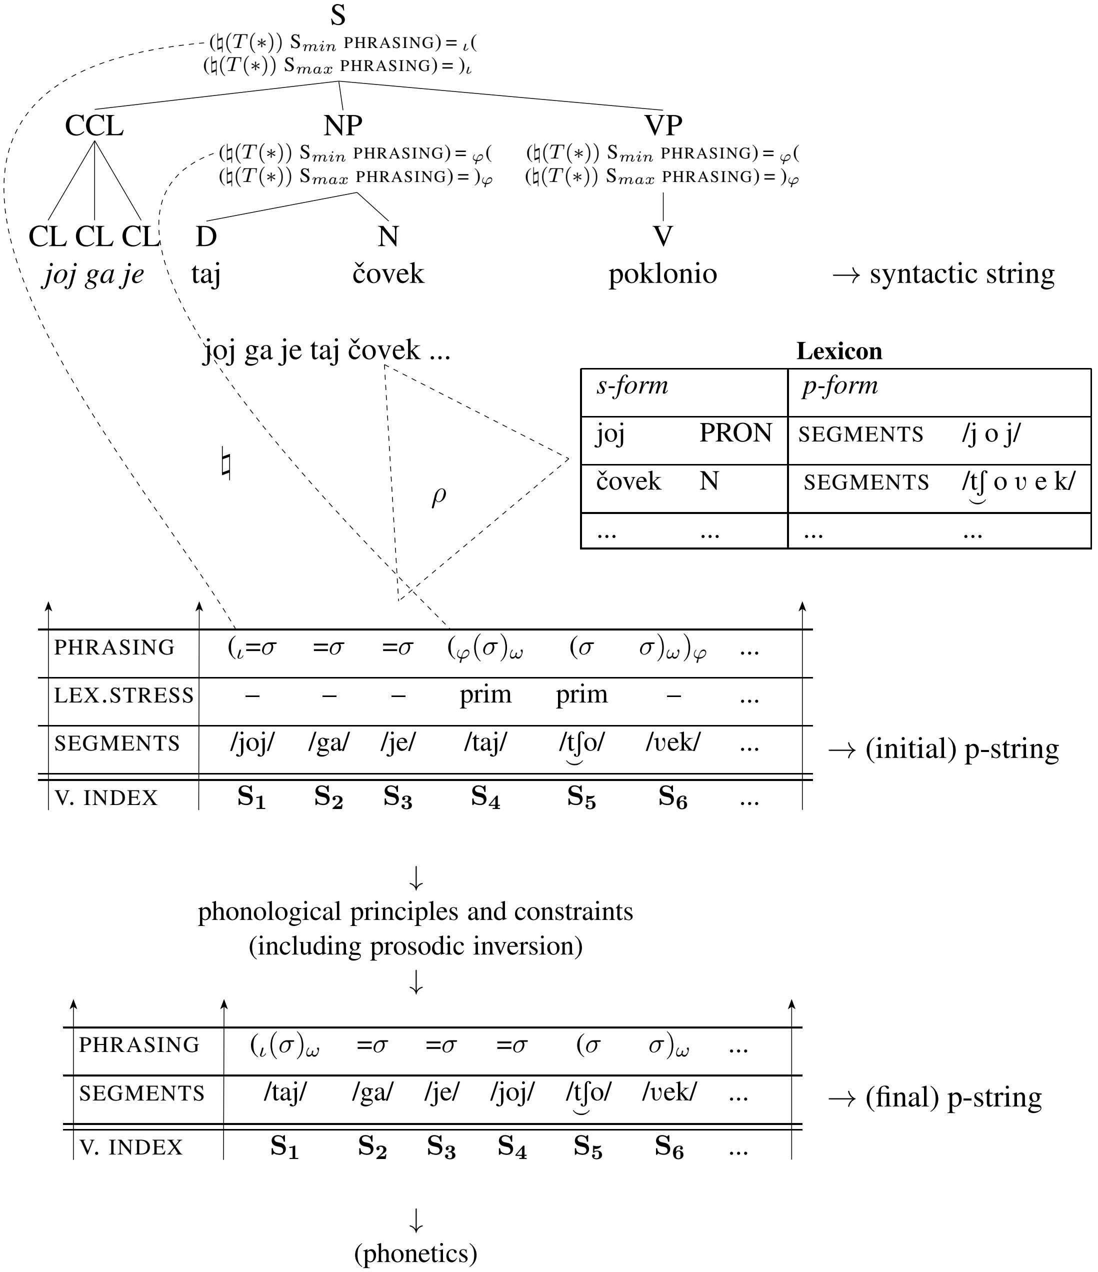

Figure 19: The syntax–prosody interface and the p-structure analysis for example (21)

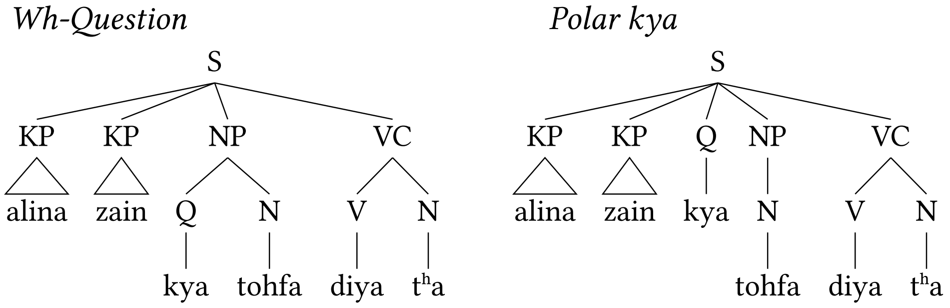
including notorious problems where the concept of lexical integrity (Bresnan & Mchombo 1995) is seemingly at stake. Such phenomena, among them Pashto endoclitics (Bögel 2015: Ch. 6) and Vafsi mesoclitics (Bögel et al. 2018), are difficult to explain from a purely syntactic perspective, but can be explained in a straightforward fashion with the proposal made here, as prosodic restructuring is based on prosodic constraints alone and is not concerned with syntactic constraints like word integrity.

The 2P clitic analysis just discussed was an example for production, i.e., the analysis first considers syntactic structure and then builds prosodic structure. The framework proposed in Bögel (2015) also allows for comprehension as is demonstrated in the following with an example from Butt et al. (2017, 2020) on Urdu polar *kya*. Consider example (23), where the sentence can be understood either as a polar question or as a wh-constituent question.

(23)	alina=ne	zain=ko	kya	tohfa	di-ya	t^h-a?
	Alina=Erg	Zain=Acc	what	present.M.Sg	give-Perf.M.Sg	be.Past-M.Sg

Constituent Question: ‘What gift did Alina give to Zain?’
Polar Question: ‘Did Alina give a gift to Zain?’

This ambiguity corresponds to two different possible syntactic analyses, as shown in Figure 20. In the wh-constituent interpretation, *kya* is phrased together with the following noun *tohfa*. In contrast, in the polar interpretation, *kya* is analyzed as an immediate daughter of S.



Wh-Question

Polar kya

Figure 20: C-structures for the *wh*-reading and for *polar kya*

Prosody is essential to the disambiguation of this structure: *kya* carries an H* accent if it is part of a constituent question while it has a flat pitch in the polar interpretation. In order for the grammar to make use of this disambiguation possibility, the information on pitch accents thus has to be available at the interface to p-structure.

The categorical interpretation of pitch accents is dependent on a number of attributes in a given speech signal; for a H* pitch accent, there needs to be a sudden rise followed by a relatively abrupt drop in the fundamental frequency F_0. The p-diagram in Figure 21 allows for the integration of this (and additional) speech signal information on the 'signal' level (here: medium F_0 and duration for each syllable) with a categorical interpretation of the relevant acoustic cues given on the 'interpretation' level in form of a ToBI annotation: H*.[30]

Phras.	$(_\iota$	...	...	...	...	...	...	...	...	...	...	$)_\iota$	interpret.
ToBI	...	...	...	...	...	...	**H***	...	...	...	...	L%	↓
Dur.	0,08	0,16	0,14	0,17	0,28	0,23	0,21	0,20	0,16	0,13	0,11	0,22	signal
F_0	164	211	239	243	228	229	**247**	229	162	147	136	(83)	↓
Value	[ə]	[li]	[na]	[ne]	[zæn]	[ko]	**[kja]**	[t̪oh]	[fa]	[d̪i]	[ja]	[tʰa]	
Index	S_1	S_2	S_3	S_4	S_5	S_6	S_7	S_8	S_9	S_{10}	S_{11}	S_{12}	

Figure 21: P-diagram for the speech signal corresponding to the constituent question in (23)

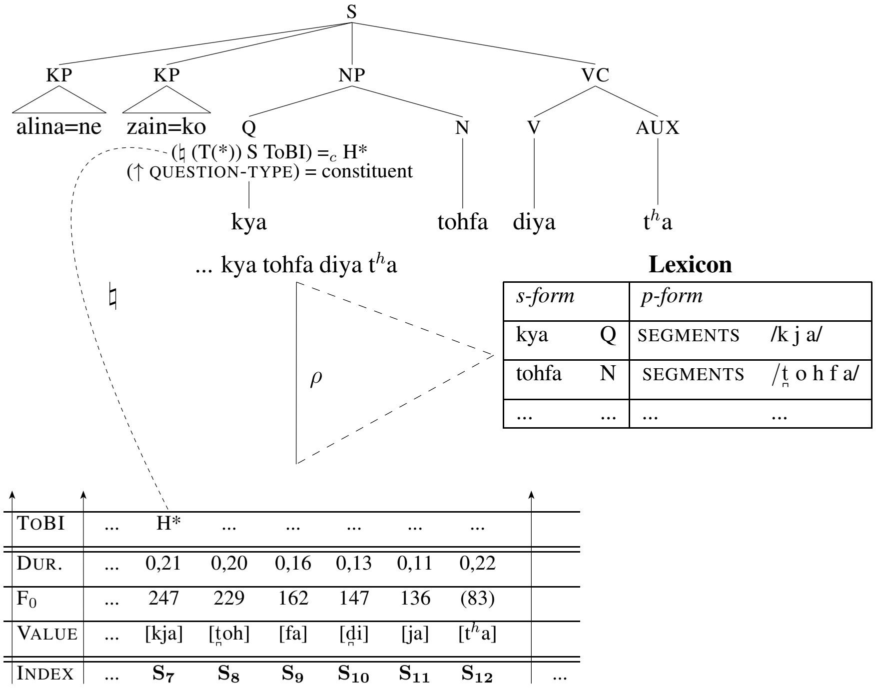
This effectively provides for an interface between phonetics (i.e., a concrete speech signal) and phonology/prosody and allows for the integration of information given in a speech signal into an LFG grammar. The relevant information on the H* accent again becomes available at the interface to c-structure via the transfer of structure and the transfer of vocabulary.

As shown in Figure 22, the transfer of vocabulary identifies the correct p-forms in the multidimensional lexicon and makes the associated s-forms available to c-structure. The transfer of structure then 'checks' whether the syllable associated with the c-structure node Q carries an H* accent – in which case the attribute-value pair [QUESTION-TYPE = constituent] is projected to f-structure. This approach also allows for the disambiguation of syntactically ambiguous structures where the boundary domains are the crucial indicators (Bögel 2020) and has also been applied to more complex pitch accent phenomena (Bögel & Raach 2020).

Summing up, the directional indirect reference approach proposed in Bögel (2015) allows for a differentiation of production and comprehension and has been

---

[30] The annotation on the interpretation level is greatly reduced on purpose. There is not yet a fully developed 'UrduToBI' or a clear conception of possible prosodic domains and how these are defined (but see Urooj et al. 2019 for discussion) – an interpretation in terms of the English/German annotation system might thus be misleading.



s-form		*p-form*	
kya	Q	SEGMENTS	/k j a/

Figure 22: *kya* as part of a constituent question (Butt et al. 2020)

applied to a large variety of different linguistic phenomena. It is the first approach in LFG which integrates spoken language in the form of concrete speech signal data and which pushes LFG towards a more psycholinguistic model of language as discussed in Section 3.

5 Conclusion

This chapter gave a chronological overview of the different approaches to prosody and its interfaces in LFG. As the different proposals show, work at this particular interface always requires a discussion of grammar architecture in general and of module interaction in particular. In general, two schools of thought can be distinguished in the LFG literature: the indirect reference approach and the parallel approach. The indirect reference approach assumes that p-structure is influenced by information from different modules, for example syntactic constituency. In addition, p-structure is assumed to be subject to its own principles and constraints, among them rhythmic principles, prosodic inversion, or constraints on the size of prosodic domains. The indirect reference approach was pursued in Butt & King (1998), O’Connor (2005), and Bögel (2015) and subsequent papers. While these proposals show differences with respect to the overall architecture, the interfaces between modules in all of these approaches are organised according to the traditional co-descriptive LFG annotations.

The second school of thought, the parallel approach, assumes that modules are built up in parallel. Under this view, each module is built on its own principles and constraints without 'input' from the other modules. P-structure is assumed to be formed on rhythmic principles, thus accounting for the mismatches found between prosodic and syntactic constituency. The interface between c- and p-structure is reduced to the interface between the syntactic and the phonological string, which are extended to include prosodic and syntactic/semantic information. The information present in both strings is then 'matched'. This approach is most prominently pursued in Dalrymple & Mycock (2011), Mycock & Lowe (2013), and subsequent work. Bögel et al. (2009, 2010) also fall into this second group. However, the exact nature of p-structure is never defined under this approach and it is thus harder to demarcate.

A second main point of this chapter was that the majority of the proposals presented here assume a certain directionality, which is also in line with psycholinguistic and computational approaches (Forst & King 2023 [this volume]): 'production' in the case of Butt & King (1998), 'comprehension' in Bögel et al. (2009, 2010), O'Connor (2005), and an open discussion of both in Bögel (2015). This distinction is not evident in the proposals by Dalrymple & Mycock (2011) and Mycock & Lowe (2013), which represent a perspective where each module builds structure independently of the other modules. The discrepancy between these views of the grammar architecture and of the analysis of language in general has, to my knowledge, not yet been openly debated. This chapter hopefully contributes to a more general discussion of grammar architectures in that it aims to show in a very concrete way what each school of thought pursues and how these ideas can be realised.

Acknowledgements

I would like to thank Tracy H. King, Miriam Butt, and two anonymous reviewers for their detailed comments, and Mary Dalrymple for her infinite patience.

Chapter 18

Information structure

Annie Zaenen
Stanford University

The first section of this chapter gives an overview of the conceptual discussions in information structure (IS), and the second section describes the LFG work in the area. The third section intends to be an exhaustive overview of the LFG work on IS.

1 Introduction

In LFG, attention to information structure has led to many interesting language-specific studies but, contrary to the situation in, for instance, syntax, there is no generally accepted view of either the distinctions needed or the terminology to be adopted. Given this situation, we start with a general, non-LFG-specific overview of conceptual discussions in IS (Section 2). The hope is that this will alert the reader to check which notion of say, topic, focus or contrast, is used in the LFG contribution they happen to be reading. In Section 3, we describe the general lines of the LFG work, highlighting some of the concepts that are often appealed to and the major proposals that have been made about how IS should be integrated in the LFG architecture. Section 4 gives exhaustive thumbnails of the LFG work on IS. The overview in this chapter does not include historical studies. These will be covered in Booth & Butt 2023 [this volume].

2 What is Information Structure?

Information Structure looks at how a producer of an utterance presents linguistically encoded information to the audience. It studies the sentence-internal aspects of this organization, while Discourse Structure (DS) studies the overall organization of bigger units of a text. The term INFORMATION STRUCTURE (IS)

Annie Zaenen. 2023. Information structure. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 823–853. Berlin: Language Science Press. DOI: 10.5281/zenodo.10185972

was coined by Halliday (1967); Chafe (1976) introduced the term INFORMATION PACKAGING, which is also used by Vallduví (1992). Recently it has been generally accepted that it is desirable to keep DS and IS separate, but it is often not possible to describe IS without making some assumptions about DS: for instance, the notion of sentence topic and discourse topic are related and often not kept clearly separated. Both DS and IS are generally considered to be part of pragmatics and different from semantics, which is mainly concerned with INFORMATION CONTENT, while DS and IS are concerned with INFORMATION MANAGEMENT (cf. Krifka 2008). But, again, certain aspects of information content and information management are closely intertwined, e.g. scope phenomena, the notion of predication, and pronoun interpretation (see e.g. Reinhart 1981 and King & Zaenen 2004).

IS distinctions can be realized through *prosody*, *word order* and/or *morphology*. In this section we mainly discuss word order and morphology; for prosody, see Bögel 2023 [this volume].

IS entities can be talked about as being linguistic in nature, e.g. NPs, VPs, etc., or they can be thought of as psychological. In most cases the only thing we can access and study are the linguistic reflexes of psychological states. This leads to terminological confusion. For example, is a topic a textual entity in the sentence, or is it the entity/state of affairs which the producer of this utterance intends to talk about, the denotation? Reinhart's discussion, for instance, is very much in terms of linguistic entities: all the NPs in a sentence are possible topics, and new information will be added to the file card for the NP or a new file card will be created, in the sense of Heim (1982) or Kamp (1981).

In the discussion of topic, the ambiguity is often not too harmful. It leads to more confusion in the discussion of focus. Consider the sentence *John washed it* as an answer to *What happened to the car?* Here *John washed* is taken to be the focus, but in most syntactic theories this is not a constituent at any level, the exception being Steedman's Categorial Grammar framework (see e.g. Steedman 2000).

Lambrecht (1994) and Vallduví (1992) state explicitly that they see topic and focus as psychological, and that the linguistic entities should be termed TOPIC and FOCUS EXPRESSIONS. They appeal to a pragmatic notion of common ground[1]

---

[1] The original notion comes from Stalnaker (1970), who defines it as the set of pragmatic presuppositions shared by interlocutors at the moment of the utterance of the sentence. For Stalnaker, a proposition is pragmatically presupposed when the participants in the discourse "take its truth for granted", and "assume that others involved in the context do the same". It is not totally clear that Lambrecht has the same idea. Lambrecht (1994: 44) states: "'To have knowledge of a proposition' is understood here in the sense of 'to have a mental picture of its denotatum', not in the sense of 'to know its truth'". See Dryer 1995 for an extensive discussion.

in which interlocutors' intentions play a role. This relates to the issue of how IS fits into a full-fledged formal representation of text, which is often left rather vague. The most common metaphor is that the IS gives instructions to update file cards. For Lambrecht (1994), the pragmatic presupposition and assertion are sets of propositions, and topic and focus structure is defined in relation to them. How all this is ultimately represented in the human mind is definitely outside of the scope of this overview. For convenience, I will assume that interlocutors have a structured representation of the discourse they are engaged in, and I will refer to this as the DENOTATION of the linguistic entities that encode IS.

IS, viewed as part of pragmatics, assumes that information transmission relies on the interlocutors having a common ground from which the interaction proceeds, with the producer of the utterance introducing information not yet known by the audience. The interlocutors are in a particular information state that they intend to change through the interaction. An utterance, then, can be divided into two parts, one that links it to what precedes and one that introduces new information. Under this bipartite subdivision, the TOPIC, THEME or BACKGROUND is the part that relates it to the preceding discourse and the COMMENT, RHEME or FOCUS advances the discourse by providing new information. Even ignoring the notion of DISCOURSE TOPIC and the existence of ALL FOCUS utterances, both sets of notions are unclear and defined differently by different authors. A useful way to get a grip on the main distinctions is to start from Dahl's (1974) observation (see also Jacobs 1984) that, assuming a context in which what John drinks is at issue, a sentence such as *John drinks beer* can simultaneously be analyzed as having *John* as its topic and *drinks beer* as the comment or *John drinks* as the background and *beer* as the (narrow) focus. The sentence is about *John* (the topic), so the rest is comment, but the new information, the focus, is *beer*, as we already know that John drank something. Researchers interested in focus often see the main division as BACKGROUND-FOCUS, whereas those interested in topic see it more often as TOPIC-COMMENT. The two views are combined in the tripartite proposal of Vallduví, who proposes LINK-FOCUS-TAIL, where LINK and TAIL together form the GROUND.

Apart from these discrete views, there are views that see information structure as gradient. For instance, the Prague school (e.g. Firbas 1975) describes topics as the material lowest in "communicative dynamism", where the latter is determined by three parameters: linear order, semantic considerations (e.g. the type of the verb), and the degree of context dependency. These views are not often referred to in the LFG literature, but some researchers have proposed hierarchical analyses with respect to the notions of activation/salience (see Andréasson 2009 and O'Connor 2006) or topic-worthiness (Dalrymple & Nikolaeva 2011)

Other authors have proposed to further analyze notions such as topic and focus as feature bundles, as we will discuss in Section 3.1. This allows for more fine-grained distinctions.

There is no accepted view of IS in LFG, but the views that have had the most influence are Lambrecht (1994), Vallduví (Vallduví 1992, Vallduví & Vilkuna 1998, Vallduví & Engdahl 1996), and Reinhart (1981). Only a few LFG proposals address the conceptual issues wholesale.

In what follows I will review some IS notions in more detail and then discuss the LFG work in the area.

2.1 Notions of topic

One of the most influential proposals is that of ABOUTNESS TOPIC, so named by Reinhart (1981), but the idea goes back at least as far as Kuno's early work, later published as Kuno (1987) (see also Dahl 1974). The link to the previous discourse that is assumed here is rather broad: the referent of a topic is presupposed to exist (based on Strawson 1964). Reinhart, following Kuno, uses locutions such as *X says about Y*, *Speaking of X*, *As for X* as tests to distinguish the topic from other NPs in the sentence. It is recognized that these tests do not work very well. *Speaking of X*, for instance, is an expression notoriously used to change the topic, so it cannot be used as a diagnostic for continuing topics.

Reinhart uses the file card metaphor (cf. Heim 1982) to explain what a topic does: it indicates where the hearer should store the information contained in the sentence. The proposal does not distinguish between continuing topics and switch topics (see below) and makes the explicit assumption that every sentence has only one topic. For instance, for the sentence *All crows are black*, the information provided is classified under crows and understood as an assertion about the set of all crows. (So, the natural way to assess it will be to check the members of the set of crows and see if any of them are not black, rather than checking the non-black things to see if any of them are a crow.) This view seems to be based on an overly literal conception of a file card. With a discourse fragment like *What about John and Mary? They got married but he doesn't love her* (adapted from Lambrecht 1994), it seems difficult to claim that this information is stored only under *John* rather than (also) under *Mary*.

The one-topic idea is explicitly rejected by Lambrecht (1994), who sees Reinhart's (1981) distinction between topics and non-topic definites as a difference in salience. This view has led to the proposal to distinguish between primary and secondary topics (see below). Lambrecht also rejects Reinhart's semantic notion of presupposition. For Reinhart, following Strawson (1964), topics are presupposed to exist. Lambrecht's notion of presupposition is pragmatic and does not require this. For him, the most important pragmatic articulation of a structured meaning is that between PRAGMATIC PRESUPPOSITION and PRAGMATIC ASSERTION (comment), where the pragmatic presupposition is assumed by the speaker to be equally assumed by the hearer and the pragmatic assertion is what the hearer is expected to assume after having heard the sentence. For Lambrecht, the negative quantifier *nobody* can be a topic. Most authors, however, confine the notion of topic to referents that can be expressed by definites or specific indefinites. However, not everybody agrees with this: see e.g. Endriss (2009) and Gécseg & Kiefer (2009).

Vallduví's (1992) notion of LINK is close to that of topic, but it is explicitly restricted to elements in first position. He sees this first position[2] in terms of a requirement for such elements to act as address pointer, instructing the hearer to go to an address or card in the sense of Heim (1982). When the elements in the sentence do not require a pointer to a new address, they are not LINKS (topics) but TAILS. Tails correspond more or less to what others have called SECONDARY or CONTINUING TOPICS. Vallduví's notion of link is restricted to what have been called SWITCH TOPICS: topics that are different from the topic of the previous sentence.[3]

As this short discussion shows, it is useful to distinguish topics depending on properties of the element in the previous discourse with which they are in an anaphoric relation. (The discussion tends to be restricted to consideration of elements in the previous sentence.) The antecedent can be a topic, in which case we have a CONTINUING TOPIC; or it can be a focus, in which case we have a SWITCH TOPIC (corresponding to Vallduví's LINK). It has been claimed that some constructions explicitly signal switch topics.[4] The notion of CONTINUING TOPIC comes close to that of DISCOURSE TOPIC. The two might be distinguished in the sense that a continuing topic has to be the topic of the immediately preceding discourse unit (e.g. sentence), whereas the discourse (or FAMILIAR) topic can be broader, but not all authors make that distinction. Some authors reserve the term ABOUTNESS TOPIC for SWITCH TOPIC and hence distinguish them from CONTINUING TOPICS (see e.g. Frascarelli & Hinterhölzl 2007, who show that in Italian and

---

[2] He allows for two topics under the condition that they precede all other elements in the sentence.

[3] The discussion in section 5.1.1 of Vallduví & Engdahl (1996) shows that the alignment between switch topic and first position cannot be right for all languages. It also shows that restricting the notion of topic to switch topic is awkward, as Swedish examples show this is also a position of continuing topics.

[4] For example, first position elements in Catalan as analyzed in Vallduví (1992).

German these have a different linguistic realization). CONTINUING TOPICS are often not overtly expressed (e.g. in so-called pro-drop languages). Some authors consider these sentences as topicless, while others assume the understood topic to be part of the IS of the sentence.

A further distinction is invoked with the term CONTRASTIVE TOPIC. Contrast is most often invoked with respect to foci, and the concept will be discussed further in Section 2.2.1. Here we point out that topic expressions can contain elements that are new as well as old. For example, in the short discourse *What about cars? Which ones do you like? – Fast cars I like*, *cars* is topical, but *fast* is new information. Contrastive topics are seen as implying that a set of alternatives is active in the speaker's mind. They can be linked to the notion of D-LINKING (Pesetsky 2007). D-linked elements are defined (following Büring 2003) as related to the question under discussion (QUD). This, again, brings discourse topics into the discussion of sentence topics.

The types of topics mentioned above are typically expressed as NPs, but there is a kind of topic that is most often realized as a PP. It occurs in so-called "all focus" sentences such as *In California, there are often forest fires.* Here, the initial element restricts the range of the rest of the sentence. These elements were dubbed STAGE TOPICS by Erteschik-Shir (2007), but they have been discussed earlier, e.g. Gundel (1974). Erteschik-Shir claims there is a silent stage topic in all-focus sentences that do not have an overt topic. Some researchers seem to think the stage topic only occurs in sentences that have no other topic, but for others, stage topics can co-occur with ABOUTNESS topics. Bentley & Cruschina (2018) discuss the specific lexical-semantic restrictions on all-focus constructions in Romance languages. LFG researchers have not worked on stage topics, but Szűcs (2017) discusses English adverbials that could be considered as, in part, falling in that class.

2.1.1 Accessibility hierarchies

Apart from the aboutness tests proposed by Reinhart, some proposals in IS appeal to notions, such as salience or topic-worthiness, that distinguish among the entities that are assumed to be in the discourse participants' consciousness at the moment a new utterance is produced or heard. Following Chafe (1987), who introduced the idea, various hierarchies or, at least, classifications have been proposed (see e.g. Givón 1983, Ariel 1988, Lambrecht 1994, Erteschik-Shir 2007). Within LFG the ones that are referred to are Prince's (1981) notions of DISCOURSE OLD/NEW and HEARER OLD/NEW, EVOKED, and INFERRABLE (see also Ward & Birner 2001) and Gundel's GIVENNESS HIERARCHY (e.g. Gundel et al. 1993).

Prince's categories are about entities. If they have been mentioned in the discourse, they are discourse old; if not, they are discourse new (or inferrable). Referents may also be old/new with respect to (the speaker's beliefs about) the hearer's beliefs. In feature decomposition approaches in LFG, following Choi (1996), the +NEW feature corresponds to Prince's notion of discourse new. Lambrecht (1994) proposes a connection between Prince's notions and topics (his Topic Accessibility Scale) but notes that inherent semantic factors such as animacy may also play a role.

The GIVENNESS HIERARCHY of Gundel et al. (1993) proposes six ordered cognitive statuses: in focus > activated > familiar > uniquely identifiable > referential > type identifiable. These statuses determine the form of referring expressions and are assumed to correspond to the status of the referent in the memory of the discourse participants. For instance, for English:

- TYPE IDENTIFIABLE: necessary for the appropriate use of any nominal expression
- REFERENTIAL: speaker refers to a particular object, hearer needs to know the referent; necessary for appropriate use of definite expressions
- UNIQUELY IDENTIFIABLE: necessary for the appropriate use of *the*
- FAMILIAR: necessary for the uses of personal and definite demonstrative pronouns
- ACTIVATED: necessary for all pronominal forms and sufficient for demonstrative *that* and stressed personal pronouns
- IN FOCUS: necessary for the use of zero and unstressed pronouns.

Especially the last two items on the scale have been used to argue for differences in status between elements which are not treated equally: cognitive accessibility relates to how prominent the entity is in memory. This does not in itself determine whether it will be a topic or a focus. The accessible elements are all topic-worthy, but depending on their place on the scale, they will require different linguistic expression.

2.1.2 Other hierarchies

The topic-worthiness of a discourse element has also been claimed to be influenced by the prominence features that play a role in the REFERENTIAL HIERARCHY (Silverstein 1976, Dixon 1994), such as person, definiteness, and animacy. This hierarchy has played a more important role in studies about the alignment of grammatical functions but, as Simpson (2012) (following Bickel 2012) observes, a hierarchy with pronouns on one end and full NPs on the other is bound to have something to do with IS.

In recent literature, it is generally accepted that topic-worthiness or accessibility are not enough to guarantee topichood, and that ABOUTNESS is the crucial factor. It is, however, not clear how aboutness can be detected. The decision to construct a sentence/utterance about a particular sentence topic seems to be a decision that the speaker/writer makes which is constrained, but not uniquely determined, by the previous discourse. In some languages this choice must always be clearly marked, while in others that is not the case and a specific marking may be absent or optional.

2.2 Focus and related notions

The focus is (or is part of) what is informationally new in a sentence, what is not assumed to be common ground between the hearer and the speaker at the moment that the sentence is uttered. A common proposal is that the focus can be found by considering what question the sentence could be an answer to. The focus is what replaces the wh-term in the question.[5] A typical set of question-answer pairs is the following:

(1) Q: What did Mary do?
A: She [washed the car].

(2) Q: What did Mary wash?
A: She washed [the car].

(3) Q. Who washed the car?
A: [Mary] washed the car.

(4) Q: What happened to the car?
A: [Mary washed] it.

(5) Q: What happened?
A: [Mary washed the car].

---

[5] This test runs into problems when a particular language has a special marking for answers to questions that distinguishes these from other arguable foci. Another more general problem with the test is that full answers to wh-questions are often unnatural. Most of the topical information would be silent. These versions are, however, rather uninformative when the test is used to probe word order constraints.

(6) Q: What did Mary do with the car?
A: She [washed] it.

The focus of each answer is the material in square brackets. Lambrecht (1994) distinguished three notions of focus structure: PREDICATE FOCUS (1 and, presumably, 4 and 6), ARGUMENT FOCUS (2 and 3) and SENTENCE FOCUS (5)

The question-answer approach tends to tie the IS notion of focus to alternative sets as used in semantics, as the meaning of wh-questions can be considered as the set of possible answers (Hamblin 1973), or one can think of the alternative sets of Rooth's (1992) view on focus and focus particles. The problem with appealing to these semantic notions is that one can get bogged down by the issue of how explicit these alternatives have to be. It is clear that, in a certain sense, every assertion is made against the background of all other possible assertions that could have been made at that particular moment in the discourse, but that does not mean that one can list/define a set of alternatives (see below).

It is often claimed that different types of foci are distinguished by the degree to which the set of alternatives has been made explicit. In the examples discussed so far, the syntax is unremarkable and the stress pattern is what would be found in normal narrative text. The foci in these examples are called INFORMATION or COMPLETIVE or IDENTIFICATION FOCI. They are often expressed in what is thought of as 'neutral' or 'default' syntax. In some languages, specific constructions allow the speaker to signal whether she has a particular set of alternatives in mind, or even whether she wants to convey that only one option is possible. This has led to the distinction between the foci above and CONTRASTIVE and/or EXHAUSTIVE FOCI. Moreover, EXCLUSIVE foci can be distinguished from EXHAUSTIVE foci: exclusive foci exclude some alternatives, while EXHAUSTIVE foci exclude all alternatives. Some researchers have proposed additional subdivisions of focus. Dik et al. (2008) distinguish COMPLETIVE focus, which is NON-CONTRASTIVE, from all other CONTRASTIVE forms: PARALLEL, SELECTIVE and three types of corrective foci: EXPANDING, RESTRICTING, and REPLACING. Most of these subtypes can be seen as specifying relations between the set of alternatives and the focus.[6]

---

[6] Not all researchers distinguish clearly between the FOCUS DOMAIN and FOCUS EXPONENT. For instance, in the English examples (1-6), focus is normally indicated with pitch accent. As discussed at least since Jackendoff (1972), the nuclear stress rule assigns stress to the final constituent of a focus, while the focus itself can be projected up any higher constituent, so the answers in (1), (2), and (5) get the same stress assignment but have different foci. Even when phenomena such as FOCUS PROJECTION are recognized, researchers tend to concentrate their attention on FOCUS MARKERS and are often not very clear on what constitutes the FOCUS DOMAIN. For some it is actually the markers that deserve the term focus. In this overview I assume that the conceptual category can be distinguished from its realizations.

In running text, it is not always clear what the question is. Consider example (7) (adapted from Vallduví & Engdahl 1996).

(7) a. Mary bought a book yesterday morning.
b. She read it in the afternoon.

Sentence (7b) can be seen as an answer to the question *What did she do then?* as well as an answer to the question *What did she do with the book?* In the first case, (the denotation of) the VP is focal. In the second case, both *she* and *it* are topics and the rest of the material is focal. Written material, especially reduced by a window of at most two sentences, is prone to being pragmatically ambiguous. By turning the text into a set of questions and answers, an interpretation is imposed which reduces the ambiguity. Looking at larger pieces of text might also help in figuring out what the right question is in a particular context, but that leads to discourse analysis as distinct from information structure.

2.2.1 Contrast

Although there are many subdivisions of focus, the main dividing line seems to be between non-contrastive and contrastive focus. Once this line has been drawn, however, one realizes that contrast is not only relevant for focus but also for topic. Take, for instance, an exchange like the following:

(8)
- Q. Which foreign languages do your children speak?
- A. Anna speaks English and Maria speaks German.

In languages such as English there will be CONTRASTIVE STRESS on *Anna* and *Maria* as well as on *English* and *German*. Some researchers see this as a reason to adopt contrast as an independent notion and propose to distinguish between ±CONTRASTIVE topics and foci.

Here, again, a confusing factor is that contrast can be used to refer to an abstract category or to a linguistic signal, e.g. a particular stress pattern. Contrastive focus, then, can mean that the focus has some special stress or pitch pattern (dubbed Kontrast by Vallduví & Vilkuna 1998) or it can mean that the focus element contrasts with other elements that could fill the same position in the sentences by being an alternative to these elements. When seen as the latter, the notion is as confusing as that of focus and, in fact, it is difficult to see a difference between the two.

The various notions of contrast are discussed in Repp (2016). She distinguishes:

(9) a. Restricted, contextually clearly identifiable set of alternatives: *John* would be marked for contrast in an example like *John, Pete and Josie all offered help. I asked John.* (É. Kiss 1998).
b. Alternatives must be in the sentence.
c. Substitution of alternatives must create a false statement (Neeleman & Vermeulen 2013).
d. Alternatives always contrast, simply by being different (alternative semantics) (Vallduví & Vilkuna 1998, also Krifka 2008).
e. Interlocutors' belief systems: unexpected, remarkable (Frey 2006).

These are, by and large, the notions of the set of alternatives which have been proposed in discussions of focus. At the limit, we find notions such as *unexpected, remarkable* that seem to depend on the speaker's frame of mind without being independently detectable. Moreover, as we have seen above, contrast is not limited to foci: it can also occur with topics. Some researchers have bit the bullet and taken contrast as the correct notion, e.g. Kruijff-Korbayová & Steedman (2003). Under that view, contrast within the topic indicates that part of the topic is actually focal (Krifka 2008, Erteschik-Shir 2007). Others, however, see contrast as an additional distinction, and much work in LFG takes that approach. This is a view that has been argued for explicitly by, for example, Neeleman & Vermeulen (2013), who distinguish between contrastive and non-contrastive topics as well as contrastive and non-contrastive foci. They illustrate their approach with word order data in Dutch, but claim that in other languages it can be detected through prosodic marking. As noted above, their notion of contrast relies on the generalization that in contrastive contexts, the substitution of alternatives leads to false statements.

2.2.2 Relational newness

For researchers who treat CONTRAST as a feature that can belong to both topics and foci, the question remains: what is the characteristic that distinguishes focus from topic? Choi (1996), among others, proposes that foci must be DISCOURSE NEW in the sense of Prince (1981). This view is, however, contested by e.g. Lambrecht (1994) and Gundel (1974), who draw attention to examples such as (10) (adapted from Lambrecht 1994):

(10) a. Last night Anne and Paul were bored.
b. They hesitated between going to the neighborhood restaurant or going to the new movie at the Rex.
c. Finally they went to the movie.

(The denotation of) *last night* in (10a) can be considered to be a stage topic and the rest of the material in that sentence is focal. In (10b) and (10c), the aboutness topic is (the denotation of) *they* (=Anne and Paul). (10b) and (10c) (as well as (10a)) establish new relations between these referents and the rest of the sentence. In (10c), *the movie* and even *going to the movie* are as much old information as *they*. What is new is the relation between the elements. The referents of the NPs have become part of the common ground between speaker and hearer before the sentence is uttered. They are not DISCOURSE NEW in Prince's sense or REFERENTIALLY NEW in Gundel's terminology. Rather, they are RELATIONALLY NEW in Gundel's terminology. Once it is determined that the topic is (the denotation of) *they*, the choice between the restaurant and the movie is the relevant relationally new information. Thus, (the denotation of) *the movie* is the element about which a new relation is asserted, marked as +NEW. It is the alternative that is chosen in opposition to all other possible choices.[7]

Note that under this view of newness, it is not immediately clear that (the denotation of) *they* is the topic: the relation between (the denotation of) *they* and (the denotation of) the rest of the sentence is also new. To determine the focus, it is necessary to know already what the topic is and what we are adding information about. Here we are assuming that (10a) leads to the question *What were they going to do about being bored?* and (10b) to *Where did they go?*

A sentence can establish new relations between several different entities. In (11b), the *give* relation holds between three participants.

(11) a. Mary was wondering what she would give little Hansi: the candy bar or the chocolate chip cookie.
b. She gave him the chocolate chip cookie.

Assuming that *Mary* is the topic, (11b) can be analyzed as the answer to *What did Mary do?*, in which case the denotation of the whole VP is the focus, or as the answer to *What did she give to him?*[8], in which case the denotation of *the chocolate chip cookie* is the focus. The second question presupposes that both speaker and hearer already assume that Mary has given Hansi something, so the relational new information is that it is a chocolate chip cookie. What is the status of *him* under that analysis? Here it seems useful to remember the terminological

---

[7] Some authors, most clearly Lambrecht (1994), see the relation itself as new, and hence as the focus. Still others, e.g. Erteschik-Shir (2007), see the focus as a complex structure that can contain topical material.

[8] There are other possibilities which we ignore here. Our point is not an exhaustive analysis of this stretch of text.

ambiguity remarked upon in the introduction: is focus seen as a synonym of comment, or is it to be opposed to background? When one assumes an opposition to background, it is reasonable to consider *him* to be part of the background and, possibly, as a special part of the background: a secondary topic.

The comment can also consist of more than just the focus. Consider the question-answer pair in (12):

(12) a. Q: Where was Mary?
b. A: She was cooking potatoes in the kitchen.

Here *in the kitchen* is the answer to question (12a) and presumably the focus, but *cooking potatoes* is also new information. Presumably it is part of the COMMENT. It can be seen as supplementary or COMPLETIVE information.[9]

3 The LFG approach

For LFG, there are two main issues related to IS: (1) what are the relevant distinctions to be made, and how are they encoded? and (2) how does IS interact with the LFG architecture? We discuss these in turn.

3.1 Feature decomposition

In the previous section we have seen that the notions of topic and focus, although generally accepted, are felt to be insufficient to encode all relevant IS distinctions. With respect to topic, there seems to be a need to further distinguish between different levels of salience and/or topic-worthiness of the entities which are accessible to the discourse participants. With respect to focus, there seems to be a need to distinguish between explicitly contrastive and not explicitly contrastive elements. Moreover, it has been observed that some topical information assumes the existence of subsets among which a choice has to be made. This has led many researchers, including many LFG researchers, to use features, most often binary

---

[9] What has been analyzed in the literature as focus marking is very heterogeneous. This has led some researchers, most prominently Matić & Wedgwood (2013), to question the assumption that the linguistic processes that are described in the literature as marking foci indeed have a uniform function. Hedberg (2006) already argues that several proposals about the relation between pitch accent and IS in English are not mutually compatible, nor are the proposals about *wa* in Japanese or those about *nun* in Korean. Matić & Wedgwood (2013) go further and try to show that many proposals invoking focus marking in various languages actually isolate markers whose functions are quite different and whose effect on the focus is only a byproduct of these functions.

features, to describe the IS behavior of linguistic entities and to define notions such as topic and focus. There is at this point no closed set of such features. Descriptive studies in this vein would provide a good basis for more theoretical investigations if the terminology was constant and explicit. Unfortunately, this is not the case. The same labels are used for different concepts and often no clear definition is given that allows the reader to figure out which meaning of an ambiguous term is intended. There are, however, some general tendencies: many researchers follow Choi (1996) and Butt & King (1996) and decompose the notions of topic and focus with two binary features.

In the light of the preceding discussion, one might expect that the notion of contrast would be represented in these dichotomies. This is, however, not the case in the proposals of Choi (1996) and Butt & King (1996).

Choi proposes the features ±NEW and ±PROM, for 'prominence', as shown in Table 1. Her notion of NEW is Prince's (1981) discourse new. Above, we saw that that notion is based on what is mentioned in the discourse and, hence, is problematic for certain analyses of focus. Choi's notion of PROM collapses the distinction between contrastive and completive focus and that between tail and link in Vallduví's sense. She does not discuss explicitly what such a collapsed notion would correspond to intuitively.

Table 1: Choi's features

Discourse function	Topic	Contr Focus	Tail	Compl/Pres Focus
PROM	+	+	−	−
NEW	−	+	−	+

Table 2: Butt and King's features

Discourse function	Topic	Focus	Background	Completive Info
PROM	+	+	−	−
NEW	−	+	−	+

Butt & King (1996) adapt Choi's proposal, making the distinctions in Table 2. Butt & King (1996) do not use the PROM feature to distinguish between contrastive and non-contrastive focus, as they only discuss cases of what they consider non-contrastive focus in their paper. This, of course, leaves open the question of which distinctions need to be made to account for the cases that have been discussed as contrastive versus non-contrastive focus.

Another difference between the two feature systems seems to be whether IS should be a full representation of everything in the sentence, or just some important parts. Whereas Choi's version of the features suggests that only some parts of the sentence will be represented, Butt & King's (1996) labeling assumes a full representation of the sentence. This latter view is also espoused in more formal treatments (see Section 3.2).

Another version of the scheme is found in Gazdik & Komlósy (2011), who use the d-link distinction of Pesetsky (2007) instead of the ±NEW feature, as shown in Table 3. They consider continuing topics to be background, and discuss the difference between hocus and focus in Hungarian as well as the status of question words. This more recent proposal takes into account the most important distinctions discussed in the literature reviewed above. The notion of prominence seems to correspond to the notion of contrast, and d-linking is a way to distinguish between more and less salient elements. This proposal is, however, only worked out for Hungarian.

Table 3: Gazdik and Komlósy's features

Discourse function	Focus, Question word, Hocus	Contrastive Topic, Question word	Completive	Background
PROM	+	+	−	−
D-LINKED	−	+	−	+

The switch in interpretation between Choi (1996) and Butt & King (1996) and the further switch in interpretation in Gazdik & Komlósy (2011) shows that the features are not clearly enough defined to apply unambiguously. It might be just this vagueness that has allowed several other LFG accounts, e.g Marfo & Bodomo (2005), Dalrymple & Nikolaeva (2011), Mycock (2013), Mycock & Lowe (2013) and Otoguro & Snijders (2016) to adopt the approach of Choi (1996)/Butt & King (1996).

What these two-feature approaches suggest is that, on an abstract level, only four distinctions need to be made to account for the IS distinctions that natural languages encode, even if these distinctions are not exactly the same in all languages. This is not necessarily false, but it is not something that has been argued for in any detail.

With respect to TOPIC, we often find one further distinction, although some authors have proposed more subdivisions. Bresnan & Mchombo (1987) distinguish between CONTRASTIVE (new) topics and NON-CONTRASTIVE ones. Although they refer mainly to early work by Lambrecht, their distinction seems to be basically Vallduví's distinction between LINK and TAIL. The distinction between LINK and TAIL is also appealed to in Dalrymple & Nikolaeva (2011) as closely corresponding to their distinction between PRIMARY and SECONDARY topics. Based on an analysis and data treated in more detail in Nikolaeva (2000), Dalrymple & Nikolaeva (2005) argue explicitly for a distinction between PRIMARY and SECONDARY TOPIC in Ostyak: according to the *what about X?* test, the primary topic has to be a subject in this language, but agreeing objects are secondary topics. They are typical answers to questions such as *What did X* (= primary topic) *do to Y* (= secondary topic)? This analysis is further developed for several other languages by Dalrymple & Nikolaeva (2011) in the context of their discussion of differential object marking.

Abubakari's (2018) FAMILIARITY and CONTRASTIVE topics (in Kusaal) seem to be intended to capture the distinctions between SWITCH and CONTINUING topic, but he seems to assume that there could be more than two varieties of topic. Mchombo et al. (2005) use the feature ±CONTRASTIVE to make a distinction within the class of SWITCH TOPICS; switch topics themselves are distinguished from CONTINUING TOPICS. Kifle (2011) proposes three topics in certain sentences in Tigrinya. Szűcs (2014) sees the distinction between CONTRASTIVE and NON-CONTRASTIVE topics (= −NEW elements) as crucial for left-dislocation and 'topicalization' in English: the topic position can be occupied by a contrastive element, be it topic or focus, whereas left-dislocation requires a non-contrastive new element. His distinctions seem to be similar to the ones made in Mchombo et al. (2005), but similarities and dissimilarities are not discussed.

Early work on FOCUS often distinguishes between CONTRASTIVE and PRESENTATIONAL focus (e.g. King 1995). A distinction between CONTRASTIVE and NON-CONTRASTIVE FOCI is made in Abubakari (2018). Dahlstrom (2003) appeals to Lambrecht's (1994) three-way distinction among foci: PREDICATE FOCUS, ARGUMENT FOCUS, and SENTENCE FOCUS. Gazdik & Komlósy (2011) also distinguish between HOCUS and FOCUS in Hungarian.

When four distinctions are felt not to be enough, appeal is made to various hierarchies to introduce further distinctions. The GIVENNESS HIERARCHY is invoked to make distinctions among topical and/or focal elements: see e.g. O'Connor (2006) and Andréasson (2008, 2009, 2013), who appeal to the notion ±ACTV (activated). Andréasson's and Connor's analyses are based on the Gundel hierarchy, but similar ideas are found in Lambrecht (1994).

Morimoto (2000) appeals to an animacy hierarchy in her analysis of subject-object inversion; following Bresnan (2001), she treats subject as a grammaticalized discourse function, and shows that animacy plays a role in the determination of the subject function in Bantu. Other hierarchies proposed are the Silverstein hierarchy (e.g. Simpson 2012 and similar hierarchies of topic-worthiness: Dalrymple & Nikolaeva 2011), or appeal to animacy, definiteness and specificity as in Mayer (2006). Mycock (2013) adds a feature for questions that can co-occur with all other features. O'Connor (2006) adds the feature ±OPEN to capture representations with and without a variable. The most extensive feature taxonomy in LFG, to my knowledge, has been proposed by Cook & Payne (2006) (see Section 4).

In general, the LFG analyses would profit from more cross referencing and more discussion of the similarities and dissimilarities among the various proposals. An exception is Dalrymple & Nikolaeva (2011), who adopt the two-feature scheme of Butt & King (1996) and discuss how their notions of PRIMARY and SECONDARY TOPIC are different. The feature CONTRASTIVE is liberally used by various authors, but often not further defined. Given how problematic it is, it would profit from a systematic clarification.

In general, not much attention is spent on the question of how to identify topic or focus independently of their syntactic, prosodic or morphological characteristics. Thus, it is not always clear that the marking that is thought to be that of an IS unit might not mark another distinction.

3.2 Representation of IS in LFG

3.2.1 From f-structure functions to a separate IS representation

The first mention of IS notions in LFG can be found in the discussion of the TOPIC/FOCUS functions in Kaplan & Bresnan (1982) and Zaenen (1985). These are taken over from the phrase structure treatment of long distance dependencies in the grammatical frameworks that were then current. The discussion of what these discourse functions did was limited to the observation that they were "overlay" functions, requiring an extension of the coherence principle: topics or foci were not only topics or foci, but also had an argument function such as subject or object. The actual content of the notions topic and focus was not discussed. The discourse functions were treated in the f-structure, just like other functions. In the early nineties, several Stanford theses (e.g. Alsagoff 1992, Joshi 1993, Kroeger 1991) investigated the relation between SUBJECT and TOPIC in Asian languages in syntactic terms.

In the first studies to discuss IS as such, the grammaticalized discourse function approach is also used, e.g. by Bresnan & Mchombo (1987) and by King (1995), who investigates in detail the phrase structure configuration needed to account for the configurational encoding of Russian discourse relations.

King (1997) discusses the drawbacks of an approach that integrates IS notions into the c-structure and the f-structure. She illustrates in detail the potential mismatches between f-structure units and IS units, and proposes to handle IS as a separate projection. This is what most researchers have done in subsequent work. We will refer to this separate module as the *i-structure*.

As already indicated above, most researchers start from a two-feature analysis of topic and focus, in most cases augmented with background and completive roles. The representation given is generally an attribute-value matrix (AVM), with the roles as attributes. The nature of the values depends on the way the relation of the i-structure to the other projections is articulated.

3.2.2 How does the IS relate to the other components of the grammar?

As IS can be signaled in various ways, the flow of information from the different components to the separate i-structure has to be modeled. LFG has a modular structure which allows researchers to experiment with various approaches while keeping other aspects of the framework constant. One of two models is generally adopted. One is proposed in an early paper by Butt & King (1996) and King (1997) and discussed further in Butt & King (1997); a later, different one is proposed in Dalrymple & Nikolaeva (2011) and further work in glue semantics.

In Butt & King (1996, 1997), the c-structure feeds into the i-structure. The i-structure and the f-structure feed into the semantic structure and the i-structure is related to the f-structure, as every PRED appearing in the f-structure has to be linked to a discourse function. Butt & King's model is assumed in Sulger (2009), Dione (2012) and Andréasson (2007), but it has not been worked out in detail.

Dalrymple & Nikolaeva (2011) develop a structured meaning approach à la von Stechow (1982) and Krifka (2006). In their view, the semantic structure encodes how meaning constructors relate to each other. The i-structure adds further structure specifying the pragmatic relations. Every meaning constructor in a sentence has to have a role at i-structure. What this role is can be positionally determined, through a c-structure annotation, or morphologically or prosodically determined. The feeding relations are c-structure to f-structure to s-structure to i-structure. The Dalrymple & Nikolaeva model is worked out in detail in Dalrymple et al. (2019). For discussion of how the prosodic information fits in, see Dalrymple & Mycock (2011), Mycock & Lowe (2013), Mycock (2013) and Bögel 2023 [this volume]. Apart from these two proposals, there are proposals by individual researchers that draw attention to specific problems; for example, O'Connor (2006) stresses the importance of the i-structure (his d-structure) relation to prosody. For him, part of the goal is to link an AVM representation for i-structure (his discourse structure) to a tree representation for prosody. Otoguro (2003) discusses the relation to morphology. Dahlstrom (2003) draws attention to the necessity of allowing constructional information to distinguish the various types of focus, especially sentence focus, and tentatively proposes an i-structure organized as a set of propositions.

Several researchers (e.g. O'Connor 2006, Choi 1996, and Andréasson 2010) propose an Optimality-Theoretic calculation to determine what is topic or focus or what is reanalyzed in a particular way, but no precise proposals are made about how this OT part fits with the rest of the architecture.

4 Studies of IS phenomena in LFG

In the following, I list LFG contributions in IS in chronological order, with some short comments intended to inform the reader which language data can be found in the contribution and which issues are most prominent.

Bresnan & Mchombo (1987) *Topic, pronoun, and agreement in Chichewâ.* This early paper treats the IS concepts as part of the f-structure. It discusses mainly word order and the notions subject and object in Chichewâ and some other Bantu languages.

King (1995) *Configuring topic and focus in Russian.* A revised version of a PhD thesis. Discusses topic, contrastive and presentational focus and background in Russian, Serbo-Croatian and Bulgarian. The IS notions are encoded in c- and f-structure, and other possible architectures are discussed.

Choi (1996) *Optimising structure in context: scrambling and information structure.* This PhD thesis discusses scrambling in German and Korean and appeals to the notions of aboutness topic and contrastive and presentational focus. It influenced later research by introducing the feature decomposition ±NEW and ±PROM(inent) and by its use of Optimality Theory to calculate the results.

Butt & King (1996) *Structural topic and focus without movement.* The paper discusses word order and discourse configurationality in Urdu and Turkish and distinguishes topic, focus, background and completive information. It is influential in the new way it used the features ±NEW, ±PROM.

King (1997) *Focus domains and information-structure.* The paper explicitly discusses the problem created by representing IS in the c- and the f-structure on the basis of Russian data. It proposes an i-structure parallel to the f-structure.

Sharma (1999) *Nominal clitics and constructive morphology in Hindi.* The focus of this paper is the representation of focus clitics in Hindi via inside-out uncertainty.

Broadwell (1999) *The interaction of focus and constituent order in San Dionicio Zapotec.* The paper uses Optimality Theory to calculate the right word order for focused constituents in Zapotec.

Morimoto (2000) *Discourse configurationality in Bantu morphosyntax* (see also Morimoto 2009) This dissertation looks at Kirundi and Kinyarwanda and discusses subject-object inversion. Following Bresnan (2001) in analyzing SUBJECT as both an argument and a discourse function and using the features of Choi (1996), it argues for two notions of topic in Bantu: external and internal topic. The distinctions are encoded in the f-structure.

Butt & King (1997) *Null elements in discourse structure.* The paper discusses pro-drop in Hindi/Urdu. It adds the distinction between switch and continuing topic to the distinctions made in Butt & King (1996). It uses a separate i-structure projected mainly from the c-structure.

Otoguro (2003) *Focus clitics and discourse information spreading.* The paper studies focus clitics in Japanese and argues for an architecture in which the c-structure is the input to the i-structure as well as to the f-structure and both are input to the morphology. It uses Optimality Theory to calculate the outcomes.

Dahlstrom (2003) *Focus constructions in Meskwaki.* The paper starts from Lambrecht's (1994) three focus types and discusses the various constructions, exemplifying them in Meskwaki. Following Lambrecht (1994), it proposes an i-structure which is structured as a set of propositions.

Dalrymple & Nikolaeva (2005) *Non-subject agreement and discourse roles.* The paper makes an argument for the notion secondary topic based on agreement facts in Ostyak. It assumes a separate i-structure.

Marfo & Bodomo (2005) *Information structuring in Akan question word fronting and focus constructions.* Starting from Akan question word fronting, the paper studies the difference between focus and background. It assumes a separate i-structure.

Mchombo et al. (2005) *Partitioning discourse information: A case of Chichewa split constituents.* The paper argues that the topic in Chichewa can be split into a −PROM and a +PROM part. The +PROMINENT part can be in initial position or not, and it can be ±CONTRASTIVE.

Cook & Payne (2006) *Information structure and scope in German.* The paper examines the interaction between word order and scope in German and claims we need to distinguish between ±TOPIC, ±NEW and ±CONTRASTIVE. The facts discussed relate to what others have called topic-within-focus. The account uses a separate i-structure, glue semantics and Optimality Theory.

Mayer (2006) *Optional direct object clitic doubling in Limeño Spanish.* The paper discusses clitic doubling in Limeño Spanish. It contains an extensive discussion of the factors that are usually associated with differential object marking (DOM): animacy, definiteness and specificity. It proposes that some of the objects discussed might be secondary topics.

O'Connor (2006) *Information structure in lexical-functional grammar: The discourse-prosody correspondence.* This dissertation discusses prosody and pitch accent in Serbo-Croatian and their link to IS notions. It is based on Lambrecht's (1994) distinction between presupposition and assertion and the distinction between active and non-active referents. In O'Connor's terminology, discourse structure corresponds to what is called i-structure in this paper. O'Connor represents discourse structure as an AVM and discusses how it should be linked to the prosodic structure that is represented as a tree.

Simpson (2007) *Expressing pragmatic constraints on word order in Warlpiri.* The paper discusses word order in Warlpiri, arguing for a distinction between prominent and non-prominent information as well as the distinction between new and not new. The AUX marks the transition from prominent to less prominent information. New information precedes the verb. Both prominence and newness are seen as relational notions. The separate IS is intended to be capable of representing hierarchies of newness and prominence.

Kifle (2007) *Differential object marking and topicality in Tigrinya.* See also Kifle (2011). The discussion is based on Dalrymple & Nikolaeva (2005), but it is claimed that for Tigrinya further distinctions are needed. The topic is represented at f-structure in the implementation.

Andréasson (2007) *The architecture of i-structure.* The paper argues for a function SCENE distinct from GROUND and RHEME and from STAGE TOPIC. The data come from Scandinavian languages, mainly Swedish, where the SCENE is placed between the GROUND and the RHEME. A separate i-structure is assumed, but it is not clear how it relates to the rest of the grammar.

Andréasson (2008) *Not all objects are born alike.*
Andréasson (2009) *Pronominal object shift — not just a matter of shifting or not.*
Andréasson (2010), *Object shift or object placement in general?*
Andréasson (2013) *Object shift in Scandinavian languages: the impact of contrasted elements.* This series of papers studies the different factors that influence Object Shift in Scandinavian, especially in Danish and Swedish. Andréasson (2008) argues for an accessibility hierarchy a la Gundel et al. (1993); Andréasson (2009) argues for the importance of factivity when clausal antecedents are involved; and Andréasson (2013) explores the role of contrastive focus. They assume a separate i-structure and discuss its link to the c-structure.

Sulger (2009) *Irish clefting and information-structure.* The paper argues for the distinction between GROUND and FOCUS in Irish clefts. It assumes a separate i-structure projected from the c-structure.

Gazdik (2010) *Multiple questions in French and in Hungarian: An LFG account.* The paper studies questions in French and Hungarian, making a distinction between FOCUS, TOPIC and BACKGROUND using a separate i-structure.

Dalrymple & Nikolaeva (2011) *Objects and information structure.* This book discusses (differential) object marking and agreement in several languages (Uralic languages including Ostyak, Tundra Nenets, Vogul; Iranian languages; Indo-Aryan languages) with a typological and historical perspective. It mainly discusses primary and secondary topics and distinguishes the notion of topic from that of topic-worthiness, which is based on prominence features such as animacy, definiteness, and specificity. It uses Lambrecht's (1994) notions of assertion and presupposition. It proposes a separate i-structure and provides a structured meaning representation for topic and focus projected from the semantic structure.

Gazdik & Komlósy (2011) *On the syntax-discourse interface in Hungarian.* The paper discusses word order and prosody in the Hungarian preverbal field. It distinguishes between the hocus (an element that highlights an unusual feature of a otherwise usual event) and the focus, and proposes a revision of Butt & King's (1996) schema appealing to the notion of d-linking (Pesetsky 2007). It uses a separate i-structure.

Simpson (2012) *Information structure, variation and the referential hierarchy.* The paper discusses agreement and word order in Warlpiri and Arrernte and points out the importance of the Silverstein hierarchy to account for the data. It does not address architectural issues.

Dione (2012) *An LFG approach to Wolof cleft constructions.* The paper mainly discusses clefts in Wolof. It argues that the i-structure can be part of the f-structure when it has been syntactized.

Mycock (2013) *Discourse functions of question words.* The paper discusses questions in English and Urdu/Hindi. It follows Butt & King's (1996) proposal but adds a Q mark to all distinctions. It assumes a separate i-structure.

Mycock & Lowe (2013) *The prosodic marking of discourse functions.* The paper discusses the prosody of broad and narrow focus in English. The IS distinctions are based on Dalrymple & Nikolaeva (2011). It addresses the relation between c-structure, i-structure and p-structure.

Butt (2014) *Questions and information structure in Urdu/Hindi.* The paper develops the distinctions made in Butt & King (1996), proposing more subdivisions to account for questions in Urdu/Hindi. It assumes a separate i-structure, but does not discuss the relation between projections.

Szűcs (2014) *Information structure and the English left periphery.*
Szűcs (2017) *English left-peripheral constructions from an LFG perspective.* These papers discuss the English left periphery based on insights from Prince (1981) and Ward & Birner (2001). They argue for a distinction between ±NEW and ±D-LINKED which is further subdivided into ±CONTRASTIVE. The IS notions are represented in the f- and the c-structure.

Zymla et al. (2015) *Modeling the common ground for discourse particles.* The paper discusses discourse particles in German in the context of the PARGRAM AKR (Abstract Knowledge Representation).

Otoguro & Snijders (2016) *Focus clitics and discourse information spreading.* The paper discusses quantifier float in Dutch, English and Japanese. Based on Butt & King's (1996) distinctions, it argues that quantified NPs are topics and the floated quantifer is part of the focus.

Belyaev (2017) *Information structure conditions on agreement controller in Dargwa.* The paper argues for the importance of the notion PIVOT as defined in Falk (2006) to account for agreement in Dargwa. The notions used are syntactically encoded.

Abubakari (2018) *Information structure and the Lexical-Functional framework.* The paper argues for a subdivision of focus in contrastive and completive based on data from the morphological markings on focus and topic in Kusaal. The morphological markers themselves are retained in the i-structure.

Szűcs (2019) *Left-dislocation in Hungarian.* The paper argues for a distinction between topic left-dislocation and clitic topicalization in Hungarian. It mainly discusses the f- and the c-structure.

Acknowledgements

Thanks to three anonymous reviewers and to Tracy Holloway King for comments on an earlier version. Needless to say, only I am responsible for any remaining errors or omissions.

Chapter 19

Morphology in LFG

Ash Asudeh
University of Rochester

Daniel Siddiqi
Carleton University

Lexical-Functional Grammar has been consistent over the past 4+ decades about its conception of syntactic structure and the sorts of rules that license it. However, despite being a highly lexicalist model of grammar, LFG has not developed a similarly consistent model of morphology. LFG has in fact assumed a variety of different models of morphology and interfaces with distinct 'morphological' modules and theories in this time. This is perhaps because LFG early on solved the problem of how morphology and syntax can communicate in a common formal language — the language of functional descriptions, which can be both associated with words and their parts and with syntactic elements. We first introduce some important concepts from morphological theory. We then look at some early LFG analyses which treated morphology *incrementally*. Subsequently, we review work on the syntax–morphology interface in LFG. We end with a discussion of *realizational* approaches to morphology in LFG.

1 Introduction

Lexical-Functional Grammar has been fairly consistent over the past more than four decades about its conception of syntactic structure and the sorts of rules that license it. However, despite being a highly lexicalist model of grammar, LFG has not developed a similarly consistent model of word-formation. LFG has in fact assumed a variety of different models of word-formation and interfaces with distinct 'morphological' modules and theories in this time. This is perhaps because

Ash Asudeh & Daniel Siddiqi. 2023. Morphology in LFG. in Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 855–901. Berlin: Language Science Press. DOI: 10.5281/zenodo.10185976

LFG early on solved the problem of how morphology and syntax can communicate in a common formal language — the language of *functional descriptions*, which can be both associated with words and their parts and with syntactic elements. Together with the Lexicalist Hypothesis (Lapointe 1980, Chomsky 1970, Bresnan et al. 2016: 92), this entailed that syntactic terminals are morphologically complete words, with possibly complex associated f-descriptions, but the theory did not have to really say anything about the exact mechanism for word formation or how contributions were made to complex f-descriptions by specific parts of words. In addition, LFG has distributed what might be considered aspects of word-formation to various components besides a lexicon, including for example prosodic or phonological structures (Dalrymple & Mycock 2011, Bögel 2015).

In this context, it is perhaps better to start this chapter with a brief overview of some of the range of variation in morphological theory so that we can better situate LFG in the landscape of morphological possibilities (Section 2). We then look at early LFG analyses which treated morphology incrementally (Section 3). Then we review work on the syntax–morphology interface in LFG (Section 4). This sets the stage for a look at current approaches to morphology in LFG, which are realizational (Section 5). We will not have anything to say about the interactions of morphology, syntax, and prosody in LFG, because that is covered by another chapter in this volume, Bögel 2023 [this volume].

2 Morphological theory and terminology

The landscape of morphological theory is defined by many key ‘decision points’ that we summarize here for subsequent use. These decision points are pretheoretically distinct from each other, but they have a tendency to cluster together in ways that will be reflected in morphological theories interfacing with LFG. We attempt to be neutral for each decision point, and also as brief as possible. We leave the detailed description of these distinctions to sources like Hockett (1954), Beard (1995), and Stump (2001), but also textbooks like Haspelmath & Sims (2010), which does an especially good job of describing these decisions.

2.1 Morphemes vs. words

The first of these is also the most basic. What are the ‘atoms’ of morphological theory? What are the inputs to morphological rules? What are the elements that morphology manipulates? Morphological theories fall into two basic classes:

those that subscribe to the *morpheme hypothesis* and those that do not. The former are typically called *morpheme-based* theories (or *morphemic* theories). The latter are typically called *word-based* theories (or *lexemic* theories).

In morpheme-based models, the inputs to morphological operations are idealized as one-to-one pairings of sound and meaning called *morphemes*. Later morpheme-based models, such as Distributed Morphology (Halle & Marantz 1993), have redefined 'morpheme' to mean 'abstract morphological feature'. In these models, the sound-meaning pairing is better considered a *listeme* (Di Sciullo & Williams 1987) but is often called a *vocabulary item*. Historically, a 'word' is the morphological domain above morphemes. In most contemporary models of this kind, the 'word' is mostly epiphenomenal or refers to an extra-morphological domain (typically prosodic/phonological). In this context, a so-called 'simplex word' is nothing more than a domain containing only a single morpheme, while a so-called 'complex word' is a domain containing more than one morpheme.

In word-based models (Aronoff 1976), words are the atoms of the grammar. Morphological operations have words as their input and words as their outputs. In contemporary instantiations of word-based models, the *input* and *output* are not really the appropriate terms. Rather, 'words' have both abstract representations and phonological representations. The abstract form of a word is called a *lexeme*.[1] A lexeme is the basic representation of a word (often analogized to a dictionary entry). A lexeme may be derived from another lexeme via derivational morphology or compounding (and thus can be complex) but is never inflected. The phonological form of a word, which is fully inflected, is called a *word-form*, which can be conceptualized as a particular, (grammatically) context-sensitive, instantiation of a word. The word-forms of a lexeme are typically organized into paradigms.

There are many reasons why a theory might choose to assume words or morphemes — more than we could possibly summarize in this space. We posit the following as an oversimplified summary. The basic tendency observed in the crosslinguistic state of affairs is that morphology is affixal and morpheme boundaries are clearly identifiable. This is tautologically true in isolating and agglutinative languages, but even fusional languages, which almost always have *portmanteau* (many-to-one) morphemes, tend to have clear morpheme boundaries. On the other hand, divergences from this tendency are legion and likely exist in

---

[1] Word-based and lexeme-based models are not strictly the same (Aronoff 1994: 7). For example, not all word-based models assume lexemes, and some lexeme-based models are actually not word-based in the strict sense (lexemes are taken to be atoms of morphological descriptions, but words are not). For the purposes of this overview this simplification suffices. We thank an anonymous reviewer for helping us sharpen this point.

every language. *Templatic* (or root-and-pattern) morphology, such as found in Semitic languages, is not easily accounted for as affixation. *Stem allomorphy* and *suppletion*, especially in high frequency words, often involves a morphological alternation without clear morpheme boundaries. Furthermore, complex words frequently have lexicalized meaning, i.e. non-compositional meaning that is more than the sum of the contained meanings. These exceptional data are usually given exceptional explanations, such as diachronic ones. Put simply: the morpheme hypothesis captures the basic concatenative cross-linguistic tendency of morphology, but lacks synchronic empirical coverage of seemingly exceptional data. The word hypothesis is its opposite, capturing all the data, but needing to attribute the basic concatenative tendency to something else, such as diachronic pressures like grammaticalization.

2.2 Arrangement vs. Process vs. Paradigm

The second decision point is the types of rules that operate on the atoms. This distinction is originally described by Hockett (1954) as the contrast between *item-and-arrangement* (IA), *item-and-process* (IP), and *word-and-paradigm* (WP) models. The names for these models reflect their workings. In an IA model, morphology is simply the set of morphemes in a word and the arrangement of those morphemes. Thus, the arrangement itself (which is essentially simple concatenation) is the only 'morphological process'. In an IP model, rules (such as *affixation*, *reduplication*, *juxtaposition*, *suppletion*, etc.) are applied to a *base* (or *stem*), which may be complex or simplex, to generate a new complex form. IP models are compatible with both morphemes or words being the 'base'. Finally, WP models assume the morphology is the process through which all the word-forms in a word's paradigm are inferable from each other via some mechanism that generates a paradigm.

The reasons for adopting any of these three are similar to the reasons in Section 2.1. IA models have two strengths. Firstly, they capture the basic cross-linguistic generalization: the vast majority of morphology can be explained with simple concatenation. Secondly, many practitioners of IA models find such a simple operation to have an elegance and restriction that are laudable metatheoretical goals. Because of this, IA would be preferred by those theorists for whom such theoretical elegance is a high-ranking concern. Again, we find that such practitioners are satisfied that putatively non-concatenative processes have potential diachronic explanations.

There are familiar reasons to assume IP models, which again, as in Section 2.1 appear to be the opposing reasons. Chief among them is that IA models under-describe the data. IA models end up accounting for everything with affixation, including apparently non-affixal morphology like *functional shift*, *back-formation*, *stem allomorphy*, *suppletion*, *stress shift*, *truncation*, and *reduplication*. Affixal explanations for these phenomena tend to be fairly stipulative and lead to a proliferation of null morphemes that condition these changes (which are themselves a violation of theoretical parsimony, despite this concern being a primary motivation of such approaches). IP practitioners point out that there is also a ready-made counter-explanation from diachrony for the prevalence of concatenation: the chief source of morphology is grammaticalization, which (ultimately) leads to affixes. Furthermore, although rule-based morphological models are undoubtedly much more powerful than IA models, that power comes with significant empirical coverage, which is arguably worth the trade-off. In many varieties of both WP and IP models, in the idealized case, any two word-forms can be mutually predictive. This allows rules to apply 'backwards', capturing phenomena such as *backformation* or *cross-formation* (see, e.g., Becker 1993). These types of morphological alternations are difficult to capture in an IA model.

The appeal of WP models over the other two is the ability to make reference to the paradigm as an abstract entity. In the domain of inflection, many generalizations, especially *morphomic* ones, can be captured by referring to the paradigm itself. A *morphome*, as described in Aronoff (1994) and Luís & Bermúdez-Otero (2016), among others, is a purely morphological pattern. The existences of morphomes is controversial (a debate captured well in Luís & Bermúdez-Otero 2016). The most salient of proposed morphomes in this debate are root allomorphy patterns like the 'L pattern' and the 'N pattern' (see Maiden 2018), which are literally described as patterns in a paradigm (e.g., cells arranged in an L or an N). Thus WP models are uniquely well-situated to account for these. On the other hand, arrangement accounts usually deny the existence of morphomes as paradigm effects and instead account for them via some other mechanism (see Trommer 2016).

Similarly, patterns of syncretism lend themselves to paradigmatic explanations. Paradigmatic explanations are especially well suited to highly fusional languages as are common in Indo-European. They also lend themselves easily to complex agreement patterns that are cross-linguistically ubiquitous. Furthermore, because a paradigm cell can contain multiple forms or even no forms, WP models allow explanations for both *optionality* and *defectiveness*/*ineffability*. The tradeoff here is paradoxical: on the one hand, paradigmatic models tend to have little to say about derivation[2] and compounding, so they under-describe the data;

---

[2] There are some notable exceptions, though, such as Booij (2010) and Spencer (2013).

on the other hand, paradigms are much more powerful than needed for most of the world's languages, so in another respect, they over-describe the data.[3]

2.3 What is the lexicon?

The third decision point is the nature of the word-storage component of the grammar. For example: Is the lexicon a productive component of the grammar or simply a passive list of memorized forms? While the terminology here is far from consistent in the literature, for the purposes of this chapter we will use *lexicon* to denote a generative/productive component of the grammar responsible for word-formation. We will use *vocabulary* for a passive component which is simply a list of memorized items. There is nothing inherently contradictory about a model having both a lexicon and a vocabulary. It just happens that most models with a productive component typically assume that that component is also the one responsible for word-storage. Indeed, this dual role is central to many models of *blocking*, such as the original one developed by Aronoff (1976). On the other hand, Di Sciullo & Williams (1987) argue for both a lexicon and a vocabulary (without using those terms).

There are some downstream effects of the decision to have a component dedicated to word-formation. If it is assumed that the lexicon is productive, a decision must be made on how much it is responsible for. The *Single Component Hypothesis* claims that all three distinct types of morphology (derivation, inflection, and compounding) are handled by the same generative component. On the other hand, the *Split Morphology Hypothesis* claims that derivation and inflection are handled by separate components. Thus, it is not uncommon to have two distinct word-formation components, one for derivation and one for inflection, depending on a particular model's definition of *lexeme*. This is made explicit in the WP model of Anderson (1982, 1992), where the paradigms are only responsible for inflection.[4]

Provided you assume that morphology is not its own domain, there seem to be two obvious non-morphological components involved in ordering morphological elements. One of these is prosody/phonology, as seen in models such as Optimality Theory (Prince & Smolensky 2004). The other, more common, account for ordering morphological elements outside of a lexicon is the syntactic component. The *Morphosyntax Hypothesis* — this is not its common name but will suit our purposes — assumes that all of morphology and syntax are handled

---

[3] Word and Paradigm models encompass more than just what is described here, including adaptive discriminative models such as Blevins et al. (2016), but these have not yet been meaningfully interfaced with LFG, so we set them aside here.

[4] Split morphology theories are properly ambivalent about the place of compounding; we do not address compounding in this chapter.

by the same component of the grammar. This entails the strong claim that autonomous morphological phenomena do not exist, and are instead attributable to the morphological interfaces with phonology and syntax. The *Weak Lexicalist Hypothesis* separates derivation from inflection: Derivation is handled by a lexicon while inflection is part of the syntactic structure. By contrast, the *Strong Lexicalist Hypothesis* assumes that all of word-formation is Lexical/non-syntactic.

We won't get into the reasons why a syntax model might adopt variations on the Lexicalist Hypothesis. We leave that to elsewhere in this handbook. From the point of view of morphological theory, there are distinct reasons to consider breaking the class of things called 'word-formation' into distinct components. Data on morphological structure suggests compounding and derivation are of a kind that is distinct from inflection. In the domain of derivation and compounding, fully productive morpheme ordering overwhelmingly generalizes as *headed hierarchical structure* (the type of structure usually represented by trees in syntactic theory). In inflection, on the other hand, to the extent that morpheme boundaries are even identifiable, they tend to be arranged in ordered flat structure (i.e., a *list*). Constituency tests that show hierarchical structure tend to fail, despite strict ordering. Alternatively, when boundaries are less identifiable, the morphology appears to be arranged *paradigmatically*. This difference is mostly captured by the distinction between an agglutinative and a fusional inflectional system. A key reason for treating inflection as different from other kinds of morphology is precisely because of the apparent structural distinction between a linear structure (inflection) and a hierarchical structure (derivation). Conversely, while inflection is overwhelmingly productive and expresses compositional meaning, derivation and compounding have a much greater (but still small) likelihood of having non-compositional meaning and being less than fully productive. This is yet another reason to partition morphology into distinct classes.

Finally, and perhaps most importantly, to the extent that we can today justify that derivation is a distinct empirical category from inflection, following Anderson (1982), the chief generally observed distinction (outside of the hierarchical/ linear/paradigmatic ones above) is that inflection is relevant to the syntax. Inflection comes in two varieties. The first empirical category is those inflections that express grammatical configurations (*contextual inflection;* Booij 1996). For example, case and subject/object agreement on verbs express the relationship between verbs and their dependents. Similarly, nominal concord expresses the relationship between nouns and their dependents. Importantly, languages appear to have the option of expressing these relationships either via morphology or through a fixed word order (or both). The other empirical category of inflection is those morphological reflexes of so-called 'morphosyntactic' or 'morphosemantic' categories (*inherent inflection;* Booij 1996). These are such properties as tense, aspect, voice, mood, number, definiteness, etc. Again, languages appear to have the choice of expressing these properties morphologically or syntactically (through separate categories such as auxiliaries, clitics, prepositions, etc).

Given these differences, it makes sense to split a *lexicon* into two pieces: one that handles so-called *lexeme-formation* and another that handles inflection (but see Booij 1996 for counter-arguments). These two components can then have fundamentally different types of processes and can have different relationships with the syntactic component. And indeed, this division of labor is common in Word-and-Paradigm models today. For a review of the history and state-of-the-art of WP models, see Blevins (2018).

Since syntax is also naturally represented, at least in part, by headed hierarchical structures, the parsimonious approach to grammar is to identify the extent to which all such structure can be done with the same component — in other words, to assume a single component that generates headed hierarchical structure, whether the structure represents 'syntax' or 'morphology'. Compounding and derivation can similarly easily be accommodated to a component that generates headed hierarchical structure, especially if we restrict the model to only the most productive processes and we are willing to assume that non-compositional morphological meaning is fundamentally the same as non-compositional idiomatic syntactic constructions. We would have to then be willing to postulate vacuous hierarchical structure in inflection, but this postulation is arguably worth the trade-off for overall parsimony. The call of parsimony is heightened by the definitional interdependence of syntax and inflection. In fact, an Item-and-Arrangement model has already made certain empirical sacrifices for parsimony and restriction goals. It seems that no further sacrifices are needed to assume a single morphosyntactic component. The gain in parsimony is even further support for Item-and-Arrangement from this point of view, so it is not surprising that most models today that assume an Item-and-Arrangement model reject the Lexicalist Hypothesis and adopt a passive *vocabulary*. But deciding to approach morphology by reducing it to syntactic (and/or phonological) operations is not restricted to Item-and-Arrangement approaches. Similarly, *construction-based* approaches to morphology (Booij 2010, Masini & Audring 2018) generally assume that the *construction* is both a morphological and syntactic mechanism. This property of having a shared mechanism is often summarized as 'X all the way down', where X is *constructions* in construction-based approaches, *syntax* in standard Distributed Morphology, and *constraints* in Lexical-Realizational Functional Grammar.

Approaching morphology via a single morphosyntactic component has significant empirical justifications as well. There are several commonplace phenomena that blur the lines between word and phrase, suggesting that distinction is more one of convenience than a justifiable categorical contrast. Such phenomena include for example: clitics, phrasal affixes, phrasal compounds, valence changing devices, separable prefixes (of the Germanic variety; e.g., Booij 2002), object incorporation (of the Mohawk variety; e.g., Baker 1988). Because these phenomena appear to be both syntactic and morphological, it is appealing to these practitioners to find unitary explanations, which ultimately rest on not positing a syntax/morphology distinction.

2.4 Lexical vs. inferential

While not strictly distinct from our classification above, it is worth taking a moment to describe a distinction that is common in the literature, especially within models that interface with LFG. Stump's (2001) typology of morphological theories of inflection includes a distinction between two types of theory: *Lexical* and *Inferential.* In a lexical model, the lexicon (or vocabulary) stores associations of inflectional properties and phonological properties. A complex word is an ordered set of these associations. Conversely, in an inferential model, the systematic associations are between a lexeme and its word-forms. Word-forms are inferred from their stems by rules (not restricted to concatenation) that associate aspects of form with aspects of grammatical content. In sum, lexical models are concerned with listed lexical objects (words or morphemes), whereas inferential ones are concerned with rules.

In the typology that we are describing here, these distinctions are not basic. Instead, they are composites of the distinctions above. While it may not be the case that Stump (2001) intends "lexical" to comprise these four properties, the examples of *lexical* models that Stump (2001) lists all share in common that they are *morpheme-based*, *Item-and-Arrangement*, and *morphosyntactic* with a passive *vocabulary*. In contrast, an *inferential* model is *word-based*, and assumes *Strong Lexicalism* (at least for inflection, which is what Stump 2001 is concerned with).

2.5 Incremental vs. realizational

The final distinction that we describe here concerns the relationship between information and morphology. In an incremental model, morphology is *information-adding*. That is, a word gains grammatical complexity (i.e., morphosyntactic properties) at the same time, or as a function of, gaining complex morphology. For example, on this conception, adding the plural morpheme to the word is what makes it plural. In opposition to this stand *realizational* models. In a realizational model, morphology is *information-expressing*. Some aspect of grammar that is external to the morphology supplies a set of morphosyntactic properties (which may or may not include a *root*). What we conceptualize as morphology then expresses that set of morphosyntactic features. Depending on other choices made, this expression might be a passive mapping to phonology or the application of a realizational rule. In these models, morphology provides the *exponence* of morphological properties (the *exponenda*).

This distinction is not so much an active distinction today since most contemporary morphologists assume *some* variety of realizational morphology. This can be achieved via paradigms (Paradigm Function Morphology; Stump 2001, 2016, Spencer 2013), morpheme-insertion (Distributed Morphology; Halle & Marantz 1993), or constructions (Construction Morphology; Booij 2010, Masini & Audring 2018; Optimal Construction Morphology; Inkelas et al. 2006, Caballero & Inkelas 2013, Inkelas 2016). The simple reason for this is that morphology, especially inflection, both under- and overdetermines its featural content.

The underdetermination part has always been well-known. For example, a fundamental property of inflection and primary explanandum of morphological theory is the fact that the morphosyntactic features overtly expressed by an inflected form are often a subset of those properties that are associated with the word. For example, it is common for gender to be unexpressed in combination with participant persons (1^{st} and 2^{nd}). Similarly, it is also common for person features to be unexpressed in combination with past tense or plural number (see, for example, Bjorkman et al. 2021).

Interestingly, the reverse is true as well, which demonstrates the case of overdetermination. Morphosyntactic properties are often expressed *multiply* without additive meanings; this is usually called *multiple exponence*. For example, *children* is not 'multiply plural' despite having three distinct reflexes of plural (vowel change, historic *-r* plural, historic *-en* plural). What is noteworthy here is that the multiple expression of plurality is *grammatical*. One wouldn't expect this of an iterated plural function, which is what multiple applications of a plural morpheme might lead one to expect (see, for example, Harris 2016).

3 Incremental morphology and LFG

3.1 Phrase structure rules as word-formation rules

An obvious approach to concatenative morphology is to capture morphological well-formedness using similar (annotated) phrase structure rules to the ones that license c-structures (Selkirk 1982). The difference is that the morphological ones use morphological categories. However, standard LFG assumes *Strong Lexicalism*, so it is important to note that this is happening in different combinatorial components of the grammar — morphology versus syntax. Pedagogical presentations, such as Bresnan et al. (2016), out of necessity simplify representations in such a way that this important distinction is masked. In the problem set on West Greenlandic (Bresnan et al. 2016: 364–369), we find the example in (1) below, analyzed with the assistance of the morphological rule in (2), and the sketch of an analysis for (1) in (3).[5]

(1) West Greenlandic
Angisuu-mik qimmeq-arpoq.
big-INS dog-have.IND.3.SG
'He has a big dog.'

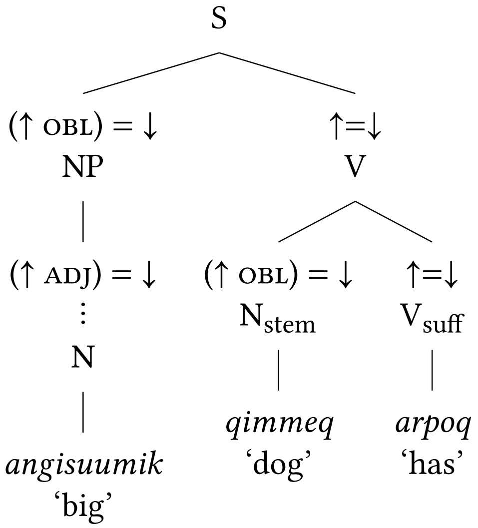
(2)
$$\begin{array}{llcc} \text{V} & \longrightarrow & \text{N}_{\text{stem}} & \text{V}_{\text{suff}} \\ & & (\uparrow \textsc{obl}) = \downarrow & \uparrow=\downarrow \end{array}$$

Note that this rule looks just like a c-structure rule, except with a c-structure category on the lefthand side of the rule and morphological categories on the righthand side. In other words, it is the *outputs* of these morphological rules that form the *inputs* to the c-structure rules.

---

[5] We have left the morphological glosses off the free English translation in (3), which is not present in Bresnan et al. (2016: 446); this is just a rough approximation of the glossing in (1). We have also elided some annotations from the original.

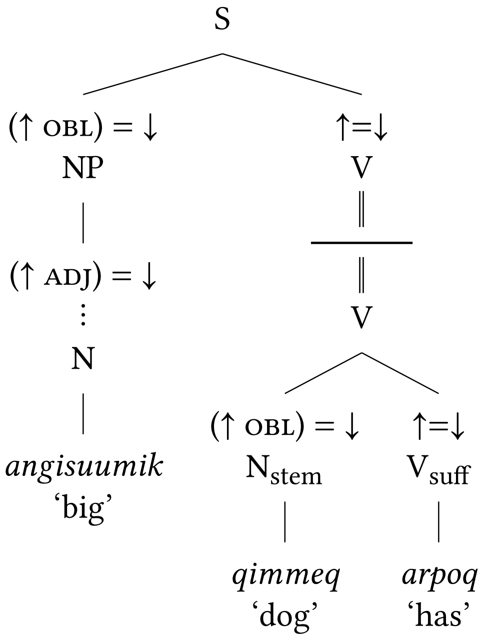
(3)



However, notice that the node labelled V in this tree is actually licensed by the *morphological* rule in (2). In another sense, this very same V is also licensed by the c-structure rule for S, which is easily inferable from (3).

However, if morphology and syntax are distinct grammatical modules, per Strong Lexicalism, then it can't actually be a single rule set that captures both aspects of V, as implied by (3), even if the mechanisms involved are the very same for both syntax and morphology (annotated phrase structure rules) in this incremental approach to LFG morphology. Thus, a more transparent way to represent (3) may be something like the following (based on Ishikawa 1985: 285):

(4)



The horizontal line represents the syntax/morphology ‘boundary’ and we see that V has a foot on each side. This representation is arguably more transparent about the full set of theoretical claims behind (3). But it also highlights that the licensing mechanisms for c-structure and morphology are redundant in this sort of incremental morphology for LFG.

It is important to realize, though, that in early LFG, incremental morphology through phrase structure rules was not merely a pedagogical simplification. There were proposals in early LFG research on morphologically rich languages that involved phrase-structural incremental morphology, such as Baker (2006 [1983]), Ishikawa (1985: ch. 3)[6] and Nordlinger (1997, 1998). For example, Nordlinger (1997: 107) proposes the following morphological rule for case affixation in various dependent-marking languages of Australia (including, e.g., Kayardild, Martuthunira, Thalanyji, Wambaya):

$$\begin{array}{llll} \text{(5)} & \text{N} \longrightarrow & \text{N} & \text{Aff} \\ & & \uparrow=\downarrow & \uparrow=\downarrow \end{array}$$

Nordlinger subsequently revised this incremental analysis in favour of a realizational approach (Sadler & Nordlinger 2004, 2006), which will be discussed further in Section 5.1.

In sum, the early incremental approach to morphology that was commonly assumed by LFG was a straightforward, even traditional, *morpheme-based*, *item-and-arrangement* approach.

3.2 Finite-state morphology

Another question that arises with incremental phrase-structural morphology is one of computational complexity/power. One way of expressing the intuition that morphology is generally concatenative is to observe that regular languages/ finite state automata, which are the Type 3 grammars in the Chomsky Hierarchy (Chomsky 1957, 1965, Partee et al. 1990: part E), are computationally sufficient for generating concatenative morphology. One can make an even stronger claim, which is that almost all of morphology requires no more than finite-state power, except for total reduplication (Beesley & Karttunen 2003, Roark & Sproat 2007: 25, 53–60), which is beyond finite-state power, since it requires exactly matching a preceding string of potentially unlimited length.[7]

---

[6] See Bresnan et al. (2016: 396) for a simplified presentation of some of Ishikawa’s proposals.

[7] Note that Beesley & Karttunen (2003) build their system around the operation of *concatenation*, whereas Roark & Sproat (2007) argue that the operation of *composition* is more general and is to be preferred. Among other considerations, *composition* gives a more natural finite-state solution to templatic (root-and-pattern) morphology (Kiraz 2001, Roark & Sproat 2007: 41–44).

Let's now turn back to the particular kinds of proposals for phrase-structural morphology that we saw in Section 3.1. The computational power of phrase-structural morphology is at least context-free, which is more powerful than required and corresponds to a higher level in the hierarchy. In other words, representing concatenative morphology in a phrase structure format gives the morphological component more potential power than seems justified by linguistic data. Moreover, once we add f-structure annotations to morphological phrase structure rules, we are potentially in the yet more powerful class of mildly context-sensitive languages (Joshi et al. 1991), since we would have the full power of LFG. This seems too powerful.

For example, if morphology were mildly context-sensitive, we might expect to see *morphological* long-distance dependencies or cross-serial dependencies, but we are not aware of any morphological phenomena that straightforwardly demand such analyses. It might seem that phenomena such as circumfixion or vowel harmony are candidates for morphological long-distance dependencies, but these can in fact be handled by finite-state means (Beesley & Karttunen 2003). Some agreement phenomena, like the Ojibwe PERSON discontinuity in (35) below, might similarly seem long-distance, but are in fact clause-bounded, so we expect that finite-state morphology (FSM) could handle them. We are aware of so-called 'long-distance agreement' (Butt 1993, Bhatt 2005), but we are not aware of any such case for which there is no viable non-long-distance solution. Lastly, it might seem that templatic morphology shows a morphological need for an indexed language (mildly context-sensitive) to line up consonants and vowels properly. However, it has been shown that a composition-based finite-state approach can indeed handle templatic morphology (Kiraz 2001, Roark & Sproat 2007).

It should be noted that actual computational work on LFG, in the context of the Parallel Grammars (ParGram) project (Butt et al. 1999; Forst & King 2023 [this volume]), uses finite-state morphology, rather than incremental phrase-structure morphology. Indonesian is among the languages in the ParGram project and does have productive total reduplication. The ParGram Indonesian grammar only allows for reduplication of words already in the dictionary/lexicon. This means that the FSM can extract the morphological feature encoded by the reduplication (because there is a finite vocabulary). However, on encountering a word for the first time, such a system cannot recognize the reduplication and so cannot extract the morphological feature encoded.[8] Thus, the full productivity of Indonesian reduplication is not modelled in the ParGram grammar.

In sum, the FSM approach is a restrictive approach that also yields broad coverage of morphological phenomena; for example, see the many case studies in

---

[8] We thank Ron Kaplan (p.c.) for discussion of this point. Any remaining errors are our own.

Roark & Sproat (2007). The restrictiveness of the FSM approach makes it very attractive, even more so when coupled with the fact that FSM approaches have revolutionized applications that require morphological analysis, such as spell-checkers, part-of-speech taggers, and speech recognition and production systems (Kaplan & Kay 1994, Beesley & Karttunen 2003, Roark & Sproat 2007). Nevertheless, this does not mean that we should conflate theories with their formal or computational bases. Using an analogy from syntax, the mildly context-sensitive formalisms of Lexicalized Tree-Adjoining Grammar, Categorial Grammar, and LFG form a computational equivalence class but nevertheless underpin distinct theories. As Roark & Sproat (2007) themselves emphasize, theoretical distinctions may matter even if the options are computationally equivalent. For example, they consider Tagalog *-um-* infixation, as in *tawag* ('call') versus *tumawag* ('call (perfective)'). They note that it is computationally "immaterial" from an FSM perspective whether we conceive of the infix as attaching to *t-* or to *-awag* (Roark & Sproat 2007: 30–31). However, from a theoretical perspective, these two solutions are clearly not equivalent. In particular, Tagalog *um* is an infix in consonant-initial words (with some exceptions, where it cannot appear at all), but is a *prefix* in vowel-initial words, such as *abot*, which becomes *umabot* ('reach for (perfective)') (Orgun & Sprouse 1999: 204). On theoretical grounds, it therefore seems preferable to think of *um* as attaching to the element to its right, as McCarthy & Prince (1993) and Orgun & Sprouse (1999) conclude, but to FSM the two options (dependency on the preceding or following element) are equivalent and the distinction immaterial.

3.3 Lexical rules

Throughout the early history of LFG, theorists made crucial use of *lexical rules*, such as found in Bresnan (1982). These lexical rules were almost always employed to capture argument structure alternations, like passivization. Another way to think about the effect of lexical rules is that they concern the remapping of grammatical functions. These rules frequently had morphological reflexes in addition to their argument-structure-changing properties, but they also frequently did not (see the example lexical rules for gerundives in Bresnan et al. 2016: 316–317). In fairness, these rules were not normally postulated from the point of view of morphological theory, so the emphasis was not on their morphological reflexes or how to use them to capture morphological generalizations. Moreover, lexical rules were not systematically codified into a model that we could discuss explicitly here.

Nevertheless, it was clear that these rules are explicitly non-syntactic. For example, in Falk's textbook they are described thus (Falk 2001: 93):

> [A] lexical rule of this kind is not monotonic: it takes existing information and changes it. This is ruled out in principle in the syntax on grounds of processing: syntactic information cannot be changed. But a lexical rule is not a syntactic rule. Lexical rules do not represent on-line processing, but rather regularities relating stored lexical items. When a lexical rule is applied productively, the result is stored as a new lexical item. For this reason, the usual LFG constraint against changing information is inapplicable here.

Falk's pedagogical point is revealing of an important foundational tenet of LFG: syntax is monotonic, so no non-monotonicity can be syntactic. It therefore follows that argument alternations are non-syntactic, since they are non-monotonic. In other words, allowing the lexical rules to behave non-monotonically shields the syntax.

On the other hand, Baker (1985) explicitly considers lexical rules from the point of view of morphological theory, arguing precisely that because GF-rules (argument structure rules) and word-formation rules align on the same element in LFG (i.e., the lexical rule as developed in Bresnan 1982), LFG was especially well equipped to capture the "lexicalist approach" to the Mirror Principle (Baker 1985: 409). To the extent that these lexical rules were codifiable in the categories we have laid out, these rules often generated affixation as in the types described by Baker (1985), but most frequently required the power and mechanisms of an *Item-and-Process* approach to morphology, especially because they were often expressed with non-concatenative (frequently null) morphology and were explicitly both information-adding and information-destroying, the latter of which cannot be done with concatenation alone.

4 The syntax–morphology interface

Some work on morphologically conditioned syntactic order (e.g., restrictions on verbal sequences, as found in English 'affix hopping'; Chomsky 1957) has proposed a structure called m(orphological)-structure to shield f-structure from features that are morphological in nature (Butt et al. 1996, Frank & Zaenen 2002). This unfortunately gives the impression that m-structure is the morphological component of LFG, but this is not really the case, as we'll see in Section 4.2. First, though, we turn to a general framework for the interface between an LFG syntax and a realizational morphology (Dalrymple 2015). This better sets the context for the discussion of m-structure.

4.1 A general framework

Dalrymple (2015) presented a new, systematic approach to realizational morphology for LFG (see also Dalrymple et al. 2019: ch. 12). It is clear, though, that the morphological output is intended to be something similar or identical to Paradigm Function Morphology (Stump 2001, 2016). We return to that aspect of the Dalrymple analysis in Section 5.1, where we discuss it along with other approaches to a PFM interface with LFG (Ackerman & Stump 2004, Sadler & Nordlinger 2004, Spencer 2013, Thomas 2021).

Dalrymple (2015) assumes, following Dalrymple & Mycock (2011), Mycock & Lowe (2013), that the traditional lexical phonological string is comprised of two aspects, the *s-string* which interfaces with c-structure via the π correspondence function and the *p-string* which interfaces with prosodic structure (via the β correspondence function; Dalrymple et al. 2019: 409). This is illustrated explicitly in Figure 1.

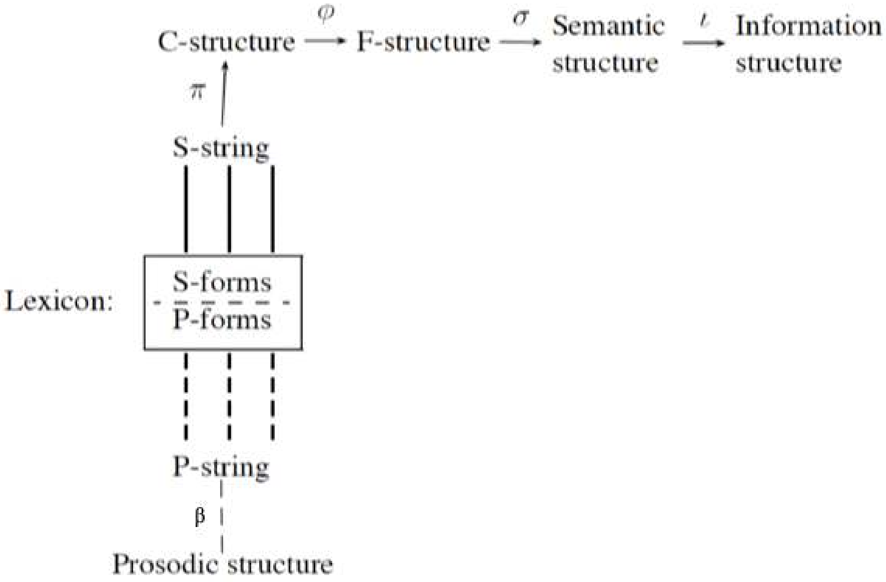


Figure 1: Proposed LFG Correspondence Architecture. From Dalrymple & Mycock (2011: 178, (5); see also Dalrymple et al. 2019: 409); used with permission.

A sample lexical entry for *dogs* from Dalrymple (2015: 67, (3)) is shown here:[9]

---

[9] This simplified lexical entry sets information structure aside; see Dalrymple (2015: 66).

(6)

s-form	(• FM) = dogs
c-structure category	$\lambda(\pi(\bullet))$ = N
f-description	(↑ PRED) = DOG
	(↑ NUM) = PL
p-form	/dɔgz/

It is convenient to represent the information in lexical entries as a relation (Dalrymple 2015: 67 (4)):

(7) $\mathcal{L}\langle$s-form, p-form, category, f-description$\rangle$

The particular information in (6) can therefore compactly be represented as (Dalrymple 2015: 67 (5)):

(8) $\mathcal{L}\langle$dogs, /dɔgz/, N, {(↑ PRED) = DOG, (↑ NUM) = PL}$\rangle$

This lexical entry generates the structures and correspondences in Figure 2.

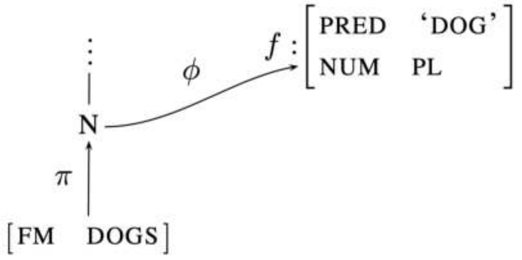

Figure 2: *Dogs*, contributions to the s-string, c-structure, and f-structure. Adapted from Dalrymple (2015: 66, (2)); used with permission.

Dalrymple (2015: 68) assumes, following Spencer (2013), that a *lexemic entry* consists of information about the form of the root (and any non-predictable alternations), any syntactic information and requirements, a representation of the semantics of the lexeme, and an arbitrary unique lexemic index. Dalrymple (2015: 68, (7)) therefore defines a lexemic entry as follows:

(9) *Lexemic entry*
⟨root & idiosyncratic stem forms, f-description, lexemic index⟩

She gives the following particular examples (Dalrymple 2015: 68 (8–9)):

(10) a. ⟨{ROOT: dog}, {(↑ PRED) = DOG}, DOG1⟩
b. ⟨{ROOT: child; STEM1: children}, {(↑ PRED) = CHILD}, CHILD1⟩

The question is how these lexemic entries interact with the morphological component to produce complete lexical entries. For example, how does the lexemic entry for DOG1 produce the lexical entry (8)?

The answer is illustrated in the diagram in Figure 3. The realization of the s-string form (*s-form*) and the p-string form (*p-form*) are handled by the morphological realization function, *R*, which also contributes morphological features (*m-features*) based on the ID of the lexemic entry (LI). The morphosyntactic description function, *D*, uses the m-features to represent the syntactic category and morphologically contributed f-description. The final lexical entry has the s-form and p-form that are computed by the realization function *R* (based on the m-features), the syntactic category that is computed by the description function *D* (again based on the m-features), and the f-description that is the union of the lexically contributed f-description from *LE* and the morphologically contributed f-description from *D*.

The relations between the different elements can be illustrated in a logic-programming-style representation, as in Figure 4. This representation reveals some redundancy. In particular, it's not clear why *R* and *D* each need access to both the lexemic index (LI) and the set of m-features (M), especially given that M must be computed based on LI. A more streamlined representation would eliminate LI from *D*. It would certainly be theoretically elegant if the set of m-features was sufficient to determine the category C and the morphologically contributed f-description G. However, there are empirical cases that show that *D* must be directly conditioned on LI, such as the syntactically singular but morphologically plural *measles* (Dalrymple 2015: 75).

As we mentioned above, Dalrymple's (2015) model is not a theory of morphology, but rather a theory of the interface between syntax and morphology. Nevertheless, it is most compatible with a morphological theory that is *lexemic*, is *Word-and-Paradigm*, and assumes *Strong Lexicalism*.

4.2 M-structure

As noted above, Dalrymple (2015) sees her framework as a general framework for realizational morphology and it is a feature of the approach that it is very much backwards-compatible with existing LFG proposals about morphological conditioning of syntax, such as the proposals for adding a m(orphological)-structure to the Correspondence Architecture proposed by Butt et al. (1996) and Frank & Zaenen (2002), which are both LFG accounts of affix ordering restrictions (e.g., English 'affix hopping'). The main distinction between the two proposals is that the first holds that m-structure is projected from c-structure (Butt et al. 1996),

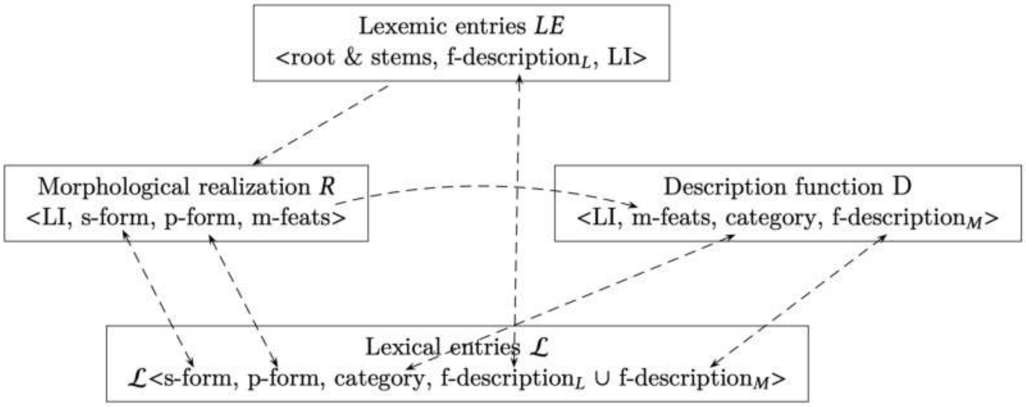

Figure 3: How the set of lexical entries, $\mathcal{L}$, is computed from the set of lexemic entries, *LE*, using a morphological realization function, *R*, and a description function, *D* (Dalrymple 2015: 70 (15); used with permission)

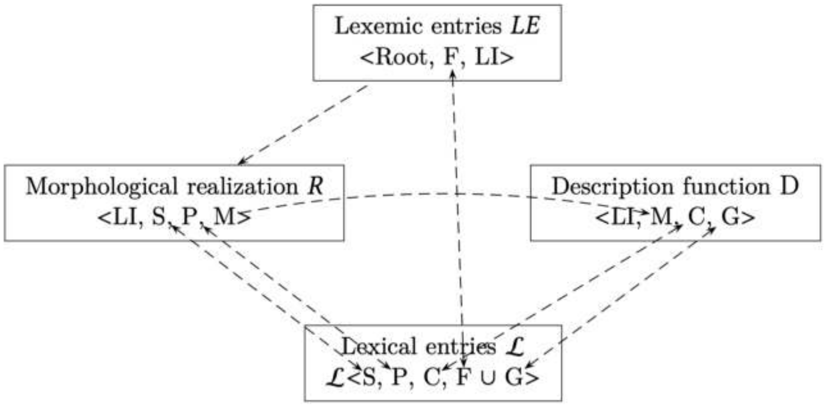

Figure 4: Logic-programming-style representation of the relations between $\mathcal{L}$, *LE*, *R*, and *D*

whereas the second holds that m-structure is projected from f-structure (Frank & Zaenen 2002).

The *morphological entry* (m-entry), i.e. instance of *R*, based on Butt et al. for *swimming* is shown here:

(11) *R*⟨SWIM1, swimming, /swɪmɪŋ/, {M-CAT:VERB, M-VFORM:PRESPART}⟩

The relevant *D* mapping would then be:

(12) M-VFORM:PRESPART $\overset{D}{\Rightarrow}$ {($\hat{*}_\mu$ VFORM) = PRESPART, (↑ ASPECT) = PROG)}

Given the same m-entry in (11), the relevant *D* mapping based on Frank & Zaenen would instead be:

(13) $\textsc{m-vform:prespart} \overset{D}{\Rightarrow} \{(\phi(\hat{*})_{\mu}\ \textsc{vform}) = \textsc{prespart}, (\uparrow \textsc{aspect}) = \textsc{prog})\}$

We have represented things this way for maximum comparability with (12), but $\phi(\hat{*})$ is just ↑, so we could have written $\uparrow_{\mu}$ instead:

(14) $\textsc{m-vform:prespart} \overset{D}{\Rightarrow} \{(\uparrow_{\mu}\ \textsc{vform}) = \textsc{prespart}, (\uparrow \textsc{aspect}) = \textsc{prog})\}$

Note that there are other differences between the Butt et al. theory and the Frank & Zaenen theory, but we've kept things as simple as possible for direct comparison. See Dalrymple (2015) for further details regarding both of these approaches to m-structure. It's important to realize, though, that m-structure concerns morphological conditioning on syntactic order and is not a theory of morphology per se. However, we have seen that the Dalrymple (2015) framework, which *can* provide the foundation for a theory of morphology, accommodates both approaches. This demonstrates the Dalrymple framework's generality. M-structure is most compatible with a morphological theory that is *lexemic*, is *Word-and-Paradigm*, and assumes *Strong Lexicalism.*

5 Realizational morphology and LFG

As noted in Section 2.5, realizational morphology is done today in three major ways:

1. The word-based approach, such as Paradigm Function Morphology (Stump 2001, 2016, Spencer 2013).
2. The morpheme-based approach, such as Distributed Morphology (Halle & Marantz 1993) and Nanosyntax (Starke 2009, Caha 2009)
3. The construction-based approach, such as Construction Morphology (Booij 2010) or Optimal Construction Morphology (Caballero 2008)

To our knowledge, neither Construction Morphology nor Optimal Construction Morphology has been interfaced with LFG, so we set them aside here. We focus in particular on PFM and DM interfaces to LFG. PFM and LFG have a history going back at least to Sadler & Spencer (2004). There has also been renewed interest in PFM+LFG (Dalrymple 2015, Dalrymple et al. 2019), as well as recent interest in DM+LFG (Melchin et al. 2020, Asudeh et al. 2021, Everdell et al. 2021, Asudeh & Siddiqi 2022).

5.1 LFG interfaced with PFM

The first attempts to interface LFG with Paradigm Function Morphology (Stump 2001, 2016, Spencer 2013) were undertaken by Sadler & Nordlinger (2004, 2006) to account for highly complex case-stacking in certain Australian languages and by Ackerman & Stump (2004) to deal with the general problem of *periphrasis*. However, the complexity of the data and phenomena involved precluded either of these collaborations from simultaneously providing a general theory of realizational morphology for LFG. As we have seen, steps in that direction were taken by Dalrymple (2015) and Dalrymple et al. (2019). Although the Dalrymple framework is general and not specifically geared towards PFM, there is a deep compatibility between LFG's version of Strong Lexicalism, the Lexical Integrity Principle (see (38) below), and PFM. As Dalrymple (2015) presumably wishes to preserve Lexical Integrity/Strong Lexicalism — the traditional/default stance in LFG theory — then it is natural that she envisages a word-based morphology. Thomas (2021: 22) aptly sums up this underlying compatibility as follows:

> Unlike many other theories of morphology, the concept of a 'morpheme' is irrelevant to PFM: there is no conception of a form-meaning pair below the level of the word, as only fully inflected forms are associated with morphosyntactic property sets. This aligns with the Lexical Integrity Principle of LFG, by which terminal nodes must correspond to fully inflected words, rather than to morphemes or other sub-word elements.

If one wishes to retain LFG's Strong Lexicalism, such that the fundamental building blocks of syntax are words, then it makes sense to interface the syntax with a word-based theory of morphology. And PFM is arguably the most formally well-developed realizational, word-based morphological theory, making it a natural choice. Indeed Thomas (2021: 23) notes in passing that PFM's rigorous formalization offers another natural point of compatibility between PFM and LFG: "PFM also shares with LFG a commitment to being formally explicit and rigorously testable, as well as computationally implementable."

PFM's fundamental claim is that lexemes are represented as pairs of a form and a set of morphological properties (captured as features). Thus, in $\langle X,\sigma\rangle$, X is the form and σ is the set of properties. A paradigm function relates the lexeme to its inflectional realizations, by mapping the input form to an output form given the morphological properties:

(15) $\langle X,\sigma\rangle \xrightarrow{f} \langle Y,\sigma\rangle$

These paradigm functions are defined in terms of realization rules, which consist of *rules of exponence* and *rules of referral.* Rules of exponence realize the property set directly. Rules of referral instead refer the realization of their property sets to one or more other realization rules. There is a limited number of additional rule types; furthermore Stump's (2001) notion of paradigm has been refined in Stump (2016), which is typically called PFM2. However, this simple account will have to serve our purposes.

The realization rules in PFM are arranged into ordered rule *blocks*; however, there is no ordering within blocks. Given Panini's principle, the effect of block ordering mimics concatenation, but allows a morphologically synthetic form (*portmanteau*[10]) to block a morphologically analytic form. Selection of the correct rule in any given block is governed by Paninian blocking: the most specific rule that can apply in any given rule block must apply. PFM also assumes a principle called the Identity Function Default (IFD), which states that the identity function is a member of every rule block: If no other rule applies, the output is identical to the input.

This is exemplified by the following rules for Swahili future and past tenses (Stewart & Stump 2007: 402–403), which Thomas (2021: 22) presents in simplified form.[11] We have adapted the representation for maximal consistency with (15) above.

(16) Block A ⟨X,σ:{CAT:verb,TNS:fut}⟩ ⟶ ⟨*ta*X,σ⟩
⟨X,σ:{CAT:verb,TNS:past}⟩ ⟶ ⟨*li*X,σ⟩
⟨X,σ:{CAT:verb,POL:neg,TNS:past}⟩ ⟶ ⟨*ku*X,σ⟩

Block B ⟨X,σ:{CAT:verb,AGR(su):{PERS:1,NUM:sg}}⟩ ⟶ ⟨*ni*X,σ⟩
⟨X,σ:{CAT:verb,AGR(su):{PERS:2,NUM:sg}}⟩ ⟶ ⟨*u*X,σ⟩
⟨X,σ:{CAT:verb,AGR(su):{PERS:3,NUM:sg},GEN:{1,2}}⟩ ⟶ ⟨*a*X,σ⟩
⟨X,σ:{CAT:verb,AGR(su):{PERS:1,NUM:pl}}⟩ ⟶ ⟨*tu*X,σ⟩
⟨X,σ:{CAT:verb,AGR(su):{PERS:2,NUM:pl}}⟩ ⟶ ⟨*m*X,σ⟩
⟨X,σ:{CAT:verb,AGR(su):{PERS:3,NUM:pl},GEN:{1,2}}⟩ ⟶ ⟨*wa*X,σ⟩

Block C ⟨X,{CAT:verb, POL:neg}⟩ ⟶ ⟨*ha*X,σ⟩

Recall that the identity function, ⟨X,σ⟩ ⟶ ⟨X,σ⟩, is a member of every rule block, according to the IFD. Thus, we see for example, that the negated third singular past tense form is correctly predicted to be *ha-a-ku*-ROOT and not **ha-a-li*-ROOT,

---

[10] Note that, in this literature, the term *portmanteau* has a more restrictive use than how we use it here. What we have been calling a portmanteau would be called *cumulative exponence.*

[11] The simplification does not account for all the nuances of the paradigms that are captured by the rules in Stewart & Stump (2007).

because the portmanteau form *ku* expresses both the past tense and the negation. From Block A, then, the third rule must be chosen. From Block B, the third rule best expresses the features. Lastly, the rule in Block C can apply, given the input features. The result is the well-formed *ha-a-ku*-ROOT, which undergoes phonological shortening to *ha-ku*-ROOT.

Sadler & Nordlinger (2004) presented an LFG interface to PFM for case-stacking in Australian languages that display that phenomenon (e.g., Kayardild, Martuthunira, Thalanyji, Wambaya). Sadler & Nordlinger (2006) subsequently presented the actual PFM morphology, i.e. realization, of case-stacking morphology. The two papers together constitute an instance of LFG interfaced with PFM. Sadler & Nordlinger (2004: 172–180) provide a detailed analysis of the following example from Martuthunira (Dench 1995: 60, (3.15)):

(17) Martuthunira
Ngayu nhawu-lha ngurnu tharnta-a mirtily-marta-a
I saw-PST that.ACC euro-ACC joey-PROP-ACC
thara-ngka-marta-a.
pouch-LOC-PROP-ACC
1 saw the euro with a joey in (its) pouch.

Sadler & Nordlinger (2004: 174, (28)) provide the following lexemic entry[12] for the word *tharangkamartaa* in (17):

(18) ⟨*thara*, {Case$_C$: LOC, {Case$_C$: PROP, {Case$_C$: ACC}}}⟩

Sadler & Nordlinger (2004: 174, (25)) provide the following interpretations of these case features:[13]

(19)

M-feature	F-description
Case$_C$: LOC	$(\uparrow \text{CASE}) = \text{LOC}$
	$(\text{ADJ}_{loc} \in \uparrow)$
Case$_C$: PROP	$(\uparrow \text{CASE}) = \text{PROP}$
	$(\text{ADJ}_{prop} \in \uparrow)$
Case$_C$: ACC	$(\uparrow \text{CASE}) = \text{ACC}$
	$(\text{OBJ} \uparrow)$

---

[12] We use the terminology of Dalrymple 2015; see Section 4 above.

[13] Their table does not include ACC but what its entry should be is clear from their (30) (Sadler & Nordlinger 2004: 175). Also, we have adjusted for the feature ADJ being set-valued by using the symbol $\in$.

In the Dalrymple (2015) notation this would be:[14]

(20) *LE*⟨{ROOT: pouch}, {(↑ PRED) = POUCH}, POUCH1⟩

R⟨POUCH1, tharangkamartaa, /t̪araŋkamaʈaa/,
m-features:{M-CAT:N, M-CASE: LOC, {M-CASE: PROP, {M-CASE: ACC}}}⟩

D⟨POUCH1, m-features, N, (↑ NUM) = SG
(↑ CASE) = LOC
(ADJ$_{loc}$ ∈ ↑)
((ADJ$_{loc}$ ∈ ↑) CASE) = PROP
(ADJ$_{prop}$ ∈ ADJ$_{loc}$ ∈ ↑)
(((ADJ$_{prop}$ ∈ ADJ$_{loc}$ ∈ ↑)) CASE) = ACC
(OBJ ADJ$_{prop}$ ∈ ADJ$_{loc}$ ∈ ↑)⟩

$\mathcal{L}$⟨tharangkamartaa, /t̪araŋkamaʈaa/,
N, {(↑ PRED) = POUCH
(↑ NUM) = SG
(↑ CASE) = LOC
(ADJ$_{loc}$ ∈ ↑)
((ADJ$_{loc}$ ∈ ↑) CASE) = PROP
(ADJ$_{prop}$ ∈ ADJ$_{loc}$ ∈ ↑)
(((ADJ$_{prop}$ ∈ ADJ$_{loc}$ ∈ ↑)) CASE) = ACC
(OBJ ADJ$_{prop}$ ∈ ADJ$_{loc}$ ∈ ↑)}⟩

This complex lexical entry $\mathcal{L}_{tharangkamartaa}$ licenses the following f-structure:

(21)
$$\left[\begin{array}{ll} \text{OBJ} & \left[\begin{array}{ll} \text{CASE} & \text{ACC} \\ \text{ADJ}_{prop} & \left\{\left[\begin{array}{ll} \text{CASE} & \text{PROP} \\ \text{ADJ}_{loc} & \left\{\left[\begin{array}{ll} \text{PRED} & \text{POUCH} \\ \text{NUM} & \text{SG} \\ \text{CASE} & \text{LOC} \end{array}\right]\right\} \end{array}\right]\right\} \end{array}\right] \end{array}\right]$$

Thus, we can observe that the Dalrymple (2015) notation accurately reconstructs the intended f-structure from Sadler & Nordlinger (2004: 178, (36)).[15]

However, some work remains to be done. How is the realization of *tharangkamartaa* determined based on the root, lexemic ID, and the m-features? The Dalrymple (2015) framework is silent on this issue, because it is meant to be a *general*

---

[14] The (↑ NUM) = SG part of the f-description occurs by default, following the assumption in Dalrymple (2015: 76) that singular number is the default for nouns (i.e., M-CAT:N in the absence of M-NUM introduces the f-description {(↑ NUM) = SG}).

[15] Modulo our use of ∈, which they simplify away, and the [NUM SG], which comes from Dalrymple's default; see footnote 14 above.

interface between LFG syntax and realizational morphology. In order to preserve its generality, the framework remains silent on the question of exponence. As mentioned above, Sadler & Nordlinger (2006) provide a PFM account, which we can plug into the Dalrymple framework. Adapting their proposal (Sadler & Nordlinger 2004: 471, 23) — which in any case is for Kayardild, not Martuthunira — we get the following case rule block, using the Dalrymple (2015) *R* function:

(22) a. *R*⟨POUCH1, tharangka, /t̪araŋka/,
{M-CAT:N, M-CASE: LOC}⟩
b. *R*⟨POUCH1, tharangkamarta, /t̪araŋkamaʈa/,
{M-CAT:N, M-CASE: PROP}⟩
c. *R*⟨POUCH1, tharangkamartaa, /t̪araŋkamaʈaa/,
{M-CAT:N, M-CASE: ACC}⟩

The effect of these functions on the s-form can be captured in the following simplified PFM representation, based on (15).[16]

(23) ⟨X,σ:{M-CAT:N, M-CASE:LOC}⟩ ⟶ ⟨X*ngka*,σ⟩
⟨X,σ:{M-CAT:N, M-CASE:PROP}⟩ ⟶ ⟨X*marta*,σ⟩
⟨X,σ:{M-CAT:N, M-CASE:ACC}⟩ ⟶ ⟨X*a*,σ⟩

In other words, in the context of the features M-CAT:N and M-CASE:LOC, the input exponent becomes extended with additional morphological information, the suffix *ngka*. In the context of the features M-CAT:N and M-CASE:PROP, the input exponent becomes extended with additional morphological information, the suffix *marta*. And, in the context of the features M-CAT:N and M-CASE:ACC, the input exponent becomes extended with additional morphological information, the suffix *a*.

In sum, much work in LFG has adopted Paradigm Function Morphology as its morphological theory. PFM is an *inferential-realizational* theory of morphology. It is *lexemic*, it is *Word-and-Paradigm*, and it assumes *Strong Lexicalism*.

5.2 The targets of exponence

What realizational theories have in common is that morphology realizes things; what they don't have in common is what those things are. In a paradigm model, like PFM, morphology realizes a lexeme and a valuation of a fixed set of attributes.

---

[16] Note that the simplified formalization in (23) does not account for the set-based embedding in (17) above. But it should be easy enough to replace the second coordinate of the input to their function with **contains**(f), where **contains** is a function that recursively searches σ for its argument, f, a feature, e.g. M-CASE:LOC.

It must be a *fixed* set of attributes, by definition of a paradigm. As Spencer (2013) notes:

> On this […] conception we abstract away from actual word forms and just consider the set of oppositions or contrasts that are available in principle to a lexeme. (Spencer 2013: 9)

"The set of cells embodying the set of oppositions open to a lexeme" is what Spencer (2013: 9) calls the *property paradigm*. It's *this* abstraction, the property paradigm, that is realized by word forms (the *form paradigm*) in what Spencer calls the *form-property paradigm* (Spencer 2013: 9). In this kind of conception, in order to preserve Strong Lexicalism one must simply have an intervening function that maps a lexeme to a syntactic word:

(24) form-property paradigm $\xrightarrow{f}$ set of instantiated lexical entries for syntax

The mapping f can be a structured mapping, if there are features of the mapping itself that the grammar needs to refer to. This could be represented as an attribute-value matrix. In other words, m-structure (see above) is one possible characterization of the structured mapping f. And an AVM is also indeed how Spencer (2013) models the structured mapping f; see Figure 5. This paradigm shows the lexeme DELAT′ ('make') from Russian, which has stem alternants in the present (*delaj-*), infinitive (*dela-*), and predicative adjective (*delal-*).

Ackerman & Stump (2004) make an antecedent proposal to that of Spencer (2013) which is very similar, although not as well-developed (as a consequence of the former being a paper and the latter a monograph). However, it is worth reading the following passage from Ackerman & Stump (2004) to get a different perspective on the form-property paradigm of Spencer (2013), especially because it refers more directly to LFG structures:

> In distinguishing a lexeme's content-theoretic aspects from its form-theoretic aspects, we will pursue an innovative conception of the lexicon and its relation to c-structure, f-structure, and morphological realization. On this conception, a language's lexicon is bipartite with respect to content and form: one part of its lexicon is its LEXEMICON, whose individual entries are lexemes bearing lexical meanings: the complementary part is its RADICON, whose individual entries are roots, i.e. elements of form. Every member L of a language's lexemicon has an associated CONTENT-PARADIGM C-P(L) such that each cell in C-P(L) consists of the pairing of L with a complete set of morphosyntactic properties; we refer to any such pairing as a

> content-cell. Crucially, content-cells represent ensembles of semantically interpretable information. In contrast, every member r of a language's radicon has an associated form-paradigm F-P(r) such that each cell in F-P(r) consists of the pairing of r with a set of differentiating morphosyntactic property labels; we refer to any such pairing as a form-cell. A language's paradigms of form-cells house the information necessary to deduce the morphological realization of the cells in that language's content-paradigms. (Ackerman & Stump 2004: 117–118)

Although their terminology is different, there are obvious correspondences with Spencer (2013). Ackerman & Stump (2004) assume that a lexicon consists of two parts. The first part is the lexemicon, which "has an associated content-paradigm". Their content-paradigm corresponds to Spencer's property paradigm. The second part of the lexicon for Ackerman & Stump (2004) is

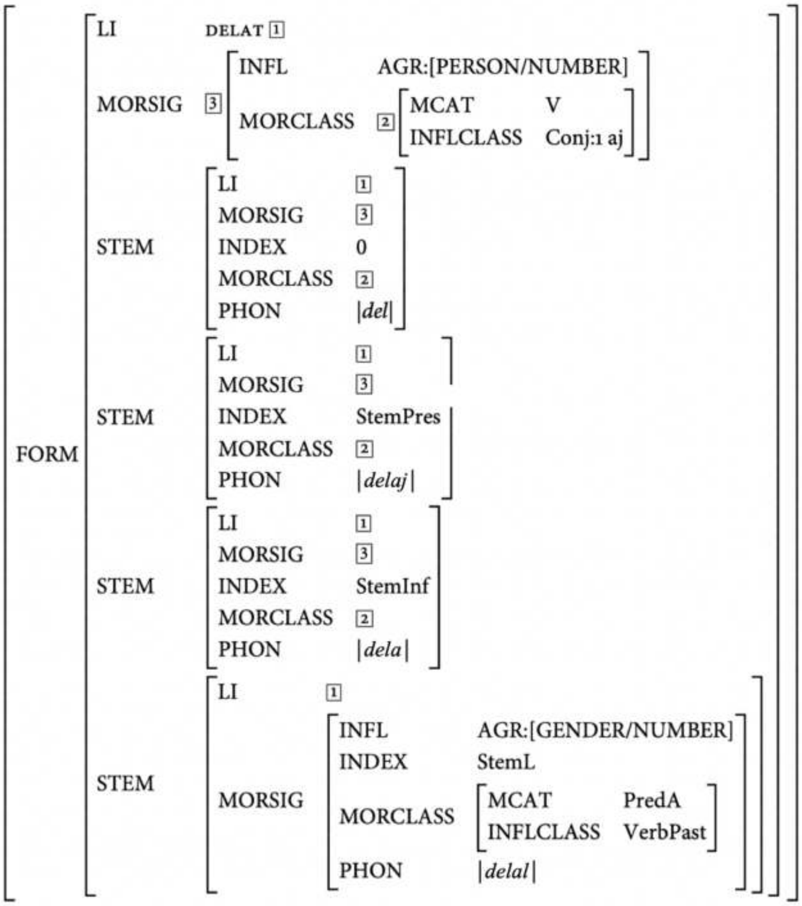

Figure 5: The form-property paradigm for Russian delat′ ('make'). From Spencer (2013: 263, (56)); used with permission.

the RADICON, which “has an associated FORM-PARADIGM”. Their form-paradigm corresponds to Spencer’s form paradigm. Taken together, then, Ackerman & Stump’s (2004) lexicon is equivalent to a set of Spencer’s (2013) form-property paradigms. As a consequence, the mapping in (24) above also accurately characterizes the Ackerman & Stump (2004) proposal, which is about periphrasis — when a paradigm cell is filled by more than one word. Further work in this vein can be found in, e.g., Ackerman et al. (2011) and Spencer (2015). We have chosen to describe the Spencer (2013) and Ackerman & Stump (2004) work because of their close connection to LFG, but PFM2 (Stump 2016) incorporates similar principles.

The important takeaway here is that in lexemic morphology there is a mapping (structured or not) from an abstract property paradigm — whose features are purely morphological — to syntax. One could imagine instead having morphology realize the syntactic representation(s) directly, which is the approach taken in Distributed Morphology (DM; Halle & Marantz 1993), and theories like it (e.g., Nanosyntax; Starke 2009, Caha 2009). This comes at the expense of (at least some of) Strong Lexicalism, as discussed below in reference to (38), but it does away with the abstraction of the property paradigm. In a morphemic model, like DM, morphology realizes the information in the terminals of some syntactic representation. There will necessarily be information about syntax, but also possibly about semantics and other aspects of grammar (if they are modelled separately).

5.3 LFG interfaced with DM

In Section 5.1, we explored LFG paired with PFM, an inferential-realizational framework for morphology. In this section, we see LFG paired with Distributed Morphology, a lexical-realizational framework. This combination is called Lexical-Realizational Functional Grammar ($\mathrm{L_RFG}$; Asudeh & Siddiqi 2016, Melchin et al. 2020, Everdell et al. 2021, Asudeh & Siddiqi forthcoming). $\mathrm{L_RFG}$ accomplishes this synthesis of LFG and DM by mapping information from the c-structure to a realization, or *exponent*, called *vocabulary structure*.

Importantly, $\mathrm{L_RFG}$ assumes that c-structure terminals are not *words*, but just grammatical and semantic information, with no associated information about the form (e.g., *s-form*; see Section 4.1) included in the c-structure. This fact, together with the fact that $\mathrm{L_RFG}$ follows DM in postulating highly articulated morphological structure, differentiates $\mathrm{L_RFG}$ c-structures from LFG c-structures. However, $\mathrm{L_RFG}$ uses the LFG formal machinery and assumes the same kinds of annotated c-structure rules. In $\mathrm{L_RFG}$, the categorial information in c-structure *preterminals* and the other information in c-structure *terminals* are realized by L$_{\text{R}}$FG's *v* correspondence function as v(ocabulary)-structures. Since L$_{\text{R}}$FG assumes a version of LFG's Correspondence Architecture (Kaplan 1989, 1995), the information that v-structures express is not *purely* syntactic. V-structures also express information about semantics (encoded in Glue Semantics *meaning constructors*: see Asudeh 2023 [this volume]) and can indeed express information structure or any other aspect of grammar that is encoded in distinct modules in the Correspondence Architecture.

L$_{\text{R}}$FG seeks to add to LFG's strengths in accounting for *nonconfigurationality* by adding DM's strengths in accounting for *polysynthesis.* These two properties co-occur with some frequency in non-European languages. L$_{\text{R}}$FG also seeks to account for highly agglutinative languages like Finnish and Turkish. Additionally, because the realizational module, v-structure, interfaces with prosodic structure, L$_{\text{R}}$FG draws on existing LFG work, especially Bögel (2015), on clitic ordering and extends it to affixation. Asudeh et al. (2022) develops the interface between v-structure and p(rosodic)-structure (by the ρ correspondence function) and the mapping from p-structure to the p(honological)-string (by the *o* correspondence function).

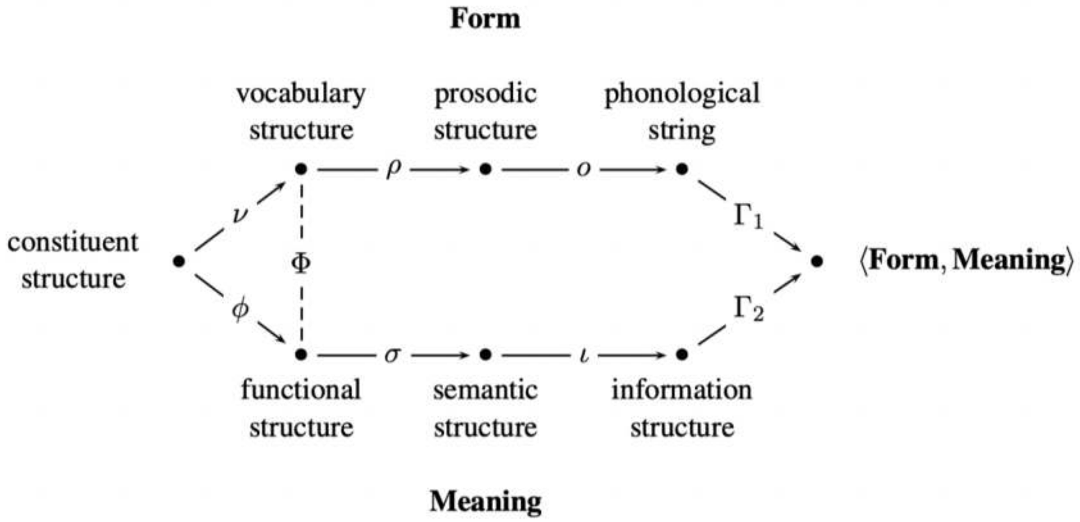

Figure 6: L$_{\text{R}}$FG's version of LFG's Correspondence Architecture. From Melchin et al. (2020: 271); used with permission.

L$_{\text{R}}$FG's version of LFG's Correspondence Architecture is shown in Figure 6, which shows that there is a lot shared between L$_{\text{R}}$FG and LFG. However, there is no lexicon feeding the c-structure in L$_{\text{R}}$FG. Rather, there is a Vocabulary in L$_{\text{R}}$FG that consists of a set of mappings from n-tuples that contain categorial information and an f-description to vocabulary structures that realize the content of the input. In recent L$_{\text{R}}$FG work on morphosemantics (Asudeh & Siddiqi 2022), we suggest that, for the purposes of the ν-mapping, the f-description could be usefully partitioned into a set consisting of information about non-f-structural aspects of the grammar (in particular, Glue meaning constructors for compositional semantics) and the set consisting of the rest of the f-description, which is information about f-structure.[17] The following example shows Vocabulary Items (VIs) for Ojibwe and English roots for *see* (Asudeh & Siddiqi 2022):[18]

(25) Ojibwe

$$\langle\ [\sqrt{}], \Phi\{(\uparrow \textsc{pred}) = \textsc{see}\}, \{\textbf{see} : (\uparrow \textsc{obj})_\sigma \multimap (\uparrow \textsc{subj})_\sigma \multimap {\uparrow_\sigma}\}\ \rangle \xrightarrow{\nu} \textit{waab}$$

(26) English

$$\langle\ [\sqrt{}], \Phi\{(\uparrow \textsc{pred}) = \textsc{see}\}, \{\textbf{see} : (\uparrow \textsc{obj})_\sigma \multimap (\uparrow \textsc{subj})_\sigma \multimap {\uparrow_\sigma}\}\ \rangle \xrightarrow{\nu} \textit{see}$$

The first coordinate of the input is a list of c-structure categories, typically of length 1. However, it is actually an ordered list of preterminals from the c-structure, such that the list can be longer in cases of *spanning* (Ramchand 2008, Haugen & Siddiqi 2016, Svenonius 2016, Merchant 2015), which is used in some versions of DM for *portmanteau* phenomena. The result is similar to the Lexical Sharing model proposed for LFG by Wescoat (2002, 2005, 2007), but maintains, like DM, that the complex internal structures of words are part of syntax.

In the cases above, the list is of length 1 and has the sole category $\sqrt{}$, the category of all roots. The second coordinate uses the *bridging function*, Φ, to map the f-description to the set of f-structures that it describes. The third coordinate is not subject to Φ and contains semantic information modelled in Glue meaning constructors.

Meaning constructors are pairs of terms from two logics (the colon is an uninterpreted pairing symbol):

(27) $\mathcal{M} : G$

$\mathcal{M}$ is an expression of the *meaning language* — anything that supports the lambda calculus. G is an expression of *linear logic* (Girard 1987), which specifies semantic composition based on a syntactic parse that instantiates the general terms in G to a specific syntactic structure.

The meaning constructors serve as premises in a linear logic proof of the *compositional semantics.* Consider example (28).

---

[17] The new third coordinate could potentially also include i-structural information; or perhaps this would be better captured in a separate fourth coordinate. We plan to explore this in future work.

[18] We will present the *bridging function*, Φ, shortly.

(28) Alex likes Blake.

We obtain the following meaning constructors from the relevant VIs.

(29) Meaning constructors:
$$\begin{aligned}&\textbf{alex} : a\\ &\textbf{blake} : b\\ &\lambda y.\lambda x.\textbf{like}(y)(x) : b \multimap a \multimap l\end{aligned}$$

Note that $\lambda y.\lambda x.\textbf{like}(y)(x)$ is η-equivalent to just **like**, but it is useful to use the expanded form to make the structure of the following proof more obvious.

(30)
$$\dfrac{\boxed{\textbf{alex} : a} \qquad \dfrac{\boxed{\lambda y.\lambda x.\textbf{like}(y)(x) : b \multimap a \multimap l} \qquad \boxed{\textbf{blake} : b}}{\lambda x.\textbf{like}(\textbf{blake})(x) : a \multimap l}}{\textbf{like}(\textbf{blake})(\textbf{alex}) : l}$$

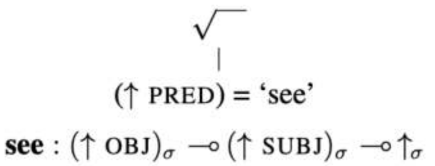
In the proof, the meaning constructors in (29) are shown in boxes to aid the reader less familiar with Glue; this is not a part of the proof as such. It highlights the meaning constructors versus the compositionally derived meanings. For brief overviews of Glue Semantics, see Asudeh (2022); Asudeh 2023 [this volume].

Recall the Vocabulary Item for Ojibwe *waab* in (25):

(31) $\langle\ [\sqrt{\ }],\ \Phi\{(\uparrow \textsc{pred}) = \textsc{see}\}, \{\textbf{see} : (\uparrow \textsc{obj})_\sigma \multimap (\uparrow \textsc{subj})_\sigma \multimap \uparrow_\sigma\}\ \rangle \xrightarrow{v} \textit{waab}$

This information can be represented as follows in a c-structure:

(32)



The c-structure is licensed by c-structure rules of the usual kind, but containing categories like $\sqrt{\ }$, which are less familiar in LFG. Thus, the annotated c-structure rule for licensing (32) in a c-structure would be as follows, leaving the mother category underspecified and similarly the sister of $\sqrt{\ }$:

(33)
$$\begin{array}{lccc} \mathrm{X}^n & \longrightarrow & \sqrt{\ } & \mathrm{X}^{m,\ m\leq n}\\ & & \uparrow=\downarrow & \uparrow=\downarrow \end{array}$$

Note that it is X^m that projects the c-structure mother X^n in a co-head structure with $\sqrt{\ }$. Thus, X is necessarily a functional category (Bresnan et al. 2016: ch. 6).

In short, we can think of the lefthand side of a Vocabulary Item as a tree admissibility condition (McCawley 1968) on a subtree whose preterminal yield is the list of categories in the first coordinate of the v function such that the f-description in the second coordinate and the meaning constructors in the third are the union of its terminal yield. Alternatively, we can think of it in terms of terminal expansions, such as:

(34) $$\sqrt{} \longrightarrow \left\{ \begin{matrix} \{(\uparrow \textsc{pred}) = \textsc{see}, \textbf{see} : (\uparrow \textsc{obj})_\sigma \multimap (\uparrow \textsc{subj})_\sigma \multimap \uparrow_\sigma\}, \\ \vdots \end{matrix} \right\}$$

We prefer the tree admissibility route, but observe that whether we go that route or the terminal expansion route, there is no information about form in the input side of the Vocabulary Item. That is the job of the *ν* correspondence function. Recall that *ν* maps the information in c-structure terminals and c-structure categorial information to v-structures, as shown in (25–26).

Here is an example from Ojibwe (*Anishinaabemowin*, Algonquian; Melchin et al. 2020: 288):

(35) Ojibwe

gi-	gii-	waab	-am	-igw	-naan	-ag
2	PST	see	VTA	INV	1PL	3PL

‘They saw us(incl).’

The L_RFG c-structure and f-structure and the *ν* correspondence from c-structure to v-structure are shown in Figure 7 (Melchin et al. 2020: 288). Note that we have only shown the form part of each v-structure, and only using an orthographic rather than phonemic representation. V-structures also minimally contain prosodic information — such as information about phonological dependency (e.g., for *clisis*) and the identity of the host (e.g., for *affixation*) — and any purely morphological information (e.g., *inflectional class*). Asudeh et al. (2022) propose the v-structure representation that is schematized in (36).

(36) $$\left[\begin{array}{ll} \begin{array}{l}\textsc{phon(ological)} \\ \textsc{rep(resentation)}\end{array} & \textit{phonological realization \& conditions} \\ \textsc{p(rosodic)frame} & \textit{prosodic unit} \\ \textsc{p(rosodic)level} & 1|2 \\ \textsc{dep(endence)} & \{\textsc{left},\textsc{right}\} \\ \textsc{class} & \{\textit{inflectional classes}\} \\ \textsc{type} & \textsc{verbal}|\textsc{nominal}|\textsc{adjectival} \\ \textsc{host} & \left[\begin{array}{l} \textsc{identity}\ \ \textsc{aunt}|\textsc{niece} \\ \left\{ \left[\begin{array}{ll} \textsc{phon.rep} & \ldots \\ \textsc{pframe} & \ldots \\ \textsc{plevel} & \ldots \\ \textsc{class} & \ldots \\ \textsc{type} & \ldots \end{array} \right] \right\} \end{array} \right] \end{array} \right]$$
