
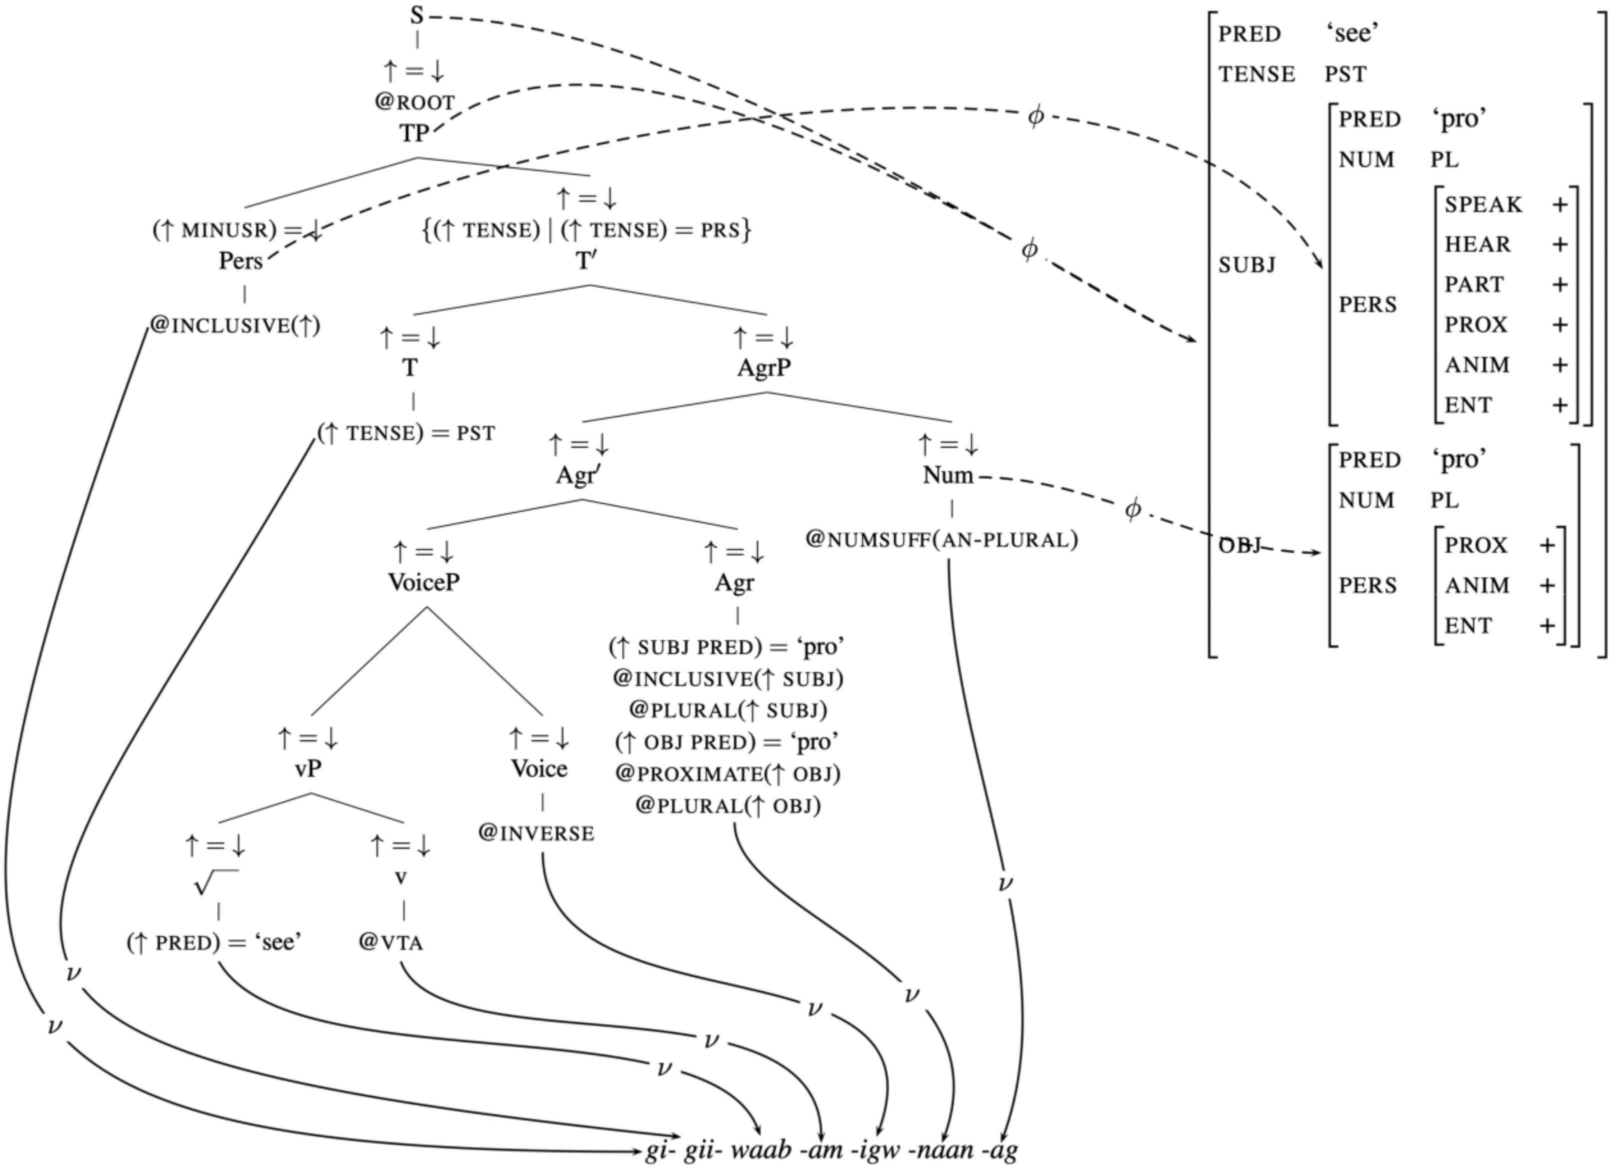

Figure 7: L$_{\text{R}}$FG c-structure, f-structure, and (simplified) v-structure for Ojibwe *gigiiwaabamigwnaanag* ('They saw us(incl)')

A v-structure is thus a feature structure that minimally contains information about form and morphophonology (PHON.REP, PFRAME, PLEVEL, and DEP), properly morphological information (CLASS, TYPE), and morphosyntactic information about its HOST, where relevant. All features can be left underspecified (i.e., when they are not mentioned in the description that defines the v-structure).

The obvious point of contrast between L_RFG and LFG concerns the Lexicalist Hypothesis (Chomsky 1970, Lapointe 1980):

(37) *Lexicalist Hypothesis*
No syntactic rule can refer to elements of morphological structure.
(Lapointe 1980: 8)

In LFG, this is captured in the *Lexical Integrity Principle*, through formulations like the following:

(38) *Lexical Integrity*
Morphologically complete words are leaves of the c-structure tree, and each leaf corresponds to one and only one c-structure node.
(Bresnan et al. 2016: 92)

This statement has two parts:

1. L_RFG *upholds* the part that states that "each leaf corresponds to one and only one c-structure node".
2. L_RFG *rejects* the part that states that "morphologically complete words are leaves of the c-structure tree".

Clearly, the c-structure leaves/terminals in L_RFG are not "morphologically complete words". The c-structure leaves/terminals are feature bundles that *map* to form, but the form itself is not part of the terminal node; hence 2. Yet there is never multidominance in an L_RFG c-structure; hence 1.

However, notice that the notion *morphologically complete word* is left unanalyzed in the definition in (38). In fact, it is far from clear that "morphologically complete word" is a coherent notion (for discussion, see e.g., Anderson 1982). The essential problem is that there are multiple relevant notions of wordhood, and they don't align on a single type of object that we can point to and unambiguously and confidently call a word (Di Sciullo & Williams 1987).[19] In fact, there can be mismatches between the phonological, syntactic, and semantic aspects of words (Marantz 1997). Of course, the LFG Correspondence Architecture is designed around the notion of mismatches between modules, which is carried over into L_RFG.

---

[19] This is a long and broad discussion that we cannot possibly do justice to here.

5.3.1 Conditions on exponence

Recall that the exponence function $(\overset{v}{\rightarrow})$ maps a triple to a v-structure. The first argument of the triple is a list of preterminal categories, typically of length 1, which are taken in the linear order they appear in the tree. The second argument is itself a function, Φ, which maps an f-description to the set of f-structures that satisfy the description; i.e. $\Phi(d \in D) = \{f \in F \mid f \vDash d\}$, where D is the set of valid f-descriptions and F is the set of f-structures.[20] The third argument is a set that includes *meaning constructors* from Glue Semantics (Glue; Dalrymple 1999, 2001, Dalrymple et al. 2019, Asudeh 2012, 2022).

Let V^i be the domain of the exponence function v in some language L, i.e. the set of inputs to Vocabulary Items in L. We write $V^i(\alpha)$ to indicate the domain of some particular Vocabulary Item, α. We write $\pi_n(V^i(\alpha))$ to indicate the nth projection of $V^i(\alpha)$. For example, $\pi_1(V^i(\alpha))$ returns the c-structure list in the first projection of the input to Vocabulary Item α.[21] The following conditions on exponence hold based on the input side of the v correspondence function (Asudeh & Siddiqi 2022).[22]

(39) **MostInformative**$_c(\alpha, \beta)$ returns whichever of α,β has the longest list of overlapping c-structure categories.

Intuition. Prefer portmanteau forms, whenever possible, on c-structural grounds. Choose the VI that realizes the greater list of categories.

Formalization. We define a function **span** that compares two lists for overlap.[23]

Given two Vocabulary Items, α and β,

$$\textbf{MostInformative}_c(\alpha, \beta) = \begin{cases} \alpha \textbf{ if } \pi_1(V^i(\alpha)) = f \wedge \pi_1(V^i(\beta)) = g \wedge \textbf{span}(f, g) \\ \beta \textbf{ if } \pi_1(V^i(\alpha)) = f \wedge \pi_1(V^i(\beta)) = g \wedge \textbf{span}(g, f) \\ \bot \textbf{ otherwise} \end{cases}$$

(40) **MostInformative**$_f(\alpha, \beta)$ returns whichever of α,β has the most specific f-structure in the set of f-structures returned by Φ applied to α/β's collected f-description.

---

[20] We thank Ron Kaplan (p.c.) for discussion of this point. Any remaining errors are our own.

[21] This π is just standard notation for retrieving arguments to functions and should not be mistaken for a correspondence function.

[22] Note that all these conditions are Paninian, as is typical in morphological analysis. The analog in PFM is actually called Panini's Principle (Stump 2001) and in DM it is called the Subset Principle (Halle & Marantz 1993).

[23] Asudeh & Siddiqi (2022) define **span** as follows:

$$\textbf{span}(list_1, list_2) = \begin{cases} \mathsf{first}(list_1) = \mathsf{first}(list_2) \wedge \textbf{span}(\mathsf{rest}(list_1), \mathsf{rest}(list_2)) \\ list_1 \neq elist \wedge list_2 = elist \end{cases}$$

Intuition. Prefer portmanteau forms, whenever possible, on f-structural grounds. Choose the VI that defines an f-structure that contains the greater set of features.

Formalization. The proper subsumption relation on f-structures (Bresnan et al. 2016: ch. 5) is used to capture the intuition.
Given two VIs, α and β,

$$\textbf{MostInformative}_f(\alpha,\beta) = \begin{cases} \alpha \textbf{ if } \exists f \forall g. f \in \pi_2(V^i(\alpha)) \land g \in \pi_2(V^i(\beta)) \land g \sqsubset f \\ \beta \textbf{ if } \exists f \forall g. f \in \pi_2(V^i(\beta)) \land g \in \pi_2(V^i(\alpha)) \land g \sqsubset f \\ \bot \textbf{ otherwise} \end{cases}$$

(41) **MostInformative**$_s(\alpha,\beta)$ returns whichever Vocabulary Item has the more specific meaning.
Intuition. Prefer portmanteau forms, wherever possible, on semantic grounds. Choose the VI whose denotation is more semantically contentful.
Formalization. The proper subset relation on set-denoting expressions is used to capture the intuition.
Given two Vocabulary Items, α and β,

$$\textbf{MostInformative}_s(\alpha,\beta) = \begin{cases} \alpha \textbf{ if } f = \pi_3(V^i(\alpha)) \land g = \pi_3(V^i(\beta)) \land [\![f]\!] \subset [\![g]\!] \\ \beta \textbf{ if } f = \pi_3(V^i(\alpha)) \land g = \pi_3(V^i(\beta)) \land [\![g]\!] \subset [\![f]\!] \\ \bot \textbf{ otherwise} \end{cases}$$

In addition, there is a constraint on exponence that concerns the output of the ν correspondence function (Asudeh & Siddiqi 2022), i.e. the expression of prosodic and phonological information. Let V^o be the co-domain of the exponence function ν in some language L, i.e. the set of outputs of Vocabulary Items in L. We write $V^o(\alpha)$ to indicate the co-domain of some particular Vocabulary Item, α (i.e., the output vocabulary structure).

(42) **MostSpecific**(α,β) returns whichever Vocabulary Item has the most restrictions on its phonological context.

Intuition. Prefer affixes whenever possible.

Formalization. The proper subsumption relation on feature structures — i.e., v-structures — is used to capture the intuition.
Given two Vocabulary Items, α and β,

$$\textbf{MostSpecific}(\alpha,\beta) = \begin{cases} \alpha \textbf{ if } (V^o(\beta)\ \textsc{host}) \sqsubset (V^o(\alpha)\ \textsc{host}) \\ \beta \textbf{ if } (V^o(\alpha)\ \textsc{host}) \sqsubset (V^o(\beta)\ \textsc{host}) \\ \bot \textbf{ otherwise} \end{cases}$$

The upshot is that **MostSpecific** chooses the VI whose output v-structure has more specific content in the HOST feature.[24]

Note that **MostInformative**$_c$ and **MostInformative**$_f$ are *morphosyntactic* constraints, **MostInformative**$_s$ is a *morphosemantic* constraint, and **MostSpecific** is a *morphophonological* constraint. Note also that each constraint can result in a tie, represented by ⊥. However, there are regularities in the mappings/interfaces between structures, so it would be unlikely for all four constraints to yield ⊥. We are not currently aware of any empirical case that would merit such an analysis. Lastly, it is important to note that these constraints apply simultaneously and universally (whenever they can), much like standard constraints and equations in LFG. There is no constraint-ordering and the constraints are not soft constraints.[25]

In sum, L$_\text{R}$FG is a daughter framework of LFG that uses the LFG formalism in a conservative fashion. However, L$_\text{R}$FG theory makes some different assumptions from traditional LFG theory. Namely, it rearranges the Correspondence Architecture, adds a new structure with new properties (v-structure), upholds only part of the Lexical Integrity Principle, and has a more articulated c-structure than standard LFG, in order to provide a morphemic theory of morphology. These theoretical distinctions are due to the influence of DM, since L$_\text{R}$FG is also a daughter framework of DM.

As its name states, Lexical-Realizational Functional Grammar is a *lexical-realizational* theory of morphology. It is *morphemic*, *Item-and-Arrangement*, and *morphosyntactic.*

6 Conclusion

A feature of LFG is its f-descriptions, which can occur in both lexical entries and on c-structure nodes. The result is that both morphology and syntax can contribute information to f-structure. This ‘common language’ between morphology and syntax has allowed LFG to remain agnostic about the precise nature of

---

[24] Note that if (f FEAT) does not exist, (f FEAT) resolves to the empty feature structure, notated ⊥ (not to be confused with the ⊥ explicitly mentioned in the constraints above). as it’s the bottom of the f-structure lattice. The empty f-structure subsumes all f-structures. Therefore, if (v HOST) does not exist, but (v' HOST) does exist, then (v HOST) $\sqsubset$ (v' HOST) returns true. If (v' HOST) also does not exist, then (v HOST) $\sqsubset$ (v' HOST) returns false, since it is false that ⊥ *properly* subsumes ⊥.

[25] An anonymous reviewer wonders what the system would do if one constraint picks α and another picks β. This is an interesting point that deserves further investigation and we thank the reviewer for highlighting it.

morphology. In its initial construal as just a theory of syntax, based around c-structure and f-structure, this was pretty harmless. But once a general grammatical architecture, the Correspondence Architecture, was proposed (Kaplan 1989, 1995), LFG began to owe a better account of how it interfaces with morphology.

In early LFG, morphology was generally done incrementally, using annotated phrase structure rules of the same kind that license c-structures, but whose categories are morphological instead of syntactic. Morphological theory in general, though, has been converging on the idea that morphology is realizational, not incremental. Therefore, more recent work has focused on exploring the syntax–morphology interface (Dalrymple 2015, Dalrymple et al. 2019: ch. 12) in light of an interface with realizational morphology. This work can be thought of as providing a universal adapter between LFG syntax and some kind of realizational morphology. Much of the theoretical work on morphology for LFG over the last couple of decades has focused on interfacing LFG with Paradigm Function Morphology. Other recent work has presented an alternative in the guise of L$_{\mathrm{R}}$FG, a framework that instead interfaces LFG with Distributed Morphology.

The existence of two different approaches to morphological realization in LFG, i.e. PFM and L$_{\mathrm{R}}$FG, mirrors two different interpretations of 'morphological complexity' as a set of phenomena requiring explanation. *Paradigmatic* morphological complexity (see, e.g., Baerman et al. 2017) concerns complex patterns of syncretism, root allomorphy, and templatic morphology. *Syntagmatic* morphological complexity concerns concatenative morphology whose structures seem to encode syntactic structure, in other words structure *within* what we pretheoretically call words. PFM addresses the former kind of morphological complexity, while L$_{\mathrm{R}}$FG addresses the latter.

Acknowledgements

We thank Farrell Ackerman, Jim Blevins, Greg Stump, and Andy Spencer for fruitful discussions about some of the issues covered here over the last several years. Greg in particular deserves a special thank you for reading some precursors of this material, especially Section 2. We also thank our students† and collaborators‡ on the L$_{\mathrm{R}}$FG project: Oleg Belyaev‡, Bronwyn Bjorkman‡, Tina Bögel‡, Veronica Burrage†, Michael Everdell‡, Paul B. Melchin‡, Will Oxford‡, and Sam Turnbull†. Thank you to the anonymous reviewers of this paper for helping us to improve it, including spotting some serious errors. Last but most definitely not least, we thank Mary Dalrymple for taking on the mammoth task of editing this volume, for her patience and help with this particular paper, and for the inspiration that her own work on morphology in LFG has provided us. All remaining errors and misconceptions are our own.

Abbreviations

Besides the abbreviations from the Leipzig Glossing Conventions, this chapter uses the following abbreviations.

INV	inverse voice	VTA	verb transitive animate object
PROP	proprietive case

Linguistic disciplines

Chapter 20

LFG and historical linguistics

Hannah Booth
Ghent University

Miriam Butt
University of Konstanz

This chapter looks at the opportunities and perspectives that LFG offers for the study of language change, surveying existing LFG approaches within historical linguistics and providing examples of sample phenomena. We discuss how reanalysis, a major driver of language change, can be accounted for elegantly within LFG's parallel architecture thanks to its crucial separation of form from function and, moreover, how different types of reanalysis can be understood, whether they involve rebracketing, recategorization, or changes at the lexical level commonly discussed in terms of grammaticalization. As we also discuss, LFG's fundamental design principles and resulting flexibility of c-structure allow for complex, nuanced accounts of word order change. Furthermore, we survey the opportunities that LFG offers for exploring the complex relationship between variation and change, and in particular frequency effects and gradual change which proceeds via competition. Finally, we signpost future possibilities for work in this relatively underexplored but promising area.

1 Introduction

This discussion of historical linguistic work in LFG builds on two previous meta-discussions.[1] One is Vincent's (2001) wide-ranging and satisfyingly deep, comparative look at the possibilities which LFG's particular projection architecture

---

[1] An additional discussion of previous diachronic LFG accounts relating specifically to the history of English is Allen (2012).

Hannah Booth & Miriam Butt. 2023. LFG and historical linguistics. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 905–960. Berlin: Language Science Press. DOI: 10.5281/zenodo.10185978

and its combination of both functionalist and generative perspectives offer for an analysis of various different types of language change. The other is a recent handbook article by Börjars & Vincent (2017), which offers more detail on c-structural analyses of language change in several Germanic languages that have emerged since the seminal *Time Over Matter* book. The *Time Over Matter* book (Butt & King 2001) represents the first collection of historical linguistic work within LFG, in which Vincent's (2001) contribution represents more of a position paper than a mere introduction to a collected volume.

In this chapter, we provide a discussion of architectural issues and perspectives on language change in Section 2. However, our intention is not to reproduce the in-depth discussions already found in Vincent (2001) and Börjars & Vincent (2017), so we keep this section comparatively brief and proceed on to discussing examples of lexical and functional change in Section 3. This includes phenomena generally dealt with under the rubric of "grammaticalization", but also an understanding of complex predication, passives and case. Section 4 provides a discussion of language change at c-structure, which includes "growing" functional categories, understanding changes in word order and the syntactic configuration of a language and the development of mixed categories. Finally, we address the possibilities for modelling the complex relationship between variation and change within LFG in Section 5.

2 The LFG Architecture and mechanisms of language change

As Vincent (2001) and Börjars & Vincent (2017) point out, LFG is like most theories in the generative tradition in that it was not specifically designed with diachrony in mind. There is no paper tackling language change in the landmark Bresnan (1982) volume. Serious historical work within LFG mainly began in the 1990s, with an early exception represented by Allen (1986): see Section 3.2. However, as demonstrated by Vincent (2001), LFG's fundamental design principles and its parallel projections are particularly well-suited to modelling diachronic change (see also the discussion of paradigms in Börjars et al. 1997).

In their textbook on language change, Harris & Campbell (1995) articulate a position whereby reanalysis, along with extension and borrowing, is seen as a key mechanism of language change. Reanalysis in their terms covers quite a broad range of phenomena, involving morphophonological and morphosyntactic changes.[2] A relevant touchstone here is Langacker's (1977: 59) classic definition of reanalysis, which Vincent (2001: 11) notes is most useful in an LFG setting, namely that reanalysis concerns "[a] change in the structure of an expression or class of expressions that does not involve any immediate or intrinsic modification of its surface manifestation". Because LFG does not conflate syntactic position and syntactic functions and, thus, by extension, is able to cleanly separate out surface appearance (at c-structure) from functional and semantic import (at f-structure, a(rgument)-structure and s(emantic)-structure), it is particularly well-suited to help understand different types of reanalysis, whether they concern simple syntactic rebracketing, morphosyntactic change of the type where a dative argument or object is reanalyzed as a subject (Allen 1995, Schätzle 2018), the rise of a recipient passive (Allen 1995, 2001) or the development of complex predication (Börjars & Vincent 2017). Other changes may involve the reanalysis of one syntactic category as another (Börjars & Burridge 2011), also leading to the existence of mixed category phenomena (Nikitina 2008), for example, again with attendant functional changes. Van Gelderen (2011) discusses such diachronic developments in terms of "Linguistic Cycles" and works with changes in feature specifications that are attached to lexical items and categories. The analyses are couched within Minimalism and work with a very restricted set of features — we would argue that LFG is much better poised to account for changes in feature systems in relation to phrase structure (see Section 4.1).

Cases of classic reanalysis at a lexical level, many of which have been prominently discussed as instances of grammaticalization (Hopper & Traugott 2003, Narrog & Heine 2017, but also see Roberts & Roussou 2003 within Minimalism) are also easily modelled and predicted by an architecture which separates surface syntactic form (c-structure) from function (f-structure). As we discuss in Section 3.1, a verb can retain its surface form but begin functioning as a perception raising verb, an auxiliary or a light verb (Barron 2001, Butt & Lahiri 2013). Over time, these functional changes may also result in a change in the surface form of the relevant item – typically some kind of morphophonological reduction, but also changes in the paradigmatic behaviour. The design of the LFG architecture allows for this associated process to be captured distinctly from the actual strict process of reanalysis as per Langacker's definition. In fact, it can also predict which types of functional and semantic elements are more prone to change than

---

[2] While phonological change has been overall a central topic in historical linguistics, the focus in this chapter is on morphosyntactic change, reflecting the centrality of syntax in the LFG architecture and the fact that diachronic work within LFG has focused on morphosyntax. A natural framework to work within from an LFG perspective with respect to sound change would be Lexical Phonology (Kiparsky 1982a,b, Mohanan 1986), for example as in Lahiri (2000a).

others and in what way. For instance, in terms of lexical or semantic bleaching one would predict that a verb loses its predicational power (the PRED feature) at f-structure, but retains certain functional information. Or, with respect to originally spatial terms being drawn into the case-marking system of a language, one can imagine working with underspecification and/or the loss of particular features characterizing the spatial terms, e.g., the PLACE and/or PATH specifications (Ahmed Khan 2009).

On the other hand, some instances of language change concern changes at the c-structural level, without necessarily resulting in attendant functional change. Examples are changes with respect to word order and constituent structure such as those found in Germanic and Romance languages, where a previously freer distribution and "discourse-configurational" organization (É. Kiss 1995) yields to a system where grammatical relations are increasingly licensed by position (Kiparsky 1995, 1997, Hinterhölzl & Petrova 2010, Luraghi 2010, Ledgeway 2012, Ponti & Luraghi 2018, Booth et al. 2017, Booth & Schätzle 2019, Booth & Beck 2021). Given that LFG's c-structure represents actual linear order, constituency and hierarchical relations, is not dogmatic about binary branching, and allows for endocentric as well exocentric phrasal organization, there are several parameters across which languages would be expected to vary and change and they indeed do. Thus, the common trend for languages to shift over time from a freer word order to a more fixed word order can be captured in terms of the development of an increasingly endocentric c-structure, as we discuss in Section 4.3. In such a scenario, the mappings between c-structure and f-structure will necessarily change, fed by the changing positions licensed at c-structure, as typically manifested in the changing realization of grammatical relations, as we discuss in Section 4.5.

Of course, most instances of language change do not involve just one change within one module of grammar (i.e. c-structure or f-structure), but are more complex. Given the inherently interactional nature of language change, certain changes which initially occur at c-structure may in turn feed changes at f-structure, and vice versa. In this sense, keeping surface form, syntactic categorization and functional information apart as in the LFG architecture allows one to neatly model the step-wise nature of such developments. Vincent (2001) notes that one of the most complex series of changes he has seen analyzed is that presented by Simpson (2001) on the grammaticalization of associated path in Warlpiri (see Section 3). Indeed, as Vincent (2001) also points out, another consequence of the complex interactional architecture of LFG is that an LFG perspective on language change does not expect abrupt, cataclysmic shifts in grammar as proposed in the influential work by Lightfoot (1979, 1991, 1997), for example. Rather, it is expected that a series of small changes, many of them at the lexical level, will combine together and gradually, over time and with attendant variation in usage, will result in a major structural change. This is what is argued for with respect to the introduction of ergativity in Indo-Aryan by Butt & Ahmed Khan (2011), for example (cf. also Traugott & Trousdale (2010) for an overview discussion).

Indeed, variation as an inherent property of language has been closely linked to language change in a strong tradition of work (e.g., Kroch 1989, 2001, Labov 1994, Pintzuk 2003). However, this empirical fact generally presents a challenge for generative frameworks, which did not originally feature gradience or stochastic variation as part of their basic design principles. One proposed architectural solution here has been in terms of Optimality Theory (Kager 1999), in particular stochastic Optimality Theory (Boersma & Hayes 2001). As we discuss in Section 5, this avenue has also been explored within LFG as a way to model gradual syntactic change via competing variants (Clark 2004), using OT-LFG (see Kuhn 2023 [this volume]).

Having briefly surveyed the explanatory potential of LFG with respect to diachronic change via a set of examples in this section, we delve into the issues and phenomena more deeply in the next sections, also involving other parts of LFG's projection architecture, most prominently a(rgument)-structure.

3 Lexical and functional change

We begin by discussing examples of lexical and functional change in Section 3.1, many of which have been analyzed as instances of grammaticalization. We then move on to more complex series of changes which involve a restructuring of the mapping relationship between semantic arguments (a-structure) and grammatical relations (f-structure) in Section 3.2.

3.1 Grammaticalization

The original characterization of the idea behind grammaticalization goes back to Meillet (1912: 131), who defines it as: "l'attribution du caractère grammatical à un mot jadis autonome [the attribution of a grammatical value to a formerly autonomous word]" (Vincent & Börjars 2020: 134). Essentially, this is a process by which an item with lexical content becomes reanalyzed as a functional element (Bybee et al. 1994). Recent decades have seen a substantial body of work on grammaticalization phenomena, where grammaticalization has been treated both as a grammatical framework (e.g., Lehmann 1985, Hopper & Traugott 2003) and as a pre-theoretical notion which is to be formalized via the tools and concepts available within a particular framework (e.g., Campbell 2000, Newmeyer 2000, Roberts & Roussou 2003, van Gelderen 2011). LFG belongs in the latter class: it sees grammaticalization as a pre-theoretical concept which describes certain observed historical changes that are to be modelled via the formal tool-kit and assumptions available as part of the projection architecture.

The progression from lexical to functional is typically not accomplished in one fell swoop, but consists of the combined effects of a number of individual changes (see, e.g., the various papers in Traugott & Trousdale 2010). The grammaticalization literature proposes that change progresses along a cline, for example as shown in (1) for a crosslinguistically well-established change in which auxiliaries, clitics and finally affixes develop from an originally contentful lexical verb. This change is also generally associated with the concept of "semantic bleaching", by which the item undergoes the gradual loss of semantic content until the formerly lexical content word is reanalyzed as a functional element.

(1) full verb > (vector verb) > auxiliary > clitic > affix
Typical Grammaticalization Cline (Hopper & Traugott 2003: 108)

Note that the cline represents a mixture of surface and functional changes (form and function): the change from a main (full) verb to auxiliary mainly revolves around a change in function, while the change from auxiliary to clitic/affix is very prominently a change in surface form. Given that LFG very clearly differentiates between form (c-structure) and function (f-structure), it seems particularly perspicuous to address issues of grammaticalization from the perspective of LFG, as we aim to illustrate in this section.

The category *vector verb* in the cline in (1) was introduced specifically for instances of light verb formation in Indo-Aryan (Hook 1991) and this has been taken up in discussions within LFG by Butt & Lahiri (2013), who argue that light verbs should not be placed on a grammaticalization cline, but are diachronically stable. Butt and Lahiri contrast the diachronic evidence available for Indo-Aryan light verbs with that of auxiliary formation and show that these two categories exhibit very different diachronic behaviour. Light verbs show no signs of morphophonological surface changes or further functional changes which often follow a categorial reanalysis in instances of grammaticalization. However, auxiliaries do. This is illustrated in (2) for the Bengali verb 'be' and in (3) for the Urdu verb 'go'.

In Bengali the verb ɑʧʰ 'be' can function as a full verb (2a), but also as a light verb (2b), in which case it is always form-identical to the main verb. On the other hand, the same verb 'be' has given rise to new verbal paradigms whereby the perfect is realized via a cliticized version of a former auxiliary version of ɑʧʰ 'be' (2c) and the progressive shows a fully affixal version (2d).[3] The cliticized and affixal versions of a former auxiliary are as expected/predicted by the grammaticalization cline in (1).

(2) Bengali

a. ɑmi bʰɑlo ɑʧʰi
I.NOM well be.PRES.1
'I am well.' Main Verb

b. amar mone ɑʧʰe
I.GEN mind.LOC be.PRES.3
'I remember.' Light Verb

c. rɑm ʧitʰi pe-(y)e=ʧʰ-ilo
Ram.NOM letter.NOM receive-PERF=be-PAST.3
'Ram had received letters.' Clitic

d. rɑm ʧitʰi pɑ-ʧʧʰ-ilo
Ram.NOM letter.NOM receive-be-PAST.3
'Ram was receiving letters.' Affix

Similarly, the verb ʤa 'go' in Urdu/Hindi has a light verb use (3b) that is always form-identical to its main verb use (3a). When the surface form of the main verb changes due to language change, the light verb version mirrors this change. On the other hand, the auxiliary version of 'go' that furnished the basis for the innovated future morpheme in Urdu/Hindi went through a clitic phase (3c) and is now an affix whose surface form is *-g-*, as in (3d).

(3) Urdu/Hindi

a. mɛ̃ gɑ-ya
I.NOM go-PERF.M.SG
'I went.' Main Verb

b. bɑʧʧa gɪr gɑ-ya
child.M.NOM fall go-PERF.M.SG
'The child fell (down).' Light Verb

c. kɑh-ũ=hi=ga
say-1.SG-EMPH-FUT.M.SG
'I will say (it), of course.' Clitic
(Kellogg 1893: s399)

---

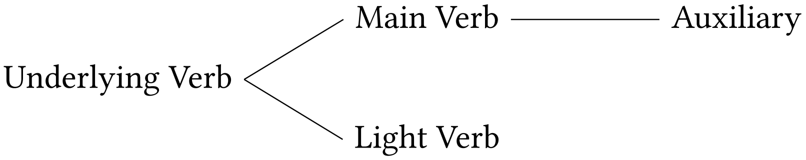
[3] For a full analysis of the morphophonological changes that led to the formation of new verbal paradigms in Bengali, see Lahiri (2000b).

d.	pʊlɪs	ʧor=ko	pɑkṛ-e-g-i
	police.F.SG.NOM	thief.M.SG=ACC	catch-3.SG-FUT-F.SG

‘The police will catch the thief.’ Affix

Butt and Lahiri focus on developing a theory as to why light verbs should be diachronically stable, proposing an underspecified approach to the deployment of lexical semantic information by which light verbs are inextricably linked to their full verb versions via a single underlying entry, see (4). When deployed as a light verb, they require combination with another predicational element, with which they form a complex predicate.

(4)



The diachronic path of change from verb to auxiliary to clitic and potentially an affix is assumed to be based on the main verb version. Along with other work on grammaticalization in LFG, Butt and Lahiri assume that grammaticalization primarily involves a loss or difference in functional information at f-structure, while the surface form is initially held constant. That is, the difference between a main verb use of ‘go’ and an auxiliary use of ‘go’ would be expressed in terms of a difference in functional information associated with the respective lexical entries. In the illustrative main verb entry (V) in (5a) vs. the auxiliary version (I) in (5b) one major difference in functional information involves the loss of the predicational power of the verb in terms of its PRED function. This then also instantiates the “semantic bleaching” generally observed in the grammaticalization process.

(5) a. *go* V (↑ PRED) = ‘GO⟨(↑ SUBJ)(↑ XCOMP)⟩’

b. *goes* I (↑ TENSE) = FUT

Thus, in the main verb use, the verb ‘go’ subcategorizes for a SUBJ and an XCOMP. In the auxiliary use that develops over time, this information is absent and is instead replaced by a futurate use of the verb. As such, the auxiliary version then merely provides tense information to an overall predication. That is, grammaticalization primarily involves a change in the functional information associated with an item. This functional change then engenders further changes, such as the reanalysis of the syntactic category of the item (from V to I) and possible ensuing changes in the morphophonological realization of the item due to its new functional status, so that the item eventually develops into an affix (typically via a clitic stage), as illustrated for Bengali and Urdu/Hindi in (2) and (3) above.

Grammaticalization does not tend to occur in one sudden step, but happens gradually over time and tends to involve several intermediate steps. It also does not take place randomly, but is generally motivated by a semantic reinterpretation of a given configuration (e.g., ‘goes to go’ ⟶ ‘go.FUT’). This type of semantically motivated change is also discussed in a recent paper by Börjars & Vincent (2019) with respect to Germanic *will* verbs. Börjars & Vincent (2019) propose an LFG analysis of how an original verb of desire (‘want’) undergoes change to a verb of intention and further to prediction, giving rise to a new modal in some languages and a futurate auxiliary in others. This semantic change goes hand in hand with a change in functional information (e.g., from a control to a raising verb) and a concomitant reanalysis at c-structure.

Similarly, Camilleri & Sadler (2018, 2020) postulate a total of four separate steps in the formation of a progressive auxiliary from a main verb meaning ‘sit’ in Arabic. Unlike Butt and Lahiri and Börjars and Vincent, who work with diachronic data, but in keeping with many studies on grammaticalization, the evidence Camillieri and Sadler adduce is mainly from synchronic variation found in dialects of Arabic, which are taken to be indicative of stages of diachronic development.

Camillieri and Sadler associate the origin of the progressive auxiliary in Arabic with constructions in which the posture verb ‘sit’ is used together with an adjunct clause, as in (6). The verb ‘sit’ is considered to be a V that projects a VP and this is modified by a VP adjunct. The corresponding (simplified) f-structure analysis is given in (7).[4]

(6) Wādi Ramm Jordanian Arabic

(Almashaqba 2015, cited by Camilleri & Sadler 2020: 24)

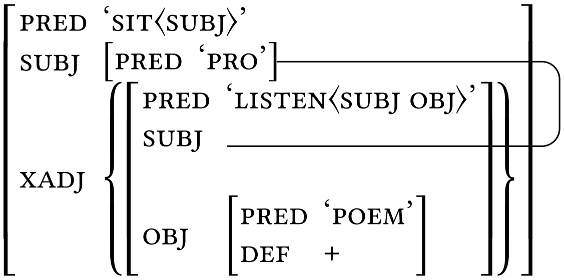
lagē-ta-h	gāʕid	ya-smaʕ	al-giṣidah
find.PFV-1SG-3.SG.M.ACC	sit.ACT.PTCP.SG.M	3M-hear.1PFV.SG	DEF-poem

‘I found him sitting down listening to the poem.’

---

[4] Note that the f-structure in (7) differs from the original one in Camilleri & Sadler (2020: 26) in that we have rendered the XADJ as a set containing one element, which is what is described in Camilleri & Sadler (2020: 26), but not represented in their f-structure.

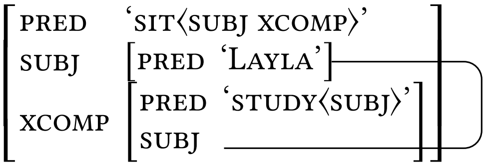
(7)



In a second stage this optional modifying XADJ is reanalyzed as an obligatory clausal complement of the posture verb ‘sit’, as shown in the f-structure in (9) for the attendant example in (8).

(8) Kuwaiti Arabic (Camilleri & Sadler 2020: 28)
layla gāʕd-a ta-dris
Layla sit.ACT.PTCP-SG.F 3F-study.IPFV.SG
‘Layla is (sitting) studying.’

(9)

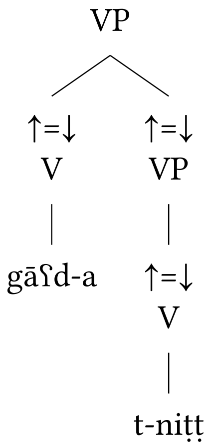


This use of ‘sit’ in combination with a clausal argument is in turn reanalyzed as signaling durational, stative semantics, abstracting away from the original postural, locational meaning. Once the step from a concrete postural meaning to an aspectual meaning dimension is made, the verb is assumed to lose its predicational power in terms of the PRED feature and to only contribute the durational aspectual information to the clause, resulting finally in an innovated progressive marker (cf. Deo (2015) for more discussion and evidence of this type of crosslinguistically attested language change). An example is shown in (10) with a corresponding f-structure analysis in (11). Under Camillieri and Sadler’s analysis the syntactic category of ‘sit’ itself is not reanalyzed; it merely no longer projects a VP of its own, but functions as a co-head with the formerly embedded verb, as shown in (12).

(10) Kuwaiti Arabic (Camilleri & Sadler 2020: 30)
gāʕd-a t-niṭṭ
PROG-SG.F 3F-jump.IMPFV.SG
‘She is jumping.’

(11)
$$\begin{bmatrix} \textsc{pred} & \text{‘}\textsc{jump}\langle\textsc{subj}\rangle\text{’} \\ \textsc{subj} & \begin{bmatrix}\textsc{pred} & \text{‘}\textsc{pro}\text{’}\end{bmatrix} \\ \textsc{tense} & \textsc{pres} \\ \textsc{asp} & \textsc{prog} \end{bmatrix}$$

(12)



The change by which an adjunct is reanalyzed over time as a core argument of a verb has also been argued to play a role in Latin in the innovation of raising predicates such as ‘seem’ from verbs of perception such as ‘see’ (Barron 2001) and the grammaticalization of associated path in the Australian languages Warlpiri and Warumungu (Simpson 2001). It also plays a role in the spread of dative subjects in Icelandic, as argued for by Schätzle (2018) and discussed in Butt 2023 [this volume], as well as in Section 3.2 below.

Barron (2001) provides a theoretically sophisticated account for the development of Latin *videri* ‘seem’ from the perception verb *videre* ‘see’. The general idea is that the epistemic raising verb develops from a passivized version of *videre* in situations where there is a small clause (secondary predication), such as ‘Laelius was seen as an ideal person.’ This was reinterpreted as ‘Laelius seemed an ideal person’ and over time was generally concomitantly structurally reanalyzed as a raising predicate. The analysis is complex and involves changes at the semantic level which translate into functional changes at f-structure.

Another level of complexity is added by Simpson’s (2001) account of associated path in Warlpiri and Warumungu. The puzzle she addresses is how the path expressions (‘thither’ vs. ‘hither’) in (13) came to be grammaticalized as morphemes on a verb, given that the languages generally allow for free word order. She assumes that at some point there must have been a stage in which the path expressions were preferentially placed just after the verbs and that this preferential word order then paved the way for grammaticalization along the cline in (1).

(13) Warumungu (Simpson 2001: 174)

a. **Juku-nturrarni**=angi angkinyi kina ngurraji kina?
carry-THITHER.PAST=2S your to camp to
'Did you take it to your home?'

b. **Juku-ntukarni**=ajjul ngurraji kina.
carry-HITHER.PAST=3S camp to
'They (more than two) brought it here to camp.'

Again, the change is conceived of as a complex chain of reanalyses. The original construction is taken to be one in which a clause like 'I went to camp' is modified by a clausal adjunct, for example: 'after yam digging'. This adjunct was then preferentially realized clause-initially: 'after yam digging, (I) went to camp', thus placing the verbs next to one another in certain situations. This adjacent placement of the verbs is thought to have triggered clause unification, yielding a monoclausal structure in which the former verb of motion is eventually reanalyzed as a morpheme expressing the associated path of the event. We thus have a preferential word order opening the way for a semantic, then syntactic and concomitant functional reanalysis of an original verb into a bound morpheme.

For further discussions and examples of grammaticalization approaches within LFG, also contextualized in terms of comparison of approaches across theories, see Vincent & Börjars (2020). We discuss some aspects of their paper in more detail in Section 4.1, since some of the case studies involve a reanalysis of syntactic categories with attendant "mixed" effects. We return to grammaticalization in Section 4.3 in the context of c-structural change. Before turning to these topics, we discuss instances of language change which primarily involve a change in the linking configuration between semantic arguments and grammatical relations in Section 3.2.

3.2 Arguments and linking

In the previous section on grammaticalization we discussed phenomena of language change that involved a number of different dimensions. In this section, we focus on changes that are primarily concerned with reconfigurations in the linking between semantic arguments and grammatical relations. Work that addresses these kinds of specific changes within LFG is: Allen (1986, 1995), Kibort & Maling (2015), Schätzle (2018) and Beck & Butt (2024).

3.2.1 Experiencer verbs

As mentioned above, a very early application of LFG to diachronic change is Allen (1986), who considers the verb *like* in the history of English. This verb can be analyzed as having an Experiencer (the liker) and a Cause (the cause of liking).[5] Such verbs are interesting diachronically because they show a change in the correspondence between semantic arguments (experiencer, cause) and grammatical relations. In Old English the experiencer argument has the positional and morphological properties of an object, e.g., (14a), but is uncontroversially a subject in Present-day English, e.g., (14b).[6]

(14) a. Old English (Jespersen 1927, as cited in Allen 1986: 376)
Ðam cynge licodon peran
the.DAT king.DAT liked.PL pears
'Pears were pleasing to the king'
b. 'He liked pears.'

Based on detailed investigations of the historical data, Allen (1986) challenges the traditional account for this change (e.g., Jespersen 1927, Lightfoot 1979, 1981), which casts it in terms of a reanalysis of preverbal object experiencers as subjects, as a direct consequence of the loss of case-marking and the fixing of SVO word order. As Allen (1986) points out, there are various problems for this account, including the fact that the OVS order required as a source for the reanalysis is relatively rare with the verb *like*, and because of chronological issues concerning the link with the loss of case-marking. Moreover, the data indicates that the change proceeded gradually, with subject and object experiencers coexisting alongside one another for several centuries over the course of Middle English and Early Modern English, which is not compatible with a "catastrophic" reanalysis account as proposed by Lightfoot, for example.

In light of these observations, Allen (1986) puts forward an alternative account, which involves a gradual change in the mapping correspondences between semantic arguments and grammatical functions, modelled in terms of the introduction and gradual favouring of a new lexical subcategorization frame, employing an early LFG approach to this type of mapping. The new subcategorization frame with a dative-marked subject experiencer, shown here in (15b), is already available in Old English for the verb *lician* 'like', but sits alongside and is less common

---

[5] Alternatively, this semantic role has been referred to as stimulus or theme, as in, e.g., later work by Allen (1995).

[6] As has been pointed out (Denison 1993: 81), the original example from Jespersen in (14a) is invented and represents a pattern which is in fact rather rare.

than the older frame in (15a) where the dative-marked experiencer maps to object.

(15) a. Older frame (adapted from Allen 1986: 388):

EXP CAUSE
lician V PRED ‘LICIAN < (OBJ) (SBJ) >’
(↑ OBJ CASE) = DAT
(↑ SBJ CASE) = NOM

b. Newer frame (adapted from Allen 1986: 394):

EXP CAUSE
lician V PRED ‘LICIAN < (OBJ) (SBJ) >’
(↑SBJ CASE) = DAT
(↑OBJ CASE) = NOM

According to Allen (1986), the gradual favouring of the correspondences in (15b) coincides with changes concerning the assignment of case-marking, specifically a shift from a system where case is lexically assigned to one in which it is structurally assigned on the basis of grammatical relations. Structural case-marking for objects is introduced in the early thirteenth century according to Allen and specification of case-marking for the experiencer subject is optional as of the mid-fourteenth century. Under pressure towards consistent structural case assignment, all lexically determined case-marking is finally lost, subjects are consistently nominative-marked and the frame for allowing object experiencers in (15a) is no longer available.

Allen (1995) develops this account of experiencer verbs in the history of English further in terms of Lexical Mapping Theory (e.g., Bresnan & Kanerva 1989, cf. Butt 2023 [this volume] and Findlay et al. 2023 [this volume]), discussing a wider range of data and additional changes including the rise of the recipient passive, which we discuss in Section 4.5. In particular, she demonstrates that lexical semantic factors, rather than loss of case-marking drives the change with respect to experiencer verbs, and that this can be elegantly modelled with LFG’s richly articulated lexicon and Lexical Mapping Theory.

3.2.2 Passives and impersonals

Kibort & Maling (2015) address the innovation of a new impersonal construction in Icelandic which they argue has emerged as a syntactically active construction via reanalysis of an impersonal passive with passive morphology. The new construction is thought to have been emerging approximately over the last fifty years (Thráinsson 2007) and has prompted a good deal of debate concerning what the precise analysis should be (Maling & Sigurjónsdóttir 2002, Eythórsson 2008, Jónsson 2009). Maling & Sigurjónsdóttir (2002) show that this is currently a change in progress and that speakers of Icelandic show variation in the interpretation of examples such as (16): some interpret it as an impersonal passive (Reading A), others as an active transitive with a [+human] agentive pro subject (Reading B). Such variation is expected when there is a change in progress, as we discuss further in Section 5.

(16) Icelandic

Loks	var	fundið	stelpuna	eftir	mikla	leit.
finally	was	found.n.sg	girl.the.f.acc	after	great	search

Reading A: 'The girl was finally found after a long search.'
Reading B: 'They finally found the girl after a long search.'

Kibort & Maling (2015) argue that this variation and change arises when a former impersonal passive with passive morphology is reanalyzed as an active form. They argue for a series of step-wise changes, beginning with the potential for the linking configurations of an impersonal passive and a regular passive being confused with one another when the obl$_\theta$ agent argument of the passive is left unexpressed, as is often the case in Icelandic language use. This means that a regular passive on the surface often looks very much like an impersonal passive, where there is a covert pro subj, as illustrated in (17) for transitive verbs (adapted from Kibort & Maling 2015).[7]

(17) a.

$$\begin{array}{llll} \textit{verb}_{\textit{passive}} & < & \text{arg}_1 & \text{arg}_2 & > \\ & & [-o] & [-r] & \\ & & [+r] & & \\ & & (\textsc{obl}_\theta) & \textsc{subj} & \end{array}$$

b.

$$\begin{array}{lllll} \textit{verb}_{\textit{impers\_passive}} & < & \text{arg}_1 & \text{arg}_2 & > \\ & & [-o] & [-r] & \\ & & [+r] & & \\ & & \textsc{pro}_{\textit{impers}} & \textsc{subj} & \end{array}$$

---

[7] In the version of Mapping Theory which Kibort & Maling (2015) employ, argument positions (arg$_1$, arg$_2$ etc.) are separated out from semantic participants and the thematic roles they instantiate. Here, for ease of exposition, and because this separation is not relevant for the changes discussed, we just represent the argument positions.

Kibort & Maling (2015) assume Kibort's version of Mapping Theory (Kibort 2013, 2014) by which argument slots and types are defined via an overall template allowing for specific types or argument slots, shown above as 'arg_1', 'arg_2' in the case of transitives. The linking between arguments and grammatical relations is accomplished via the $[\pm r, o]$ features of LFG's standard Mapping Theory. See Findlay et al. 2023 [this volume] for a detailed exposition on Kibort's Mapping Theory, also cf. Butt 2023 [this volume]. Maling and Kibort discuss several different paths of change that are predicted as possible within their assumptions as to Mapping Theory and draw on additional examples from Slavic as well as Mayan to illustrate the possible changes.

With respect to Icelandic, they propose that "non-promotional" versions of the passive opened the way for a reanalysis of the impersonal passive as an impersonal active. In these non-promotional passives, the patient/theme argument of transitives is not "promoted" and realized as a subj, as is usually the case under passivization. Instead, it is realized as an obj in examples such as (16) (as indicated by the accusative marking on 'girl' in (16)). The configuration for the non-promotional passive is shown in (18a). This configuration is in turn very close to that of an active impersonal in which there is a pro subj and so that is what it is reanalyzed as, see (18b).

(18) a. $$\mathit{verb}_{\mathit{passive\_obj}} \quad < \quad \begin{array}{cc} \text{arg}_1 & \text{arg}_2 \\ {[-o]} & {[-r]} \\ {[+r]} & \\ & \\ (\textsc{obl}_{\theta}) & \textsc{obj} \end{array} \quad >$$

b. $$\mathit{verb}_{\mathit{impers\_active}} \quad < \quad \begin{array}{cc} \text{arg}_1 & \text{arg}_2 \\ {[-o][-r]} & {[-r]} \\ & \\ \textsc{pro}_{\mathit{impers}} & \textsc{obj} \end{array} \quad >$$

Thus, a series of reanalyses that initially arose out of ambiguous surface structures are seen to lead to an overall diachronic reanalysis in which an originally passive construction is reinterpreted as a transitive, syntactically active impersonal with a pro subj and an obj, as illustrated in (18). This reanalysis was enabled by the variation in interpretation that arose from the ambiguous surface structures. Note that under this scenario, the verb does not change, nor does the passive morphology. The surface realization remains the same. What changes is the mapping or linking between arguments of the verb and the grammatical relations.

3.2.3 Dative subjects

Another example of a change involving only the linking configuration between semantic arguments and grammatical relations is the rise and spread of dative subjects in Icelandic and Indo-Aryan. Dative subjects were innovated as part of diachronic developments in New Indo-Aryan (NIA) from about 1100 CE onwards. Icelandic dative subjects can be traced back to the earliest documented stages of the language, but these only go back to 1150 CE, about the same time as the new case marking systems of the NIA cousins were developing.

Schätzle (2018) analyzes diachronic data from Icelandic and finds that dative subjects in Icelandic have increased over time. Besides the well-documented process of "dative sickness" or "dative substitution" (Smith 1996, Jónsson 2003, Barðdal 2011), by which accusative experiencer subjects are systematically replaced by datives, Schätzle finds that dative subjects arise via originally middle forms of verbs of searching or perception to give rise to lexicalizations of experiencer predicates which take a dative subject. As in the example of Latin raising verbs (Barron 2001) and the Arabic progressive (Camilleri & Sadler 2020), Schätzle identifies an intermediate stage involving secondary predication as an important step in the series of reanalyses that take place. We do not provide Icelandic examples and details of Schätzle's analysis here; the interested reader is referred to Butt 2023 [this volume] for a summary and examples.

Schätzle works out a theory of Linking or Mapping that is based on Kibort (2013, 2014), but that crucially integrates an event-based approach. She includes a notion of subevental participants that draws on Ramchand's (2008) tripartite view of events. She further introduces a way of determining relative argument prominence by including a notion of Figure vs. Ground (Talmy 1978), as well as information on Proto-Role properties (Dowty 1991) as suggested by Zaenen (1993) for LFG. The resulting linking system is complex, but it does justice to the complex interface between morphosyntax and lexical and clausal semantics that is involved in the relationship between semantic roles, event semantics and the realization of grammatical relations.

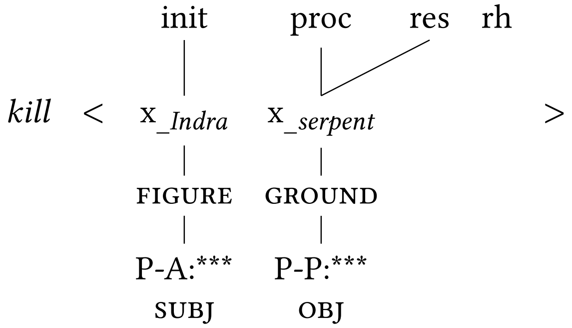
Beck & Butt (2024) refine Schätzle's framework and address dative subjects in both Icelandic and Indo-Aryan. The general linking schema they assume is shown in (19). As can be seen, a maximum of four argument slots are assumed. This number derives from the maximum of four subevental parts identified by Ramchand: 1) the init(iation) subevent, which requires an initiator (or agent) of the event; 2) the proc(ess) or progress of the event, which requires an undergoer or patient of the process; 3) the res(ult) of the event, which requires a resultee argument (often but not necessarily identical to the undergoer of the process). Finally there is (4) the rheme, which is not strictly speaking a subevent, but which can serve to modify the overall event in some way, i.e. by providing information on where the event took place or the manner in which it took place.

(19) General Linking Schema

		init	proc	res	rh	
Predicate	<	x	x	x	x	>
		FIGURE	GROUND			
		SUBJ	OBJ	OBJ_{theta}	OBL	

The linking in (20) provides an example of a typical agentive transitive verb. The verb 'kill' has two arguments. One of these ('Indra') is associated with the initiation subevent and thus serves as the initiator/agent participant of the event. The other argument ('serpent') is the undergoer of the event and thus affected as part of the on-going proc(ess) of the event, with a clear res(ult), namely that it is dead. This argument is thus associated with two subevents.

(20) Indra killed the serpent.

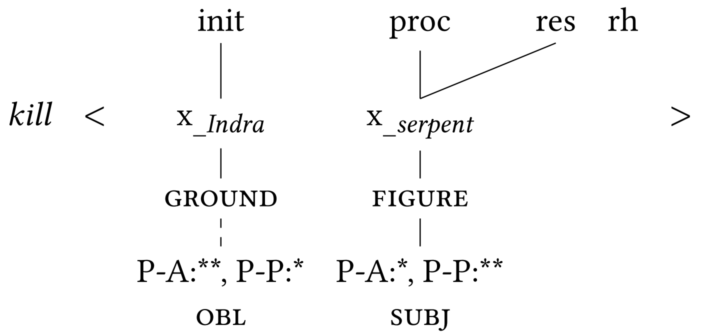


The initiator is naturally also the Figure of the event, and the undergoer serves as the Ground. This basic linking constellation is interpreted with respect to Proto-Role properties in the following way: a) one Proto-Agent (P-A) property each is adduced for: initiation and Figure; b) one Proto-Patient (P-P) property each is adduced for: proc, res, and Ground. In addition, sentient arguments accumulate an additional P-A property. The Proto-Role properties are registered via an ‘*’ in the linking schemas.

Overall, the linking of arguments works as follows. If an argument has more P-A than P-P properties, it is linked to subj. An argument with more P-P than P-A properties is linked to obj. When an argument has equally many P-A and P-P properties or no P-A and P-P properties, then other information must be taken into account. In this case the type of subevent the participant is associated with is taken to play a crucial role. That is, if the argument associated with init vs. res have equal amounts of P-A and P-P properties, the init argument will be associated with subj. This is also true for third and potentially fourth arguments of an event – once the subj and obj linking has been determined, the subevental semantics play a role in determining the linking to a secondary object (obj$_{\theta}$) or an oblique (obl). Obliques are likely to correspond to spatial terms and paths (rhemes) or an init-ground combination. Secondary objects are likely to be related to undergoer semantics. An init argument that serves as the ground rather than the figure is prohibited from being linked to the subj — this is the well-known effect of passivization that has often been described as “demotion” or “inversion” in the literature (e.g., Perlmutter & Postal 1977).

This constellation is illustrated in (21). The association of arguments with subevents remains the same, but the Figure-Ground relationship is flipped. This affects the number and type of Proto-Role properties associated with each argument.

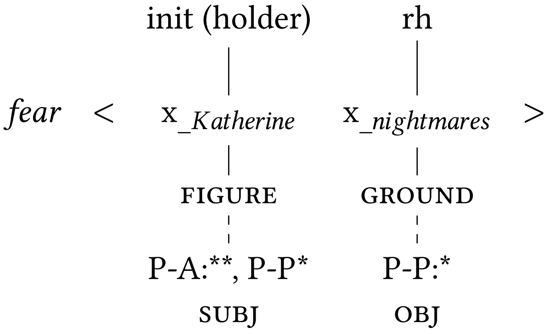
(21) The serpent was killed by Indra.



Since ‘Indra’ is no longer available to be linked to subj, the ‘serpent’ is the subj. Because ‘Indra’ still has more P-A (one for init, one for sentience) than P-P (one for ground) properties, it is not associable with an obj or obj$_{\theta}$, but is linked to obl.

An example of a linking configuration for an experiencer predicate is provided in (22). As per Ramchand’s analysis, the holder of the state of experiencing something is associated with the init subevent, and the stimulus is analyzed as a rheme (since it is neither part of the process or the result of the overall event). The experiencer 'Katherine' in (22) is also the FIGURE; the stimulus 'nightmares' is the GROUND. As a sentient argument who is also a FIGURE, 'Katherine' receives two P-A properties. As the holder of a state, this argument receives one P-P property. The 'nightmares' accumulate one P-P property from being associated with GROUND. Because rhemes are not properly event participants, they contribute neither P-A nor P-P properties for the calculation. Since 'Katherine' has the most P-A properties, it is linked to SUBJ. The 'nightmares' argument has only P-P properties and is thus linked to OBJ.

(22) Katherine fears nightmares.

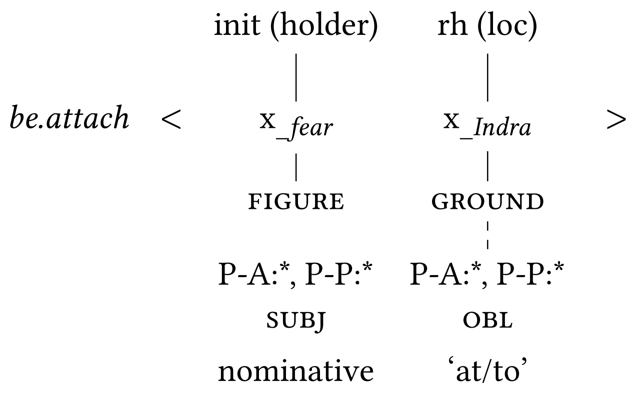


With this basic event-based linking schema in place, Beck & Butt (2024) chart a path of development for dative subjects in New Indo-Aryan. A crucial component is the innovation of ergative transitive active clauses from originally adjectival participles which featured a nominative and an instrumental adjunct (e.g., 'The by Indra killed serpent.'). Beck and Butt posit that the original instrument adjunct was a GROUND which was reinterpreted as a FIGURE in situations where the instrument could be seen as a sentient agent. This then opened the door to further Figure-Ground flips, such as with originally locative structures as in (23) (cf. also Bresnan & Kanerva 1989, Landau 2010 on locative inversion).

(23) Urdu/Hindi
ındra=ko dɑr lɑg-a
Indra.M=DAT fear.M.NOM be.attach-PRF.M.SG
'Indra was afraid.'

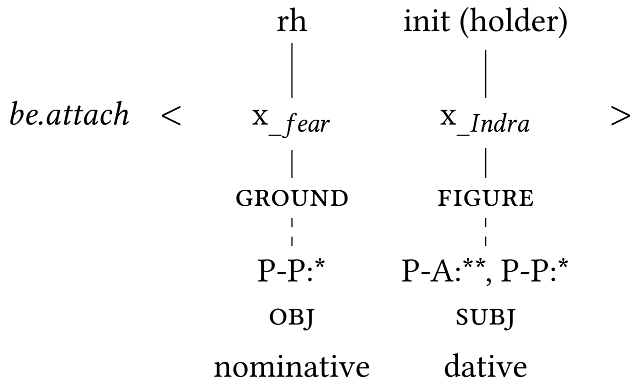
Their proposal is that the original locative predication involved a linking configuration as in (24). The overall predication is stative, so the two arguments involved are a holder of a state and a rheme. The 'Indra' argument is the location of the 'fear', so Indra is associated with a rheme and the GROUND. The 'fear' argument is then interpreted as the holder of a state: as a FIGURE it is located somewhere and receives one P-A property for being a Figure, and one P-A property for being the holder of a state. 'Indra' receives one P-P property for being the GROUND and one P-A property because it is a sentient argument. Both arguments thus have an equal number of P-A and P-P properties, but 'fear' is linked to SUBJ because it is associated with the init subevent.

(24) Fear was attached to Indra.



It is not difficult to see that the linking configuration in (24) is unstable. The two arguments have equal numbers of P-A and P-P properties and the sentient argument is associated with GROUND, which is non-canonical (Talmy 1978). Beck and Butt propose that as a consequence, in a series of steps, both the Figure-Ground relation and the association with init and rheme are flipped and the resulting linking configuration is as shown in (25), corresponding to (23). This configuration is clearly more stable as the sentient argument is more prominent and accumulates more P-A properties.

(25) Indra was afraid.



The original spatial adpositions (‘at, to’) in fact gave rise to the current dative/accusative case markers in Urdu/Hindi (and across New Indo-Aryan), resulting in the innovation of dative subjects from originally spatial terms (cf. Montaut 2003, Butt & Ahmed Khan 2011).

To summarize, the innovation of dative subjects is seen primarily as the reanalysis of an originally stative locative predication as an experiencer verb. The main change involves a reanalysis of various parts of the overall linking configuration. Beck and Butt see this as being common to both Icelandic and Indo-Aryan. In Indo-Aryan, however, there is an additional concomitant but independent change in syntactic category, from a spatial adposition to a case marker. Changes involving reanalysis of an item’s syntactic category are taken up in Section 4.1, with Section 4 focusing overall on change with respect to c-structure.

4 Syntactic change

4.1 Recategorization

Studies of language change abound with instances of syntactic recategorization, that is, instances in which an item belonging to one syntactic category is reanalyzed as belonging to a different one. We have already caught a glimpse of such a reanalysis with respect to the grammaticalization cline in (1), whereby a main verb is gradually reanalyzed as an auxiliary, which in turn often becomes a verbal affix. Within LFG, such c-structural recategorization is seen as being preceded by a change in an item’s functional import. That is, with respect to the well-studied changes such as the development of new futurate markers (e.g., Fleischman 1982), as we saw in Section 3.1 an originally fully predicating verb such as ‘want’ or ‘go’ can be used in situations describing the future attainment of a state or event (Börjars & Vincent 2019). Over time, this usage becomes conventionalized and the verb is seen as routinely fulfilling an additional function, namely the temporal placement of an event in the future. This meaning of the verb ceases to predicate fully and it develops into a functional item. Often the original lexical/content verb continues to exist side-by-side with the new auxiliary; in other cases it ceases to be used as a main verb. In English, for example, the item *will* is now only rarely used as a modal meaning ‘want’, but only as a futurate marker. On the other hand, as we saw for the examples taken from Urdu and Bengali in Section 3.1, the verbs ‘be’ and ‘go’ continue to exist as main verbs while also serving as auxiliaries and giving rise to new verbal affixes.

Within this same verbal domain, Börjars & Vincent (2017) argue for the historical development of a causative light verb in Romance from the Latin verb *facere* 'make, do', which in turn results in the reanalysis of a formerly biclausal construction as a monoclausal predication. This reanalysis of biclausal predications, where one verb embeds another into monoclausal structures, also generally results from the reanalysis of main verbs as auxiliaries (Butt et al. 2004, Butt 2010).

Vincent & Börjars (2020) go through a number of further examples of syntactic recategorization from an LFG perspective, including the development of adpositions from nouns, infinitival markers from prepositions, complementizers from prepositions (P to C; Vincent 1999) and case-marking functions from prepositions. They also engage in a comparison of analyses across frameworks (Minimalism (Chomsky 1995) and HPSG (Pollard & Sag 1994)) and ask the question of whether anything in LFG's architecture predicts the mainly *unidirectional* change in categorial reanalysis (meaning that a verb will change into an affix, but an affix does not change into a fully predicating main verb). The answer to this question is "no", unlike the clear predictions made by Roberts & Roussou (2003) within Minimalism, for example, where such reanalysis is seen as an instance of a lexical category raising upwards into the functional domain of a syntactic tree and eventually being reanalyzed as simply originating in that functional position. Upward "mobility" is expected in this framework, while downward movement is prohibited. However, Vincent & Börjars (2020) point out that while this type of grammaticalization along a cline from more lexical to more functional can be accounted for well within Minimalism, instances of "lateral" change whereby the recategorization involves adjacent categories like deictic markers into copular verbs (Börjars & Vincent 2017) are more challenging. In this case, an originally nominal category is reanalyzed as belonging to the verbal domain.

Another example of a recategorization that does not necessarily involve directionality can be observed in Chinese, where Börjars & Payne (2021) argue that nouns which originally denoted a container or a measure and which had the syntactic distribution and modificational properties of standard nouns in the language were reanalyzed over time as measure words and classifiers. They argue that the reanalysis as measure words involves only a syntactic recategorization by which these nouns have a more restricted syntactic distribution and modificational properties in comparison to standard nouns. This syntactic change is not accompanied by a systematic semantic or functional change: the words still measure out units, as in the original usage and appear to retain their full lexical semantics.

Van Gelderen (2011) seeks to address issues of recategorization by thinking of language change in terms of cycles (though there seems to be no discussion of actual full cycles of language change) and working heavily with features that are associated with syntactic categories. Changes in the features associated with an item eventually lead to reanalysis at the level of syntactic categories. Interestingly, this take on language change seems to move towards the separation out of functional vs. categorial characteristics of an item that is already in-built into LFG, but with a comparatively impoverished understanding of feature theory.

The difference in how many and what kinds of features and functionality are associated with an item can also lead to debates as to whether syntactic recategorization has taken place at all. Vincent & Börjars (2020: 144) discuss this with respect to prepositions being used to mark the subcategorized for arguments of a predicate, thus acquiring the properties of case markers and note: "Within Minimalism such shifts can be seen as involving a change from P to K, whereas once again, in HPSG and LFG, the change is in the information associated with the argument of P rather than in the category itself." This view of the relationship between adpositions and case clashes with the lexical semantic approach to case taken by Butt & King (1991, 2003, 2004), who use the category K to model the status of case markers in New Indo-Aryan as independent clitics that have a range of functional and lexical information associated with them. Ahmed Khan (2009) shows how spatial adpositions may be associated with feature structures specifying EX:HISTORICAL:PATH and PLACE and how changes in the specification of these features can result in case markers. Butt & Ahmed Khan (2011) further chart the development of originally spatial adpositions into case markers, analyzed as K, in modern Urdu.

4.2 Mixed categories

Recategorization as described in Section 4.1 also generally does not happen in one fell swoop, but via a number of intermediate stages. One side-effect of these intermediate stages is the emergence of *mixed categories*. Verbal nouns or gerundives, which have the external distribution of nouns, but the internal properties of verbs, are one well-known example. A recent survey and analysis of mixed categories by Nikolaeva & Spencer (2020) shows that there are several different types of mixed categories (see also the discussion in Lowe 2016b).

In her diachronic take on mixed categories, Nikitina (2008) argues for a clear disassociation of the lexical and syntactic components of category mixing, precisely because of the range of mixed properties displayed by syntactic categories. She investigates and analyzes phenomena from Romance and Wan (Mande) and proposes that a clear distinction be made between instances of *function retaining* derivational changes in syntactic category and *structural reanalysis*, including rebracketing. An example of the former function retaining change is the English *-ing* nominalization, whereby the head distributes as a noun, but retains the functional predication of a verb. Over time, this retention of function may be lost, resulting in a straightforward nominal, rather than a syntactic category with mixed properties. Examples of the latter (structural reanalysis) include types of instances discussed in the previous section, i.e. the development of adpositions and case markers from nouns and the development of complementizers from verbs (Lord 1993) or adpositions.

The work by Vincent & Börjars (2010) on the slippery slope between adpositions and adjectives serves as another example. Vincent & Börjars (2010) look at Germanic and Romance languages which are losing their overall case system and investigate paths of change that serve to compensate for this loss. One path of change involves the use of adpositions like Latin *prope* 'near' and English 'near'. These subcategorize for an OBJ and have the spatial meaning of adpositions, but can be used as adjectives and take comparative and superlative morphology. See also Vincent & Börjars (2020) for some further discussion on this issue.

Formal analyses of mixed categories in LFG have often invoked *lexical sharing* of one type or another (Bresnan & Mugane (2006), Lowe (2015, 2016a); see discussion in Section 4.4). Butt et al. (2020) propose an alternative to this approach in their analysis of complement clauses in Tamil. The complement clauses show a mixed set of nominal and verbal properties, which is due to a historical development by which an originally relative clause type structure incorporated a pronoun and thus acquired the external properties of a noun while retaining the internal verbal predication of a finite clause. Butt et al. (2020) propose an analysis of mixed categories in terms of the formal tool of *complex categories* first introduced in the context of the ParGram computational grammar development effort (Butt et al. 1999, Crouch et al. 2011). This approach essentially allows for the parameterization of syntactic categories, avoiding the monolithic assignment of one syntactic category to a given lexical item or phrase.

4.3 The growth of structure

The diachronic phenomena discussed under the term "grammaticalization" in Section 3.1 involved a change whereby an individual lexical item comes to be reanalyzed as a functional element. This could be considered grammaticalization in the narrow sense, in which the focus is on the changing status of a particular item, as in much of the classic work on grammaticalization where changes occurring above the level of individual lexemes (e.g., changes in word order) are typically secondary concerns. For example, in their seminal textbook, Hopper & Traugott (2003: 24, 59) suggest that word order changes, though "deeply interconnected" with grammaticalization, are not to be considered under the term on the basis that they do not exhibit the unidirectionality typical of grammaticalization (see also Sun & Traugott 2011 for a similar view). At the same time, some authors have called for a broader take on grammaticalization, encompassing also cases where a particular fixed word order comes to encode certain functional information. This type of change is argued for by Börjars et al. (2016) as grammaticalization involving a "template" made up of slots and categories, one example being V1 clauses which have grammaticalized to varying degrees so as to encode conditionality across the Germanic languages (see also Hilpert 2010). Börjars et al. (2016) extend the remit of grammaticalization further still, proposing a specific type of grammaticalization, couched within LFG, which involves two concomitant developments: (i) the development of a grammaticalized meaning in a particular item and (ii) the increasing association of that grammaticalized meaning with a particular structural position.

Börjars et al. (2016) propose this special type of grammaticalization on the basis of diachronic data concerning the development of definite markers and noun phrase syntax in North Germanic, specifically from Old Norse to modern Faroese. They provide empirical evidence which shows that Old Norse lacks an obligatory dedicated (in)definiteness marker via paired examples such as (26), where the bold element in (26a) receives a definite interpretation and that in (26b) an indefinite interpretation, despite the fact that neither is overtly marked for (in)definiteness.

(26) Old Norse (Börjars et al. 2016: e10)

a. **Austmaðr** kvezk …
east.man said
'The Norwegian said …'

b. Ok gekk **kona** fyrir útibúrsdyrrin
and went woman in.front.of outhouse.door.DEF
'A woman went in front of the door of the outbuilding'

Moreover the relative order of elements within the noun phrase is relatively free, although the initial position is associated with prominent and contrastive elements, as in the two instances of prenominal possessive pronouns with contrastive emphasis in (27).

(27) Old Norse (Börjars et al. 2016: e14)
at **minn** **faðir** væri eptirbát **þins** **fǫður**
COMP 1.SG.POSS father was after.boat 2.SG.POSS.GEN father.GEN
'that my father trailed in the wake of yours'

In the next diachronic stage which Börjars et al. consider – early Faroese (ca. 1298 CE) – they provide evidence which indicates that overt marking of definiteness is now obligatory, since unmodified nouns must occur with a definiteness marker in order to receive a definite interpretation, e.g., (28a). Indefinite markers are not yet obligatory, however, as evidenced by examples like (28b), which is interpreted as indefinite without any overt indefinite marker.

(28) Early Faroese (Börjars et al. 2016: e18)

a. Bardr Peterson war ritade **brefet**
B.P. was written letter.DEF
'Barður Peterson had written the letter.'

b. Ef **sauþr** gengi j annars haga …
if sheep goes in other's field
'If a sheep goes into another man's field …'

Moreover, unlike in Old Norse, where different definiteness markers can cooccur, by this stage of Faroese they are in complementary distribution. Only later in the history of Faroese — the representatives which Börjars et al. examine are a newspaper from the 1890s and data from Present-day Faroese — does overt marking for indefiniteness become obligatory via *ein*, e.g., (29a), and a prenominal syntactic definiteness marker (*tann* or *hinn*) is generally required when there is premodification, leading to "double definiteness", e.g., (29b)–(29c).

(29) Present-day Faroese (Börjars et al. 2016: e22–e23)

a. ein ungur maður
INDEF young.STR man
'a young man'

b. tann stóra gatan
DEF big.WK mystery.DEF
'the/that big mystery'

c. hin største vindmylluparkin í Europa
DEF biggest windmill.park.DEF in Europe
'the biggest wind farm in Europe'

In sum, the history of Faroese exhibits the grammaticalization of dedicated (in)definiteness markers which only later come to be associated with a particular structural position (the left edge of the noun phrase), in line with an overall increasingly fixed word order within the noun phrase.[8] Börjars et al. (2016) take advantage of the flexible nature of LFG's c-structure to model the observed gradual changes, building on a diachronic account of word order change in the context of grammaticalization concerning Romance prepositions by Vincent (1999). Central to both Vincent's (1999) and Börjars et al.'s (2016) accounts is the assumption that a new category can emerge diachronically without it necessarily needing to project a full endocentric phrase straightaway. Indeed, in the two accounts the full endocentric phrase projected by the new category is "grown" gradually at c-structure over time. This view is in line with the c-structure principle of Economy of Expression (Bresnan et al. 2016), which privileges lexical over phrasal expression and is radically different to the more standard universal application of X-bar theory in certain other generative approaches whereby, as soon as one posits a category, one also needs to posit a full endocentric phrasal projection complete with a specifier and complement position (cf. also Toivonen 2001, 2007 on non-projecting categories within LFG).

Applied to the Faroese story, Börjars et al. (2016) propose three c-structures to capture the structure of nominal phrases in the three periods: Old Norse (30a), early Faroese (ca. 1298) (30b) and Present-day Faroese (30c). In the earliest structure in (30a), word order is largely free (captured in the flat structure under NOM(inal)) but there is an initial position associated with information-structurally privileged elements. Crucially, in (30a) there is no category D; this only develops in early Faroese, cf. (30b), but at this point it is not yet associated with a particular structural position. Once definite markers are structurally associated with the left edge of the noun phrase, one can assume a projectional functional category, as captured in the endocentric DP structure for Present-day Faroese in (30c). The proposed growth of c-structure thus captures the grammaticalization of (in)definiteness in the context of a gradual shift from relatively free word order driven by information structure to a much more rigid, syntactically constrained word order as exhibited in modern Faroese.

---

[8] Specifically, the definiteness marker was originally associated with the adjective in Old Norse, and frequently occurred postnominally, to the left of the adjective. The proposal by Börjars et al. is that, as adjectives became increasingly prenominal, the definiteness marker became associated with the left edge of the noun phrase overall.

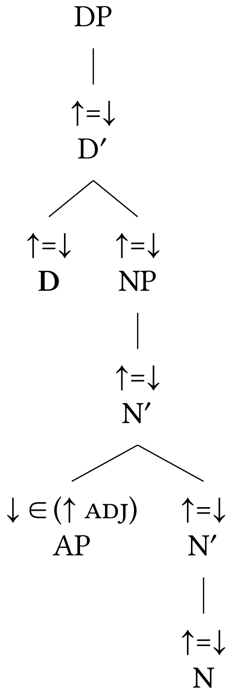
c. Present-day Faroese

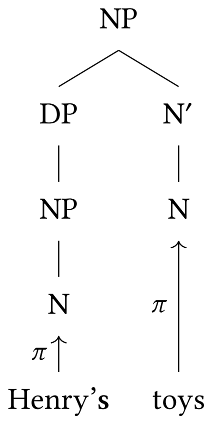


4.4 Degrammaticalization and lexical sharing

Another way in which gradual degrees of syntactic change have been captured at c-structure is via “Lexical Sharing”, as originally proposed within LFG by Wescoat (2002, 2005, 2007, 2009) and further developed by Lowe (2015, 2016a) as “Constrained Lexical Sharing”. Lexical Sharing is essentially a mechanism which allows two or more constituents at c-structure to map to a single lexical element. As we discuss in this section, Lowe (2015) employs this in the context of diachrony as a way to model degrees of “*de*grammaticalization” (see e.g., Norde 2009, Willis 2017) with respect to the English possessive marker *’s*, building on a synchronic analysis of Present-day English in Lowe (2016a).

The starting point for Lowe’s account is Present-day English, which indicates a mixed picture with respect to whether the possessive marker *’s* has clitic or affixal status. This is reflected in the literature, where some argue for it to be a clitic (e.g. Quirk et al. 1985, Anderson 2008) and others for it to be an affix (e.g., Zwicky 1987, Payne 2009). In this context, Lowe (2016a) claims that synchronically *’s* has dual status, i.e. that Present-day English exhibits both clitic forms and affixal forms and shows how this complex status can be modelled via Constrained Lexical Sharing. As Lowe points out, the lexicalism underpinning LFG leads to a discrete distinction between clitic and affix. An affix is assumed to attach to its host in the lexicon and will thus map to the same c-structure node as its host, e.g., (31a), while a clitic is a distinct lexical element which occupies its own c-structure node, e.g., (31b). The example c-structures here are as in Lowe (2015: 213).[9]

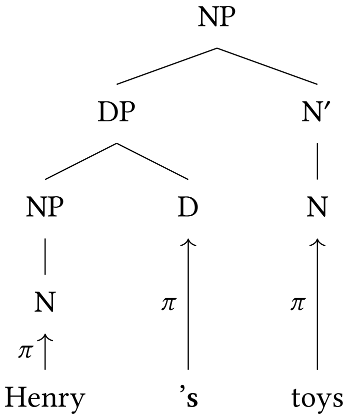
(31) a. Affix:



---

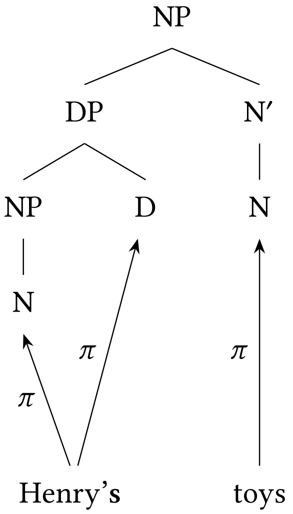
[9] In both Lowe (2015: 213) and Lowe (2016a: 174), different structures are provided for the possessum *toys* depending on whether one assumes the affix analysis or the clitic/lexically shared affix analysis; for the affix analysis, the immediate daughter of N’ is N, but for the clitic and lexically shared analysis the immediate daughter of N’ is given as an NP. Although Lowe does not provide any explanation for this difference, for the sake of consistency we simply repeat the structures here.

b. Clitic:



Rather than assume the straightforward affixal analysis in (31a) for affix-like instances of *’s*, however, Lowe (2016a) proposes an account involving (Constrained) Lexical Sharing. This allows one to capture the affixal status of *’s* whilst being able to maintain a consistent syntactic structure for possessive phrases, irrespective of the affixal/clitic status of *’s*. Wescoat’s original formulation of Lexical Sharing (Wescoat 2002, 2005, 2007, 2009) assumes an additional dimension, l(exical)-structure, which consists of a linearly ordered set of words. The idea behind Lexical Sharing is that it is possible for two adjacent c-structure elements to map to a single element at l-structure, i.e. “sharing” the same lexical exponent. Within the Constrained Lexical Sharing of Lowe (2015, 2016a), Wescoat’s l(exical)-structure is identified with the syntactic string (s-string) of Kaplan (1989), and thus Lexical Sharing refers to instances where a single element at the s-string is associated via the relation π with two adjacent c-structure nodes. In Lowe’s account, the affix-like *’s* is a lexically shared affix, e.g., (32), i.e. constitutes a single lexical element with its host but maps to a separate node from the host at c-structure, resulting in an overall structural configuration parallel to that for the clitic analysis in (31b).

(32) Lexically shared affix:



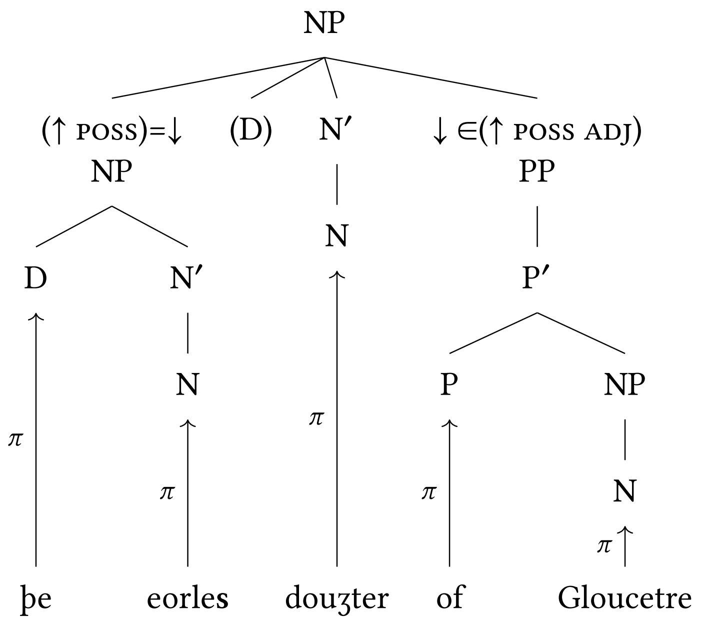
Applied specifically to diachrony, Lowe (2015) shows how this approach can be used to represent degrees of "*de*grammaticalization" of the English possessive marker, which "*de*grammaticalizes" over time from an unambiguous affix to a clitic (cf. the typical grammaticalization cline in (1) above). At the earliest attested stage, the Old English ancestor of Present-day English *'s*, *-es*, is one of a number of genitive case allomorphs and is uncontroversially an affix which is fully integrated with its stem in the s-string and maps to the same c-structure node as its host, cf. (31a). Crucially, as Lowe (2015) points out, drawing on data discussed by Allen (1997, 2003, 2008), the emergence of the clitic over the subsequent centuries is gradual and involves degrees of degrammaticalization and small-step changes from affix to clitic.

Specifically, in the period ca. 1100–1400 CE several changes are underway which affect the affixal status of the possessive marker: the various genitive case forms are largely lost and *-(e)s* becomes the possessive marker for most nouns, while possession is increasingly marked on just the head of the possessor, rather than on every element of the possessor. Lowe (2015) cites two construction types in particular which are attested during this period and indicate the beginning of a change in the morphosyntactic status of the possessive marker: (i) possessors which involve coordination where possession is marked only on the rightmost head, e.g., (33a) and (ii) possessor phrases with split postmodification flanking the possessum, where possession is marked on the head of the possessor, e.g., (33b).

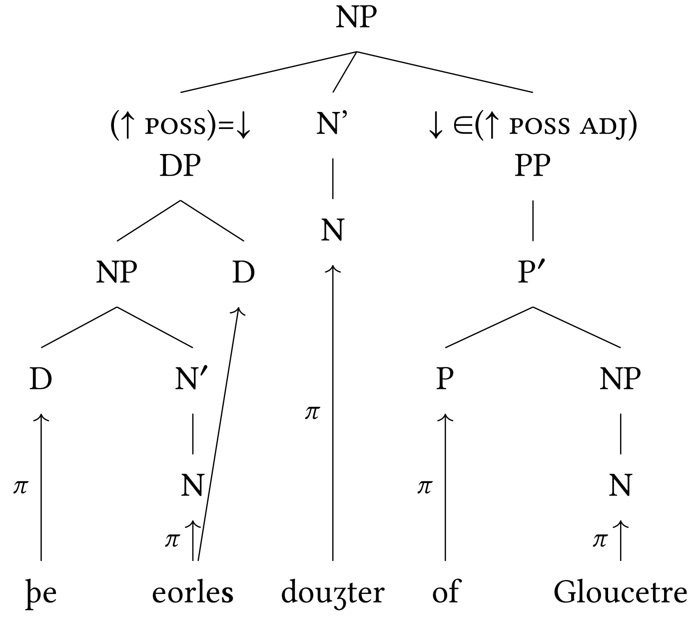
(33) Middle English
a. wif & were**s** gederunge
wife and man.GEN union
'The union of man and wife.'
(*Hali Meidenhad*, c. 1225 CE)
b. þe eorle**s** douʒter of Gloucetre
the earl.GEN daughter of Gloucester
'The Earl of Gloucester's daughter'
(*Polychronicon* VIII, ca. 1380)
(Lowe 2015: 217–218)

The two constructions in (33) show a strong positional constraint, whereby the possessive marker on the head of the possessor phrase must immediately precede the possessum. Lowe interprets this as evidence that the possessive marker is no longer fully affixal, since it is now constrained by the syntactic context in which it appears, rather than just being dependent on the position of the word to which it attaches. In the Lexical Sharing approach, this change can be captured by assuming that the original affix (modelled in (34a)) is reanalyzed as a lexically shared affix as shown in (34b) (structures from Lowe 2015: 222). In (34a), an optional D node is assumed, which is later incorporated into the head of the possessor phrase (see (34b)), once possessor phrases come to supply the definiteness of the possessum, in line with the broader grammaticalization of the definite article which is underway in the period.

(34) a.



b.



However, the Middle English lexically shared affix in (34b) is not yet equivalent to the status of the possessive marker in Present-day English but rather has a subtle difference. As Lowe (2015) points out, in the former, the noun component must supply the head of the possessor phrase. This is captured in the lexical entry in (35a), where the N component is associated with an f-description which requires that the f-structure of the noun serve as the value (or a member of a set of values) of the feature POSS in a wider f-structure; the D does not need to have any f-descriptions associated with it. By contrast, for Present-day English – where the possessive marker is closer to a clitic – Lowe assumes the lexical entry in (35b), "Partitioned Lexical Sharing", which involves two c-structure nodes each with their own set of f-descriptions (structures from Lowe 2015: 215, 223).

(35) a. Unified Lexical Sharing:

eorles:	N	D
	(↑ PRED) = 'earl'	
	(POSS (ϵ) ↑)	
	((POSS ↑) DEF) = +	

b. Partitioned Lexical Sharing:

species':	N	D
	(↑ PRED) = 'species'	(POSS ↑)

According to Lowe, only from the end of the 14th century are "phrasal possessives proper" attested, i.e. phrasal possessives with postmodified possessors with possessive marking on the right edge of the postmodifier, rather than on the head of the possessor as in early examples, cf. (33b). The example Lowe provides is from Chaucer (ca. 1400 CE), shown here in (36). These more clitic-like examples coexist alongside the more affix-like split examples as in (33b) throughout the Middle English and Early Modern English periods, with an increasing preference for the more clitic-like type in (36). This is modelled in terms of gradually shifting preferences in favour of the Partitioned Lexical Sharing analysis, cf. (35b) over the Unified Lexical Sharing analysis, cf. (35a).

(36) Middle English (Lowe 2015: 219)
The grete god of Loves name

'The great God of Love's name.'

Taking advantage of Lexical Sharing thus allows Lowe (2015) to model the nuanced steps involved in syntactic change via degrammaticalization and, applied to Present-day English, also to capture the coexistence of older and newer variants at a synchronic level (Lowe 2016a).

A very different approach to the mix of clitic and affixal properties is exemplified by Bögel & Butt (2012), who work out an analysis of various different Urdu possessive constructions, including case clitics and the originally Persian *ezafe* construction. Their analysis factors in prosodic features typical of clitics (rather than leaving them out) and avoids the introduction of lexical sharing or other complex formal machinery.

4.5 Grammatical relations and licensing

As Vincent (2001) points out, the fundamental design of the LFG architecture, in which position and function are captured separately, means that it is well suited to modelling changes concerning grammatical relations. A consequence of assuming f-structure as an independent level of representation for abstract functional information is that grammatical functions such as SUBJ and OBJ are viewed as basic building blocks of the theory. As such, unlike in some other generative approaches, SUBJ and OBJ need not be defined in terms of structural position. This allows one to neatly capture the full cross-linguistic spectrum with respect to how languages encode grammatical relations, from those where structural position plays a strong role, e.g., modern English, to those where morphological marking is the dominant encoding means, e.g., Latin, but also languages which use a mixture of means, e.g., Chicheŵa (Bresnan & Mchombo 1987) and Icelandic (Zaenen et al. 1985). Previous work in this area has tended to focus on the cross-linguistic possibilities from a synchronic perspective; see Nordlinger (1998) and Snijders (2015) for relevant typologies. But this approach to grammatical relations also has much to offer for diachronic studies, since change concerning how languages encode grammatical relations is well-attested across languages (e.g., Kiparsky 1997, Hewson & Bubenik 2006, Ponti & Luraghi 2018) and individual historical stages will naturally exhibit intermediate stages along a change trajectory, with a particular balance between structural and morphological encoding strategies.

4.5.1 Word order and recipient passives

A complex change in this area which has been investigated in detail by Allen (1995, 2001) is the rise of the recipient passive in English, i.e. constructions like (37), where the recipient rather than the theme is treated as the subject.

(37) He was given a book.

According to Allen (2001), recipient passives are unattested in Old English; the earliest known example of a recipient passive is from 1375 CE, alongside other scarce examples from the late fourteenth and early fifteenth centuries. The earliest example according to Allen, from 1375, is shown here in (38).

(38) Middle English (Award Blount, p. 207, Allen 2001: 51)
Item as for the Parke, she is alowyd Every yere a dere and xx Coupull of Conyes and all fewell Wode to her necessarye…
'Item: as for the park, she is allowed a deer every year and 20 pairs of rabbits and all firewood necessary to her…'

As with the change concerning experiencer verbs discussed in Section 3.2, Allen again challenges classic accounts of this development (e.g., Jespersen 1927, van der Gaaf 1929, Campbell 1998), which assume that recipient passives emerged via reanalysis of an ambiguously case-marked fronted indirect object as the subject, as in (39).

(39) Middle English (Ric.Couer de L. 1307, Auchinleck MS, Allen 2001: 49)
The Duke Mylon was geven hys liff, and fleygh out of land with his wife.
'Duke Mylon was given his life, and fled out of the country with his wife.'

Allen (2001) points out that the chronology does not stack up to support the classic account, for a variety of reasons. This includes the observation that the loss of the morphological distinction between nominative and dative which results in the prerequisite ambiguity for the classic reanalysis account occurred long before the first recipient passive examples are attested, with a gap of 175 years.

Allen (2001) argues instead for a change involving reanalysis of the indirect object (theme) of active sentences as the direct object, which in turn has consequences for the status of the recipient argument and ultimately facilitates its promotion to subject under passivization. Rather than being driven by ambiguous case-marking, as assumed in the classic accounts, Allen argues that her reanalysis story was triggered by the fixing of the relative word order of two objects. This is based on the observation that the first attestation of recipient passives coincides with the disappearance of examples like (40), in which a (non-pronominal) NP which is the Theme precedes a (non-pronominal) NP which is the Recipient. According to Allen, such orderings with two NPs are unattested as of the last quarter of the fourteenth century.

(40) I gave [a gift]$_{\text{theme}}$ [the king]$_{\text{recipient}}$

Allen suggests that once nominal recipients became fixed in the immediately postverbal position, the simplest analysis from the perspective of the language learner was to analyze the recipient as an OBJ, due to the fact that the learner could now calculate grammatical relations directly on the basis of position, and in turn the semantic relations too. Specifically, a new processing strategy arose which stated that the first non-pronominal NP after the verb would be the OBJ, provided no pronoun preceded it — the strategy for pronouns would be rather different according to Allen, presumably owing to the special positional distribution of pronouns in Early English. As a result, the semantic role could now be determined on the basis of position: if the OBJ was followed by another NP, the OBJ could only be the Recipient and the second NP could only be OBJ_θ, with the only possibility in terms of semantic role as the Theme. In this way, the fixing of the order eases the hearer's processing concerning the assignment of grammatical relations and thematic roles. Moreover, since the Recipient as an OBJ is now $[-r]$, it can map to SUBJ under passivization in accordance with the natural classes which fall out from the features $[\pm r, o]$. Thus recipient passives are now possible.

Allen's account thus investigates the connection between word order and the assignment of grammatical relations and in particular a change whereby grammatical relations become increasingly encoded via position. Next, we discuss other work which has considered this type of change within LFG.

4.5.2 Positional licensing and information structure

Change whereby structural position becomes an increasingly dominant licensing strategy for grammatical relations over time is well attested cross-linguistically; cf. the rise of (argument) configurationality (e.g., Hewson & Bubenik 2006, Luraghi 2010). In the linking theory developed by Kiparsky (1987, 1988, 1997, 2001), where case, agreement and position are viewed as interacting licensing strategies for grammatical relations, this type of change has been formalized as the rise of "positional licensing" (Kiparsky 1997). Focusing on the history of English, Kiparsky (1997) argues that as English lost its morphological case system, position became the dominant licensing strategy for grammatical relations. Beyond Allen's analysis of the recipient passive, this idea has been explored more recently within LFG by Booth et al. (2017), who present a positional licensing account in LFG terms for the diachrony of subjects in Icelandic. As both Kiparsky (1997) and Booth et al. (2017) point out, Icelandic offers an interesting point of comparison with Kiparsky's original account since, unlike English, Icelandic has maintained rich morphological case up to the present day.

Booth et al. (2017) observe that Icelandic subjects are increasingly realized in the clause-initial prefinite position and capture this change in terms of the rise of positional licensing, also bringing information structure into the account. Two other concomitant changes are observed and feed into their analysis: (i) a decrease in V1 declaratives as in (41) and (ii) the emergence of the expletive *það* which is positionally restricted to the clause-initial prefinite position; cf. the contrast in (42), when the expletive is ruled out in contexts where this position is otherwise occupied.

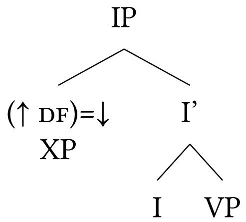
(41) Middle Icelandic (Georgius, 1525, Booth et al. 2017: 111)
Sýndi drottinn mikla miskunn vin sínum
show.pst.3sg lord.nom.def great.acc mercy.acc friend.dat his-own.dat
sankti Georgíum
saint.dat George.dat
'The Lord showed great mercy to his friend St. George.'

(42) Modern Icelandic (Booth et al. 2017: 111–112)
a. **Það** var ekki minnst á önnur dýr.
expl be.pst.3sg neg mention.ptcp on other.acc animals.acc
b. Ekki var minnst á önnur dýr.
neg be.pst.3sg mention.ptcp on other.acc animals.acc
'There was no mention of other animals.'

Following a proposal by Hinterhölzl & Petrova (2010) for the history of West Germanic, Booth et al. (2017) put forward an information-structural account for the rise of the expletive *það* and in turn the decrease in V1 declaratives, assuming that the finite verb serves as an information-structural boundary separating topic and comment. The change is captured in terms of the growth of structure, whereby a flat structure lacking functional categories yields to a more articulated structure making use of functional categories and projections, similar to the account of North Germanic noun phrases by Börjars et al. (2016) (see Section 4.3). In Booth et al.'s account at the clausal level, the relevant functional projection which emerges from an earlier flat structure is IP, headed by the finite verb in I; cf. the LFG accounts of modern Scandinavian clause structure by Sells (2001, 2005) and Börjars et al. (2003).

Once the IP structure is established, various changes occur concerning the nature of the clause-initial prefinite position, i.e. SpecIP. The information-structural role of the finite verb as a boundary between topic and comment leads to SpecIP becoming increasingly associated with a discourse function (df) capturing given or topical information, cf. (43).

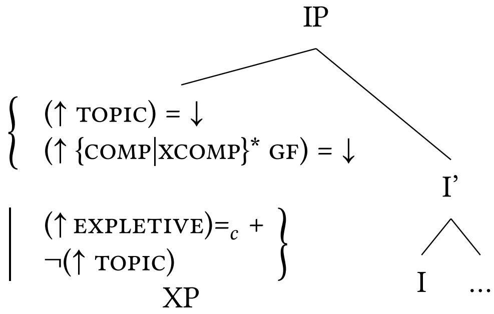
(43)



In their account, this increasing association of SpecIP with topicality can in turn explain the observed increasing realization of subjects in this position. Agentive and sentient entities tend to make for better topics than non-sentient entities, and, since subjects typically represent the more agentive, sentient semantic participants, subjects will accordingly often occur in this new topic position (see also Givón (1990), who discusses subjects as “grammaticalized topics”).

However, as Booth et al. show, SpecIP does not straightforwardly develop into a designated subject position, since subjects can still occur postfinitely in modern Icelandic. In particular, in clauses which lack a topic altogether, i.e. impersonal and presentational constructions, the expletive occurs in the SpecIP topic position as a signaller that the clause lacks a topic. As such, they propose the functional annotations in (44) for SpecIP in the modern stage: it can be occupied by any topical GF, or alternatively the expletive, provided the clause lacks a topic.

(44)



Thus the reorganization of information structure and word order in Icelandic, and in particular the changing status of SpecIP, is seen as the underlying shift which results in a decrease in V1 in favour of V2 sentences with a clause-initial topic or an expletive in topicless contexts. Booth et al.’s study shows that information-structural properties are an important consideration in the context of change with respect to word order and the licensing of grammatical relations. For a similar account which presents this change in terms of shifting correspondences between c-structure, f-structure and LFG’s i(nformation)-structure (Butt & King 1996, King 1997), see Booth & Schätzle (2019) and Booth & Beck (2021). In a similar vein, Booth (2021) shows how assuming that languages can gradually change their status with respect to argument configurationality and discourse configurationality can account for subtle changes in word order between Old and Modern Icelandic, which have otherwise prompted heated debate within approaches which assume configurationality to be a binary parameter (e.g. Faarlund 1990, Rögnvaldsson 1995).

5 Variation and change

In this last section, we turn to the question of the role of variation. It is well-known that language change is gradual and goes hand-in-hand with variation (e.g., Weinreich et al. 1968, Kroch 1989, Labov 1994, 2001, Pintzuk 2003, Chambers & Schilling 2013). However, formal grammars are discrete in nature, so a natural question which arises is how to combine the inherent variability and gradualness associated with language change into formal models of grammar.

One very popular way forward has been the combination of *Optimality Theory* (Boersma et al. 2000, Kager 1999) with stochastic methods (Boersma 2000, Boersma & Hayes 2001), which has been argued to account for patterns of variation and language acquisition. Optimality Theory (OT) was adapted into LFG very early on to yield a version of LFG dubbed "OT-LFG" (Kuhn 2023 [this volume], Bresnan 1996, 1998) and combined with stochastic methods to yield explanations for gradience in judgements (Bresnan et al. 2007, Bresnan & Nikitina 2010) and variation across dialects (Bresnan 2007, Bresnan & Hay 2008, Sharma et al. 2008, Bresnan et al. 2001).

In terms of historical linguistics, Clark (2004) is the first to lay out a formal model of diachronic variation that has led to gradual change.[10] He works with two case studies from the history of English: 1) word order change from primarily OV to VO; 2) the preferred association of subjects with the clause-initial position. Clark models the observed changes within stochastic OT-LFG and shows how the model parallels the observed stages in the historical development and variation in the corpora. Change is essentially effected via competing variants, as in much influential work on syntactic change in recent decades (e.g., Kroch 1989, Pintzuk 2003). In Clark's OT-LFG account, these competing variants are taken to be the result of constraints that are liable to be re-ranked with respect

---

[10] Note that 'gradual' in this context refers not to incremental steps along, e.g., a grammaticalization cline as in (1) but rather the gradual diffusion of a particular change through a population of speakers, or even possibly the gradual establishment of an innovation in the grammar of an individual.

to one another due to inherent "noise" in the communication process between humans and the asymmetry of goals between perception (more information is generally useful for decoding) vs. production (producing less information is generally less burdensome). The stochastic OT-LFG approach is able to capture the steady quantitative rise in the use of an innovated structure by associating it with gradual changes in the relative strength of the relevant constraints. A constraint re-ranking that may be due to "noise" variation may become statistically preferred and from there finally lead to a categorical change.

In a comprehensive look at auxiliary contraction in English, Bresnan (2021) proposes a new hybrid model of LFG and a usage-based mental lexicon to explain the synchronic distribution and diachronic development of auxiliary contractions/clitics. The usage-based mental lexicon is conceived of as a combination of ideas coming from Pierrehumbert's examplar-based model of the mental lexicon (Pierrehumbert 2001, 2002) and Bybee's usage-based approach (Bybee 2006). The frequent co-occurrence of certain combinations of words, e.g., *you+are* or *we+will*, are predicted to undergo contraction. Frequencies are calculated using a measure termed *Informativeness*, which is the logarithm of the inverse of the conditional probability of one word following the other. In Bresnan (2021), the corpus study, the frequency calculations and the development of the hybrid LFG plus usage-based mental lexicon make for a rich and complex paper which combines the strengths of formal grammar modelling with by now well-established effects of frequency and variation in usage.

The auxiliary contractions themselves are modelled via the formal concept of lexical sharing within LFG (cf. Section 4.4) and this is where Bresnan (2021) draws a concrete connection to diachrony: "lexical sharing as a formal construct can be viewed as a grammaticalization of high-probability syntactic distributions in usage…". However, as argued for by Bögel (2015), clitics do not necessarily need to be modelled via lexical sharing. She instead proposes a more articulated architecture of the prosody-syntax interface for an analysis of clitics and provides a means for integrating effects of frequency and variation (Bögel & Turk 2019). Frequency effects can also be modelled via preferences applied directly to rules or lexical items, as practiced with respect to computational grammar development in LFG (Frank et al. 2001, Dost & King 2009).

Overall, the area of variation and change provides an interesting area of research for LFG, with initial architecturally complex and sophisticated proposals having recently been formulated, pointing the path towards innovative and exciting research in this area.

6 Summary

This chapter has endeavored to provide an overview of the types of work done within LFG on language change. Like most formal theories of grammar, LFG did not address language change from the outset and the first serious work on language change only began appearing in the 1990s. However, as LFG is fundamentally designed to separate form from function, the complex interaction between the function of an item and its overt realization can be modelled very well. Indeed, given LFG's complex formal design, in which the different components of grammar are represented with component-appropriate rules and representations, and interface with one another via the projection architecture, one might argue that there are too many moving parts to permit a clearly delineated theory of language change.

In one sense this is correct, but in another sense, one could argue that, as with synchronic description, what LFG provides is a broad formal framework, which must be specified by linguistic theorizing. By its very nature LFG pursues an *inductive* approach — the framework provides a broad perspective on the data (e.g., form and function are assumed to be separate, c-structure is assumed to model linear order, constituency and hierarchical relations, grammatical relations and argument structure are core objects over which generalizations can be stated, etc.) but the linguistic explanations and generalizations themselves emerge from the data and can be stated independently of the theory, thus allowing for potential cross-theoretic validity. Another aspect of the inductive approach is that the overall framework can be adjusted in the face of strong empirical evidence. For instance, when there is strong empirical evidence that information about frequency of items plays a role, the theory is adjusted and opens up interesting new ways of modelling language change, as we saw in Section 5.

Furthermore, the fact that LFG is very functionally oriented allows for an open channel of communication with the functional-descriptive and grammaticalization literature, leading to natural and insightful accounts of lexical and functional change, as we discussed in Section 3. Change in terms of syntactic categories and clausal organization is seen as being motivated by changes in function in the first place, with syntactic recategorization and reorganization following to reflect the change in underlying function (Section 4).

In this chapter, we have followed the very broad notion of reanalysis adopted by Harris & Campbell (1995) and hope to have shown how LFG can naturally account for reanalysis at various different levels: lexical, functional, categorical. In fact, one could see LFG as providing a firm formal basis for understanding the possible moving parts involved in reanalysis as part of language change, while also providing a basis for understanding how the well-attested gradualness, variation and frequency-based effects of language change can be modelled formally. That said, and despite the length of the chapter, it should be obvious to the reader that the existing body of historical linguistic work within LFG is so far not large and there is thus much room for investigation into language change. There is also room for experimentation and innovation with respect to how to represent and understand language change. This might include a new model of the lexicon, a new version of LFG or the introduction of new methods of probabilistic modelling, as we have seen above, or working with new ways of accessing the diachronic data, for example by means of a platform developed together with experts from visual analytics (e.g., Schätzle et al. 2019, Beck & Butt 2020, Beck et al. 2020).

Chapter 21

LFG, Optimality Theory and learnability of languages

Jonas Kuhn

University of Stuttgart

Optimality-Theoretic accounts of grammar specification do not rely (exclusively) on rules and descriptions that every expression in the implied formal language has to satisfy strictly. Instead, a universal set of violable constraints is posited, and most grammatical expressions are not perfectly harmonic in all respects, but violate some of the constraints. A particular language is characterized by a certain priority ranking over the universal constraint set. This conceptualization of grammatical knowledge gives rise to the prediction of cross-linguistic variation: across languages, the same underlying meaning is realized by different expressions since different rankings of the constraints make different candidates optimal. The framework comes with a straightforward algorithmic formulation of the language learning problem – as error-driven constraint reranking.

Optimality Theory (OT) was combined with many linguistic description frameworks in the 1990s. LFG turned out to be a very appropriate base formalism for specifying the candidate representations in OT's competition-based definition of grammaticality. The novel way of characterizing formal languages prompted a range of debates regarding central assumptions in linguistic theorizing; various extensions of the competition-based setup were proposed; and the concept of violable constraints was taken over as an effective modeling device for managing ambiguities in broad-coverage computational grammar development. This chapter provides an introduction of the core concepts of OT as fleshed out on the basis of LFG, it illustrates the most influential extensions, and it reviews important conceptual debates triggered by the approach.

Jonas Kuhn. 2023. LFG, Optimality Theory and learnability of languages. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 961–1032. Berlin: Language Science Press. DOI: 10.5281/zenodo.10185980

1 Introduction

The term Optimality Theory (OT) refers to a family of grammatical frameworks developed in various subfields of linguistics following the original proposal for phonology by Prince & Smolensky (1993). Bresnan (1996), in her keynote address at the first LFG conference,[1] showed that LFG constitutes a natural base formalism for an OT account of syntax, laying the foundation for substantial research activities in the late 1990s and early 2000s.

The key idea behind OT is that grammatical knowledge is not captured in distinct rule systems for each language, but theorists assume a universal set of constraints responsible for determining the harmony or markedness of potential realizations of some underlying input representation. For example, both the clause structure *you see who?* and *who do you see?* are candidate realizations for expressing a *wh*-question that asks for the object of a transitive verb. In some languages, the equivalent of the former is grammatical, whereas in English, the latter is. Neither of the two variants is perfectly unmarked; each violates certain constraints (in essence: an interrogative phrase is best realized at the beginning of the clause vs. the object of a verb is best realized in the canonical VP-internal complement position). What differs across languages is the relative prominence among the universal constraints, such that there are different winners in the competition for the most harmonic/least marked candidate, which is defined to be the language-particular output. Learning a language thus amounts to determining the correct prominence ranking over a known set of constraints to replicate the behavior observed in adult speakers. A more technical illustration of an OT system building on the LFG formalism will follow in Section 1.1.

The notion of violable grammar constraints inspired linguists to explore the explanatory potential of a competition-based definition of grammaticality for a whole range of linguistic subfields. Moreover as Section 1.2 will discuss, the notion turned out fruitful for computational work aiming at linguistically grounded broad-coverage grammars: expanding "classical" constraint-based grammar formalisms with a novel type of violable constraints enables a competition-based filtering of ambiguity sources and thus greatly facilitates the treatment of relatively rare lexical variants and grammatical constructions (Frank et al. 2001). An outline of the remaining sections of this chapter will be provided in Section 1.3.

---

[1] Details of the analysis presented in the keynote address are discussed in Bresnan (2001a) and Bresnan (2002).

1.1 Example of an OT-LFG analysis

The tableau in Figure 1 demonstrates more technically how an OT-LFG account predicts *who will she see?* to be the grammatical structure for realizing this type of question in English. It is adapted from Bresnan (2001a), a contribution that recasts Grimshaw's (1997) OT analysis of English verb inversion in an LFG framework assuming Extended Head Theory (as detailed in Bresnan 2001b: ch. 7 and Bresnan et al. 2016: ch. 7).

Input: $\left[\begin{array}{ll}\text{PRED} & \text{`see(x, y)'}\\ \text{GF}_1 & [\text{"you"}]\\ \text{GF}_2 & [\text{"who"}]\\ \text{Q-FOC} & \text{———}\\ \text{TNS} & \text{FUT}\end{array}\right]$	Op-Spec	Ob-Hd	Stay
a. ⟨ $[_{\text{IP}}$ you will $[_{\text{VP}}$ see who]], ...⟩	*!		
b. ⟨ $[_{\text{CP}}$ who *e* $[_{\text{IP}}$ you will $[_{\text{VP}}$ see *e*]]], ...⟩		*!	*
☞ c. ⟨ $[_{\text{CP}}$ who will $[_{\text{IP}}$ you *e* $[_{\text{VP}}$ see *e*]]], ...⟩			**

Figure 1: Tableau for the competition that leads to *who will you see?* being the most harmonic candidate under the constraint ranking for English. The candidates' c-structure trees are shown as bracketing expressions; their full f-structures is not shown here. Only a small subset of the candidate set is listed, omitting other realization variants. These are excluded for English by additional constraints, but could be grammatical in other languages and are thus included in the candidate set.

The tableau shows the comparison of three candidate realizations for the underlying content, the input – here the proposition *see*(x, y), where x is a pronominal for the second person singular, y is the focus of a question, and the clausal realization expresses future tense. Particular syntactic choices, for instance the realization of the semantic arguments by grammatical relations such as SUBJECT and OBJECT are underspecified in the input. In the OT-LFG framework, the range of realization options across languages can be captured very well by assuming that the input is a partially specified f-structure, and the candidate set consists of all fully specified LFG analyses whose f-structure is subsumed by the input.

The excerpt from the full candidate set shown in Figure 1 focuses on c-structural realization alternatives for clause structure. In Extended Head Theory, functional categories (such as I and C) and their c-structure projections are mapped to the same f-structure as their corresponding lexical categories (V). The functional projections occur optionally, but they offer the possibility to realize additional head elements such as tense auxiliaries and they come with one c-structural specifier position each, which can for instance be used for *wh* operators. Also, it is a possibility across languages for verbal head elements to be realized in a higher, c-commanding, position (e.g., V in I or I in C, as in candidate c.). By definition, elements in such a functional position are still *extended heads* of the lower projections. This nonderivational account of head mobility, which Bresnan (2001b: ch. 7) also formalizes in a non-OT setting of LFG, thus opens up a considerable spectrum of alternative candidate realizations for the basic clause structure.

Let us now consider what effect the three violable constraints have that Figure 1 shows in the order of the ranking for English (the constraint formalization will be discussed in more detail in Section 2.2). The harmony/markedness of a candidate is determined by its constraint violation profile. In the tableau notation, a violation is signalled by a star in the row for the corresponding constraint. Since OT assumes a *ranking* of the constraints (and not a more general weighing as for instance in Harmonic Grammar, Legendre et al. 1990), one can simply proceed from left to right through the constraints to determine the winning candidate(s): at each constraint, only the candidates that have the fewest violations for this constraint are kept. The other candidates have no more chance of winning the competition, even when they do not violate any of the lower-ranking constraints. It is common to mark the decisive constraint violations with an exclamation mark following the star; the cells for the lower-ranking constraints are often grayed out in tableaux. In our example competition, the Op-Spec constraint demands that syntactic operators such as *wh* phrases be realized in c-structural specifier positions (highlighting the operator's prominence). Candidate a. violates this constraint, since the *who* is realized inside the VP. Op-Spec is the highest-ranking constraint and the other candidates satisfy this constraint, hence candidate a. is excluded from further comparison. The Ob-Hd constraint (for obligatory head) says that every projected category (X′, X″) should have a lexically filled extended head. Candidate b., which includes a CP projection without a lexically filled head, incurs a violation of this constraint.[2] The third constraint, Stay,[3] states that categories should *dominate* their extended heads, thus punishing c-structural realizations in higher, c-commanding positions: In candidate c., the *wh* phrase in the CP-Spec position incurs one Stay violation (due to a lexically empty DP inside the VP), the *will* that is not realized within IP another one. Since Stay is low in the constraint ranking for English, candi-

---

[2] The notion of *extended* heads leads to the situation that the empty I head in candidate c. does not incur an Ob-Hd violation: The C head, which contains *will*, is in a c-commanding position and thus acts as an extended head for the I′ and IP.

[3] The name Stay is carried over from Grimshaw's (1997) account, which assumed a derivational base formalism with upward movement in trees. The reconstruction is entirely nonderivational.

date c. is optimal despite the two violations: there are no surviving competitors with fewer violations.

Under different rankings of the same three constraints, different clause structures come out as optimal. When Stay outranks Op-Spec, for instance, candidate a. is the most harmonic. This predicts non-echo matrix questions like in (1) to be grammatical, as is the case in a *wh*-in-situ language like Chinese.

(1) Mandarin Chinese (Huang 1982: 253)
ni kanjian-le shei?
you see-ASP who
'Who did you see?'

According to OT assumptions, a language learner starts out with an uninformed initial constraint ranking. Whenever they hear an utterance by an adult speaker of the language, they check whether the observed output (for a contextually inferred input) is the same that their current ranking would have predicted. If not, the constraints responsible for the error are demoted in the ranking (Tesar & Smolensky 1998). Details of the OT approach to characterizing grammaticality and the OT-LFG formalization will be discussed Section 2.

1.2 Ranked soft constraints in computational grammar development

As mentioned, Joan Bresnan gave a keynote at the first LFG conference in 1996, presenting her proposal for integrating the competition-based grammatical framework of Optimality Theory with LFG's declarative specification of parallel representations that are in imperfect correspondence (Bresnan 1996). The concept of violable constraints immediately prompted interest in the computational LFG community, which was working towards implementations of LFG grammars that robustly cover real-life text data, most notable in the Parallel Grammar Development project ParGram (see also Forst & King 2023 [this volume]).

As Frank et al. (2001) discuss, violable constraints can alleviate a considerable practical problem with broad-coverage grammars that aim for linguistic precision: the *ambiguity management* problem. To reach an acceptable coverage of real corpus data with a linguistically precise grammar, the rules have to cater for essentially all conceivable realizations of variable phenomena – even for those that are infrequent and tend to underlie special contextual restrictions. In a grammar with such a comprehensive rule set however interactions among multiple variable phenomena can lead to an enormous degree of ambiguity in parsing. Although ambiguity packing techniques keep the computational parsing task itself tractable (Maxwell & Kaplan 1989) (see also Cahill & Way 2023 [this volume]), it can become hard for the grammar writers to keep track of whether the contextually justified readings are among the readings predicted by the grammar (King et al. 2004). The notion of violable constraints puts grammar writers in a position to overcome the ambiguity management problem via perspicuous filters.

The following examples may illustrate the proliferation of sources of ambiguity in a comprehensive grammar. In English, temporal adverbials can have the shape of a plain NP headed by a time expression such as *year, day, moment*, etc., as for instance in (2a,b). A carefully constrained grammar will rely on a lexical marking of the relevant nouns to avoid overgeneration. Without such a lexical restriction, any intransitive verb used with an NP in object position, such as (2c), would be incorrectly predicted to form a grammatical sentence.

(2) a. The car had problems all weekend.[4]
b. What are your future plans the next half year?[5]
c. * Lou yawned two big bones.

The rule in (3) uses a constraining equation to ensure that the adverbial NP comes with the marking [NTYPE TIME +].

(3)
$$\begin{array}{lllllllll} \text{VP} & \rightarrow & \text{V} & \text{(NP)} & \{ & \text{PP} & | & \text{NP} & \}^{*} \\ & & \uparrow=\downarrow & (\uparrow\textsc{obj})=\downarrow & & \downarrow\in(\uparrow\textsc{adj}) & & \downarrow\in(\uparrow\textsc{adj}) & \\ & & & & & & & (\downarrow\textsc{ntype time}) =_{c} + & \end{array}$$

Examples (4a,b) show however that adverbial uses of plain NPs can also occur with nouns that do not refer to time expressions.

(4) a. Being prepared will save your soles from aching the entire trip.[6]
b. And WoW had problems every expansion for years […][7]

By a semantic process of type coercion (see, e.g., Pustejovsky 1995), NPs referring to segments of a process (e.g., during spatial movement, as in (4a), or in repetitive processes, as in (4b)) can receive a temporal reading. A grammar that strictly ties adverbial NPs to a lexical marking of time expressions will fail on these examples. And since such coercion processes are relatively productive, grammar writers

[7] https://forums.newworld.com/t/fix-your-product-this-isnt-an-indie-company/247609/59

face a difficult tradeoff between maximizing coverage and risking a proliferation of ambiguity.

The issue is amplified when several variation phenomena interact, as the following considerations demonstrate. Completely independent of the type coercion process we just saw, many transitive verbs in English can occur with an understood object in appropriate contexts – i.e., without a syntactically realized direct object: *enjoy* and *announce* are both strictly transitive, but (5a,b) show that occasionally, an understood object can be filled in contextually.

(5) a. [Text message with a video posting:]
Here it is. Lean back and enjoy for the next 7 minutes.[8]

b. [News headline:]
Troy Williams will announce tomorrow[9]

To capture such uses, one could have transitive verbs optionally fill in a pronominal PRED value for their object (this can for instance be done by putting an optional equation in the lexical template for transitive verbs: { (↑ OBJ PRED) = 'pro' }). The pronominal PRED value indicates that its referent can be contextually inferred.

Both the temporal type coercion discussed previously and understood objects occur rather infrequently overall; yet, a broad-coverage grammar should cater for these constructions. Unfortunately, it is impossible to fully capture the contextual constraints on the use of such constructions within a knowledge engineering approach – individual uses may depend on inferences involving situational knowledge and general world knowledge.

By employing violable "soft" constraints inspired by Optimality Theory in a broad-coverage LFG grammar, the infrequent constructions can be captured in the grammar without causing a proliferation of ambiguity for the core constructions. Sentence (6a) is an example of a plain transitive use of the verb *announce*. A conspiracy of the two infrequent constructions we just discussed would however also lead to an understood object reading of *announced* (corresponding to the only reading available for (5b)) when *every expansion* would be analyzed as a coerced temporal adjunct (like in (2e)). With a comprehensive grammar allowing for these rare options, every single transitive VP (as in (6b)) would receive duplicate readings – although a temporal reading of the NP is extremely implausible in most cases. As (6c) shows, even an NP including a time expression will

---

[8] https://mobile.twitter.com/automobilirimac/status/765505874425180160

[9] https://www.on3.com/teams/kentucky-wildcats/news/troy-williams-will-announce-tomorrow/amp/

rather fill the position of the direct object than acting as an adverbial NP alongside an understood object (although in this particular case, the two readings are semantically hard to distinguish).

(6) a. The company announced every expansion.
    b. The dog chases every bird.
    c. [From a comment page for a music band:]
       Super talented, professional. We enjoyed every minute.[10]

The mechanism of ranked violable constraints discussed by Frank et al. (2001), which is implemented in the XLE system (Crouch et al. 2011), provides a highly convenient way of dealing with this situation. In (7), template definitions are seen that optionally[11] introduce the infrequent construction of a type-coerced common noun (such as *expansion*, *trip* and even *bird*) and an understood object with a transitive verb.

(7) a. common-noun(_p) ≡ (↑ pred) = '_p'
       { (↑ ntype time) = +
       TypeCoercionToTimeNoun ∈ *o*(*) }
    b. transitive(_p) ≡ (↑ pred) = '_p ⟨ (↑ subj) (↑ obj)⟩'
       { (↑ obj pred) = 'pro'
       UnderstoodObj ∈ *o*(*) }

Note that the optional functional descriptions go along with statements of the form 'xyz ∈ *o*(*)'. These have the effect of introducing so-called optimality marks (xyz etc.) to a data structure projected from c-structure to a novel *o*-projection (for Optimality projection).[12] Mathematically, the data structure is a multiset (i.e., a generalization of sets that can include two or more identical 'copies' as distinct elements). The purpose of this multiset is simply to implement a counting mechanism that keeps track of how many times a certain functional description was used in the construction of a particular LFG analysis. In c-structure rules $A \rightarrow B_1 \dots B_n$, the union of the multisets from all daughter categories $B_1 \dots B_n$ forms the multiset projected from the mother category A. So the root node of

---

[10] https://www.esteemlivemusic.com/we-enjoyed-every-moment/

[11] Enclosing functional descriptions in curly brackets has the effect of creating one option with the descriptions and one without.

[12] Like the ϕ-projection, the *o*-projection starts out from c-structural entities (i.e., lexical or phrasal c-structure nodes, denoted by '*'). This makes it possible to introduce distinct marks from several c-structure nodes that map to the same f-structure. This can for instance be relevant for economy constraints that favor structures with fewer nodes.

a c-structure tree will always provide access to the aggregate counts of marks from the full tree.

The multiset of optimality marks provides the basis for filtering a set of candidate analyses, very much like in the OT tableaux illustrated in Section 1.1. The grammar writer can define the relative ranking of the violable constraints (the OPTIMALITYORDER) that guides the filtering:

(8) OPTIMALITYORDER UnderstoodObj TypeCoercionToTimeNoun.

Starting with the highest-ranking type of optimality mark, the set of readings is successively reduced; for each type of OT mark only the candidates that have the fewest marks are kept. The effect of this is that the structures for infrequent constructions as illustrated in (4) and (5) will only be seen in the final output of the grammar when there is no alternative, more canonical way of analyzing the same string. In our example scenario, plain transitive sentences like (as (6b)) will hence receive only the canonical subject-object reading. At the same time however, the OT-style ranking system *does* cover uses of type coercion or understood objects. For instance when analyzing sentences that contain type-coerced adverbial NPs like (4a,b), *all* candidate analyses include at least one mark TypeCoercionToTimeNoun, hence they will survive this step of the filtering.

With such a filtering mechanism, the grammar writers can transparently control many of the interaction effects of the linguistic phenomena they are dealing with – without having to come up with explicit descriptions of contextual conditions for the rare special uses. The approach has hence been widely applied in the broad-coverage grammars of the ParGram project. As we will see in Section 2.6, some modifications of the plain ranking mechanism open up further functionality for grammar development.

To conclude this section we note however that there is a clear difference in the conceptual role played by the competition among candidate analyses (i) in OT-LFG, as discussed in Section 1.1) vs. (ii) in the "OT-style" filtering approach in grammar development, as discussed in this section: in the former case, the competition serves to define grammaticality in a given language, whereas in the latter case, all candidates are assumed to be grammatical in principle, and the competition serves to filter out implausible readings.

1.3 Chapter outline

The remainder of the chapter is organized into four sections and a conclusion: Section 2 discusses the OT framework and its combination with the LFG formalism in more detail. Section 3 provides a number of demonstrations of how the competition-based notion of grammaticality can systematically derive variation patterns within a language and predict typological patterns across languages. Section 4 goes into important extensions of the standard OT framework and reviews discussions of the status of key components of an OT system such as the violable constraints. It also provides a discussion of linguistic formalisms and learnability of languages. Section 5 reviews the developments after the mid-2000s, with an emphasis on a comparison of OT and other competition-based architectures. It also includes a discussion of the relationship between OT and the recent so-called neural modeling paradigm in Machine Learning and Natural Language Processing research. Section 6 concludes with a summary of important epistemological considerations regarding the OT approach.

2 OT: Formalism and computational considerations

Section 2.1 discusses the key components of an OT system in general and their motivation for the Theory of Grammar. On this basis, Section 2.2 addresses the application of OT systems in syntax and expands on the OT-LFG approach outlined in the introduction. Section 2.3 contrasts the OT-LFG approach with OT syntax approaches using a derivational base formalism.

Section 2.4 discusses the most important computational considerations regarding OT-LFG. An excursion in Section 2.5 addresses potential concerns regarding plausibility of OT-LFG that might arise if one assumes that the declarative specification of the candidate set has any direct psychological reality during human sentence processing. Section 2.6 provides some more details on the use of soft constraints in broad-coverage grammar development illustrated in Section 1.2.

2.1 Key components and assumptions of OT

The initial example shown in Figure 1 already provided an illustration of the key components of Optimality Theory in general and OT-LFG in particular. Within an OT system, the set of grammatical expressions for a particular natural language L is defined using (i) a language-independent function *Gen*, which maps a given input representation to a set of candidates, (ii) a universal set of violable constraints *Con*, and (iii) a harmony evaluation function *Eval*, applying a language-specific prominence ranking $\gg_L$ that is defined over the constraint set. We define an expression to be grammatical in L if it is (one of) the most harmonic candidate(s) in the set of competing realizations for some input according to $\gg_L$. A candidate C_1 is more harmonic than a candidate C_2 iff it contains fewer violations for the highest-ranked constraint in which the marking for C_1 and C_2 differs.

With the variable ranking relation over a universal set of constraints, an OT system does not just predict an individual language, but essentially an entire constellation of possible languages, the so-called factorial typology. The task for a theorist working on some family of phenomena is to find a set of constraints that plausibly predicts the spectrum of cross-linguistic variation as it is empirically attested in the languages of the world.

A key methodological assumption of linguistic work employing OT systems is that the input includes no language-specific information or restrictions. This is called the "richness of the base" (Smolensky 1996). A construction that is only available in some languages should not be explained by differences in the input, but must be derived as an effect of constraint ranking. In other words, the role of candidate generation, *Gen*, is limited to providing the space of possibilities; the substantive linguistic regularities should by assumption all be dealt with in the constraint set.

In phonology, the input can be thought of as the target sound sequence a speaker intends to realize. In the case of loan words, this target sequence may include sound clusters that cannot be expressed in the language. For instance, the Dutch loan word *plan* is realized as *päläna* in Sinhalese:

(9) Sinhalese (Indo-Aryan; Boersma et al. 2000: 5, citing Sannasgala 1976)
päläna
'plan'

The OT explanation is that there is a constraint against complex syllable onsets and that in the constraint ranking for Sinhalese, this constraint is ranked higher than a constraint against the addition of epenthetical vowels. As a consequence, a surface realization that deviates from the target sound sequence arises as optimal. To capture the full spectrum of phonological systems, *Gen* must make far-reaching deviations from the input available.

Constraints that evaluate whether a property from the input is preserved in the output are called *faithfulness constraints*; there are three types, punishing (a) the insertion and (b) the deletion of a segment and (c) the alteration of some feature value (e.g., devoicing of a voiced consonant) (Prince & Smolensky 1993, McCarthy & Prince 1995). Which part of the space of more or less faithful candidates a language uses for a certain phenomenon is determined by the relative ranking of faithfulness constraints and a second class of constraints, the so-called *markedness constraints*. These constraints assess the output shape of a candidate, irrespective of the input it is supposed to convey. By and large, OT predicts typological differences to arise from different strategies of reconciling conflicts among faithfulness and markedness constraints.

2.2 Optimality-Theoretic Syntax and its formalization

The predictive potential of OT systems regarding language typology as demonstrated in phonology soon attracted researchers working on different subfields of grammar, including syntax (Grimshaw 1997, Samek-Lodovici 1996, Pesetsky 1998, Legendre et al. 1998).[13] Technically, it is relatively straightforward to assume that some modular part of a conventional theory of grammar is replaced by an OT system: instead of the conventional output representation, a set of alternative candidates is assumed whose harmony is then assessed based on ranked violable constraints.[14] (It should be noted however that depending on which part of a conventional approach is being replaced by the output of an OT competition, there can be great differences in the predictive potential of the model component; we come back to this in Section 2.3.)

The fact that the explanatory power of an OT system comes largely from constraint interaction had an interesting effect in terms of sociology of science: Optimality-theoretic extensions of base formalisms from different schools of thought could be subjected to a meaningful comparison, even where diverging assumptions in the conception of the base formalisms themselves had before made comparisons very difficult. This led to an opening up of channels for exchange among theoretical frameworks (see for instance the collection of contributions in Legendre et al. 2000).[15]

Early work on OT syntax sometimes relied on an intuitive and informal conception of the syntactic structures that should compete with each other in the same candidate set. To preserve the idea from OT phonology that all conceivable alternatives for saying the same thing are included in the candidate set, the natural assumption for the input in OT syntax is an abstract representation of the syntactically relevant *semantic content* of an utterance. As Bresnan (1996) points out, this intuition can be cashed out straightforwardly if candidate generation

---

[13] The account of unaccusativity in French by Legendre et al. (1990) in the framework of Harmonic Grammar predates much of the work in OT phonology. Nevertheless, many syntacticians presumably only took notice of competition-based approaches in the aftermath of the success of OT phonology and reacting to Grimshaw's (1997) paper.

[14] The approach of "Harmonic Serialism" assumes an architecture that is broken down into a sequence of steps with local optimization. Müller (2020) for instance explores an extension to morphology.

[15] This unifying potential is discussed for instance by Newmeyer (2002: 44).

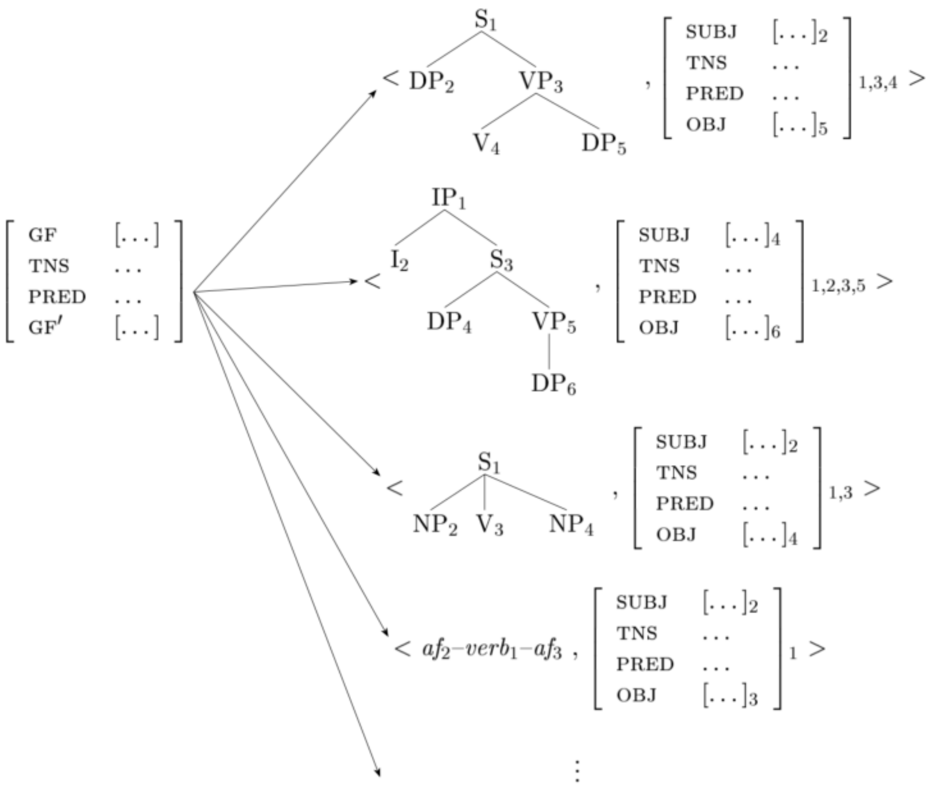

Figure 2: Illustration of candidate generation in OT-LFG (Bresnan 2001a): an underspecified functional structure (on the left) is the basis for generating full LFG analyses (c-structure/f-structure pairs) whose f-structure is subsumed by the input.

is based on a monotonic unification formalism like LFG: the input can be operationalized as a partial representation including the relevant semantic information, and the set of candidates as all the complete representations expanding this input representation – in the case of LFG pairs of c-structures and corresponding f-structures that are subsumed by the input presentation, as is illustrated in Figure 2 from Bresnan (2001a). Cross-linguistic variation at the level of constituent structure is captured by including all typologically different options for expressing some core semantic information in the candidate set.

A formal definition for the candidate generation function *Gen* in OT-LFG is shown in (10) (Kuhn 2003: 74).[16] *Gen* depends on an LFG-type base grammar G_{inviol}, which specifies the space of structurally valid candidate tuples from the full typological spectrum by means of the 'inviolable principles', and is applied to a partially specified f-structure Φ_{in}.

(10) Restricted definition of *Gen*

$$\begin{aligned} Gen_{G_{inviol}}(\Phi_{in}) \;=\; \{\; & \langle T, \Phi' \rangle \in L(G_{inviol}) \,|\, \Phi_{in} \sqsubseteq \Phi', \text{ where } \Phi' \text{ contains} \\ & \text{no more semantic information than } \Phi_{in} \qquad \} \end{aligned}$$

The candidate set generated by *Gen* includes all c-structure/f-structure pairs from the base grammar whose f-structure Φ' (i) is subsumed by the input f-structure Φ_{in} and (ii) does not add any semantic information.[17]

The violable constraints in OT-LFG operate on the candidate representations. It is in principle conceivable to include the detection of constraint violations already in the specification of the base grammar G_{inviol}, using disjunctive f-annotations of the kind shown in Section 1.2 on soft constraints in computational grammar development and introducing marks to a special *o*-projection for counting. However, the specification would presumably become unmanageable fast, since the representational patterns addressed in the various constraints are interdependent; moreover, many constraints address not only patterns in f-structures, but make reference to portions of c-structure. The formalization of OT constraints in Kuhn (2003: ch. 4) therefore proposes to leave constraint marking out of G_{inviol} and assume a conceptually separate step for detecting the constraint violations for each c-structure/f-structure pair in the candidate set. This step can employ straightforward descriptive constraint *schemata* which use a special metavariable $\star$ that is successively being instantiated to every structural element in a candidate analysis, i.e., to each c-structure node, and to each (sub) f-structure.

In (11), the schema-based formal capturing of Bresnan's (2000) constraints Op-Spec and Ob-Hd, which were discussed in Section 1.1, is seen (for details, see Kuhn 2003: 90ff):[18]

(11) a. Op-Spec ('An operator must be the value of a DF in the f-structure.')

$$(\textit{f-str}(\star) \land \exists v.[(\star\ \textsc{op}) = v])$$
$$\rightarrow \exists f.[(f\ \textsc{df}) = \star]$$

---

[16] The language $L(G)$ generated by an LFG grammar G is here defined as the set of tuples $\langle T, \Phi \rangle$ such that T is a c-structure generated by the context-free skeleton in G and Φ is a valid f-structure for T according to the functional descriptions in G.

[17] The restriction excluding surplus semantic information will be addressed in Section 2.4.

[18] The schemata assume appropriately defined auxiliary predicates *cat* (for category) etc.

"If $\star$ is an f-structure bearing a feature OP (with some value v), then there is some f-structure f such that $\star$ is embedded in f under a DF function."

b. Ob-Hd ('Every projected category has a lexically filled extended head.')

$(\mathit{cat}(\star) \wedge (\mathit{bar\text{-}level}(\star, 1) \vee \mathit{bar\text{-}level}(\star, 2))$
$\rightarrow \exists n.[\mathit{ext\text{-}hd}(n, \star)]$

"If $\star$ is an X-bar or X-max category, then there is some node n which is the extended head of $\star$."

The evaluation function *Eval* is operationalized as a trial of all schemata in the constraint set C on every structural element of a candidate analysis (c-structure node or partial f-structure). For the trial, the metavariable $\star$ is instantiated to the element under consideration; the count for the relevant constraint is increased in case the proposition is satisfied. The language-specific ranking $\gg_L$ over the constraints then controls the filtering of the most harmonic candidate(s), in the same way as illustrated in Figure 1 in Section 1.1.

All candidates that are optimal (under the constraint ranking for a given language L) for some underlying partial f-structure Φ_{in} then form the language (= set of c-structure/f-structure pairs) generated by an OT-LFG system for language L (Kuhn 2003: 117):

(12) Definition of the language generated by an OT-LFG system $O = \langle G_{inviol}, \langle C, \gg_L \rangle \rangle$ for language L:

$$L(O) = \{ \langle T_j, \Phi_j \rangle \in L(G_{inviol}) \mid \exists \Phi_{in} : \langle T_j, \Phi_j \rangle \in \mathit{Eval}_{\langle C, \gg_L \rangle}(\mathit{Gen}_{G_{inviol}}(\Phi_{in})) \}$$

The OT-LFG formalization thus provides a declarative, fully operationalized framework for specifying a theory of the typological space of options for a range of grammatical phenomena, predicting specific realization patterns for languages associated with certain constraint rankings. Computational considerations, in particular regarding the complexity of *Gen*, will be addressed in Section 2.4.

Combining the OT concept of competition-based specification of grammatical knowledge with the LFG formalism for operationalizing the components of such an account was beneficial for both sides: For OT theorists interested in exploring the expressiveness of the Optimality-Theoretic approach when applied to phenomena from the broad field of morphology/syntax/semantics, the OT-LFG framework provided a basis whose formal and computational properties were well understood. Consequently, (i) concrete accounts for phenomena of interest could be worked out and tested against attested linguistic data, and (ii) formal and computational implications of the novel conceptualization of modeling grammatical knowledge could be pinpointed. In the reverse direction, the LFG community benefited from the extension of the classical formalism, since OT-LFG provided a formalized framework for predicting patterns in the variation observed across languages (and within a language). By couching an LFG account for a phenomenon in the OT-LFG framework, its generality thus becomes testable against empirical data from language typology. And even when trying to capture variation patterns within a single language, an OT-LFG approach readily supports a reasoning that reduces the range of available realization options to a small set of independently justifiable directives.

2.3 OT-LFG's conceptual advantages over a derivational base formalism

A large proportion of work in OT syntax is not couched in the OT-LFG framework, but assumes a derivational base formalism such as Principle-and-Parameter Theory (Chomsky 1981) or Minimalism (see Grimshaw's 1997 original account and much subsequent work, e.g., Pesetsky 1998). With candidate analyses that are inherently derivational, an implementation of the original OT idea – that the input corresponds to the semantic content of the expressions under consideration – inevitably leads to a more complicated architecture. In the study of syntax, the expressions under consideration are full sentences; so, to implement the original OT idea, all alternative surface sentences expressing the same semantic content should be included in a candidate set. The complication for an OT architecture now arises from the fact that in a Chomskyan derivational approach, semantic interpretation is located at the level of logical form (LF), which is by definition one of the end points of a derivational process that starts out from a D-structure (as in the T-model underlying Principle-and-Parameter Theory, shown in Figure 3) or a set of lexical items, the "numeration".

In a non-OT framework, the derivational processes that lead to a phonological form and a logical form are controlled by language-particular factors. When the derivational processes are taken to be the candidates of an OT system that adheres to the richness of the base, the derivational mechanisms have to be opened up in such a way that all language-particular restrictions on the derivations are lifted – generating all conceivable variants as alternative candidate derivations and leaving the calculation of language-particular effects to *Eval*, which selects the optimal derivation based on the constraint ranking. The input (for the definition of the OT candidate set) has to be (some relevant part of) an LF representation, and the set of candidates that *Gen* assigns to such an "input" LF must

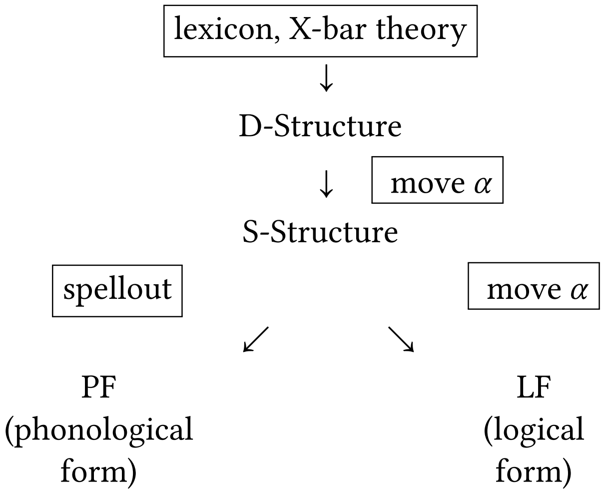

Figure 3: The T-model (or Y-model) of the derivation processes underlying a single analysis couched in Principle-and-Parameter Theory (Chomsky 1981)

be all derivations that *end in* this LF via unconstrained derivation – from any possible starting point (i.e., any numeration of lexical items that could arrive at this LF through unconstrained transformational derivations). Leaving aside concerns regarding the computational tractability of such a system, it is challenging to conceptualize the workings of the OT constraints if the candidate-internal derivation is taken literally as a (potentially destructive) structure-transforming process: if the evaluation of candidate derivations does not take place until a particular LF has been reached, how can the constraints be used to control the language-specific choices in the derivation steps happening early on in the process?

The constraint evaluation challenge can be resolved by viewing the derivational process inherent to the candidates as some abstract process that produces a *representation* including a record of all relevant steps (such as traces of a movement). With this representational strategy, a definition of the candidate set via a shared LF becomes possible. Let us call this an LF-as-input OT system, which preserves the original, meaning-related concept of the OT input (but enforces an abstract view of the derivations, with a representational record).

For a research approach starting out with a derivational framework, it may seem more natural however to resolve the constraint evaluation challenge in a different way: giving up the fully meaning-related notion of the OT input, one can turn to a different way of characterizing the set of competing candidates: since the derivations have their own technical starting point – D-structure or a numeration of lexical items – why not adopt a conceptualization in which this part of the candidate derivations constitutes the input for the OT system and have *Eval* compare the various possible derivations with identical D-structures/numerations? Important typological considerations regarding syntax and morphology *can* be addressed under this view. In fact, when a study focuses on a small set of specific phenomena – as is common practice both for typological and for language-particular studies in linguistics – the two approaches are often indistinguishable, since the (supposedly) *relevant* variation across candidates on which the study is centered originates from the same derivational subprocess across all candidates. This is presumably the explanation for the fact that the simpler system is often tacitly assumed. However, in situations where attention is not focused on a narrowly delineated range of phenomena, the two ways of conceptualizing the input *do* make an enormous difference. Only a semantically based input will leave the choice among realizations that differ in the lexical material in non-trivial ways to *Con* and *Eval*.[19]

A numeration-as-input approach generally imposes restrictions on the candidate space that are tied to particular languages (since semantically equivalent paraphrases of the same content which use different lexical material do not compete in the same candidate set). It is actually a consequence of the predominance of the numeration-as-input approach (and similar input conceptualizations) that *language-particular ineffability* was considered a central issue for OT accounts of syntax. The issue can be characterized as follows: since by definition there is always a most harmonic candidate in any given candidate set, the OT approach appears to systematically exclude the possibility that in some languages there is no grammatical realization at all for a conceivable linguistic construction. Fanselow & Féry (2019) provide the example in (13). While (13a) is grammatical in English, there is no grammatical way of saying (the equivalent of) (13b). They argue that a standard system of OT syntax as Grimshaw's (1997) will include a candidate set of alternative clause realizations for (13b), and one of them will inevitably be the most harmonic, incorrectly predicting that there is some grammatical realization used this set of lexical items.

(13) a. Who did the president think that the foreign minister met in Afghanistan?

---

[19] Of course, not all accounts incorporating a competition-based subprocess are necessarily following the idea that all cross-lingual variation should be reduced to a global, fully meaning-based optimization. It is also conceivable to construe distinct derivational steps as separate, self-contained optimizations (compare e.g., Heck & Müller 2000, Müller 2003). Many approaches explicitly couched in a derivational setting indeed assume fairly restricted structural or derivational *domains* of local optimization (Müller 2012: sec. 4).

b. * Who did the president resign although the foreign minister met in Afghanistan?

Note however that with a sufficiently abstract semantic input, an LF-as-input OT system *could* be devised that makes reasonable predictions for all languages: Where there is no compact realization of a thought in a single clause, a more verbose, multi-clause paraphrase can be used (for (13b) maybe *Who was it that the foreign minister met in Afghanistan when the president resigned nevertheless?*). This appears like a plausible analogy to examples from phonology, where some languages enforce a very unfaithful realization of loan words or foreign names that fall outside the phonological patterns of a language (as exemplified by (9) above). Thus, the language-particular ineffability problem arising in numeration-as-input approaches is not a problem under a global meaning-based conceptualization of the input.

The considerations in this subsection have shown that while a competition-based construal of dedicated derivational subprocesses may be fruitful in order to systematically derive typological patters for a certain submodule of a broader derivational theory of grammar, the original OT idea of deriving all cross-lingual differences – and thus learnability – as an effect of constraint reranking presupposes a comprehensive global competition among all alternative candidate expressions for a given underlying meaning. For capturing constraint evaluation in global competition with a derivational base formalism, there does not seem to be a good alternative to using representational traces of the (abstract) derivational process inherent to each candidate representation.

Bresnan's (1996) recasting of Grimshaw's (1997) account of extended projections – employing Extended Head Theory as sketched in Section 1 – can be viewed as a blueprint of a strategy that translates some relevant key aspects of a derivational approach into a representational approach. So, one can effectively view OT-LFG not only as an OT extension of the LFG framework; it also provides a feasible implementation for LF-as-input approaches, in particular a whole range of work that follows the general spirit of Grimshaw's (1997) proposal.

To sum up the previous and this section, OT-LFG as proposed by Bresnan (1996, 2000, 2001a, 2002) spells out a conceptualization of OT syntax that allows for a clean and comprehensive separation of language-independent candidate generation and violable constraints capturing the spectrum of typological variation. LFG's representational framework makes this separation conceptually simple. Global competition, for instance between morphological vs. syntactic means of expressing for realizing an underlying feature is naturally accounted for since LFG assumes parallel correspondence among all representational structures.

2.4 OT-LFG: Computational considerations

Conceptually straightforward as it is, the idea of relying on feature structure subsumption to define the set of candidate analyses (i.e., tuples of c-structure, fully specified f-structure and potentially more LFG projections) in *Gen* as specified in Section 2.2 raised computational concerns. Johnson (1998) points to the issue that the parsing problem for an OT-LFG grammar is undecidable in the general case. To solve the parsing problem given a string *s*, all optimal analyses have to be found that have *s* as the yield of their c-structure tree.[20]

Figure 4 from Kuhn (2003: 173) illustrates the procedure with a semi-abstract example. In a first step (i) all potentially underlying input representations have to be found. This can be achieved by standard LFG parsing (which is decidable), using the base grammar that defines the set of all universally available candidate structures. The input information is by definition part of the f-structure in each candidate. This predicate-argument structure representation has to be filtered out (step (ii)). In a next step (iii), for each potential underlying input representation, the set of all candidates has to be generated (including the original as well as all alternative full c-structure/f-structure tuples); the constraints are applied to each candidate (iv) and the most harmonic candidate can be determined, given the relevant constraint ranking. This candidate is only included in the set of valid analyses for the original string *s* if *s* is indeed the yield of the optimal candidate (v).

We note that step (iii) involves generation with an LFG-type grammar from a partially specified f-structure. Wedekind (1999) shows that the general problem of generation from partial f-structures, given some LFG grammar, is undecidable. This implies that there could be cases in which the candidate set for a given input f-structure cannot be computed, so it would also be impossible to determine the effect of an OT system. However, Wedekind also points out that the decidability problem for generation with plain LFGs occurs only with certain technical feature representations that are not used to represent the semantics of natural-language sentences. How does this translate to the application of an

---

[20] Johnson (1998) assumes stronger conditions for the optimal candidate: the input representation determined in the first step needs to be included in the optimal analysis of the string. This corresponds to (strong) bidirectional optimality, as discussed in Section 4.4. For standard OT, only the production-based competition is relevant, as assumed in the remainder of this section.

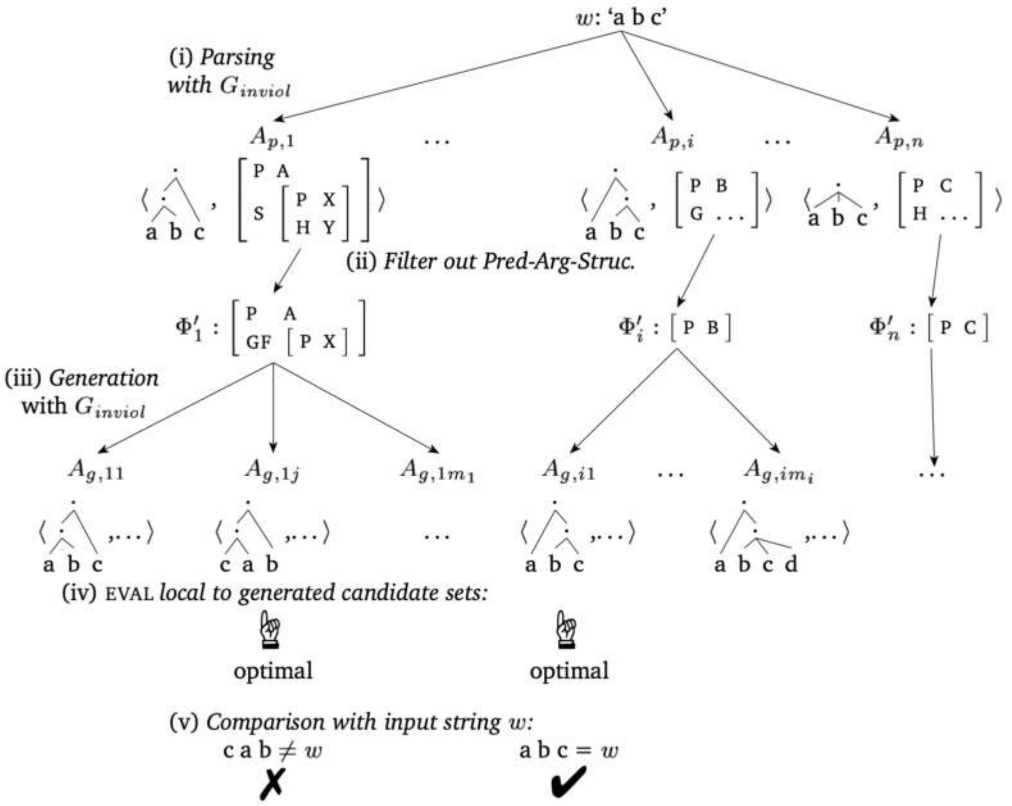

Figure 4: Illustration from Kuhn (2003: 173) for the parsing procedure for a standard OT system, with grammaticality based on production-based optimality.

LFG-style grammar in OT candidate generation? Is it possible to formulate restrictions on admissible partial f-structures and thus guarantee decidability of the parsing problem?

Potentially problematic cases are candidates that include violations of faithfulness constraints, as they are for instance assumed to derive *do*-insertion in English questions (Bresnan 2000: ex. 44). As we will see in the following, restrictions on the formalism can be devised that guarantee decidability but nevertheless permit the use of faithfulness constraints to derive syntactic variation of this kind. Taking advantage of the explanatory potential of OT, Bresnan's (2000) analysis does not stipulate a special, PRED-less lexicon entry in *do* insertion (like in standard LFG), but derives insertion of an additional verb as a consequence of the ranking of violable constraints. To achieve this effect, the *Gen* function underlying in this system has to be able to add "unfaithful material" quite freely. Does this mean that we are confronted with the decidability problem?

As Kuhn (2003: ch. 4) discusses, the option of adding unlimited amounts of material in a candidate is not only undesirable from a computational point of view. It also goes against the key idea of treating all candidates as potential verbalizations of some identifiable semantic content. The definition of *Gen* should therefore be restricted in such a way that the candidates' f-structures (i.e., the interpretable part of the representation) are not only subsumed by the input f-structure, they also may not contain any additional semantic information.[21] With this restriction, it can be guaranteed that the set of candidates stays computationally tractable (Kuhn 2002, Kuhn 2003: 199ff). The definition (10) above already incorporated the necessary restriction.

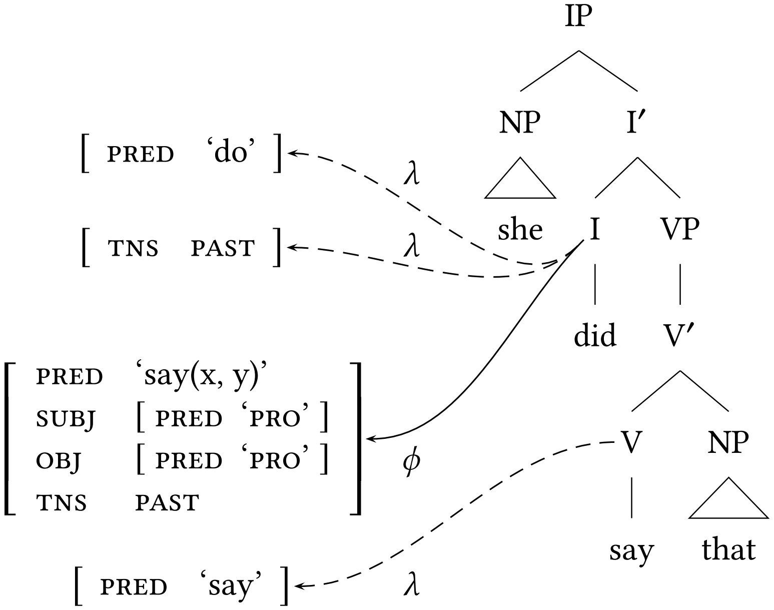

Figure 5: Illustration of a candidate incurring a faithfulness violation, following the technical formalization of Kuhn (2003: 112); c-structure nodes project not only to f-structure (via function ϕ), but also to a (very local) lexical structure (via function λ).

Figure 5 illustrates a formalization of faithfulness violations that is compatible with this restriction and can be used to derive *do* insertion in English. The key idea from Bresnan (2000: ex. 44) is that the lexical contribution of elements that are inserted "unfaithfully" (as a way of satisfying some other constraint

---

[21] It is allowed for candidates to contain additional non-semantic f-structure information and material at the level of c-structure and other projections; this is unproblematic for decidability, since the amount of information that can be added is bounded by the size of the grammar.

that is higher-ranking than faithfulness) does not make it into the candidate's f-structure. The technical operationalization from Kuhn (2003: 112) uses a special λ-projection to keep track of all lexical contributions from the words, which may or may not re-appear in f-structure. In case they do *not* re-appear, a violation of a faithfulness constraint (Dep-IO) will be recorded by *Eval.*

The lexical entries underlying the analysis in Figure 5 are specified as shown in (14) (adapted from Kuhn 2003: ex. 140):

(14)	*did*	I	$g_1 = \lambda(\mathcal{M}*)$ $(g_1\ \textsc{pred}) = \text{‘}\textsc{do}\text{’}$ $\{\, g_1 = \uparrow \}$ $g_2 = \lambda(\mathcal{M}*)$ $(g_2\ \textsc{tns}) = \textsc{past}$ $\{\, g_2 = \uparrow \}$
	say	V	$g_1 = \lambda(\mathcal{M}*)$ $(g_1\ \textsc{pred}) = \text{‘}\textsc{say}\text{’}$ $\{\, g_1 = \uparrow \}$

In these entries, the functional annotations make use of local metavariables (such as g_1 and g_2) in the following way: The equation $g_1 = \lambda(\mathcal{M}*)$ defines g_1 as the variable name for an attribute-value structure that is λ-projected from the current element's c-structural mother (= the node I for *did*). The equation $(g_1\ \textsc{pred}) = \text{‘do’}$ introduces a PRED feature and value into the attribute-value structure. The third equation $\{\, g_1 = \uparrow \}$ identifies the local l-structure with the c-structural elements normal f-structure (i.e., its ϕ-projection; recall that $\uparrow$ is defined as $\mathcal{M}*$). What is crucial is that the third equation is enclosed in curly brackets, which means that it is applied optionally. Hence, the lexical specification will either be included in the f-structure or not. (Since the rest of the LFG structure leads to an identification of the f-structure projected from *did* and from *say*, maximally one of the two entries can introduce their PRED value to f-structure.)

The enormous variation opened up by this optionality is controlled by the faithfulness constraint Dep-IO, which in this setup can be formalized as in (15):

(15) Dep-IO (referred to as Fill in early OT work)
General OT formulation (Kager 1999: 68): ‘Output segments must have input correspondents.’

$$(\mathit{atomic\text{-}f\text{-}str}(\star) \rightarrow$$
$$\forall n, P.[(\mathit{cat}(n) \wedge \mathit{feature\text{-}path}(P) \wedge (\lambda(n)P) = \star) \rightarrow (\phi(n)P) = \star])$$

> "For all categories *n* and feature paths *P*, if ⋆ is an atomic value under *P* in the *λ*-projection from *n*, then ⋆ is also the value under *P* in the *ϕ*-projection from *n*."

Recall that in the application of the *Eval* function, every structural element in a candidate representation – i.e., every c-structure node, every local f-structure, and also every local l-structure – will be tested for all constraints. For the topmost l-structure seen in Figure 5, ⋆ will be instantiated to the PRED-value 'do', which *is* an atomic f-structure and which is also in the *λ*-projection of a node *n* (namely I) under a path *p* (namely PRED). So to satisfy the DEP-IO faithfulness constraint, PRED 'do' should also be in the f-structure for I, which it is not. This leads to the desired effect of capturing an insertion in c-structure which has no correspondence in f-structure as a DEP-IO violation.

To sum up, the insertions that are required to implement a generalized OT account are compatible with the restricted definition of *Gen*. By definition, the semantic information in a candidate's f-structure is always the same as the semantic information in the underspecified input f-structure Φ_{in}. Additional material can only occur in locally projected l-structures. While it is not forbidden to have infinitely many distinct candidate structures for an input f-structure, the restriction keeps the candidate set computationally tractable (Kuhn 2003: ch. 6).[22]

2.5 Excursion: The cognitive status of "directional" candidate set specification

As established in the previous subsection, it is possible to provide a declarative formal characterization of the language generated by an OT system. Thanks to the non-derivational character of (tuples of) LFG structures, it is possible to use the sharing of the semantic part of the structures as the defining element for candidate sets (independent of the question of how a computational system might be implemented that takes a string of words as an input and produces all fully specified LFG structure tuples with that surface string that are optimal for some input according to the OT system for a given language). Moreover, it can be shown that the task of determining whether a string of words is in the language generated by an OT system is not computationally undecidable. This subsection is an excursion that discusses a reaction that LFG practitioners might have when confronted with the multi-step breakdown of the abstract parsing task for an (LFG-based) OT system sketched in Figure 4: the assumption of a back and forth

---

[22] Exploiting results from Kaplan & Wedekind (2000), recursive loops that lead to infinite candidate sets can be captured in a tractable way.

of generation and parsing processes seems to go against the goal of developing a cognitively plausible model architecture to capture grammatical knowledge.

The intuitive algorithmic breakdown of parsing with plain LFG does not carry over to parsing in the OT-LFG framework, which necessarily has to incorporate a production-based directionality, while parsing models comprehension. Parsing with a plain LFG grammar follows the logic of the structure specification step by step: given a string, matching lexicon entries and c-structure rewrite rules are used to construct a set of c-structure trees spanning the string. To narrow the set down to the trees which correspond to a valid f-structure, functional descriptions from the lexical annotations and the rule annotations are then taken into account in a process of model construction (in a feature logic), and wherever we find a valid f-structure, we have one possible analysis for the input string. The intuitive simplicity of the algorithmic breakdown has presumably played a role in the attraction of the LFG formalism as a psychologically realistic framework – in particular as it contrasted with the model of Chomskyan derivational approaches, which work with a notion of an underlying deep structure (D-structure or numeration). The theoretically motivated transformation of an underlying deep structure into a surface structure does capture intuitions regarding the highly systematic relationship between expressions like *the cat drinks milk* and *what does the cat drink?* or between *she saw the cat* and *the cat was seen*. But in comprehension, a listener is confronted with the linear string from a surface structure (say, *the cat was seen*), and there is no cognitively intuitive algorithmic process that leads back to conceivable underlying deep structures. When spelling out a parsing procedure with OT-LFG, we now find ourselves in a similar situation: if we translate the bidirectional characterization of the set of valid structures for a given string into an algorithmic procedure, we do not arrive at a plausible rendition of what could be going on in comprehension.

One might suspect that these considerations challenge the cognitive plausibility of Optimality Theory. It should be noted however that there is an oversimplification in the reasoning that assumes a direct conceptual mapping of a declarative specification of some function (such as the function from a string of words to a set of c-structures associated with valid f-structures) to the seemingly straightforward algorithmic breakdown of this function. It is misleading in the general case to assume that an intuitively appealing translation of a composite function into some procedure is the only option for realizing the theoretically motivated function in a cognitive system. As a matter of fact, there would be no computationally tractable parsers for standard LFG if one relied on the simplemost translation of the conceptual steps underlying grammatical specification in LFG into an algorithm. As the discussion in Maxwell & Kaplan (1996) illustrates, LFG parsing performs a highly sophisticated interleaving of the various sources of grammatical and lexical knowledge. Vice versa, Edward Stabler's work on the formalization of Chomskyan derivational grammar models (e.g., Stabler 2011, 2013) shows that algorithmic solutions do not have to stick to the seemingly counterintuitive procedures in the underlying theoretical characterization.

The complicated procedural breakdown of the parsing task for OT systems follows in fact from the decision to incorporate an important consideration into the conceptualization of grammatical knowledge that has nothing to do with the procedural knowledge needed for parsing a particular given input string, but rather reflects a language learner's and adult speaker's conscious or tacit knowledge of the expressive *potential* that lies in the language system: for a speaker of language X to know the grammatical way of expressing something in X amounts to knowing which other potential ways of expressing the same thing are not available in X.[23] During the acquisition of X, the speaker will have learned from exposure to adult speakers' language behavior which realizational variants can be completely excluded. So, the adult speaker's grammatical knowledge may well be thought of computationally as a "hard-wired" input-output mapping that freezes the patterns which have stabilized in the competition system (superseding a dynamic acquisition phase, during which the relevant constraint rerankings were triggered for language learner).

As a side note, the "pre-compilation" of a cascade of optimality constraints with their step-by-step filtering effect into a single input-output function was subject to research in the context of OT systems that can be fully formalized with finite-state systems. Karttunen (1998) proposed a special finite-state operator (so-called lenient composition) that has the effect of turning a sequence of individual constraints formulated as transducers into a single transducer with the same effect as an OT competition.[24] To achieve a similar computational effect for a syntactic OT-LFG system, the internal data structures built up during parsing (following a chart-based or dynamic programming approach) would have to be re-designed to simultaneously incorporate a production-based and a comprehension-based directionality – which could then be instantiated in a single bottom-up algorithmic pass, avoiding direct bidirectionality processing (compare the "interleaved" bidirectional processing approach proposed in Kuhn

---

[23] When working with a classical grammar formalism, the formal model of a speaker's grammatical knowledge provides no way of making this differential knowledge explicit, yet to arrive at a particular formal grammar in language acquisition, the learner must have pruned away certain realization options that the language under consideration does not exploit.

[24] A similar approach is discussed by Frank & Satta (1998).

2000b). Since work in computational linguistics focusing on learning without any language-specific prior knowledge had already reached a relatively advanced state using different approaches, there was no substantial practical interest in putting the full OT-LFG account to use on a larger scale.

2.6 OT-style constraint ranking in broad-coverage grammars

Section 1.2 provided an illustration of the constraint ranking mechanism implemented in the XLE system, which is widely used in grammar development. The examples showed how violable constraints allow grammar writers to include rule variants for infrequently occurring constructions without causing a proliferation of implausible readings for canonical constructions.[25]

The XLE implementation of violable constraints via a special *o*-projection provides some further mechanisms that are of high practical value in broad-coverage grammar development. The specification of the ranking of the optimality marks in (16) illustrates some of these mechanisms. We will shortly go through a number of details, but first of all we note that the ranking is specified in the configuration section of the grammar code. This means that the relative ranking of the marks (and hence of the soft constraints) can be adjusted for different application scenarios of the grammar without changing the grammar code itself. Thus the ranking specification can be used to flexibly adjust the grammar to peculiarities of certain language registers or text domains.

(16) OPTIMALITYORDER +PPasOBL (UnderstoodObj TypeCoercionToTimeNoun) NOGOOD Missing3SgMarking STOPPOINT Fragment.

In (16), the highest-ranking mark PPasOBL is preceded by a plus sign. This indicates that in the filtering of analyses, the mark is not considered to be negative, but positive. When the available readings differ in the count of PPasOBL, the ones with the *maximal* number of marks survive. This provides grammar writers with a way of giving preference to a certain variant rather than having to "punish" a different variant, which, depending on the feature representation adopted, may be impractical. Rule (17) exemplifies the introduction of PPasOBL as a preference mark for the oblique object analysis of PPs (like in *wait for someone*). The oblique reading will be preferred over the alternative of analyzing the

---

[25] Computationally, we can note in the light of Section 2.4 that XLE's OT-style constraint ranking is not normally used to modify the notion of grammaticality from the base grammar; hence, the additional complexity of a two-way application of the grammar in parsing and generation mode does not arise.

PP as an adjunct whenever both are available. This has the effect of reducing the number of parses for a considerable number of input sentences. In real-world uses of grammars, the available information makes it often hard to make an informed decision. So, in many application scenarios, it may be preferrable to make a (more or less arbitrary) decision in favor of one of the variants.[26]

(17)
$$\text{VP} \longrightarrow \begin{array}{c}\text{V}\\ \uparrow=\downarrow\end{array} \quad \left(\begin{array}{c}\text{NP}\\ (\uparrow \textsc{obj})=\downarrow\end{array}\right) \quad \begin{array}{ll} & \quad\text{PP}^*\\ \{ & \downarrow \in (\uparrow \textsc{adj})\\ | & (\uparrow \textsc{obl}_\theta)=\downarrow\\ & \text{PPasOBL} \in o(*) \quad \} \end{array}$$

The ranking in (16) also illustrates the workings of parentheses and of some specially defined keywords. The marks UnderstoodObj and TypeCoercionToTimeNoun, which were introduced in Section 1.2, are now jointly enclosed in parentheses to treat them as equally ranked. In grammar writing practice, such constraint ties are frequently used for phenomena that are independent from each other, since there is no grammar-internal justification for giving preference to one of them.

To the right of the two we see the mark NOGOOD. This is a predefined keyword that has the effect that all marks that follow receive a special interpretation that is best explained with a concrete example. Consider Missing3SgMarking: this mark is introduced in the definition of the template SubjNon3SgAgr in (18). This template is used in present tense verb forms of English like *I laugh* or *they laugh*. There is a similar template for third-person singular forms like *she laughs*. The third disjunct in (18) covers the use of the form *laugh* with a third-person singular NP like in **she laugh*, which is ungrammatical in standard English. By providing this option, the grammar will robustly cover agreement mistakes or it can be used for varieties of English that include this variant.

(18)
$$\textsc{SubjNon3SgAgr} \equiv \begin{array}{l} \{\ (\uparrow \textsc{subj num}) = \textsc{pl}\\ |\ (\uparrow \textsc{subj num}) = \textsc{sg} \quad (\uparrow \textsc{subj pers}) \sim= 3\\ |\ (\uparrow \textsc{subj num}) = \textsc{sg} \quad (\uparrow \textsc{subj pers}) = 3\\ \quad \textsc{Missing3SgMarking} \in o(*) \qquad\qquad \} \end{array}$$

---

[26] Contrary to the situation with very infrequent constructions that were discussed in Section 1.2, the filtering may here have the effect that a contextually inappropriate analysis is chosen over the more appropriate analysis (for instance in *Sue was waiting for hours*). But in a range of applications this may not be too problematic, while a reduction of the sources of ambiguity can be extremely helpful during the process of extending the grammar or fixing a certain problem. When the grammar is used in application scenarios in which it can be harmful to occasionally choose the contextually inappropriate variant, the preference mark can simply be taken out of the ranking specification, so the parser outputs both variants.

With the ranking specified as in (16), *she laugh* will receive an analysis; however due to the use of the NOGOOD mark, it will be labeled as ungrammatical by the parsing system.

A last point illustrated by (16) is the predefined mark STOPPOINT. This mark offers a way for grammar writers to control the computational behavior of the parser. Putting an optimality mark to the right of STOPPOINT (like Fragment in the example) has the effect that the functional descriptions that it marks will not be used at all in the first pass of running the parser. However, if parsing leads to an empty set of valid analyses, the parser will be reset for a second pass, this time including marks like Fragment. This mechanism can be used to make the grammar more robust without compromising the runtimes of the parser for "well-behaved" input sentences. A typical example for using STOPPOINT in the ParGram grammars is as part of a fall-back option for covering strings that do not receive an analysis with the standard root symbol of the grammar. An artificial category like FRS (for fragments) is provided as an alternative root symbol. (19) is a schematic depiction of a recursive rule for such a category. Its purpose is to collect c-structure fragments such as NPs, PPs and certain incomplete verb projections. With such a rule, problematic input sentences (e.g., with misspellings or rare constructions) will still receive an analysis for the parts that are covered correctly. The partial f-structure contributions are collected in a first/rest data structure. Note that each fragment introduces one Fragment mark, so the filtering mechanism will output the option with the fewest (i.e., on average the largest) fragments. It is even possible to use several instances of STOPPOINT in a ranking to potentially trigger several resets.

(19)
$$\text{FRS} \longrightarrow \{ \begin{array}{c} \text{NP} \\ (\uparrow \textsc{first}){=}\downarrow \\ \textsc{Fragment} \\ \in o(*) \end{array} \mid \begin{array}{c} \text{PP} \\ (\uparrow \textsc{first}){=}\downarrow \\ \textsc{Fragment} \\ \in o(*) \end{array} \mid \begin{array}{c} \text{VP} \\ (\uparrow \textsc{first}){=}\downarrow \\ (\uparrow \textsc{subj pred}){=}\text{‘pro’} \\ \textsc{Fragment} \in o(*) \end{array} \} \begin{pmatrix} \text{FRS} \\ (\uparrow \textsc{rest}){=}\downarrow \end{pmatrix}$$

As the various mechanisms we briefly discussed show, a flexible ranking for specially marked parts of the grammar conveniently puts grammar writers in a position of exerting control over the set of valid structures that an LFG grammar will assign to a given input string in parsing (and similarly for a given input f-structure in generation).[27]

---

[27] One way of looking at the addition of rankable constraints to an LFG grammar writer's means of expression is to include ideas from grammatical frameworks that never factorized the task of disambiguation out, most notably Constraint Grammar (Karlsson 1990).

An alternative approach to controlling the space of ambiguities is the use of probabilistic techniques, which have been widely applied in the context of structural analysis of realistically occurring language (Collins 1997, Riezler et al. 2000, 2002). Here, the approach to the ambiguity problem is to rely on supervised training of probabilistic models that predict the distribution of alternative linguistic representation structures, dependent on a variety of contextual factors. If a sufficiently large training corpus is available that was manually disambiguated by competent speakers of the language, a so-called treebank, the complex interaction of knowledge sources on the contextually appropriate choice of readings can be captured quite reliably. When the sentences parsed in the application scenario are similar enough to the training corpus, the disambiguation quality that can be reached is typically higher than in a knowledge engineering approach of classical grammar writing, since statistically relevant patterns of all kinds (e.g., word order preferences, lexical-semantic argument selection preferences, but even statistical effects unrelated to grammatical knowledge) are learned “in passing”.

The XLE system offers both the optimality ranking approach discussed in this section and a probabilistic filtering approach that relies on supervised treebank training. In the practice of broad-coverage grammar development with a highly expressive formalism such as LFG, both mechansisms have their place and a combination is arguably the most effective way to go: a probabilistic approach exploits the empirical distribution of interacting factors, such that a sufficiently expressive probabilistic formalism (or machine learning model) will induce implicit statistical knowledge even about patterns that could not (yet) be captured in symbolic terms (see, e.g., Cahill et al. 2007, Forst 2007). On the downside however, a plain probabilistic approach leaves little leeway for grammar writers to inject specific symbolic knowledge about certain constructions. By using symbolic optimality ranking as a pre-filter for the set of candidate analyses going into treebank training, the grammar writers can easily experiment with alternative strategies (King et al. 2000).[28]

---

[28] It has to be noted that in the combined setup, the grammar writer is not in a very informed position to determine the relative ranking among the optimality constraints for multiple different linguistic constructions – for instance UNDERSTOODOBJ and TYPECOERCIONTOTIMENOUN from Section 1.2. This is something that an empirically informed training procedure can do better. The utility of symbolic soft constraints for linguistically informed ambiguity management lies more in the flexibility of experimenting with preference, dispreference and delayed execution (via one or more STOPPOINT marks) of constraints. By leaving the ranking of OT marks within a section (before NOGOOD, between NOGOOD and STOPPOINT, etc.) very flat through the use of parentheses, the ranking decision is postponed to the subsequent probabilistic filtering module.

There are a number of publications that report on the use of ranked constraints in various contexts of grammar specification, for instance Zaenen & Crouch (2009), Bögel et al. (2009), Dione (2014).

3 Linguistic applications of the competition-based concept of grammaticality

Section 2.6 provided details on the OT-style ranking mechanism that offers very effective functionality for ambiguity management in broad-coverage grammar development. We now go back to the original, theoretically motivated OT syntax model that employs competition among candidates to determine the grammatical way of expressing an underlying meaning. The model has been broadly employed to (a) systematically derive variation patterns within a language and (b) predict typological patterns across languages.

A broad range of syntactic phenomena have been addressed with OT syntax approaches. We will take a closer look at a few accounts in this and the subsequent sections – mostly to illustrate some specific properties of OT systems, in particular in the guise of OT-LFG and extensions that have been proposed. A full overview of all important phenomena addressed in the literature is beyond the scope of this chapter.[29] This section focuses on two important predictive schemes that the OT approach offers at the interface between syntax and morphology. Section 3.1 shows how morphological blocking phenomena can be derived in a very general way. Section 3.2 reviews the harmonic alignment account of the typological spectrum of differences in argument linking.

3.1 Generalizing blocking accounts to incorporate morphology-syntax competition

LFG's system of corresponding parallel representations can be straightforwardly integrated in the competition-based grammaticality account of OT. This opens up a path for formulating a generalized theory of morphological blocking that was described before a generic mechanism of comparison was included in the overall formal framework. Prominent examples are the accounts by Andrews (1982, 1990), building on top of the Elsewhere Principle from phonology (Anderson 1969). The idea of morphological blocking offers an explanation of how

---

[29] Important areas excluded for space reasons are for instance positional alignment accounts of phrase structure such as Sells (1999, 2001). Sten Vikner and collaborators have worked out a detailed account of object shift in OT (Vikner 2001, Engels & Vikner 2014).

within a morphological paradigm such as the inflection of English verbs in present tense, an unmarked form (like *laugh*) can fill all cells in which no explicitly marked form (like the third person singular form *laughs*) is available. When alternative forms are available that express different degrees of specificity with respect to certain morphosyntactic features, the existence of a marked form for some specific feature combination (or position in a morphological paradigm) blocks the use of an unmarked form for this particular combination: *laughs*, which is marked for PERSON and NUMBER (to the values 3 and SINGULAR, respectively), blocks the unmarked *laugh*, which is underspecified for PERSON and NUMBER. Technically, Andrews (1982) proposes a blocking condition which states that a less specifically marked form A cannot be used in a position X if there is a form B that comes with a more specific marking, subsumed by A's specification.

With a competition-based definition of grammaticality, blocking effects can be construed as a consequence of general constraint interaction (Bresnan 2002, 2001a): the unmarked form is assumed to incur faithfulness violations, since it does not explicitly realize the underlying feature information in the input. For each inflectional category, a faithfulness constraint (e.g., $\text{FAITH}^{\text{NUM}}$ for number) checks whether a surface form accurately marks the underlying feature. On the other hand, a markedness constraint is assumed for each specific feature value, punishing the explicit marking of this value (e.g., *PL "avoid marking the plural explicitly", *SG "avoid marking the singular"). The markedness constraints implement the tendency in natural language to keep expressions as concise as possible. On the basis of these two antagonist constraints, learning their relative ranking for a given language[30] has the effect of learning in which paradigm cells to use a marked form vs. the unmarked form:[31] if *PL outranks $\text{FAITH}^{\text{NUM}}$ in a language, the plural (of the word class under consideration) is realized by an unmarked form in this language; under the reverse ranking, a marked form is used for plural. For fusional morphology, in which a single morpheme (like for instance the *-s* in English present tense verb forms) can realize person and number simultaneously, conjunctive faithfulness constraints to *sets* of inflectional categories have to be assumed besides faithfulness to an individual inflectional category, for instance $\text{FAITH}^{\text{PERS\&NUM}}$ (Bresnan 2001a: ex. 22). The verb inflection paradigm for present tense in modern English can be predicted by the following ranking: *PL, *1, *2 $\gg$ $\text{FAITH}^{\text{PERS\&NUM}}$ $\gg$ *SG, *3 $\gg$ $\text{FAITH}^{\text{PERS}}$, $\text{FAITH}^{\text{NUM}}$. Plural as well as first

---

[30] The learner acquires the constraint ranking through exposure to output produced by adult speakers; the speakers' underlying input has to be inferred from the situational context.

[31] To capture the finegrained differentiations inherent to inflectional paradigms, the faithfulness constraints have to be parametrized, for instance to specific verbs/verb classes for which learners have to learn distinct patterns.

and second person is never marked, since the markedness constraints for these feature values outrank all faithfulness constraints. For the combination of PERSON SINGULAR and NUMBER 3, a fusional form is used, since faithfulness to the combination of PERSON and NUMBER outranks the markedness constraints *SG and *3. For the other PERSON/NUMBER combinations, the fully unmarked form (*laugh*) is used, since $\text{FAITH}^{\text{PERS}}$ and $\text{FAITH}^{\text{NUM}}$ rank lower than the markedness constraints *SG and *3.

Given this characterization of the task of learning inflectional paradigms, the following typological spectrum is opened up by the interaction of faithfulness and markedness constraints: (i) when the markedness constraints outrank all faithfulness constraints, a paradigm with no inflectional distinctions follows; (ii) when faithfulness outranks all markedness constraints, all paradigm cells go along with an explicit forms; (iii) blocking effects occur when faithfulness is ranked in between certain markedness constraints. The account then predicts features (or feature combinations) whose markedness constraints outrank faithfulness to be realized by an unmarked form.

The OT-LFG framework makes it even possible to generalize the OT account of blocking to situations where it is not just alternative synthetic word forms that could be used to express an underlying feature bundle, but syntactically complex expressions are an additional alternative. Speakers of English have learned for instance when to use the analytical realization of a comparative adjective or adverb (such as *more quickly*) instead of a synthetic realizations (such as **quicklier*). In LFG's system of imperfect correspondence among parallel representations (Bresnan 2001b), such alternatives are just different surface realizations of the same f-structure. Now, the set-up in OT-LFG is to have such alternatives compete for the status of the most harmonic candidate. It is clearly possible for a theorist to find constraint sets that will lead to analytical realization of a phenomenon in one language an synthetic realization in another. This alone may not be considered a strong argument in favor of a competition-based framework using parallel representation structure like LFG. However, when it can be shown that having analytical and synthetic alternatives side-by-side in the candidate set for realizing an input (i.e., expanding the same partial f-structure) leads to a systematic explanation of variability in inflection paradigms that mix analytical and synthetic realizations – via a generalization of the morphological blocking effect – this constitutes persuasive evidence that the architecture of the theoretical account does capture aspects of the human cognitive system quite well. This is exactly what Bresnan (2001a) achieves by the account of negation in varieties of English she proposes.

The tableaux in Figure 6 illustrate competitions among different analytic c-structural realizations of negation; in Bresnan (2001a: ex. 43), these tableaux serve to motivate the constraint set for an account in which an analytical form blocks a synthetic form. The analysis assumes two alternative realizations for the negation of verbs or auxiliaries in English: *not* can adjoin to the auxiliary itself, which is realized in I^0, or it can adjoin to the VP. (For the modal verb *can*, the orthographic rules of English happen to make the distinction visible in the written form.) By hypothesis, both alternatives can have the meaning of a wide-scope negation, but only the latter can mean negation of the VP. Bresnan assumes one markedness constraint for each of the two possible sites for adjoining negation, *neg-vp and *neg-i; in English *neg-vp is ranked higher than *neg-i. Faithfulness to the negation scope (i.e., the constraint faith$^{\text{NEG}}$) however is ranked higher than both markedness constraints. As an effect, the neg-i option (*cannot*) arises as the optimal realization for a wide-scope reading of negation, whereas the more marked analytic form (*can not*) is required to express the VP scope of negation.

¬(poss(work(he)))	faith$^{\text{NEG}}$	*neg-vp	*neg-i
☞ a. *he cannot have been working*			*
b. *he can not have been working*		*!	

poss(¬(work(he)))	faith$^{\text{NEG}}$	*neg-vp	*neg-i
a. *he cannot have been working*	*!		*
☞ b. *he can not have been working*		*	

Figure 6: Two tableaux from Bresnan (2001a: ex. 43)

For the realization of negated forms of the auxiliary *be* in various varieties of English, analytical forms compete with synthetic forms: the negated third person singular can be realized as *is not* or as *isn't*. Moreover, a synthetic form that is unmarked for person and number is available: *aren't*. Interestingly, although Standard English has a marked form for declarative first person singular (*am*), there is a lexical gap for the negated first person singular.[32] In negated interrogative clauses, this gap is – for many speakers – filled by the unmarked *aren't* (examples from Bresnan 2001a: ex. 14-15):

(20) a. * Am I not going?
b. I am not going.

---

[32] For synchronic learnability of such an idiosyncratic gap, it is not relevant how the gap came about. Bresnan (2001a: fn. 26) mentions stigmatization of an older synthetic form *ain't* as a potential explanation.

(21) a. Aren't I going?
b. * I aren't going.

This effect can be derived in an OT-LFG analysis that assumes high-ranking markedness constraints punishing analytic negation adjoining either to C^0 (which would yield **Am not I going?*) or to VP (yielding (20a) (Bresnan 2001a: ex. 61-63). These markedness constraints outrank the constraint $\text{FAITH}_{be}^{\text{PERS\&NUM}}$, which regulates faithfulness to the person and number feature for the auxiliary *be*. A hypothetical synthetic form **amn't* marked for person and number is unavailable due to the idiosyncratic lexical gap in English that was just discussed.

How can the grammatical framework model that a person acquiring English learns about such an idiosyncratic gap? In the OT framework, it has been proposed to assume a constraint LEX parametrized for specific lexical material and incurring a violation whenever it is used. Learners of a language with an idiosyncratic gap will rank the respective LEX constraint above all other constraints (because adult speakers never use this material when one would expect them to, based on the context).[33] For the English speakers using (21a) rather than (20a) to fill the lexical gap in the interrogative case, the third analytical option, adjoining negation to I^0, is ranked lower than $\text{FAITH}_{be}^{\text{PERS\&NUM}}$. This has the effect that the pattern in (20)/(21) is predicted: when *be* can be realized in I^0 as is the case in a declarative clause, the fully marked analytic form is the most harmonic; in a question however, where *be* is in C^0, the unmarked form *aren't* wins out.

This analysis demonstrates the explanatory potential coming from a competition-based account of grammaticality that makes distinct grammatical means available in candidate sets based on an input corresponding to the underlying content.

3.2 Harmonic alignment

In many languages, certain properties that argument phrases like subjects and objects can bear (e.g., first person vs. third person, full NP vs. pronoun, overt case marking, but also the choice of grammatical relation itself) are correlated with the availability of grammatical syntactic realization options, for instance in

---

[33] Note that assuming constraints sensitive to specific lexical material in a language does not go against the principle of richness of the base, which excludes language-particular restrictions on the candidate set. However, it is not fully compatible with the assumption of a (finite) universal set of constraints. From the point of view of learning algorithms, it seems quite plausible however that instances of some constraint schema can be parametrized by lexical items that the learner has added to their inventory. See also van der Beek & Bouma (2004) for a discussion of language-particular lexicon properties within OT-LFG.

a clause with a transitive verbs. In the Australian language Dyirbal for example, the case marking patterns for transitive verbs are sensitive to such properties: "1st/2nd person pronouns are marked when they are objects, but not when they are subjects" (Aissen 1999: 674). When looking at the distribution of the relevant properties across languages, typologists have made the following observation: it is possible to organize these properties along markedness scales in such a way that the different scales tend to align with each other (Silverstein 1976). In a relational scale, subjects are used for the most salient/central arguments, followed by objects for less salient arguments, followed by obliques. In terms of thematic roles, agents are more prominent than patients. Animacy hierarchies have first and second person pronominals at the top of the scale, followed by third person pronouns, common nouns referring to humans, to animate referents and finally inanimate referents. Aissen (1999, 2003) develops an influential OT syntax account[34] demonstrating that many fine-grained observations from typological studies can be explained when the following assumption is made: the OT constraints that make reference to the various markedness or prominence scales cannot be arbitrarily (re-)ranked, but there are universal subhierarchies that are imposed over families of related constraints. These subhierarchies, technically implemented by the mechanism of harmonic alignment, have the effect that the various different markedness or prominence scales are systematically aligned.[35] For certain pairs of constraints, the relative prominence is fixed *a priori*,[36] while their interaction with other factors can still be freely learned from the observations.

For instance, Aissen's (1999) account explains the split ergativity patterns in Dyirbal, where under specific conditions argument phrases are realized without case marking: the subject is generally unmarked when it is first or second person; the object is unmarked when it is third person. When the subject is third person, case has to be marked; likewise when the object is first or second person. (22) shows the OT subhierarchies that ensure the alignment of the relational scale and the person scale (combining first and second person as "local"). In essence, it is more marked to align a high element from one scale with a low element

---

[34] Aissen does not explicitly couch her account in an OT-LFG setting, but it is fully compatible and has greatly influenced subsequent OT-LFG work.

[35] The technique of harmonic alignment across prominence scales was already introduced by Prince & Smolensky (1993) for phonological features (sonority and syllable structure).

[36] Zeevat & Jäger (2002) demonstrate that the effect of the subhierarchies may also follow empirically from a systematic skewedness in patterns of usage. To the extent that this skewedness follows from invariant aspects of human social interaction, etc., it is presumably hard to tell empirically whether *a priori* rankings should be assumed within in the language faculty.

from another scale than to align either two high elements (Su/local) or two low elements (Ob/3rd).

(22) a. *Su/3rd ≫ *Su/local
     b. *Ob/local ≫ *Ob/3rd

To capture the case marking patterns, each of the alignment constraints is locally conjoined with the constraint $^*\varnothing_{\text{CASE}}$, which punishes expressions that do not use overt marking for the respective combination – similar to faithfulness constraints. Local conjunction (C_1 & C_2) of two distinct OT constraints C_1 and C_2 within a given local domain *D* is a mechanism that captures the fact that in certain cases, it can be more marked when the two constraints are violated within the same local domain, for instance the same argument phrase, than when there are two independent violations of C_1 and C_2 (Smolensky 1995). Since the local conjunction C_1 & C_2 can be ranked independent of the individual constraints, special markedness patterns that are sensitive to the conjunction can be learned.

In Aissen's (1999) account, the universal subhierarchies assumed for alignment constraints like *Su/3rd carry over to the family of their local conjunctions:

(23) $^*\varnothing_{\text{CASE}}$ & *Su/3rd ≫ $^*\varnothing_{\text{CASE}}$ & *Su/local

Learning the case marking patterns for a particular language amounts to learning where within the universal subhierarchy a structural markedness constraint for the relevant grammatical feature is placed in that language – here the constraint $^*\text{STRUCT}_{\text{CASE}}$. In Dyirbal, $^*\text{STRUCT}_{\text{CASE}}$ splits up both of the two hierarchies from (22):

(24) a. $^*\varnothing_{\text{CASE}}$ & *Su/3rd ≫ $^*\text{STRUCT}_{\text{CASE}}$ ≫ $^*\varnothing_{\text{CASE}}$ & *Su/local
     b. $^*\varnothing_{\text{CASE}}$ & *Ob/local ≫ $^*\text{STRUCT}_{\text{CASE}}$ ≫ $^*\varnothing_{\text{CASE}}$ & *Ob/3rd

Hence, it is more harmonic to avoid using a structural case marking on an argument when this is the subject and first or second person, while for third person subjects the high ranking of the conjunction $^*\varnothing_{\text{CASE}}$ & *Su/3rd, excludes an unmarked subject in favor of a case-marked one.[37]

---

[37] We will come back to Aissen's harmonic alignment account in Section 4.2, as it forms the central target of Newmeyer's (2002) critique of functionally motivated constraint sets.

4 Extensions and debates

The competition-based definition of grammaticality in OT with its typological predictions attracted considerable attention in linguistic research communities, at the same time triggering debates about consequences of the new formal framework. Extensions were proposed to capture aspects of language(s) that the standard OT setup does not bring out. One such phenomenon is free variation, which one would expect not to exist under a plain OT approach. Section 4.1 discusses stochastic OT, an extension of the OT approach that does capture free variation.

Section 4.2 addresses a debate regarding the motivation of OT constraints. A substantial part of the OT community has been following the practice of providing a motivation for each constraint they assume which is grounded in functional considerations (for instance physiological considerations in OT phonology). This led to controversies, which are illustrative for the conceptual status different researchers assign to the constraints formulated in a theory of grammar. Section 4.3 steps back and discusses some of the cognitive considerations that led to the proposal of a competition-based account of knowledge of grammar in the first place. The section links this specifically to the question of learnability.

A second important extension of the basic architecture, bidirectional OT, is discussed in Section 4.4. It is motivated, *inter alia*, by the so-called phenomenon of word order freezing in languages with a (relatively) free order. In word order freezing, a clausal pattern that one would actually expect to be ambiguous *de facto* receives only one interpretation.

4.1 Extension I: Stochastic OT

One counterintuitive prediction of the competition-based definition of grammaticality is that languages should display very little (if any) free variation among two equally grammatical ways of expressing the same thing – for example *we need a more catchy title* vs. *we need a catchier title.* Even when it is just some minor and low-ranking constraint in which the two realization options differ, the OT system will by definition predict one variant to be ungrammatical for the relevant input.[38] Most natural languages *do* however offer free variation for certain lexical or grammatical means – there is for instance a certain amount of free word order variation in many languages.

---

[38] Of course, two equally harmonic candidates *can* arise when the relevant constraints are tied. In more comprehensive grammatical accounts however, this modeling option will only be available in exceptional circumstances, since most constraints play a role in multiple constraint interactions. So other phenomena will enforce a resolution of the ties.

The circumstance that a standard OT system covering a non-trivial range of phenomena is extremely unlikely to ever predict free variation is concealed by the fact that linguistic studies commonly focus their attention on a particular family of phenomena. When isolating a specific set of constraints that is relevant for deriving the observations regarding these phenomena, the possibility of ranking two or more constraints at the same level for a given language (= a constraint tie) *does* create a basis for explaining the systematic occurrence of free variation. For instance, Bresnan's (2001a) account of English auxiliaries discussed in Section 3.1 predicts variation among *cannot* and *can't*. However, for a more comprehensive account of grammatical knowledge, we have to assume that all the constraint sets posited for certain phenomena are combined in one larger constraint set. As a consequence, the effect of most constraint ties will go away – since the alternatives will differ in properties that are of relevance for some independent account (e.g., *cannot* has an extra syllable).

The problematic implications that standard OT has for free variation triggered several independent proposals for an extension of OT systems that will naturally predict free variation (see, e.g., Müller 2014, Asudeh 2001). One of the most influential proposals is known as stochastic OT (Boersma 1998, Boersma & Hayes 2001).[39] It preserves most of the original OT architecture; the key modification is that the ranking of the OT constraints is no longer viewed as fixed and discrete, but (1) the rank of a given constraint is a value on a continuous scale, and (2) the constraints are assumed to oscillate stochastically around their (mean) rank. Hence, at the time of harmony evaluation for a particular OT competition, it is possible with a certain probability for two constraints that are close in rank to effectively swap on the prominence scale. As an effect, a stochastic OT system (SOT) can predict variation patterns. The learning algorithm proposed for SOT operates with incremental error-driven adjustment of the constraints' mean rank, which even puts the learner in a position to replicate the quantitative distribution pattern in the observed variation data. Asudeh (2001) shows that in combination with a harmonic alignment analysis following Aissen (1999), SOT can derive optionality patterns in Marathi (Indo-Aryan, India): for non-volitional transitive verbs like *saapaḍṇe* ('to find'), either of the two arguments can be realized as the subject (while the other is realized as the object).

Bresnan et al. (2001) demonstrate with an analysis of the corpus distribution of passives that the SOT approach, again combined with Aissen's (1999) harmonic alignment analysis, can explain strong quantitative effects in a language like English (which does not categorically enforce passive for certain person constellations among the arguments of transitive verbs) in parallel to strictly categorical

---

[39] A similar account was proposed by Anttila (1997).

patterns in Lummi (Straits Salish, British Columbia). In Lummi, the realization of a transitive verb with a third person agent and a first or second person patient in active voice is ungrammatical. The underlying input has to be realized in passive voice. Now, although in English a clause like *she invited me* is not ungrammatical, Bresnan et al.'s (2001) study showed that in corpora of spontaneous spoken English, there is a significant statistical effect of an elevated passive use in this constellation (i.e., *I was invited by her*) – a circumstance that is exactly what one would expect when the standard OT treatment of Lummi is extended to English in a stochastic OT framework.[40]

4.2 Functional motivation of the constraint set

In any linguistic account that makes use of abstract descriptive categories such as 'syllable', 'subject', 'passive', 'quantifier', etc., the symbolic expressions assumed to describe formal and content-related properties of linguistic utterances are theoretical constructs. They are not directly observable. However, most linguistic theories attempt to choose their central descriptive representations in a way that permits a mapping to empirically observable properties based on as few assumptions as possible: phoneme representations are chosen based on semantically distinguishable minimal pairs, for the definition of syntactic notions like subject, operationalized tests are advanced, etc. In the same vein, the candidate representations in most OT work (and definitely in OT-LFG) are chosen under an operationalized regime assuming that all candidate distinctions can be derived from the surface distribution and contextual clues reflecting semantic distinctions.

What about the choice of constraints used to drive the typological predictions? It is important to notice that even with perfectly uncontroversial, empir-

---

[40] In their criticism of Boersma & Hayes (2001), Keller & Asudeh (2002) argue that viewing a stochastic OT system not just as a model of variation/optionality, but of some notion of graded grammaticality tied to corpus frequencies, is conceptually problematic since it blurs the standard distinction between competence and performance. It should be noted however that certain systematic observations regarding quantitative distributions in corpus data seem to make it inevitable to revise some standard assumptions. Compare Bresnan's (2011) autobiographical notes: "Strikingly, the rare, marginal, and 'incorrect' construction types in large collections of English language usage parallel the rare grammatical phenomena that can be found across languages of the world. Moreover, judgments of ungrammaticality are often unstable and can be manipulated simply by raising or lowering the probability of the context. Most remarkably, language users have powerful predictive capacities, which can be measured using statistical models of spontaneous language use. From all these discoveries I have come to believe that our implicit knowledge of language has been vastly underestimated by theoretical linguistics of the kind I had practiced." (Bresnan 2011)

ically grounded candidate representations, there are generally many extensionally equivalent choices of the constraint set for deriving the same distribution of optimal candidates (= the predicted language typology). For a given constraint set, an alternative set of *ad hoc* constraints with the same empirical prediction can be constructed. OT systems are empirically underdetermined in this respect (and this is no design fault; many formal systems employed as scientific models are underdetermined along certain dimensions). Therefore, to convince oneself that an OT analysis does indeed reflect a linguistically valid pattern, it is important to exclude that one or more of the constraints are ill-justified and merely play the role of getting the predictions right. Hence, starting out in phonological OT work, it has become good practice to provide a plausible motivation for each constraint, independent from this constraint's role *within* the constraint set – a "functional" motivation. In phonology, many constraints can be given a motivation based on considerations of articulation, aerodynamics or perception, for instance "a constraint against voiced obstruents, e.g., the Voiced Obstruent Prohibition (VOP, *[+voice], *Laryngeal) can be said to be functionally grounded, since vocal fold vibration is difficult to sustain if the outgoing airstream is blocked." (Krämer 2017: sec. 3.2.3). In syntax, the argumentation often needs to be more indirect, for instance by putting forward general considerations of economy to motivate a constraint against movement in a derivational framework, such as STAY in Grimshaw's (1997) and similar frameworks. But throughout the application fields of OT, a wide-spread argumentation practice sees the need for independent justification of constraints beyond the fact that it reaches a particular effect within the factorial typology. Many researchers welcomed that OT syntax triggered a confluence of the formalist and the functionalist perspective on language and grammars.[41] Still, Newmeyer (2002) presents a vigorous argument against the conception of "functionally-based optimality theory" (FOT) accounts, specifically targeting Aissen's (1999, 2003) harmonic alignment account. As the argumentation shows however, and as Bresnan & Aissen (2002) argue in detail in their rebuttal of Newmeyer (2002) in the same volume of *Natural Language & Linguistic Theory*, the notion of constraints that Newmeyer's argumentation is based on is not the one inherent to the standard OT conception (which completely shifts the definition of grammaticality away from a rule-based system to the interaction of violable constraints). Newmeyer criticizes that by requiring constraints to be paired with an external functional motivation, FOT "incorrectly locates the form-function interplay in the mental grammar itself, rather than see-

---

[41] Haspelmath (1999) argues for the additional need to take diachronic evolutionary processes into account.

ing the response of form to function as emerging from language use and acquisition" (Newmeyer 2002: 43). Newmeyer draws into question whether "the claim that every constraint has a functional motivation" (Newmeyer 2002: 56) is empirically contentful for OT syntax. But if we take into account that constraints are abstract constructs which are not directly observable in any particular language, this formulation somehow reverses the need for justification that a theoretician should provide for their assumptions. Putting forward some plausible motivation for theoretical constructs, beyond the technically desired effect, responds to principles of scientific practice precluding arbitrariness in an underdetermined formal system. Providing a functional motivation for an OT constraints does not amount to an empirical *claim*, but it is part of the argumentation that the abstract choices made adhere to second-order principles of good scientific practice. It is only a full OT system that is empirically falsifiable; inadequacy may come to the surface when there is no way of extending a system which plausibly covers a core set of phenomena to clearly observable additional evidence.

4.3 Learnability in the context of the broader cognitive architecture

As has become clear from the discussions up to this point, a theorist's decision to move from a conventional generative grammar formalism to the competition-based formal model of grammaticality underlying OT does not merely mean that instead of working with hard constraints they now work with violable constraints. The status of familiar descriptive devices becomes fundamentally different with the different characterization of the set of well-formed analyses. Some of the debates that this development triggered have been already addressed in the previous sections – for instance the question how ineffability might be modeled and how optionality/free variation can be accounted for.[42]

But it is worthwhile to pause and consider the status of the components of an OT system as a model of the language faculty within our broader cognitive system. The competition-based frameworks of Harmonic Grammar (Legendre et al. 1990) and Optimality Theory (Prince & Smolensky 1993, 2004) were originally developed to reconcile (i) the potential of connectionist networks for learning complex input-output functions from exposure to data following up on work in the Parallel Distributed Processing framework (Rumelhart et al. 1986)[43] with (ii) the insights from linguistic theory in the generative tradition, which models

---

[42] Wunderlich (2006), in his encyclopedia article on OT in morphology and syntax, provides a list of fundamental questions that arise when adopting an OT approach.

[43] The collection edited by Smolensky & Legendre (2006) is devoted to this perspective, but it does not seem to be very prominent in linguistic debates.

systematic generalizations in a formal system. Optimality Theory is an attempt to gain ground towards resolving some of the most central challenges for the cognitive sciences: understanding how abstract systematic knowledge (which is best described using recursive symbolic systems, relying on logical inference) is implemented in connectionist architectures and how it blends with associative knowledge (which is best captured in subsymbolic terms). We know that the neurophysiological basis for all our cognitive systems, the human brain, is a large and complex connectionist network. For artificial connectionist networks, the potential to pick up complex patterns from empirical learning data has been convincingly demonstrated for many scenarios. However, the abstract symbolic concepts that are at the core of many linguistic accounts of grammar – allowing for a very compact characterization of very far-reaching generalizations – turn out to be hard learning targets for a bottom-up empirical learning procedure with the comparatively simple artificial networks available (Marcus 2001).[44]

Given the complexity of the brain and our very preliminary understanding of the interaction of cognitive subsystems available to humans, it is no surprise at all that there is still a gap between our current understanding of systematic knowledge, captured via abstract concepts, and what we know about the level of neurophysiological implementation. Yet, when looking more specifically at knowledge about language, there seems to be a certain degree of impatience in the research communities taking a conncectionist vs. an abstract symbolic approach – possibly because on both sides of the gap, mature theories and modeling frameworks have evolved substantially over the past decades, yet the key question of how the views go together remains rather open.

From the point of view of linguistics, it may seem that the concerns about the missing path across scientific levels are just a problem for cognitive scientists who believe that a connectionist implementation of linguistic knowledge needs to be spelled out in concrete terms. Under the working assumptions of many linguistic frameworks, details of a technical implementation are of subordinate importance as long as one can convince oneself that a symbolic approach could be implemented in principle. This thinking ignores however that many of the established frameworks, including LFG, had (and have) a major weakness when it comes to capturing the learnability of languages. This weakness is no embarassment *per se*, since it was never in the focus of research interests; but it implies that it is not even clear in principle how an abstract description of grammatical knowledge could be implemented at the neurophysiological level – where it can-

---

[44] Compare e.g., the systematicity debate started by Fodor & McLaughlin (1990) (Buckner & Garson 2019).

not be the case that the relevant language-specific knowledge is symbolically encoded, but some representation needs to be learned from observable indications. Formally, the Principles-and-Parameters Theory (Chomsky 1981) has an answer to the question of learnability: the framework assumes an articulate structural system to be innate, such that learning amounts to setting a small number of switches, the parameters. The Minimalist Program (Chomsky 1995) attempts to derive the complex structural displacement patterns (which are required to reduce the complex sound/meaning relationship available in natural languages to a uniform construction plan and which by assumption must be predetermined by universal grammar) as a consequence of a small set of assumptions that are justified on the grounds of simplicity of the theory. Through innate universal grammar, the learner of a language has access to the principles that govern the displacement patterns and thus the learner only needs to learn the language-particular choice of linearizing the displacement configurations (Chomsky et al. 2019). Language learning is here conceptualized as a process of setting a number of discrete parameters. What is not very clear however is how the language acquisition system interacts with other parts of the cognitive learning system, many of which are quite clearly responding to the statistical distribution of cues. But linguistic knowledge could not be acquired and put to use if it had no effective interfaces with the statistically sensitive parts of cognition. It is hard to imagine that a learner can find out about the space of possible constructions in a language when they cannot rely on expectations regarding *typical* (= highly frequent) ways of saying something; when the learner notices that certain expectations were incorrect, this will trigger a highly informative learning step regarding the relationship between the language system and contextual factors. For instance, a learner can only learn about a rare phenomenon like heavy NP shift as in (25) if they have a notion of a canonical order, so they can reconstruct the conditions for deviations.

(25) I gave [$_{\mathrm{PP}}$ to Sue] [$_{\mathrm{NP}}$ the books that I found on my aunt’s attic]

The aspect of statistical learning is where connectionist approaches turn out to capture the empirical behavior quite realistically – but a theory that construes language acquisition as an entirely different process provides no grounds for capturing such triggers and any frequency-related patterns.

The classical constraint-based theories of grammar, such as LFG and Head-driven Phrase Structure Grammar (see Przepiórkowski 2023 [this volume]), *do* emphasize the objective of finding psychologically realistic models of the cognitive processes of production and comprehension (i.e., parsing and generation algorithms that start from an information state that corresponds to what is available to a human listener or speaker). However, the goal of coming up with realistic algorithmic accounts capturing the information processing of real cognitive agents does not traditionally extend to the cognitive process of *learning* a language, i.e., acquiring the lexical and grammatical knowledge necessary to perform the tasks of production and comprehension. The grammar formalisms are not designed in such a way that there is a formal learning procedure that always starts from the same initial state, and then takes in observations from adult speakers of Bulgarian, English or Mandarin. But this would be required to have a falsifiable theory of the way grammatical knowledge is instantiated in cognitive agents. In the classical paradigm, the precise grammatical knowledge representation for a particular language is (still) specified by a scientific observer, the linguist, who is able to "look behind the scenes" and make far-reaching decisions about the use of certain descriptive means from a meta perspective – which is clearly not a realistic rendering of the information available to human learners (who however nevertheless reach the knowledge state robustly and fast). Of course, there are good research-strategic reasons why the classical paradigm stops short of also trying to model the cognitive process of acquisition: the grammatical knowledge that is available to adult speakers of the languages of the world is complex and the systematic workings of most language-particular systems are far from being understood. So one might say that the research community is still at the stage of clarifying what the exact targets for the acquisition process are, thereby avoiding a situation where it could not be truly judged whether a learning algorithm is on the right track from a theoretical point of view. An opponent could however argue that it is not clear whether the formalism that was designed so meta observers can specify a theory of adult linguistic knowledge provides the right concepts and interfaces to ever support a realistically learnable knowledge representation of grammar and the lexicon (for instance because it is unclear how associative knowledge merges in, as mentioned above). If there is any truth in this objection, the best strategy is probably to adopt a parallel strategy: advance systematic accounts of the adult linguistic knowledge and at the same time try to explore architectures that are better suited for modeling learning and for interfacing with knowledge that is more readily captured in a connectionist framework.

The design of Optimality Theory provides a link between the abstract symbolic level, tying in with established concepts from linguistic theory, and the level of connectionist implementation. From the point of view of LFG, the greatest conceptual gain from adopting an OT perspective might lie in the fact that this provides a fleshed-out learning algorithm (Tesar & Smolensky 1998), which is compatible with insights about the low-level generalizing behavior of connectionist approaches.

4.4 Extension II: Bidirectional optimization

The standard definition of grammaticality in an OT system is based on what is often called a speaker-oriented, or production-based competition. Here, the most harmonic candidate analysis realizing some underlying content representation is determined. The characterization of the competing candidates reflects the fundamental knowledge that a competent speaker of the language has: they know which is the grammatical way of expressing some thought in their language. When they learned their language, they had to exclude other ways that would be possible in principle. The candidate set and rerankable constraints are thus a straightforward rendering of the mathematical search space for learning an input-output function capturing the speaker's competence.

A competent language user however has an additional ability: the listener is (mostly) able to reconstruct what the speakers wanted to express in the given context. Formally, the disambiguation problem for a given surface form can be construed as the mirror image of the task of realizing some underlying representation with the grammatical means of some particular language. Hence, it is tempting to explore to what extent the same competition-based architecture can be applied to model our ability to disambiguate. The representational setup of OT-LFG makes it particularly easy to implement the reverse competition: for a listener-oriented, or comprehension-based optimization, all that needs to be altered from the standard scenario is the basis for defining the candidate set. Here, all candidate analyses sharing the same surface string are compared.

A realistic model of our cognitive ability to make disambiguation decisions of course has to incorporate a lot more than just grammatical and lexical knowledge. On reading an ambiguous request/instruction like (26) (compare (27a) vs. (27b)), a reader may exploit frequency knowledge about the phrasal verb *read in* vs. the simple verb *read*, which one might argue is part of their extended lexical knowledge. However the utterance context of the request will probably play a much more important role: Does the building have a physical library? Or is the reader receiving programming hints? Ultimately, reasoning about what the speaker/author meant will draw upon any available world knowledge.

(26) Read in the library.

(27) a. Read in the comma-separated data file.
  b. Read in the living room.

So, taking all relevant knowledge sources into account, there is an asymmetry between production-based and comprehension-based optimization. Nevertheless, it is a valid question what disambiguation decisions are made when there are no grammar-external clues. If we can isolate such cases, we might learn a lot about the way our grammatical knowledge is organized.[45]

A case in point are so-called word-order freezing phenomena, which have received considerable attention in OT frameworks. For languages with relatively free word order, the following type of effect is often reported: when there are no other disambiguating clues, listeners interpret examples as unambiguous that due to freedom of word order should actually have two possible interpretations. Bouma & Hendriks (2012), who provide a detailed discussion of OT treatments of word order freezing, give the Dutch example in (28):

(28) Dutch (West Germanic; Bouma & Hendriks 2012: ex. 4)
Fitz zag Ella.
Fitz saw Ella
Only 'Fitz saw Ella' (SVO), although structurally compatible with 'Ella saw Fitz' (OVS)

The interpretive preference for cases like (28) is directly predicted if one assumes that not only the determination of grammatical (surface) outputs follows a (production-based) optimization, but also the distinction among potential underlying interpretations in comprehension – assuming the very same constraint set.[46] Accounts that make use of this idea are called bidirectional optimization accounts. Early discussions of such an account in an OT-LFG setting are found in Lee (2001) and in Kuhn (2000a, 2003).

Assuming that comprehension-based competition plays a role in a model of grammatical knowledge immediately raises questions about the relationship between the two directions: in a standard OT setting, one would not want to assume in general that listeners *only* apply constraint evaluation on the possible analysis candidates of a surface string to retrieve the semantic interpretation; they should also double check that the surface string is also optimal in the reverse direction[47] – otherwise, a listener may end up with a candidate structure that is not

---

[45] Recall from Sections 1.2 and 2.6 that comprehension-based optimization is also predominantly used with the OT-style constraint ranking scheme implemented in the XLE system (Frank et al. 2001).

[46] Zeevat (2006) argues that bidirectional optimization is not an adequate account for word order freezing; but see Bouma & Hendriks (2012).

[47] The simple comprehension-based optimization *does* play a role in work in OT phonology. The mechanism of lexicon optimization, assumed by Prince & Smolensky (1993), is such a competition. Also, Tesar & Smolensky (1998) propose a procedure of robust interpretive parsing during the learning process.

even grammatical in the language that the speaker used. For illustration, let us consider what optimizations listeners have to take into account when processing the English sentence (29a) and the German sentence (29b), which is superficially a close correspondence of the English sequence.

(29) a. Lou hopes not to arrive before Sunday.
b. German
Lou hofft nicht vor Sonntag anzukommen.
Lou hopes not before Sunday to-arrive
'Lou doesn't hope to arrive before Sunday.' or 'Lou hopes not to arrive before Sunday.'

If it was enough in comprehension to determine the optimal most harmonic structure for the observed surface string, we would expect that there is no great difference between the processing of the English and the German example. However, since in German simple negation of full verbs is grammatical, whereas in English it is not, there is a difference in the number of readings available. For (29a), a listener of English would never come up with the matrix negation reading – even in a context that would strongly favor it. This observation can be captured if we assume that a listener verifies that the most harmonic candidate in the comprehension-based optimization (with meaning $\hat{m}$) is also the most harmonic in a production-based optimization (taking $\hat{m}$ as the input). Demanding that a form-meaning pair has to be optimal both among all production-based and among all comprehension-based candidates is called *strong bidirectional OT*.

An additional variant of combining the outcome of the two optimizations was pioneered by Blutner (1998, 2000). With a so-called *weak bidirectional optimization*, not only the optimal form-meaning pairs from a competition play a role in defining meaningful expressions. The "runner-up" form-meaning pair after removing the overall winner from the competition is defined to express a more specialized form-meaning relation, and this can continue down a scale of expressions. The idea is best illustrated with the well-known example (30):[48]

(30) a. John killed the sheriff.
b. John caused the sheriff to die.

---

[48] Although the competitions assumed in bidirectional OT accounts in pragmatics like the one sketched here are inspired by the OT systems used to characterize the grammar of a language, it should be noted that a weak bidirectional approach would presumably not work if the full set of candidates was assumed, most of which are ungrammatical. OT pragmatics work focuses on relating grammatical expressions of different structural shape to the spectrum of potential meanings that can express.

(30a) is the unmarked way of expressing that John killed the sheriff. Logically, (30b) is equivalent; however, on hearing this sentence (and not (30a)), most listeners will take the speaker to implicate that the sheriff died in an indirect way from John's actions, assuming Gricean maxims. Weak bidirectional optimality predicts this by assuming that the overall competition will make the form/meaning pair of sentence (30a) and a proposition with a plain instance of a killing event the most harmonic candidate in both directions. The more marked form (30b), paired up with a "specialization" of the meaning is weakly optimal.[49]

The fields of OT semantics and OT pragmatics which in essence build on top of the idea of bidirectional OT are among the most prolific areas in terms of publications (see for instance the *Stanford Encyclopedia of Philosophy* entry van Rooij & Franke 2020). It has to be noted that the role that the constraints play in OT systems modeling systematic patterns in pragmatics is slightly different from the grammaticality-defining role of the constraint set in OT phonology and OT syntax; nevertheless, there are many systematic connection points between OT syntax and OT semantics/pragmatics, discussed for instance by Beaver & Lee (2004).

5 Developments after the mid-2000s

This section starts out with a discussion of the developments in the OT framework after the phase of the highest research activity in the late 1990s and early 2000s (Section 5.1) and furthermore asks how aspects of language learning are captured in OT vs. in mainstream work in Computational Linguistics and Natural Language Processing since the 2000s (Section 5.2). Section 5.3 addresses the relatively recent developments of neural modeling, i.e., the application of "deep" artificial neural networks.

5.1 Developments after the peak research activity

Müller (2012), in the conclusion to his survey paper on OT syntax, notes that after a phase of very high research activity, there have been comparatively few OT contributions in the area of syntax – contrary to the situation in morphology, semantics/pragmatics, and most notably phonology. To a certain degree, this development also holds for OT-LFG work on syntax. According to Müller's analysis of the situation, many ideas from derivationally based work in OT syntax live on

---

[49] The formal properties of bidirectional OT are discussed in Jäger (2002).

in the research strand of the Minimalist Program, in which for instance the decision to apply one of a number of competing elementary operations like Agree, Merge, Move, Delete etc. is resolved in different ways across languages, which can be captured in a ranking account (Müller 2012: sec. 5).

In this section, we address the question: what was the further development in the part of the OT syntax community that assumes nonderivational candidate analyses – in particular OT-LFG? Section 4.3 above ended with the observation that the couching of LFG in an OT framework adds a plausible algorithmic account of learnability of grammars, which the original formalism was missing. Against this background, one might have expected an increase of activity rather than a reduction, for instance in the computationally oriented LFG subcommunity. One can only speculate about the exact reasons for trends in research communities, but there seem to have been framework-internal factors, which are discussed in this section, and external factors in the broader computational community, which will be discussed in Section 5.2.

Looking at the framework itself, the introduction of a competition-based definition of grammaticality in syntax research, or in a subcommunity of syntax research, did not go along with a fixed catalogue of new principles that readily leads to the formation of a homogeneuous and focused research paradigm. Rather, the introduction of OT can be seen as the starting point for addressing a broad bundle of phenomena and conceptual aspects that conventional formal grammar models were not able to capture. These aspects include quantitative aspects of linguistic knowledge that draw the strictly binary notion of grammaticality and the established split of grammatical competence and performance into question.[50] The fanning out of community activities into a whole range of development lines should probably not be seen as a failure of the new framework, but as a sign of the true complexity of empirical interrelations that transcended the scope of the convential approach due to its strategic idealizing assumptions. Under such circumstances, new developments committed to the elimination of overly far-reaching idealizations cannot be couched in a single formal framework. Regarding the quantitative aspects for instance, extensions like stochastic OT (Section 4.1) provide certain alternatives, but in particular work by Bresnan (2007), Bresnan & Ford (2010), Bresnan & Nikitina (2010) went on to explore a broader range of modeling options. For other aspects, bidirectional optimization and other extensions of the architecture promise the most explanatory account.

---

[50] In her acceptance speech of the Lifetime Achievement Award by the Association for Computational Linguistics, Joan Bresnan shares her view of the development of the various descriptive frameworks that points in this direction (Bresnan 2016).

In parallel to these architectural considerations, linguistic work continues to study empirically robust grammatical patterns for which symbolic abstractions have been established – exploring a phenomenon in new languages and/or interactions among phenomena. It is hence quite natural that depending on the focus of particular studies, authors would choose to use an OT-LFG framework or a classical LFG setting.

5.2 The shift of computational syntax research in the 2000s

As just discussed, the OT approach unlocked a diverse range of new conceptual and empirical questions, which explains in part why we did not witness the development of a single, comprehensive research paradigm that couched all competition-based work in theoretical linguistics. But in addition, there were also framework-external factors that presumably precluded a streamlining of activities into a single coherent research paradigm. One of them is that the linguistically motivated exploration of the formal OT architecture was not accompanied by major synchronized efforts in a computationally oriented community[51] – contrary to the situation in the 1980s and early 1990s where formal and computational results for linguistic grammar formalisms like LFG received significant attention at the computational linguistics conferences. At first glance, this is surprising. OT as a move to a competition-based framework in theoretical work in linguistics *did* lead to an architecture that is structurally very similar to the architectures underlying the dominant data-driven approaches in computational linguistics and natural language processing (NLP) (Eisner 2000: 287). A high-level objective in both contexts lies in developing a model framework capable of using empirical ("training") data from a natural language (in principle an arbitrary one) to induce a language-particular instantiation of the framework that replicates the competence/language behavior of a speaker of that language. This is reflected by the fact that the same families of learning algorithms could be employed (which led to interesting discussions between theoretical and computational linguistics, see Keller & Asudeh 2002, Goldwater & Johnson 2003, Jäger 2007). What differs across the research contexts despite the great similarities are three interleaved points.

First, linguistic OT work by design uses a strict constraint ranking to limit the degrees of freedom in theory development and to be able to connect to the

---

[51] The use of the idea of violable constraint for postfiltering the readings predicted by a classical grammar discussed in Sections 1.2 and 2.6 is so different conceptually from OT as a grammaticality-defining device that many of the implications of the latter do not arise for the former.

long tradition of work on linguistic generalizations at the level of symbolic descriptions of linguistic structures.[52] In practically motivated machine learning approaches in NLP however, there is no reason for positing such restrictions on the learnable input-output functions. Hence, the actual learning processes for some given language input are quite different in the two research areas. Key insights from decades of research on the theory of grammar have nevertheless been incorporated in most NLP modeling efforts of the time, since supervised learning on annotated corpora ("treebanks") is the most effective approach, and the annotation categories in available corpora reflect many of the important distinctions from theoretical linguistics. Again however, the processes of generating new insights in theoretical vs. computational work is somewhat disconnected: improvements in NLP are based on enrichments of the competition and evaluation models – which is excluded by assumption in linguistic OT work.

Second, while both in linguistics and in NLP, competitions in both processing directions play a role, it is the production-based view that plays the defining role (for grammaticality) in linguistics, whereas it is the comprehension-based view (=disambiguation in parsing) that is the most fundamental in NLP.[53]

Finally, third – and related to the first and second point – there is a difference in the scope of empirical phenomena related to language and text targeted by linguistic vs. contempory NLP work. A linguistic OT approach targets grammatical phenomena and therefore controls for context factors which would discriminate among candidates but are considered extralinguistic (or orthogonal to the phenomenon under consideration). This is important to be able to isolate the effect of the abstract grammatical categories responsible for systematic generalizations. NLP work on the other hand does not aim to isolate the linguistic knowledge involved in solving processing tasks – it pursues the objective of maximizing the predicted system scores for the tasks as they realistically occur (e.g., replicating the structure assignment decision human annotators made on real-life corpus sentences, where the annotators recurred to their linguistic knowledge as much as they exploited any explicit or implicit contextual clue). From the NLP perspective, it is therefore not only legitimate, but good practice to try to exploit correlations of the actual target task with any other trends reflected in the empirical training data. For instance, a syntactic parser, say, of English, trained with NLP techniques on a treebank from a certain domain will presumably make its decisions to a large part because it has picked up grammatical knowledge regarding the positioning of grammatical subjects and objects from the treebank. To a

---

[52] Stochastic OT assumes oscillating rank values for a constraint, but each evalution is still based on the strict ranking from standard OT.

[53] Compare Sections 1.2 and 2.6 and the discussions in Frank et al. (2001) and Kuhn (2001, 2003).

certain degree, it will however also exploit non-linguistic domain knowledge reflected in the distribution of factual statements (e.g., a certain brand name being mentioned a lot more than others in a context like *buy a … watch*). The difference in the scope of empirical phenomena targeted across the subfields implies very different foci in the modeling work.

The three differences in the configuration details and application of competition-based learning architectures imply different key research challenges in theoretical vs. computational work and explain how separate agendas have evolved. Nevertheless, there are numerous connecting points that become particularly relevant when the (often tacit) simplifying assumptions underlying the respective standard approaches are relaxed. For example, the idea of bidirectional optimization from theoretical work can be translated straightforwardly to machine learning models applied to disambiguation in parsing and choice in generation (Cahill & Riester 2009, Zarrieß et al. 2011, Yu et al. 2019). An example of developments in which linguistic insights and considerations re-gained attention in the past years is the Universal Dependencies project (Nivre et al. 2016), which assembles treebanks for a growing number of languages in a cross-linguistically uniform dependency format (compare Haug 2023 [this volume]).

5.3 OT and recent neural models in natural language processing

Section 4.3 addressed the connectionist motivation behind the original proposal of OT. Interestingly, over the course of the 2010s successes in machine learning with artificial neural networks (Henderson 2020) and the broad availability of high-capacity computing resources brought about a major shift in NLP research (as well as most other areas of applied machine learning), often associated with the buzz word of "Deep Learning": neural network models replaced the conventional machine learning (ML) architectures discussed here in Section 5, which required the design and optimization of the set of ML features to reach the best generalizations from training data. (The machine learning features are the equivalent to the rankable constraint in OT – the only difference is that they are used in more general mathematical functions than in the strict relative ranking of OT.)

The training of "deep" neural networks does not rely on pre-designed ML features. Instead, it employs hidden layers of neurons that are densely connected with a neuron-based input or output representation and with other hidden layers. Weight parameters on all the connections are iteratively adjusted by supervised training based on input/output data, where weight adjustments for links involving hidden layers are percolated from the ends using backpropagation (which can be thought of as spreading out the activation of some neuron to all connected neurons in the neighboring layers). The effect is that during empirical learning, the hidden layers receive the role of couching emerging internal representations of systematic patterns observed in the training data. For instance, when certain input neurons tend to be activated when a specific output occurs, some neuron in the next hidden layer can take over the role of an internal "feature" recording the constellation. With appropriately chosen network architectures that capture task-specific properties of the input and output representation (e.g., cross-talk among neighboring elements in a sequential input such as character or word token sequences), the neural approach led to substantial improvements over conventional ML approaches for a great variety of learning tasks.

The conceptual relationship between recent computational neural networks and the OT approach as popularized in the 1990s has not been discussed prominently in the research literature, but it is worthwhile comparing the major components in these architectures – in particular since the inherent black-box characteristics of neural models have prompted wide-spread efforts into making the emerging model representations scientifically interpretable (see, e.g., Belinkov & Glass 2019). At first glance, the move away from human-designed ML feature sets, which parallel OT constraint sets, seems to have widened the gap between NLP work and a linguistic notion of OT competition. Moreover, the effective ability of neural models to induce task-relevant generalizing representations which bridge between some input and some output representation has made it possible to train neural architectures for complex input/output mapping tasks for which a conventional approach would have crucially involved a linguistically informed intermediate representation. An illustrative example is machine translation. Conventionally, it was considered unquestionable that the best possible machine translation approach would for instance exploit a parser on the source side and a generator on the target side, which take advantage of all accumulated insights regarding the grammatical systems in these languages (potentially mediated through ML-based parsers/generators trained on treebanks that capture the linguistic knowledge). Now, neural models for translation can be trained on very large numbers of pairs of input/output sentences without providing any abstract characterization of linguistic properties or composing a pipeline of substeps such as parsing, transfer and generation (for an overview, see Zhang & Zong 2015). The model parametrization resulting for the end-to-end translation process captures many of the relevant grammatical regularities in the hidden layers. The great advantage of the free induction of internal representations as systematic patterns occur in the observed input/output relation is that the model will capture not only regularities along the major dimensions underlying established modular descriptions of knowledge of language, but any other trends that are manifest in the data. And since all aspects are incorporated in a single, densely connected model architecture, cross-talk among the various knowledge sources and contextual clues is captured very effectively.[54]

But how could then a comparison with the classical OT architecture be of any use or lead to new insights? OT was designed to have an abstract symbolic representation level (OT constraints) in a quasi-connectionist model architecture that implements an input/output function with supervised training. However, with the assumed fixed set of grammatically relevant constraints, one of the key strengths of current connectionist models – the free induction of internal representations at hidden levels, without preconceived features or violable constraints – is excluded by design. Accommodating for the tension between OT's fixed set of symbolic constraints and the current neural model's completely unrestricted representational space could be the key to advances on both the linguistic and the computational side. The unrestricted neural models lack scientific interpretability, but they can use representation learning to capture cross-talk among any factors influencing the observed input/output behavior, while the OT approach enforces the exclusion of non-linguistic factors as an influence on the competitions. It is conceivable to reconcile the shortcomings on either side by building up symbolically informed diagnostic tools operating on trained neural models: such tools would in a first step allow researchers to inspect in a controlled way how a neural model trained on corpus data captures known symbolic generalizations. In a second step, it could be explored empirically how factors from additional, non-linguistic knowledge sources affect the model's "own account" of the symbolic generalizations beyond the controlled setup. Recent work in NLP has started looking at various techniques (probing tasks, causal intervention) that can serve as such diagnostic tools for inspecting neural models (Ettinger et al. 2016, Gulordava et al. 2018).

To give an idea of the potential that lies in symbolically guided analysis of the internal representations of trained neural models, Figure 7 shows an analysis of the behavior of a neural syntactic parser from Falenska & Kuhn (2019). The parser, a neural graph-based dependency parser, is trained in a supervised way to predict dependency arcs (essentially representing the grammatical relation between the words in a sentence). The model can build up and exploit its own internal representation to capture emerging systematic patterns that guide

---

[54] Recent advances in the neural modeling of text, in particular transformer-based contextual word embeddings like BERT (Devlin et al. 2019) have led to an often surprising level of emerging generalizations. Even before the advent of this generation of models, Loula et al. (2018) reported "impressive generalization capabilities" of neural sequence-to-sequence models in phrasal composition underlying the meaning of commands like *turn left twice.*

the decision for assigning a particular dependency arc. It may for example notice the influence of intervening words (as in the contrast *some prefer water* vs. *some cold water*, where the intervening word influences what is the most likely grammatical relation between *some* and *water*).

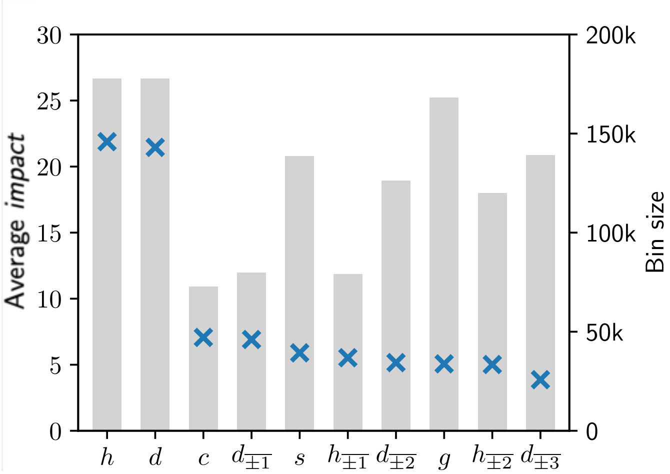

Figure 7: Analysis of trained neural dependency parsers from Falenska & Kuhn (2019), aggregating results from nine treebank training experiments (Ancient Greek, Arabic, Chinese, English, Finnish, Hebrew, Korean, Russian and Swedish): impact (blue crosses) of the information from words in various functional positions (occurring with a frequency plotted by the gray bars) on the prediction score of a multi-layer perceptron for a dependency arc in a graph-based dependency parser. The position types compared are the following: heads (h), dependents (d), children of d (c), siblings (s), grandparents (g), $h, d_{\overline{\pm i}}$ tokens at distance $\pm i$ from h or d which are none of h, d, c, s, or g.

Figure 7 shows a diagnostic analysis of the neural model that emerged from training on treebanks for nine languages. The model was specifically trained to decide whether two given tokens in a sentence should stand in a head-dependent relation, taking into account all tokens in the sentence. For the trained model, it is possible to quantify what impact on the decision the model attributes to individual tokens in the data.[55] For the analysis shown in Figure 7, the token impact was systematically aggregated based on the position of the token in the syntactic gold-standard configuration, as labeled in the treebank. (This information is not available to the model itself.) The blue crosses in the diagram indicate what impact the model itself has decided to assign to tokens in the various configurational positions. The two tokens with the greatest impact are – as one would

---

[55] The paper introduces a special normalized measure for the impact of specific word representations on the prediction.

expect – the head (*h*) and the dependent (*d*) themselves. But other tokens in the sentence have an impact too. The gray bars represent the frequency of tokens in the various configurational positions in the training corpora. In a structurally uninformed model, our expectation would be that the impact of certain types of tokens correlates with their frequency, so the blue crosses should be high on the tall gray bars and low on the short bars. The diagram reveals that the parser has for instance learned from exposure to data to be substantially more sensitive to the children of dependents (*c*) than to siblings (*s*), although the latter occur much more frequently in the training data.[56] In fact, the neural model with its self-induced internal representation achieves a better prediction quality than the best classical machine learning models, for which carefully designed configurational features are provided. Since direct information about the representational configuration is not in the input representation that the parser receives in training or application, we have an indication that the emerging internal, connectionist representation does encode implicit knowledge about important aspects of functional structure.

The linguistic questions that can be addressed with the dependency parsing example are relatively limited, but it is conceivable to generalize the approach to a more complex interplay of factors affecting linguistic expressions. Diagnostic tools of this kind may thus provide an informed view on the ability of a connectionist model to pick up patterns for which a theory of syntax has posited symbolic abstractions – capturing their systematic significance. A central challenge for theoretical interpretability of the models' predictive capacity is to further develop the diagnostic machinery for disentangling the overlaid effects of very different knowledge sources.[57]

---

[56] It should be noted that there is no delimitable locus in the model's parameter space where this information is represented – but based on the theoretically informed diagnostic tests, we can observe that whatever the model has learned correlates with the distinction.

[57] To make progress in this process of disentangling, it is necessary to cross long-established disciplinary boundaries that provided clear-cut subspaces in the study of language, text and corpora of discourses from specific contexts: theory of grammar with its subdisciplines, psycholinguistics, sociolinguistics, but also literary studies, media studies, etc.; many relevant patterns fall into the realm of scholarly disciplines that do not study language and text *per se*, such as cultural studies, history and social science. The delimited subspaces have so far justified convenient idealizations in the working assumptions – in the theory of grammar for example the idealizing assumption of a shared body of grammatical and lexical knowledge that makes up the linguistic competence of all native speakers of language X. An extra challenge comes from the divergent methodologies that have developed in the subfields as a response to the very distinct idealizations; this becomes clear in work in subareas of digital humanities and computational social science which has recently explored corpus-based modeling techniques for addressing research questions from literary studies (Kuhn 2019) or political science (Padó et al. 2019). Considerable effort is needed to appropriately incorporate findings from computational models in the respective question contexts and theoretical frameworks (Reiter et al. 2020).

6 Conclusion: Epistemological considerations

Optimality Theory was introduced to the study of language in the 1990s as a symbolic description framework for linguistic representations which can make stronger empirically testable predictions about the human language faculty than a classical formal grammar. It can be seen as an attempt to overcome an epistemological limitation of the established formalisms underlying most work in linguistics. The limitation affects plain rewrite systems from the Chomsky hierarchy as much as extensions such as for instance transformational systems, tree-adjoining grammars and unification-based grammars.

With a classical framework, the predictions that can be tested "directly"[58] against empirical observations are always tied to the formal grammar for a particular language, i.e., a specific instantiation of the class of formal systems, for example, a specific context-free grammar $G_{137} = \langle N_{137}, \Sigma_{137}, P_{137}, S_{137} \rangle$ with a concrete set of non-terminal symbols, terminal symbols, rewrite rule productions and start symbol (and similarly for more expressive grammar formalisms).

One such instantiation is typically viewed as a scientific model for (aspects of) the grammatical competence of speakers of, say, Japanese, Swahili or English. The formal system predicts a set of terminal strings, which can be experimentally compared against the linguistic behavior of competent speakers. A grammatical theory about a range of phenomena, e.g., in Japanese, is then falsifiable in the sense of Popper (1959)[59] because it is conceivable that relevant types of terminal strings predicted to be excluded from the formal language according to the theory *do* in fact occur in an experiment (potentially using corpus studies that compare against very similar string types predicted to be included).[60] The theoretical scope is however rather limited: if G_{137} fails to predict an empirically observable opposition of acceptable vs. unacceptable data in Japanese, all that the theorist can conclude is that some aspect in the specification of this formal grammar has

---

[58] "Directly" is set in scare quotes, since what goes through as direct empirical evidence in linguistic work always depends on methodological preassumptions that a community agrees on. The nature of language data in communication is such that very few event types are truly observable in a direct way. However, appeal to certain theoretical constructs and certain contextually triggered inferences is typically considered uncontroversial since they are orthogonal to research questions under debate.

[59] Falsifiability is a prerequisite for a theory with any predictive power.

[60] Most theories of grammar work with the stronger assumption that (some part of) the internal symbolic structures used by the formalism also represent relevant aspects of meaning, i.e., they can be viewed as logical forms. This provides an additional basis for testable predictions; the experiment then has to access speakers' (and listeners'/readers') interpretation of given strings. What is directly testable are however still the system's predictions for one fully parametrized (language-particular) instance of the grammar formalsm.

been inappropriate. When there are multiple ways of fixing the problem (e.g., by different strategies of introducing additional non-terminal symbols in a variant G'_{137} and by modifying some existing productions and adding some new ones in G''_{137}), there is no theoretically forceful way of distinguishing between them. Assume for the sake of the argument that only one of the modified grammars makes structural similarities with Korean, which is modeled in some grammar G_{214}, explicit. As long as the other modified formal grammars predict the same formal language, a theoretically well-founded statement differentiating between the options cannot be made (for lack of falsifiability).

In contrast to classical formal systems, an OT system can make testable predictions for quite a different type of experiment: the theory implemented in a particular OT system, with a spelled-out candidate generation function *Gen* and a set of rankable constraints *Con*, does not predict a single formal language, but – via the factorial typology implied by all possible rankings of *Con* – a whole class of formal language approximations of natural languages. Fully formalized OT systems come with a spelled-out empirical learning algorithm (Tesar & Smolensky 1998 and subsequent work in the community), which provides the basis for falsifiability of a theory about the human language faculty as such: a formal OT system predicts how a learner of any specific language in their learning behavior responds to exposure to language behavior by adult speakers of the language in question.[61] A concrete OT system can thus be falsified by evidence from *any* of the languages of the world: a particular observed adult language behavior could in principle trigger a sequence of constraint rerankings that make it impossible for the learner to converge on the constraint ranking needed for this language. If this is the case for some conjectured theory (with a constraint set, etc.) and observed language data, then the theory of some part of the human language faculty counts as falsified.

Of course, most research communities employing classical formalisms, including the LFG community, have established agreed-upon meta principles and methodological research practices which effectively ensure that empirical evidence from a particular natural language is accepted by the community as evidence affecting *all* formal systems adhering to the shared conventions (to continue with our context-free grammar illustration, the theory could be characterized as the set of formal grammars $\{G_i \mid$ the components of G_i satisfy all meta principles $\}$). There are countless examples of such meta principles: X-bar theory, extended projections, the concept of lexical redundancy rules, constraints

---

[61] Adult behavior is assumed to be observed in contexts that provide enough extra-linguistic clues to support inferences about the intended meaning where there is ambiguity.

on legitimate transformations in a derivational framework, a universal layering of functional projections, etc. With such principles it becomes possible that the grammatical theory constituted by the meta principles is falsified by language-particular evidence. Even the language learning/acquisition problem has been formulated on the basis of such framework, presumably most prominently in the Principles-and-Parameters theory (Chomsky 1981): the learner (guided by some language acquisition device that is assumed to be part of the cognitive equipment) has the task of adjusting a number of free parameters in an otherwise highly constrained innate grammatical system – in response to observed linguistic behavior by adult speakers. (A rigorous formalization as for OT learning algorithms is typically not provided.)

However, although sophisticated research practices have been established that ensure a far-reaching consensus about plausible meta principles assumed in a community, the epistemological relationship between a particular instantiation of the meta framework (say, formal grammar G_{137} for Japanese) and the framework itself, with its meta principles, remains contestable. Typically, the representational constructs developed to capture generalizations across natural languages have been established in a long process of cautious plausible reasoning – yet it is almost always conceivable that there are alternative, empirically indistinguishable ways of predicting surface-level divergences across languages. To explain unexpected patterns in some language X, a modification in the formulation of one or another meta principle could be made, or idiosyncratic lexical knowledge could be posited. The falsifiability issue of general theoretical statements is not completely resolved by the assumption of meta principles. This circumstance explains in part why there have been many controversial debates about the representational locus for capturing cross-linguistic variation in a phenomenon – take for instance Binding Principles, which one might construe along a configurational tree structure or along a functional hierarchy (Asudeh & Dalrymple 2006). In the same vein, a re-occurring type of argument against specific linguistic accounts is the accusation for overly strong theory-internal assumptions. In other words, it happens quite frequently that members of a research community develop reservations with respect to the falsifiability of parts of the established consensus framework.[62]

As just noted, OT can be technically seen as the move towards an approach that meets higher standards of falsifiability (when fully formalized). One may

---

[62] Given the underdetermination of theories of grammar by direct empirical evidence, aesthetic arguments regarding the simplicity of a theory are often advanced, most notably in Minimalism (Chomsky 1995). But even this strategy cannot escape controversies, since there are different possible starting points for seeding a theoretical accounts in fundamental propositions.

ask oneself then why it has not replaced classical formalisms in mainstream linguistic research? Section 5.1 discussed this question under the perspective of the concrete course of research activities in the 1990s and 2000s. But there are also relevant meta-theoretical considerations: since most aspects of representational choice in linguistic modeling are not directly observable (only the linear sequence of surface units of expression and semantic entailments of the content of utterances are directly observable), the space of possible OT theories remains vastly underdetermined. This means that (unless a community decides to change their research paradigm completely), plausible argumentation for abstract intermediate representations remains an important part of linguistic theorizing. And since substantial groundwork in linguistic research has always lain in the systematic capturing of regularities in variation patterns for particular languages, the justification for the use of classical formalisms has not disappeared. By choosing a strict ranking approach over violable constraints captured in terms of established symbolic representations, the OT endeavor was from the outset designed to stay connected with work using the classical formalisms; the effect of relevant constraints on a phenomenon under consideration can be calculated in manually constructed tableaux.[63] Insights from a specific OT account may thus feed back into the more general debate of what are appropriate theoretical constructs for systematically capturing a particular aspect of linguistic knowledge.

Against this background, the most important contribution of OT to generative linguistics might have been to increase the awareness in (part of) the community that a comprehensive, falsifiable account of the human language faculty has to include a formalized account of learnability of language from exposure to data.

---

[63] As was discussed in Section 5, recent machine learning approaches open up alternative avenues for modeling human language behavior. Computational models incorporating a very large parameter space can be trained on large corpora to achieve higher prediction accuracy on most tasks; however, the emerging representations (in the hidden layers of "deep" neural network models) provide no direct basis for a falsifiable theory of aspects of linguistic competence. Some connection to hypotheses that can be expressed symbolically seems to be indispensible.

Formal and computational issues and applications

Chapter 22

Formal and computational properties of LFG

Ronald M. Kaplan
Stanford University

Jürgen Wedekind
University of Copenhagen

This chapter first reviews the basic architectural concepts that underlie the formal theory of Lexical-Functional Grammar. The LFG formalism provides a simple set of devices for describing the common properties of all human languages and the particular properties of individual languages. It postulates two levels of syntactic representation for a sentence, a constituent structure and a functional structure. These are related by a piecewise correspondence that permits the abstract functional structure to be described in terms of configurations of constituent structure phrases. We then survey the mathematical and computational properties of this simple framework. We demonstrate that the recognition/parsing, realization/generation, emptiness, and other more specific decision problems are unsolvable for grammars in the unrestricted LFG formalism. A first set of restrictions guarantees decidability of recognition, realization, and other problems for grammars that are still suitable for linguistic description, but the solutions to these problems in the worst case are computationally impractical. The class of LFG grammars that meet an additional set of restrictions is equivalent to the class of mildly context-sensitive grammars, and the recognition and realization problems for grammars in this class are thus not only decidable but tractable as well.

Ronald M. Kaplan & Jürgen Wedekind. 2023. Formal and computational properties of LFG. in Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 1035–1082. Berlin: Language Science Press. DOI: 10.5281/zenodo.10185982

1 Introduction

The basic features of the LFG formalism are quite simple and have remained remarkably stable since they were first introduced by Kaplan & Bresnan (1982).[1] An LFG grammar assigns to each sentence in its language at least one constituent structure (c-structure) and at least one functional structure (f-structure). The c-structure is a phrase-structure tree that represents the order of words and their grouping into phrases. The f-structure is a hierarchical attribute-value matrix that represents the underlying grammatical relations that are expressed by configurations of c-structure nodes. The c-structure is determined in the traditional way by the rules of a context-free grammar. The f-structure is a minimal model for the functional description (f-description) that is constructed from annotations associated with the categories of rules that license the nodes of the c-structure. The f-description is obtained by instantiating those annotations on the assumption that there is a piece-wise correspondence ϕ between the nodes of the c-structure and the units of a satisfying f-structure.

This simple correspondence architecture still lies at the core of LFG theory even as it has been extended and refined to provide more insightful accounts of long distance dependencies (Kaplan & Zaenen 1989), coordination (Kaplan & Maxwell 1988), and other syntactic phenomena. In this chapter we focus on the mathematical and computational properties of the basic formalism. As is well known, its expressive power goes far beyond the capabilities of the context-free c-structure grammar. This is because the annotations may associate information that originates from different (and possibly arbitrarily distant) nodes with the same f-structure unit. The result is that such a unit must satisfy requirements that come from words in the string or nodes in the tree that do not stand in a local mother-daughter relationship. A string with an otherwise well-formed c-structure is excluded from the language if such context-sensitive f-structure requirements are inconsistent. We know that some degree of context sensitivity is needed for recognizing and parsing natural languages (Bresnan et al. 1982, Culy 1985, Shieber 1985), but the basic LFG formalism may allow for more expressive power than is actually required.

Indeed, Kaplan & Bresnan (1982) used a reduction from the Turing machine halting problem to show that the recognition/parsing problem is undecidable for

---

[1] Jürgen Wedekind passed away just as work on this chapter was coming to an end. Jürgen was a master of the LFG formalism, with deep insights into its mathematical and computational properties and how they relate to important principles of linguistic analysis. His early passing is a great loss to the LFG community. He will also be missed as a close friend and collaborator. RMK

unrestricted LFG grammars (see also Johnson 1988). This is the computationally important problem of determining whether or not a given string belongs to the language of the grammar and is assigned at least one c-structure and corresponding f-structure. Wedekind (2014) proved the undecidability of the realization problem, also of practical significance. This is the problem of determining whether the language contains at least one string to which an arbitrary given f-structure is assigned. Wedekind's undecidability proof used a reduction from the emptiness problem for the intersection of context-free languages. He also used that reduction to show the undecidability of the emptiness problem for unrestricted LFGs (Wedekind 1999). This is the problem of determining whether or not there are any strings at all in the language of a given LFG grammar. The emptiness problem for LFGs was previously shown to be undecidable by reductions from Hilbert's Tenth Problem (Roach 1983) and Post's Correspondence Problem (Nishino 1991).

We revisit these undecidability results in Section 4. We provide alternative proofs within a single, conceptually simple, framework. In Appendix A we use this framework to show that other more specific decision problems are also unsolvable.

We consider in Section 5 some formal conditions that are sufficient to guarantee decidability of the recognition and realization problems. Kaplan & Bresnan (1982) showed that recognition is decidable if c-structures with non-branching dominance (NBD) chains and/or unlimited empty nodes are excluded, and they argued that this is a reasonable restriction for LFG grammars that describe natural languages. This parsing-oriented limitation does not reduce the complexity of generation (Wedekind 2014), but an unrelated restriction has been shown to ensure the decidability of that problem (Wedekind & Kaplan 2012). This raises the question whether there is a single, linguistically plausible, condition that applies indifferently to both parsing and generation. We introduce in Section 5 such a uniform condition, proper anchoring, but we also demonstrate that this particular condition is not strong enough to guarantee that these problems can be solved with practical efficiency. In the worst case recognition and generation may take an amount of time that is exponential in the length of an input sentence or f-structure.

This leads us to examine in Section 7 a stronger set of restrictions that not only guarantee decidability of recognition and realization as well as emptiness but also ensure that those problems can be solved in polynomial time. This follows from the fact that LFG grammars that meet these additional restrictions are mildly context-sensitive in their expressive power and thus also have the known mathematical and computational properties of that class of formal grammars.

2 Basic LFG formalism

We show in Figure 1 the c-structure and f-structure that the annotated c-structure rules in (1) and lexical entries in (2) would assign to the sentence *He sees the girl.*

(1)
$$\begin{array}{lll} \mathrm{S} \rightarrow & \mathrm{NP} & \mathrm{VP} \\ & (\uparrow \textsc{subj}) = \downarrow & \uparrow = \downarrow \\ & & (\uparrow \textsc{tense}) \end{array}$$

$$\begin{array}{lll} \mathrm{NP} \rightarrow & (\mathrm{Det}) & \mathrm{N} \\ & \uparrow = \downarrow & \uparrow = \downarrow \end{array}$$

$$\begin{array}{lll} \mathrm{VP} \rightarrow & \mathrm{V} & \mathrm{NP} \\ & \uparrow = \downarrow & (\uparrow \textsc{obj}) = \downarrow \end{array}$$

(2)

he	N	$(\uparrow \textsc{pred}) = \text{‘}\textsc{pro}\text{’}$ $(\uparrow \textsc{agr pers}) = 3$ $(\uparrow \textsc{agr num}) = \textsc{sg}$
sees	V	$(\uparrow \textsc{pred}) = \text{‘}\textsc{see}\langle\textsc{subj obj}\rangle\text{’}$ $(\uparrow \textsc{tense}) = \textsc{pres}$ $(\uparrow \textsc{subj agr pers}) = 3$ $(\uparrow \textsc{subj agr num}) = \textsc{sg}$
the	Det	$(\uparrow \textsc{spec}) = \textsc{def}$
girl	N	$(\uparrow \textsc{pred}) = \text{‘}\textsc{girl}\text{’}$ $(\uparrow \textsc{agr pers}) = 3$ $(\uparrow \textsc{agr num}) = \textsc{sg}$ $(\uparrow \textsc{spec})$

The correspondence function ϕ is indicated by the arrows between the c-structure nodes and the f-structure units and also, redundantly, by the columns of node identifiers *root*, $n_1, n_2, \ldots$ attached to the f-structure units. We see even in this simple example that the function ϕ is typically many-to-one (heads and coheads of grammatical constituents are mapped into the same f-structure) but is not onto (the AGR/agreement f-structure units are not the image of any node). The function ϕ may also be partial, if nodes necessary for c-structure well-formedness have no f-structure significance.

The phrasal categories of this c-structure obviously meet the node admissibility conditions of the annotated rewriting rules (1). Lexical entries are interpreted also as annotated rewriting rules that relate the lexical categories of the c-structure to the words of the sentence. The entry for *the*, for example, is interpreted as the rule

(3)
$$\begin{array}{ll} \mathrm{Det} \rightarrow & \mathrm{the} \\ & (\uparrow \textsc{spec}) = \textsc{def} \end{array}$$

and the normal node admissibility conditions also license the proper lexical expansions for the tree.

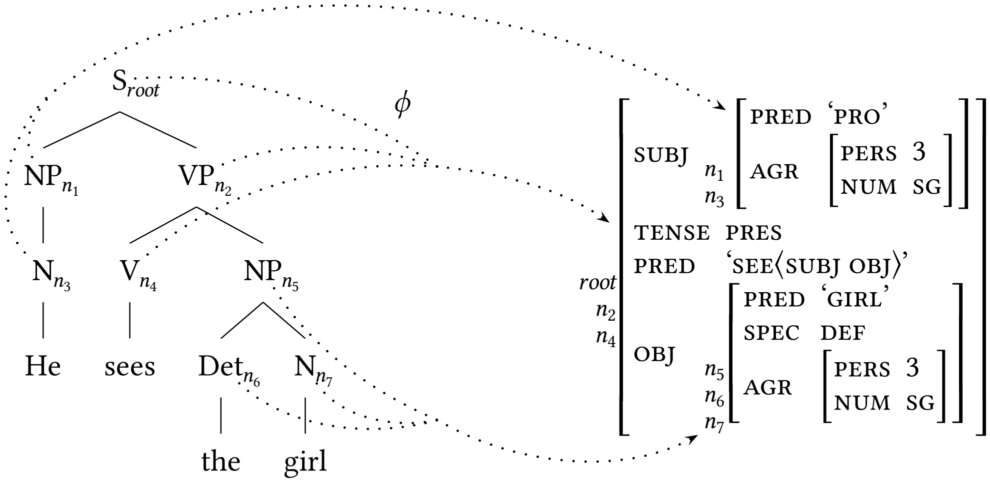

Figure 1: Illustration of the basic LFG architecture: A c-structure c and f-structure f related by the correspondence function ϕ from the nodes of c to the units of f. The f-structure units are indexed by the nodes to which they correspond.

The description that the f-structure must satisfy is constructed from the annotations associated with the daughter categories of the rules that license particular nodes in the c-structure. Each side of an equation designates an element of a corresponding f-structure, and the equation is satisfied if both sides designate the same element. The metavariable $\downarrow$ in an annotation designator instantiates to the f-structure corresponding to the node that matches the associated rule category (n_1 for $\downarrow$ in the annotation $(\uparrow \textsc{subj}) = \downarrow$ attached to the NP in the S rule), and the metavariable $\uparrow$ denotes the f-structure corresponding to the mother of that node (the node *root* for that rule). To be precise, if $*$ instantiates to the matching node and $M(*)$ instantiates to its mother, then $\downarrow$ and $\uparrow$ are abbreviations for $\phi(*)$ and $\phi(M(*))$ respectively. The metavariable instantiations are easy to read from the *annotated c-structure* in Figure 2. This is a phrase-structure tree whose nodes are labeled with the category-annotation pairs that appear in grammar rules and lexical entries.

The first NP is identified as n_1 and its mother is *root*, so the annotation $(\uparrow \textsc{subj}) = \downarrow$ instantiates directly to $(\phi(root)\ \textsc{subj}) = \phi(n_1)$. Since a parenthesized designator denotes the element reached by traversing a path of attributes from a starting f-structure, the f-structure in Figure 1 satisfies this equation because $\phi(n_1)$ is the SUBJ of $\phi(root)$ under the illustrated ϕ correspondence. The full f-description for this annotated c-structure is the conjunction of instantiated equations collected from all of its nodes, shown in (4).

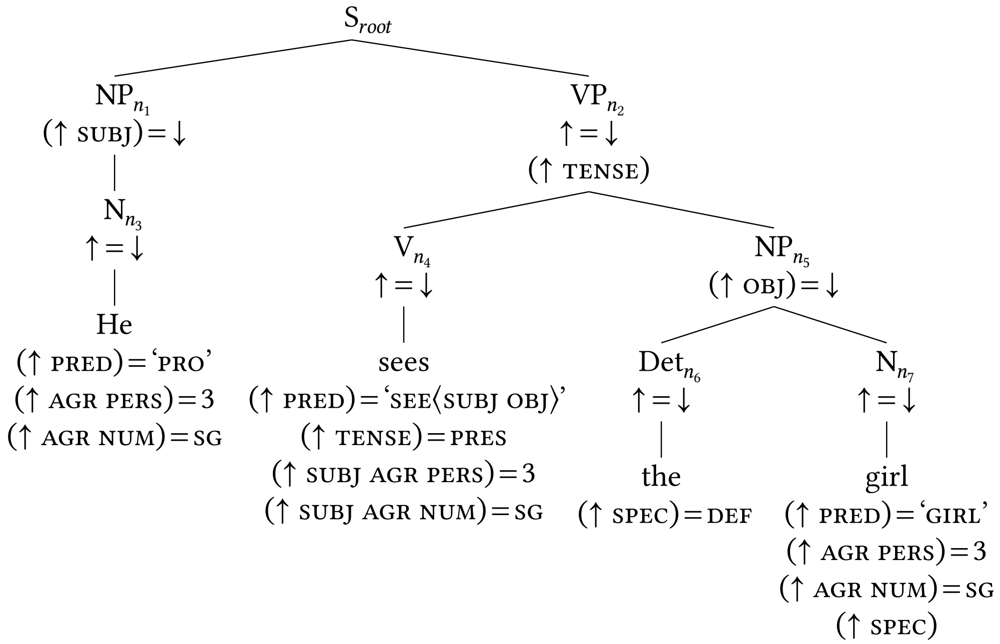

Figure 2: Annotated c-structure for *He sees the girl* with the rules in (1) and lexicon in (2).

(4) $(\phi(root)\ \textsc{subj}) = \phi(n_1)$
$\phi(root) = \phi(n_2)$
$(\phi(root)\ \textsc{tense})$
$\phi(n_1) = \phi(n_3)$
$(\phi(n_3)\ \textsc{pred}) = \text{‘}\textsc{pro}\text{’}$
$(\phi(n_3)\ \textsc{agr pers}) = 3$
$(\phi(n_3)\ \textsc{agr num}) = \textsc{sg}$
$\phi(n_2) = \phi(n_4)$
$(\phi(n_4)\ \textsc{pred}) = \text{‘}\textsc{see}\langle\textsc{subj obj}\rangle\text{’}$
$(\phi(n_4)\ \textsc{pred}) = \textsc{pres}$
$(\phi(n_4)\ \textsc{subj agr pers}) = 3$
$(\phi(n_4)\ \textsc{subj agr num}) = \textsc{sg}$
$(\phi(n_2)\ \textsc{obj}) = \phi(n_5)$
$\phi(n_5) = \phi(n_6)$
$\phi(n_5) = \phi(n_7)$
$(\phi(n_6)\ \textsc{spec}) = \textsc{def}$
$(\phi(n_7)\ \textsc{pred}) = \text{‘}\textsc{girl}\text{’}$
$(\phi(n_7)\ \textsc{agr pers}) = 3$
$(\phi(n_7)\ \textsc{agr num}) = \textsc{sg}$
$(\phi(n_7)\ \textsc{spec})$

We can test each equation separately to verify that the f-structure in Figure 1 meets all the specifications in (4). The equation $(\phi(n_4)\ \textsc{subj agr num}) = \textsc{sg}$ is satisfied, for example, because ϕ maps n_4 to the outermost f-structure, and that f-structure has a path from SUBJ through AGR to NUM, ending in the atomic value SG. That value is consistent with the requirement that the equation $(\phi(n_3)\ \textsc{agr num}) = \textsc{sg}$ imposes on the f-structure of n_3. In contrast, this grammar would assign no f-structure to the string *They sees the girl* because the f-description for its c-structure would require its subject f-structure to have inconsistent values for AGR NUM, a violation of the *Uniqueness Condition* of Kaplan &

Bresnan (1982). The correspondence ϕ and the instantiated metavariables ensure that the properties of the subject NP are consistent with the verb's agreement specification even though they do not appear together in a local mother-daughter configuration.

The f-structure in this configuration also meets the additional well-formedness conditions of LFG theory. We see that it is a *minimal* model of the f-description in the sense that at least one equation or combination of equations will no longer be satisfied if any attribute or value is removed (for example $(\phi(n_6)\ \textsc{spec}) = \textsc{def}$ fails without the SPEC feature of the OBJ).[1] Conversely, a structure with any features beyond those already present, say if the SUBJ is extended with TENSE PAST, is not minimal, because the f-description is still satisfied when that feature is removed. The minimal model is unique[2] for a given annotated c-structure and contains all and only the linguistically relevant features that are expressed by the words of a sentence.

The minimal model is important in LFG theory for another reason. It is the basis for the distinction between *defining annotations* and *constraining annotations.* The defining annotations are the simple equalities between two designators whose instantiations determine the attributes and values of the minimal model. That f-structure must then also satisfy the instantiations in the f-description of any constraining annotations. The grammar in (1) contains two constraining annotations, the positive existential constraints $(\uparrow \textsc{tense})$ and $(\uparrow \textsc{spec})$. The instantiation $(\phi(\mathit{root})\ \textsc{tense})$ is satisfied because the conjunction of defining equations in the f-description specify a particular value (PRES) for the attribute TENSE in the f-structure corresponding to the S node. This constraint excludes strings whose main verb is a participle instead of a tensed form (e.g. **He seeing the girl*) without depending on participles setting up a uniqueness clash by also adding a TENSE feature with an otherwise unnecessary and uninformative value (e.g. NONE). Similarly the instantiation $(\phi(n_7)\ \textsc{spec})$ excludes singular common nouns that have no specifier (e.g. **He sees girl*). The formalism also allows for con-

---

[1] Strictly speaking, a minimal model of the f-description includes not only the attributes and values of the f-structure but also the association of those elements with the nodes of the c-structure as instantiated via the ϕ correspondence, as depicted in Figure 1. Technically, what we usually regard as the f-structure is the restriction of such a model to just those attributes and values.

[2] As a notational convenience, the LFG formalism allows for primitive annotations to be embedded in disjunctive formulas that then might have several solutions. There is an obvious transformation of the grammar that converts disjunctions of annotations within a rule to an equivalent set of alternative rules with annotations that are no longer disjunctive. The minimal models are unique for the annotated c-structures assigned by the rules of such a transformed grammar.

straints that test the minimal model for the absence of a feature, e.g. ¬(↑ OBJ); for the presence or absence of a specific attribute value, e.g. (↑ VOICE) $=_c$ PASSIVE or (↑ VOICE) ≠ ACTIVE; for the identity of two f-structures, e.g. (↑ SUBJ) $=_c$ (↑ OBJ); and for any value other than a specific one, e.g. (↑ SUBJ NUM) ≠ SG. Constraining annotations help to avoid clutter in the f-structure by assigning syntactic significance to the presence or absence of unmarked or default features and also by capturing the difference between constituents that provide values for features and constituents that check those values. See Kaplan (2019) for a fuller discussion of underspecified values in LFG.

The quoted values of the PRED attributes in Figure 1 carry the subcategorization restrictions of the predicates they represent, and they characterize the essential interaction between syntax and semantics while staying agnostic about the details of any particular underlying semantic theory. The semantic form 'SEE⟨SUBJ OBJ⟩' contains a list of grammatical-function designators that the predicate subcategorizes for. The *Completeness Condition* requires that all listed functions appear locally in the minimal f-structure, and the *Coherence Condition* precludes the local appearance of any governable functions (COMP, OBL, XCOMP…) not included in the list. The semantic form also indicates that SEE is the semantic relation and, by virtue of their order in the list, that SUBJ and OBJ respectively map to the first and second arguments of that relation. Semantic forms do not require special treatment in our formal analysis because they can be interpreted as succinct abbreviations for collections of other annotations. Thus the positive and negative constraints (5a-b) express the subcategorization requirements of 'SEE⟨SUBJ OBJ⟩'. The semantic relation and the mapping of functions to arguments can be coded with distinguished attributes REL, ARG1, ARG2 as in (5c-d).[3]

(5) a. Completeness: (↑ SUBJ) (↑ OBJ)
b. Coherence: ¬(↑ COMP) ¬(↑ OBL) ¬(↑ XCOMP) …
c. Semantic relation: (↑ REL) = SEE
d. Argument mapping: (↑ ARG1) = (↑ SUBJ)
(↑ ARG2) = (↑ OBJ)
e. Instantiation: (↑ PRED SOURCE) = $*$

---

[3] Halvorsen & Kaplan (1988) introduced a separate semantic projection, σ, as an alternative to distinguished attributes in formulating these essential properties of the syntax-semantics interface. In that more explicit arrangement σ would be a qualifier on the (5c-d) designators. In Glue Semantics they are elaborated in collections of linear logic premises (Dalrymple et al. 1993, Dalrymple 1999).

Semantic forms are instantiated in LFG theory to mark the difference between syntactically-implied semantic coreference (as in constructions of functional control) and unrelated repetitions of similar expressions. Equation (5e) records as the value of the additional distinguished attribute SOURCE the daughter node at which a particular PRED is introduced. This makes each occurrence unique, and also supports a precedence order that can be used in regulating long distance dependencies (see Kaplan 2023 [this volume]).

3 Technical preliminaries

In preparation for the mathematical analysis in the following sections we now introduce more precise specifications of the LFG derivation machinery.

The annotated c-structure is often described as the result of a special derivation process for an LFG grammar G that treats categories and annotations separately. But it is helpful for formal reasoning to regard it as a normal derivation of the *annotated c-structure grammar* for G, an ordinary context-free grammar with a systematically modified set of rules. Suppose $X{:}A$ is an annotated category in the right side of a rule in the traditional LFG grammar format. Then for every rule expanding X the annotated grammar contains a version in which the left side is also decorated with those particular annotations. For example, because NP in (1) is annotated in S with the SUBJ assignment and in VP with the OBJ assignment, the NP rule is replaced by the rules in (6).

(6)

$$\begin{array}{cccc} \text{NP} & \rightarrow & \text{(Det)} & \text{N} \\ (\uparrow \textsc{subj}){=}\downarrow & & \uparrow{=}\downarrow & \uparrow{=}\downarrow \end{array}$$

$$\begin{array}{cccc} \text{NP} & \rightarrow & \text{(Det)} & \text{N} \\ (\uparrow \textsc{obj}){=}\downarrow & & \uparrow{=}\downarrow & \uparrow{=}\downarrow \end{array}$$

With this reformulation the normal category matching of context-free derivations allows us to make direct use of all established properties (decidability, closure, pumping) of context-free grammars and their derivations. The traditional LFG c-structure in Figure 1 is obviously just the annotation-free projection of the annotated c-structure in Figure 2.

For every annotated c-structure there is an instantiated f-description that defines a function ϕ mapping its nodes to their corresponding minimal-model f-structure units, if the f-description is satisfiable. There is also a function *Yield* that maps its nodes to the substrings of the sentence that they dominate. The set of G's derivations is then characterized by the relation Δ_G defined in (7).

(7) $\Delta_G(s, c, f)$ iff c is an annotated c-structure of G, s is the terminal string of c, and f is the minimal model for the satisfiable f-description instantiated from c.

Note that an annotated c-structure c uniquely determines both the string s and f-structure f in a derivation triple. Moreover, without further stipulation we know that the length of the string $|s|$ and the number of units $|f|$ in the f-structure are both bounded by (functions of) $|c|$, the number of nodes in the c-structure. That is, there are grammar-dependent functions $\overleftarrow{b}_G$ and $\overrightarrow{b}_G$ such that

(8) For all $(s, c, f) \in \Delta_G$, $|s| \leq \overleftarrow{b}_G(|c|)$ and $|f| \leq \overrightarrow{b}_G(|c|)$.

The function $\overleftarrow{b}_G$ depends on the number of daughters in the longest c-structure rule and $\overrightarrow{b}_G$ depends on the most complicated annotated category.

The language, f-structure, parsing, and generating projections of Δ_G are defined in (9).

(9) $L(G) = \{s \mid \Delta_G(s, c, f)$ for some c and $f\}$ = the language of G
$F(G) = \{f \mid \Delta_G(s, c, f)$ for some s and $c\}$ = the f-structures of G
$Par_G(s) = \{f \mid \Delta_G(s, c, f)$ for some $c\} \subseteq F(G)$
$Gen_G(f) = \{s \mid \Delta_G(s, c, f)$ for some $c\} \subseteq L(G)$

A parser for an LFG grammar G provides for any given string s the set of f-structures (if any) that are related to it by the grammar, and a generator provides all the strings that the grammar relates to a given f-structure (if any).

These projections allow for succinct statements of the emptiness, recognition, and realization decision problems (10).

(10) Emptiness: is $L(G)$ empty? (equivalently, are $F(G)$ or Δ_G empty?)
Recognition: for any string s is $Par_G(s)$ empty?
Realization: for any f-structure f is $Gen_G(f)$ empty?

We show in the next section that the emptiness, recognition, and realization problems are all undecidable for unrestricted LFG grammars. This implies immediately that the parsing and generation are also unsolvable. Our demonstrations involve simple phrase-structure rules with elementary defining annotations as exemplified in (11).

(11)	$(\uparrow/\downarrow\ \textsc{subj num}) = \textsc{sg}$	assign an atomic value
	$(\uparrow\ \textsc{subj}) = \downarrow$	assign a function to a daughter f-structure
	$(\downarrow\ \textsc{obj}) = (\uparrow\ \textsc{subj})$	daughter-mother control
	$(\uparrow\ \textsc{xcomp subj}) = (\uparrow\ \textsc{subj})$	traditional functional control

Annotations of these types are not exceptional, they are commonly found in linguistic grammars.

4 Undecidable problems

A standard method for showing that a formal problem of interest is undecidable is the reduction technique. A problem P is said to be *reducible* to problem P' if for any instance of P an instance of P' can be constructed such that solving the instance of P' will solve the instance of P as well. Thus, if P reduces to P' and P is undecidable, then P' must also be undecidable. As noted, this general strategy has been applied with reductions from different source problems (Turing machine halting, Hilbert's Tenth, Post Correspondence, emptiness of context-free intersection) to address the LFG emptiness, recognition, and realization problems. Here we present a single reduction-source framework, based on the emptiness problem of context-free intersection, that recapitulates these previous results.

4.1 The emptiness problem

The emptiness problem for context-free intersection is the problem of determining whether or not the languages generated by two given context-free grammars G_1 and G_2 have an empty intersection ($L(G_1) \cap L(G_2) = \varnothing$). This problem is known to be undecidable. The reduction of this emptiness problem to questions of the LFG formalism depends on the ability to construct for every context-free grammar G an LFG grammar whose f-structures contain encodings of all and only the strings of $L(G)$. We show in (12) one way in which a string pqr can be encoded in the attributes and values of an f-structure, as a H(ead)-T(ail) list representation.

(12)
$$\begin{bmatrix} \textsc{h} & \text{p} \\ \textsc{t} & \begin{bmatrix} \textsc{h} & \text{q} \\ \textsc{t} & \begin{bmatrix} \textsc{h} & \text{r} \end{bmatrix} \end{bmatrix} \end{bmatrix}$$

Without loss of generality, let G be an arbitrary context-free grammar in Chomsky Normal Form, that is, a context-free grammar with only binary branching rules of the form $A \rightarrow B\ C$ for nonterminal expansions and unary rules $A \rightarrow a$ for terminals. The schematic rules in (13) provide a template for an LFG grammar *String*(G) that creates head-tail encodings (12) for the strings of $L(G)$.

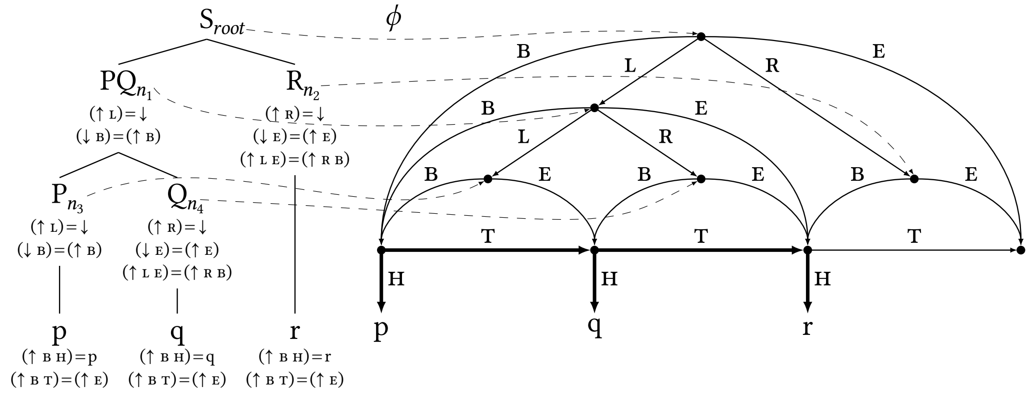

Figure 3: An annotated c-structure and f-structure derived with head-tail string encoding rules of the form in (13). Thick lines show the string encoding, thin lines show the construction scaffolding. The ϕ correspondence is depicted with dashed lines.

(13) a. $A \rightarrow \begin{array}{cc} B & C \\ (\uparrow \textsc{l})=\downarrow & (\uparrow \textsc{r})=\downarrow \\ (\downarrow \textsc{b})=(\uparrow \textsc{b}) & (\downarrow \textsc{e})=(\uparrow \textsc{e}) \\ & (\uparrow \textsc{l e})=(\uparrow \textsc{r b}) \end{array}$ b. $A \rightarrow \begin{array}{c} a \\ (\uparrow \textsc{b h})=a \\ (\uparrow \textsc{b t})=(\uparrow \textsc{e}) \end{array}$

The annotations on the binary rules (13a) transmit the string encodings from their daughter f-structures to their mother f-structure. The attributes L(eft) and R(ight) are the scaffolding needed to concatenate the encodings from the daughters by linking the end of the left-daughter encoding to the beginning of the right. Rules of the form (13b) create for each terminal the one-element head-tail encoding of their right side, with B and E attributes marking its beginning and end. Control equations such as $(\downarrow \textsc{b})=(\uparrow \textsc{b})$ and $(\uparrow \textsc{b t})=(\uparrow \textsc{e})$ are the essential ingredient in this and other string-encoding formulations: Crucially, they allow terminal-string information to propagate transparently through all intermediate nodes to the f-structure of the root. Figure 3 shows the annotated c-structure and a graphical f-structure representation for a derivation containing a head-tail encoding of a single string.

Now suppose that G_1 and G_2 are arbitrary context-free grammars in Chomsky Normal Form and assume without loss of generality that their nonterminals are disjoint and that the strings of each language end with a marker # distinct from all other terminals. We construct a new LFG grammar G by combining the rules of $String(G_1)$ and $String(G_2)$ with root categories S_1 and S_2 respectively and introducing a new root category S with start rule (14).

(14) $\mathrm{S} \rightarrow \begin{array}{cc} \mathrm{S}_1 & \mathrm{S}_2 \\ (\downarrow \textsc{b})=(\uparrow \textsc{b}) & (\downarrow \textsc{b})=(\uparrow \textsc{b}) \end{array}$

By construction of the string grammars and the B annotations of the start rule, only the string encodings of the two derived f-structures can interact. Because the string encodings are compatible only if the derived strings are identical, the LFG language $L(G)$ contains all and only strings ss for $s \in L(G_1) \cap L(G_2)$. The emptiness of context-free intersection is undecidable so the question whether $L(G)$ is empty must also be undecidable.

4.2 The recognition problem

We prove that the LFG recognition problem is undecidable by exhibiting one particular string that belongs to $L(G)$ only if $L(G_1) \cap L(G_2) \neq \emptyset$. We modify the string grammars for G_1 and G_2 by treating each terminal a other than # as a nonterminal category and adding for each of them a trivial rule

(15) $a \rightarrow \epsilon$

The effect is that only the string # belongs to the language of each of the modified string grammars, but that single string is assigned all and only the f-structures that respectively encode the original context-free languages. Again with the starting rule (14) the concatenation ## belongs to the language of the modified grammar if and only if $L(G_1) \cap L(G_2) \neq \emptyset$, that is, if and only if $Par_G(\#\#)$ is not empty.

Empty nodes are disfavored in some modern versions of LFG, particularly when long-distance dependencies are characterized by functional uncertainty rather than traces (Kaplan & Zaenen 1989, Dalrymple et al. 2015). But the undecidability of recognition can also be demonstrated with grammars $String(G_1)$ and $String(G_2)$ redefined so as to produce the same head-tail string encodings from nonbranching dominance chains without the benefit of empty nodes.

For each binary rule $A \rightarrow B\ C$ the string encoding grammars will now contain a nonbranching rule of the form (16a). This immediately derives only the left daughter B but pushes the right-daughter category C on a simulated stack for expansion lower in the derivation. Since B is the left daughter of A, the encodings of their terminal strings have a shared B(eginning).

(16)

$$\begin{array}{llllll}
\text{a. } A \rightarrow & \begin{array}{c} B \\ (\downarrow \textsc{stk cat}) = C \\ (\downarrow \textsc{stk nxt}) = (\uparrow \textsc{stk}) \\ (\downarrow \textsc{b}) = (\uparrow \textsc{b}) \\ \end{array} &
\text{b. } A \rightarrow & \begin{array}{c} C \\ (\uparrow \textsc{stk cat}) = C \\ (\uparrow \textsc{stk nxt}) = (\downarrow \textsc{stk}) \\ (\uparrow \textsc{b t}) = (\downarrow \textsc{b}) \\ (\uparrow \textsc{b h}) = a \end{array} &
\text{c. } A \rightarrow & \begin{array}{c} \# \\ (\uparrow \textsc{b h}) = \# \\ \\ \\ \end{array}
\end{array}$$

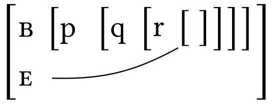
Corresponding to each terminal rule $A \rightarrow a$, for $a \neq \#$, there is a collection of rules of the form (16b), one for each right-daughter category C whose expansion may have been deferred until it reemerges at the top of the stack. The annotations pop that category from the stack while adding the terminal *a* to the front of the head-tail encoding of the terminal string under *C*. Finally, for each unary rule $A \rightarrow \#$ the string grammar contains a rule of the form (16c) to terminate the NBD derivations and install # as the final item of every string encoding. Because # is the distinguished end-of-string marker, these preterminals never appear as left daughters of binary rules and are thus always the last categories to be removed from the stack. As before, if NBD string grammars $String(G_1)$ and $String(G_2)$ are combined into an LFG grammar *G* with rule (14), then $Par_G(\#\#) \neq \emptyset$ if and only if $L(G_1) \cap L(G_2) \neq \emptyset$.

The complexity of recognition arises from the fact that, in order to assign f-structures to the strings of infinite languages, annotated c-structure grammars must include rules for recursive subderivations (rule sequences that derive a node labeled with an annotated category *A* from an *A*-labeled dominating node), and such recursive subderivations must be allowed to stack one above another. The string grammars in our undecidability proofs show that recursive subderivations can assign to a single string (#) a set of f-structures each encoding one of the strings of an infinite context-free language. Unlike the f-structures that correspond to the sentences of natural languages, those f-structures are determined only by the annotations on nonterminal categories without regard to any lexical information carried by the input string or even its length (there is no function of $|s|$ that bounds the sizes of c and f in all derivation triples).

4.3 The realization problem

We turn now to the realization problem. Also using a reduction from the emptiness of context-free intersection, Wedekind (2014) proved that realization is undecidable for unrestricted LFG grammars if there are cyclic paths in the input f-structure.[4] Whereas the emptiness and recognition demonstrations are based on head-tail string encodings, Wedekind's proof is formulated in terms of an alternative way of encoding the strings of a language, a descending chain of attributes as illustrated in (17).

(17)



---

[4] Wedekind & Kaplan (2012) established that the realization problem is decidable if the input f-structure f contains no cycles. For an acyclic f-structure the string-set $Gen_G(f)$ can be described by a context-free grammar, and the emptiness problem for context-free grammars is decidable.

The beginning of the encoding for string pqr is still accessible as the value of the B attribute, but now the end is identified by the reentrant value of the top-level E attribute. Grammars that encode context-free languages in this way are created by replacing the annotations on the terminal rules (13b) with functional control annotations as in (18).

(18) $$A \rightarrow \begin{array}{c} a \\ (\uparrow \textsc{b}\ a) = (\uparrow \textsc{e}) \end{array}$$

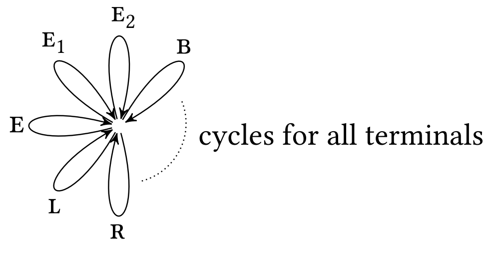
The scaffolding illustrated in Figure 3 is unchanged but the H attributes at the bottom are removed and the sequence of T attributes is replaced by the sequence of terminal-attributes.

The essence of Wedekind's (2014) proof is then captured by combining attribute-chain string-encoding grammars for arbitrary context-free grammars G_1 and G_2 into an LFG grammar G with start rule (19).

(19) $$\mathrm{S} \rightarrow \begin{array}{ccc} \mathrm{S}_1 & \mathrm{S}_2 & \# \\ (\uparrow \textsc{l}) = \downarrow & (\uparrow \textsc{r}) = \downarrow & (\uparrow \textsc{e}_1\ \textsc{e}_1) = \uparrow \\ (\downarrow \textsc{b}) = (\uparrow \textsc{b}) & (\downarrow \textsc{b}) = (\uparrow \textsc{b}) & \bigwedge (\uparrow \textsc{e}_2\ \textsc{e}_1) = (\uparrow \textsc{e}_2\ \textsc{e}_1\ x) \\ (\downarrow \textsc{e}) = (\uparrow \textsc{e}_1) & (\downarrow \textsc{e}) = (\uparrow \textsc{e}_2) & x \text{ an attribute} \end{array}$$

In the absence of atomic values there can be no atom-value clashes to exclude mismatching combinations, and the language $L(G)$ therefore contains all strings $s_1 s_2\#$ for $s_1 \in L(G_1)$ and $s_2 \in L(G_2)$. However, strings belonging to the intersection of $L(G_1)$ and $L(G_2)$ are distinguished by the fact that the end points $\textsc{e}_1$ and $\textsc{e}_2$ of their descending attribute-chain encodings are the same. In that case $(\phi(root)\ \textsc{e}_1) = (\phi(root)\ \textsc{e}_2)$ and the annotations on the terminal # entail by simple substitutions that $(\phi(root)\ x) = \phi(root)$ for all attributes x. Thus all and only strings $ss\#$ for $s \in L(G_1) \cap L(G_2)$ receive the one-element cyclic f-structure f in (20).

(20)



The realization problem is undecidable because $Gen_G(f) \neq \emptyset$ if and only if $L(G_1) \cap L(G_2) \neq \emptyset$. This shares with the recognition proof the property that infinitely many annotated c-structures of arbitrary size may have to be inspected to determine whether there is at least one that is related to a single input of a fixed size (a cyclic f-structure in this case).[5]

The undecidability results we have demonstrated here, together with other simple reductions from the emptiness problem of context-free intersection, can be used to show that other properties of the unrestricted LFG formalism are also undecidable. The following is a partial list of these undecidable questions.

(21)
a. Generation from underspecified f-structures: Is there a sentence that realizes an f-structure with more features than a given one? (Wedekind 1999)
b. Ambiguity-preserving generation: Is there a single string that realizes two different f-structures? (Wedekind & Kaplan 1996)
c. Finite versus infinite ambiguity: Is any string in the language infinitely ambiguous? (Jaeger et al. 2005)
d. Ranking in Optimality-theoretic LFG: Can an optimal derivation always be identified? (Kuhn 2003)
e. Economy of Expression: Can the smallest c-structure for a given f-structure be identified?[6]

Appendix A includes simple proofs showing that a number of more specific questions are also undecidable. Additional restrictions are clearly necessary to provide a linguistic formalism that is mathematically manageable.

5 Conservation and decidability

The recognition and realization problems are undecidable for unrestricted LFG grammars because there is no finite number of (size-bounded) annotated c-structures whose inspection is sufficient to determine whether there is a valid derivation for a given input string/f-structure. As a consequence, there is no systematic relationship between the length of a string and the sizes of its f-structure parses or the size of an f-structure and the lengths of its generated strings. Moreover, a grammar can assign infinitely many f-structures to a single string and

---

[5] Cyclic f-structures have been proposed in the analysis of complex adjunction and coordination constructions (Zweigenbaum 1988, Fang & Sells 2007, Haug & Nikitina 2012, Przepiórkowski & Patejuk 2012) and thus cannot be excluded from the LFG formalism. More to the point, example (52b) in the Appendix A shows that it is undecidable whether an arbitrary LFG grammar produces cyclic f-structures.

[6] This follows from the fact that realization is undecidable in the general case (as just sketched): if it cannot be decided whether there are any c-structures at all for an f-structure input, then the smallest such structure cannot be determined.

infinitely many strings to a single f-structure. These properties seem implausible for language as a medium of communication.

From a broader perspective, these excesses can be cast in terms of the “grammatical mapping problem”, the problem of characterizing in an explanatory and computable way the relation Γ between the sentences of a language and representations of their meanings (presumably logical formulas that can be interpreted in a representation of the world) (Kaplan & Bresnan 1982, Kaplan 1987). If s is a sentence of a language and m represents one of its meanings (that is, $(s, m) \in \Gamma$), then pretheoretically we expect the derivational machinery that translates between s and m to be information-conserving in the following sense.

(22) *Principle of Conservation*
For all $(s, m) \in \Gamma$, $|m|$ is bounded by $|s|$ and $|s|$ is bounded by $|m|$.

The size of the meaning representation can be defined in any reasonable way. The crucial claim is that the derivational machinery does not by itself add or subtract, in either direction, arbitrary amounts of information. The additional linguistically appealing property of bidirectional finite ambiguity follows as an immediate corollary.

(23) *Finite Ambiguity*
If Γ is conservative, then each sentence expresses only a finite number of meanings and each meaning is expressed by only a finite number of sentences.

In LFG-based approaches the grammatical mapping Γ is typically conceptualized as the composition of the grammar-defined syntactic derivations Δ_G and the semantic derivations Σ that map primarily between syntactic f-structures and corresponding representations of meaning.[7]

(24) $(s, m) \in \Gamma_G$ iff $(f, m) \in \Sigma$ and $(s, c, f) \in \Delta_G$ for some c-structure c.

An end-to-end mapping $(s, m) \in \Gamma_G$ is conservative if the semantic derivation $(f, m) \in \Sigma$ has grammar-dependent bounds in both directions and is thus information-conserving, and s and f of the triple $(s, c, f) \in \Delta_G$ are also co-bounded (the syntactic derivation is also conservative). Recalling that $|s|$ and $|f|$ are both bounded by $|c|$ in any derivation triple (8), it follows that

---

[7] This is not to discount the influence of linguistic features that may be formalized in other projections within the LFG correspondence architecture. The bounding requirements of the Conservation Principle would also govern mappings that include those other projections.

(25) An LFG syntactic derivation $(s, c, f) \in \Delta_G$ is *conservative* if also $|c|$ is bounded by both $|s|$ and $|f|$.

The syntactic recognition/parsing and realization/generation problems are solvable if only conservative derivations are defined to be linguistically relevant, in accordance with principle (22). In each direction only a finite number of size-limited annotated c-structures must be enumerated and inspected to determine whether a derivation belongs to Δ_G.[8]

With respect to Σ, Glue Semantics (Dalrymple et al. 1993, Dalrymple 1999) determines a meaning representation m for a string by a linear-logic deduction applied to a collection of premises associated with an f-structure f assigned to that string. The resource-sensitive nature of linear logic suggests that m will naturally be bounded by $|f|$, but that has not yet been clearly established. It is also unknown whether or under what additional conditions the f-structures that correspond to a given meaning representation m are bounded by $|m|$.[9] With the expectation that those issues will be resolved in future research, we return here to our focus on Δ_G, the syntactic component of Γ_G.

Kaplan & Bresnan (1982) were the first to show the undecidability of the recognition problem for unrestricted LFG grammars and the first to address it by imposing an information-conserving constraint on the derivations in Δ_G. Their constraint restricts the derivations of the annotated c-structure grammar so as to limit the distribution of empty nodes and nonbranching dominance chains.[10] The effect is to include as NBD-valid c-structures only those where every recursive subderivation contains at least one pair of terminal-dominating sisters. This specifically excludes the derivations that our demonstrations of recognition undecidability rely on. All NBD-valid derivations are conservative in the parsing direction, since the annotated c-structure is bounded by the length of the string, and the recognition and parsing problems are therefore solvable.

---

[8] However, the emptiness problem remains undecidable even if attention is confined only to conservative derivations. All derivations for the grammars constructed with rules (13) and (14) are conservative in the sense of (25). Emptiness requires consideration of all possible string or f-structure inputs, not just particular ones that are presented for parsing or generation. By the same token, it is undecidable whether all derivations for a given grammar are conservative.

[9] Generation from an f-structure not bounded by $|m|$ can be reduced to the undecidable problem of generating from an arbitrarily underspecified f-structure (Wedekind 1999).

[10] The NBD constraint in LFG was a specific and early example of a family of what have become known generically as *Off-line Parsability* conditions. A number of variants of Off-line Parsability have been proposed for other grammatical frameworks. See Jaeger et al. 2005 for a survey.

By a symmetrical argument, syntactic derivations will be conservative in the generation direction if they are restricted so that the size of the annotated c-structure is bounded as a function of the size of the f-structure. Unfortunately, the NBD condition is not sufficient to pick out just those information-conserving derivations and thus to ensure also that the realization and generation problems are decidable (cf. Wedekind (2014), Wedekind & Kaplan (2020)). The attribute-chain string-encoding grammars and the combining start rule (19) used in the undecidability proof for realization are ϵ-free, and it is only (nonrecursive) terminal rules that do not branch. A condition stronger than the NBD restriction is needed to guarantee that generation is conservative and thus decidable.

It has also been noted, on the other hand, that the original NBD condition may be too strong. It disallows recursive nonbranching dominance chains in every context, even when an errant subderivation is a component of a discontinuous constituent supported intuitively by an element elsewhere in the string. For example, Johnson (1986) observed that it proscribes the straightforward analysis of the Dutch double infinitive construction as provided by the grammar of Bresnan et al. (1982) and illustrated in (26).

(26) (dat) hij het boek heeft kunnen lezen
(that) he the book has able read
'(that) he has been able to read the book'

Recursive applications of the nonbranching VP rule (27) would be required to match the level of the obj 'het boek' with the level of its governing predicate in the discontinuous, extended-head configuration.[11]

(27) VP → VP
(↑ xcomp) = ↓

We address these shortcomings of Kaplan and Bresnan's NBD restriction by introducing an alternative way of identifying a subclass of conservative derivations that is better attuned to the natural flow of linguistic information. It takes into

---

[11] Johnson's particular example does not violate the very early refinement of the constraint wherein functional annotations are also taken into account in determining whether a category is recursive. This was introduced soon after the original formulation and later described by Kaplan & Maxwell (1996) and Dalrymple 2001. But this slightly weaker version would still disallow the intended analyses of sentences with more intransitive verbs and deeper xcomp embeddings as in

(dat) hij het boek moet haben kunnen lezen
(that) he the book must have able read
'(that) he must have been able to read the book'

account the architectural correspondence between c-structures and f-structures to impose a new bound on the size of generation c-structures while relaxing the bound in the parsing direction. Our new condition makes use of the following definitions.

Let c be an annotated c-structure and let n and n' be two distinct nodes in c with n dominating n'. The *subderivation from n to n'*, denoted by $c^{n}_{n'}$, is the derivation that we obtain from c by removing from the subderivation rooted by n the subtree under n'. Two subderivations $c^{n}_{n'}$ and $c^{\check{n}}_{\check{n}'}$ are said to be *stacked* if the bottom node of one dominates the top node of the other. A subderivation $c^{n}_{n'}$ is *recursive* if n and n' are both labeled with the same annotated category.

The admissibility of recursive subderivations is then defined in terms of f-structure and string anchors.

(28) Let c be an annotated c-structure with terminal string s and f-structure f. We say that a recursive subderivation $c^{n}_{n'}$ is

a. *f-anchored in f_k* if there is a node $\bar{n}$ of $c^{n}_{n'}$ such that $\phi(\bar{n}) = f_k$ and

b. *s-anchored in s_j* if there is a node $\bar{n}$ of $c^{n}_{n'}$ such that $\bar{n}$ or a node in $\phi^{-1} \circ \phi(\bar{n})$ dominates s_j.

We refer to f_k and s_j as the f- and s-anchors of $c^{n}_{n'}$. The subclass of properly anchored derivations is then defined as follows.

(29) A derivation $(s, c, f) \in \Delta_G$ is *properly anchored* iff

a. every recursive subderivation $c^{n}_{n'}$ of c is f- and s-anchored and

b. the f-anchors of any two recursive subderivations in a stack are distinct, and so are their s-anchors.

If (s, c, f) is a properly anchored derivation, then every recursive subderivation is anchored in both a functional unit of the f-structure and an element of the string (29a). Moreover, requirement (29b) ensures that the anchoring for stacked recursive subderivations is one-to-one. The anchoring of stacked recursive subderivations of such a c-structure is illustrated in Figure 4.

If N is the set of annotated nonterminal categories for a grammar G, any subderivation $c^{n}_{n'}$ with a path length equal to $|N|$ must be recursive. The annotated c-structures of properly anchored derivations are thus bounded by the respective sizes of their corresponding strings and f-structures, as stated in the following lemma.

(30) The depth of the c-structure c of all properly anchored derivations $(s, c, f) \in \Delta_G$ is bounded by $|N|(|s| + 1)$ and $|N|(|f| + 1)$, respectively, for a string of length $|s|$ and an f-structure of $|f|$ units.

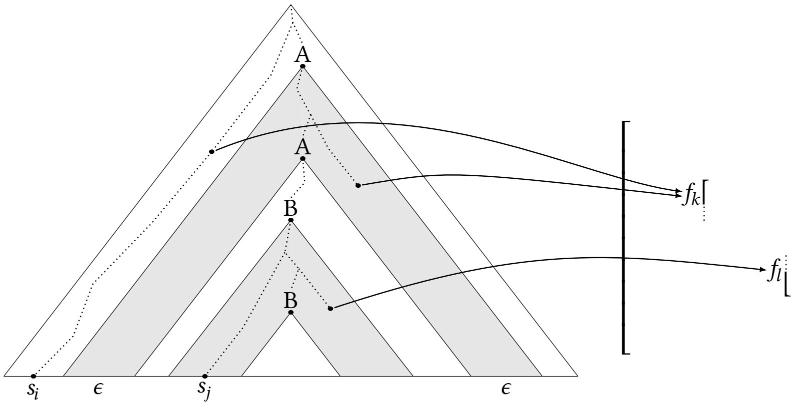


Figure 4: A c-structure with two stacked subderivations, highlighted in gray. The subderivations are f- and s-anchored at f_k, s_i and f_l, s_j, respectively, with $k \neq l$ and $i \neq j$. The upper subderivation is discontinuously string-anchored because none of its internal nodes dominates a terminal (it derives the empty string ϵ) while the lower subderivation is continuously string-anchored.

Lemma (30) implies that the properly anchored derivations for an unrestricted LFG grammar are conservative, and that the recognition and realization problems are therefore decidable if unanchored derivations are excluded from linguistic consideration. This is because only a finite number of size-bounded annotated c-structures need to be inspected in order to solve these problems.

The conditions for proper anchoring include derivations that the NBD condition does not admit and exclude derivations that NBD classifies as valid. NBD and proper anchoring, however, do agree on the status of derivations for the schematic grammars in (31).

(31) a. S → S a S → a NBD-valid
(↑ GF) = ↓ (↑ PRED) = ‘P⟨GF⟩’ (↑ PRED) = ‘A’ anchored

b. S → S S → a NBD-invalid
(↑ GF) = ↓ (↑ PRED) = ‘A’ shared s-anchor
(↑ PRED) = ‘P⟨GF⟩’

The recursive subderivations for (31a) are branching and they are thus both valid and properly string-anchored. Each subderivation is also f-anchored to a distinct unit in its f-structure's GF hierarchy. If GF is a governable grammatical function, then the f-structures of all derivations are complete and coherent and correspond to the *lexical* meanings carried by the repetitively longer strings. The grammar (31b) provides the same set of complete and coherent f-structures but associates all of them to the single one-element string. That string is infinitely ambiguous and there is no bound on the size of the constructional meaning representations determined by the recursive subderivations. These linguistically implausible subderivations are nonbranching and their string anchors cannot be distinct (29b). They are appropriately excluded as neither NBD-valid nor properly anchored.

In (32) we show grammars that provide branching derivations for every string in the set $\{a^n \mid n > 1\}$, and every derivation is thus NBD-valid but properly anchored only with respect to strings. The recursive subderivations of these grammars are excluded because they do not meet the f-anchoring conditions of (29).

(32) a. $\mathrm{S} \rightarrow \mathrm{S}\quad \mathrm{a} \qquad \mathrm{S} \rightarrow \mathrm{a}$ NBD-valid, no f-anchor

b. $\mathrm{S} \rightarrow \underset{\uparrow=\downarrow}{\mathrm{S}}\quad \mathrm{a} \qquad \mathrm{S} \rightarrow \underset{(\uparrow\ \textsc{pred})=\text{‘}\textsc{a}\text{’}}{\mathrm{a}}$ NBD-valid, shared f-anchor

The subderivations of (32a) have no f-anchors (28a) while the f-anchors for the subderivations of (32b) are not pairwise distinct (29b). The effect of the proper anchoring conditions for these configurations is consistent with other exclusionary proposals, in particular, the Different-Words version of Economy of Expression (Dalrymple et al. 2015).

As a final point of comparison, we note that the branching requirement of the NBD condition is essentially a special case of the string-anchor conditions (29) when recursive subderivations are stacked. The string anchors for valid derivations must be dominated by nodes contained within each particular subderivation. In contrast, (28b) admits stacked recursive subderivations whose distinct anchors may be dominated by nodes elsewhere in the c-structure. The linguistically significant relationship is captured in the composition $\phi^{-1}\circ\phi$. It requires only that the dominating node is an extended (co-)head of a node in a recursive subderivation, a component of the same discontinuous constituent (Zaenen & Kaplan 1995, Bresnan et al. 2016). The situation is schematized by the grammar (33).

(33) $\mathrm{S} \rightarrow \underset{\uparrow=\downarrow}{\mathrm{A}}\quad \underset{\uparrow=\downarrow}{\mathrm{P}}$ NBD-invalid, anchored

$\mathrm{A} \rightarrow \underset{(\uparrow\ \textsc{gf})=\downarrow}{\mathrm{A}} \qquad \mathrm{P} \rightarrow \underset{(\uparrow\ \textsc{gf})=\downarrow}{\mathrm{P}}\quad \underset{(\uparrow\ \textsc{pred})=\text{‘}\textsc{p}\langle\textsc{gf}\rangle\text{’}}{\mathrm{p}}$

$\mathrm{A} \rightarrow \underset{(\uparrow\ \textsc{pred})=\text{‘}\textsc{a}\text{’}}{\mathrm{a}} \qquad \mathrm{P} \rightarrow \underset{(\uparrow\ \textsc{pred})=\text{‘}\textsc{p}\langle\textsc{gf}\rangle\text{’}}{\mathrm{p}}$

The highest A and P nodes each dominate a separate stack of recursive subderivations. The subderivations of the P stack contain their distinct p string anchors, but the A stack is a nonbranching (invalid) chain over the single terminal. Because of the parallel GF function assignments, the P nodes serve as extended heads for the A nodes of the A–P discontinuous constituents, and the p terminals can thus act as distinct s-anchors for the A subderivations.[12] The number of A subderivations in each properly anchored derivation is thus bounded by the length of the p substring, and only those finitely-many derivations are made available for further filtering by the Completeness and Coherence subcategorization conditions. Derivations of this type are the basis for a natural account of the discontinuous constituents in Johnson's (1986) Dutch double infinitive examples.[13]

The proper anchoring condition (29) establishes a manageable relationship between strings and f-structures by virtue of the mediating role that recursive c-structures play in the LFG syntactic architecture. This relationship is information-conserving in the sense of (22) and (25). It crucially depends on the ϕ correspondence and the linguistically motivated notion of extended heads to correlate the depth of c-structure recursion with the sizes of strings and f-structures, as indicated by Lemma (30). The set of properly anchored derivations for a given string or f-structure is finitely enumerable. It follows that recognition and realization are decidable for that restricted subset of derivations and so are other input-specific problems as listed in (21) and in Appendix A. It is possible, for example, to identify the most economical (properly anchored) derivation for a given f-structure because there are only a finite number of candidates whose c-structures must be compared. Proper anchoring, however, is not sufficient to ensure decidability of the emptiness problem (the demonstration in Section 4.1 involves only properly anchored derivations), and other questions that require consideration of all possible string and f-structure inputs also remain undecidable.

6 Intractability of parsing and generation

The recognition/parsing, realization/generation, and other problems are decidable for the conservative, properly-anchored derivations of arbitrary LFG grammars. But the fact that the number of derivations for a given input is finite does

---

[12] This arrangement of parallel function assignments gives rise to the so-called "zipper" configuration discussed below and by Maxwell & Kaplan (1996) and Kaplan & Wedekind (2020).

[13] Note also that the same verbs could be reused as anchors for a different stack of recursive subderivations, for example, in the hypothetical case that the language allows an elaboration of this construction with a ditransitive lower verb and a dislocated OBL NP. This is because pairwise distinctness (29b) applies on a per-stack basis.

not mean that it is small, and indeed the computational cost of solving these problems may be very high. We show in this section that recognition and realization are intractable in the worst case, that is, for arbitrary grammars they cannot be solved in a number of processing steps polynomial in the size of a given input. Their intractability is demonstrated by the usual technique of reducing these problems to another problem that is already known to be intractable. The technique requires that the reduction itself is computable in polynomial time so that we know that the reduction procedure does not hide the complexity of the problems of interest.

The 3-SAT problem is the problem in the NP-complete complexity class often used for polynomial-time reductions that establish the intractability of other problems. This is the problem of determining the satisfiability of a Boolean formula in conjunctive normal form where each of the conjoined clauses is a disjunction of three literals. That is, each formula is a conjunction of the form $C_1 \wedge .. \wedge C_n$, each clause C_j is a disjunction of the form $l_{j_1} \vee l_{j_2} \vee l_{j_3}$, and each literal l_{j_i} is a propositional variable p_k or a negated variable $\neg p_k$. The question is whether there is at least one way of assigning truth values to the variables that makes all the clauses be true. The three-clause formula in (34a) is a simple problem that is satisfiable under several assignments among which is the one in (34b).

(34) a. $(p_1 \vee p_2 \vee p_3) \wedge (\neg p_1 \vee \neg p_2 \vee p_3) \wedge (\neg p_1 \vee p_2 \vee \neg p_3)$
b. p_1=TRUE, p_2=FALSE, p_3=FALSE

We show that the recognition problem is intractable by providing a small LFG grammar G such that the set of f-structures $Par_G(s) \neq \emptyset$ if and only if the string s is an encoding of a satisfiable Boolean problem in conjunctive normal form. A formula is presented as a sequence of substrings one corresponding to each clause. The substring for the i^{th} clause begins with the letter c followed by the string of digits $d_1 .. d_j$ that represents the integer i. This is followed by substrings that identify the literals that make up that clause. Every occurrence of a positive literal p_k is encoded as the character + followed by the digits representing the integer k, and every occurrence of a negative literal $\neg p_k$ is represented as the character − followed by the digits for k. According to this scheme the formula (34a) is presented as the string of characters (35).[14]

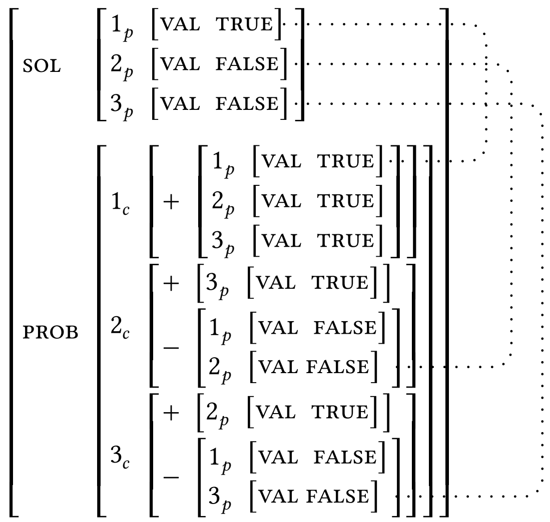
(35) c1 +1+2+3 c2 −1−2+3 c3 −1+2−3

---

[14] We would of course see longer digit strings, not just singletons, for problems with ten or more clauses or variables.

There is a simple information-conserving LFG grammar *G* that maps a string representing any satisfiable Boolean problem into f-structures that recapitulate the problem and make explicit the truth-value assignments that solve it. The linear order of clause and literal substrings is recast into descending chains of digit attributes in the f-structure. The sequences for the signed propositional variables of all literals are attached at the bottom of the attribute chain of their containing clause, and the grouping of literals within clauses is thus maintained. The lower PROB(lem) substructure shown in (36)[15] corresponds to the problem string (35).

(36)



$$\left[\begin{array}{ll}
\textsc{sol} & \left[\begin{array}{ll} 1_p & [\textsc{val}\ \textsc{true}] \\ 2_p & [\textsc{val}\ \textsc{false}] \\ 3_p & [\textsc{val}\ \textsc{false}] \end{array}\right] \\
\textsc{prob} & \left[\begin{array}{ll}
1_c & \left[\begin{array}{ll} + & \left[\begin{array}{ll} 1_p & [\textsc{val}\ \textsc{true}] \\ 2_p & [\textsc{val}\ \textsc{true}] \\ 3_p & [\textsc{val}\ \textsc{true}] \end{array}\right] \end{array}\right] \\
2_c & \left[\begin{array}{ll} + & \left[3_p\ [\textsc{val}\ \textsc{true}]\right] \\ - & \left[\begin{array}{ll} 1_p & [\textsc{val}\ \textsc{false}] \\ 2_p & [\textsc{val}\ \textsc{false}] \end{array}\right] \end{array}\right] \\
3_c & \left[\begin{array}{ll} + & \left[2_p\ [\textsc{val}\ \textsc{true}]\right] \\ - & \left[\begin{array}{ll} 1_p & [\textsc{val}\ \textsc{false}] \\ 3_p & [\textsc{val}\ \textsc{false}] \end{array}\right] \end{array}\right]
\end{array}\right]
\end{array}\right]$$

The upper SOL(ution) substructure corresponds to the truth-value assignment (34b) that makes all clauses be true.

Let $\mathrm{S}_{\mathrm{num}}$ be the root category of a descending attribute-chain grammar for the regular language Digit^{+} of arbitrarily long digit sequences, with the scaffolding attributes B and E giving access to the top and bottom of the descending chains (as in (17) above). Then the rules in (37) provide a c-structure and an f-structure for the string encoding of every well-formed and satisfiable Boolean formula. In particular, the f-structure for one of the derivations for string (35) appears as (36) when the innocuous scaffolding attributes are not displayed.

(37) a. $\mathrm{S} \rightarrow \quad \mathrm{Clause}^{+}$

$(\uparrow \textsc{prob}) = (\downarrow \textsc{b})$

$(\uparrow \textsc{sol}) = (\downarrow \textsc{sol})$

---

[15] The clause and propositional variable subscripts *c* and *p* are provided just for readability; they are not actually part of the formal structure.

b. $$\text{Clause} \rightarrow \begin{array}{ccccc} \text{c} & \text{Snum} & \text{Lit}^* & \text{Lit} & \text{Lit}^* \\ & (\uparrow \textsc{b}) = (\downarrow \textsc{b}) & (\uparrow \textsc{ce}) = \downarrow & (\uparrow \textsc{ce}) = \downarrow & (\uparrow \textsc{ce}) = \downarrow \\ & (\downarrow \textsc{e}) = (\uparrow \textsc{ce}) & & (\uparrow \textsc{sol}) = (\downarrow +) & \\ & & & (\uparrow \textsc{sol}) = (\downarrow -) & \end{array}$$

c. $$\text{Lit} \rightarrow \left\{ \begin{array}{cc|cc} + & \text{Snum} & - & \text{Snum} \\ & (\uparrow +) = (\downarrow \textsc{b}) & & (\uparrow -) = (\downarrow \textsc{b}) \\ & (\downarrow \textsc{e val}) = \textsc{true} & & (\downarrow \textsc{e val}) = \textsc{false} \end{array} \right\}$$

The start rule (37a) recognizes the conjunction of arbitrarily many clause constituents.[16] Every clause consists of one or more literals, and every literal consists of a positive or negative marking followed by the identifier of its propositional variable. The $(\uparrow \textsc{prob}) = (\downarrow \textsc{b})$ annotation promotes all the clause attribute chains to the problem substructure. The additional clause-ending scaffolding attribute ce makes it possible to connect the positive and negative literals to the bottom of their containing-clause chains. The truth-value assignments in (37c) attach the value true at the bottom of the variable chains of positive literals and false at the bottom of negative literals, thereby encoding the truth-value assignments that make each literal be true. Finally, just one of the true literals is selected to make the clause true, and the sol annotations incorporate the variable and truth-assignment of that literal (whether it happens to be positive or negative) into the global solution.

A derivation in G will succeed only if the literals chosen locally and independently for each clause result in sol truth-value assignments that are globally consistent. If a problem is unsatisfiable, then the f-description for every c-structure derivation will be inconsistent. Thus for a string s encoding an arbitrary Boolean problem, the set $Par_G(s) \neq \emptyset$ if and only if that problem is satisfiable for at least one consistent set of truth-value assignments.[17]

With this abstract formal grammar it is easy to see the potential source of computational complexity for LFG recognition. For each literal of every clause, rule (37b) produces an alternative annotated c-structure that makes a different contribution to sol. The number of properly anchored derivations that must be inspected for global consistency thus grows in the worst case as an exponential in

---

[16] For succinctness and clarity we use LFG's traditional Kleene $^+$ and * notations to specify repeating category sequences rather than their right-recursive equivalents. For example, the single rule (37a) is equivalent to the two rules $\text{S} \rightarrow \begin{array}{c} \text{Clause} \\ (\uparrow \textsc{prob}) = (\downarrow \textsc{b}) \\ (\uparrow \textsc{sol}) = (\downarrow \textsc{sol}) \end{array}$ and $\text{S} \rightarrow \begin{array}{cc} \text{Clause} & \text{S} \\ (\uparrow \textsc{prob}) = (\downarrow \textsc{b}) & \uparrow = \downarrow \\ (\uparrow \textsc{sol}) = (\downarrow \textsc{sol}) & \end{array}$.

[17] Berwick (1982) provided the first NP-completeness proof for the LFG recognition problem and Stanley Peters (p.c. 1982) offered a different argument. The demonstration here uses far less of the LFG machinery than those earlier proofs and generalizes to problems with arbitrary numbers of clauses and variables.

the number of clauses. For example, there will be 3^n derivations to consider in the case of a 3-SAT problem with *n* clauses each of which has three literals. Linguistic grammars will also have this exponential complexity profile if their fixed number of rules describe morphosyntactic agreement dependencies that range over the full length of the input string. We can also see, schematically, a configuration that is sufficient to guarantee tractability while still allowing for input strings of arbitrary length. Suppose there is a constant *k* that limits the number of clauses that a single S can expand to, as in (38), but with a new starting category S′ that allows for the concatenation of an arbitrary number of *k*-limited S's.

(38) $$\mathrm{S}' \rightarrow \mathrm{S}^{+} \qquad \mathrm{S} \rightarrow \begin{array}{c}\text{Clause}^{\leq k}\\ (\uparrow \textsc{prob})=(\downarrow \textsc{b})\\ (\uparrow \textsc{sol})=(\downarrow \textsc{sol})\end{array}$$

Crucially, there are no annotations on S′ to link the f-structures of the S nodes, and thus there can be no interaction among the truth assignments of the embedded clauses. The worst case complexity for a string of *n* 3-literal clauses is proportional to $\frac{n}{k} \cdot 3^k$. This is exponential in the grammar-dependent constant *k* but polynomial in the length of the input. This foreshadows the tractability of *k*-bounded LFG grammars that we discuss in the next section.

For recognition the Boolean problem string and f-structure are organized so that the signed propositional variables are grouped within clauses, and the grammar checks for consistency of variable truth values in the global SOL structure. For the reduction of the LFG realization problem to Boolean satisfiability, the string and corresponding f-structure are transposed so that a Boolean problem is presented with its clauses grouped within its propositional variables. We again provide a small LFG grammar G' now with the property that the string set $Gen_{G'}(f) \neq \emptyset$ if and only f is the encoding of a satisfiable Boolean problem.[18] The transposed string presentation and equivalent f-structure for problem (34a) are shown in (39).

(39) a. p1 +1−2−3 p2 +1−2+3 p3 +1+2−3

---

[18] See Wedekind & Kaplan (2021) for a fuller discussion of the technical issues particularly concerning the realization problem.

b.
$$\left[\begin{array}{ll}
1_p & \left[\begin{array}{ll} + & \left[1_c\right] \\ - & \left[\begin{array}{l} 2_c \\ 3_c \end{array}\right] \end{array}\right] \\
2_p & \left[\begin{array}{ll} + & \left[\begin{array}{l} 1_c \\ 3_c \end{array}\right] \\ - & \left[2_c\right] \end{array}\right] \\
3_p & \left[\begin{array}{ll} + & \left[\begin{array}{l} 1_c \\ 2_c \end{array}\right] \\ - & \left[3_c\right] \end{array}\right]
\end{array}\right]$$

The string indicates that variable 1 occurs in a positive literal in the first clause but in negative literals in the second and third clauses. The linear order of variables and clauses in the string is reflected in the f-structure's descending attribute chains. The clause identifiers are grouped according to the signed propositional variables of the literals that they contain.

The LFG grammar G' in (40) establishes the relationship between the equivalent string and f-structure expressions of any well-formed Boolean formula, whether satisfiable or not.

(40) a.
$$\begin{array}{ll}
\text{S} \rightarrow & \text{Var}^{+} \\
 & (\uparrow \textsc{prob}) = (\downarrow \textsc{b}) \\
 & (\uparrow \textsc{sol}) = (\downarrow \textsc{sol})
\end{array}$$

b.
$$\begin{array}{lllllll}
\text{Var} \rightarrow \text{p} & \text{Snum} & \{+ & \text{Snum} & \mid - & \text{Snum} & \}^{+} \\
 & (\uparrow \textsc{b}) = (\downarrow \textsc{b}) & & (\uparrow \textsc{ve}\ +) = (\downarrow \textsc{b}) & & (\uparrow \textsc{ve}\ -) = (\downarrow \textsc{b}) & \\
 & (\downarrow \textsc{e}) = (\uparrow \textsc{ve}) & & & & &
\end{array}$$

A sentence consists of a sequence of proposition-variable substrings each of which begins with a variable identifier followed by any number of digit substrings representing the clauses in which that variable appears. Each clause is prefixed with + and − to indicate whether the variable appears in a positive or negative literal. The annotations promote the variable's descending digit-chain to the top and attach the clause identifiers under the + or − attributes at the bottom of each variable chain, according to whether the clause is positively or negatively marked. This produces the f-structure displayed in (39b) (again with omission of the scaffolding attributes B/E and now VE). If f is an input f-structure for realization that expresses an arbitrary Boolean problem in this way, then the set $Gen_{G'}(f)$ includes a string of the form (39a).

Both the input f-structure and the grammar must be elaborated so that LFG realization distinguishes between satisfiable and unsatisfiable Boolean problems.

Along with the encoding of a particular problem the f-structure must specify the necessary and sufficient conditions for a solution, namely, that every clause is true under at least one consistent assignment of truth values to the variables. The input f-structure represents this requirement by attaching a value TRUE at the bottom of every clause identifier in the top-level SOL substructure and wherever the clause appears in the problem encoding under PROB. F-structure (41) is the elaboration of (39b) with this additional information.

(41)
$$\begin{bmatrix} \textsc{sol} & \begin{bmatrix} 1_c & [\textsc{val true}] \\ 2_c & [\textsc{val true}] \\ 3_c & [\textsc{val true}] \end{bmatrix} \\ \textsc{prob} & \begin{bmatrix} 1_p & \begin{bmatrix} + & \begin{bmatrix} 1_c & [\textsc{val true}] \end{bmatrix} \\ - & \begin{bmatrix} 2_c & [\textsc{val true}] \\ 3_c & [\textsc{val true}] \end{bmatrix} \end{bmatrix} \\ 2_p & \begin{bmatrix} + & \begin{bmatrix} 1_c & [\textsc{val true}] \\ 3_c & [\textsc{val true}] \end{bmatrix} \\ - & \begin{bmatrix} 2_c & [\textsc{val true}] \end{bmatrix} \end{bmatrix} \\ 3_p & \begin{bmatrix} + & \begin{bmatrix} 1_c & [\textsc{val true}] \\ 2_c & [\textsc{val true}] \end{bmatrix} \\ - & \begin{bmatrix} 3_c & [\textsc{val true}] \end{bmatrix} \end{bmatrix} \end{bmatrix} \end{bmatrix}$$

In this depiction the dotted line shows that the clause identifiers and their truth values in the solution are equated to all of their occurrences in the problem-statement substructure.

F-structure (41) is correctly assigned to the satisfiable problem string (39a) if the single Var expansion rule above is replaced by the alternatives in (42).

(42)

a.
$$\begin{array}{llllll} \text{Var} \rightarrow \text{p} & \text{Snum} & \{+ & \text{Snum} & \mid - & \text{Snum}\ \}^{+} \\ & (\uparrow \textsc{b})=(\downarrow \textsc{b}) & & (\uparrow \textsc{ve}\ +)=(\downarrow \textsc{b}) & & (\uparrow \textsc{ve}\ -)=(\downarrow \textsc{b}) \\ & (\downarrow \textsc{e})=(\uparrow \textsc{ve}) & & (\uparrow \textsc{sol})=(\downarrow \textsc{b}) & & (\uparrow \textsc{sol})=(\downarrow \textsc{b}) \\ & & & (\downarrow \textsc{e val})=\textsc{true} & & \end{array}$$

b.
$$\begin{array}{llllll} \text{Var} \rightarrow \text{p} & \text{Snum} & \{+ & \text{Snum} & \mid - & \text{Snum}\ \}^{+} \\ & (\uparrow \textsc{b})=(\downarrow \textsc{b}) & & (\uparrow \textsc{ve}\ +)=(\downarrow \textsc{b}) & & (\uparrow \textsc{ve}\ -)=(\downarrow \textsc{b}) \\ & (\downarrow \textsc{e})=(\uparrow \textsc{ve}) & & (\uparrow \textsc{sol})=(\downarrow \textsc{b}) & & (\uparrow \textsc{sol})=(\downarrow \textsc{b}) \\ & & & & & (\downarrow \textsc{e val})=\textsc{true} \end{array}$$

The SOL annotations in both versions lift all the clause identifiers, whether positive or negative, to the top-level. The rules differ in that (42a) also attaches the value TRUE only at the bottom of every positive-clause chain while (42b) attaches TRUE only to the bottom of every negative clause. Thus for every variable there is a choice in every derivation between the two expansions, corresponding to a guess of consistent truth-value assignments for every variable.

If a problem is satisfiable, then each clause will be assigned TRUE under at least one variable, that value will be carried with the clause identifier into the SOL structure, and it will propagate by equality to all of the other (positive or negative) occurrences of that clause. The result will be an f-structure configured as in (41), and the string corresponding to the problem substructure will be a realization of that f-structure.

Grammar G' will also derive annotated c-structures and f-structures for a string that represents an unsatisfiable problem, but each of those f-structures will be missing a required truth value for at least one of the clauses. For the trivially unsatisfiable problem $p_1 \wedge \neg p_1$ the input f for realization is the f-structure (43a) and (43b) is its corresponding string expression.

(43) a.
$$\begin{bmatrix} \textsc{sol} & \begin{bmatrix} 1_c & [\textsc{val true}] \\ 2_c & [\textsc{val true}] \end{bmatrix} \\ \\ \textsc{prob} & \begin{bmatrix} 1_p & \begin{bmatrix} + & \begin{bmatrix} 1_c & [\textsc{val true}] \end{bmatrix} \\ - & \begin{bmatrix} 2_c & [\textsc{val true}] \end{bmatrix} \end{bmatrix} \end{bmatrix} \end{bmatrix}$$

b. p1 +1−2

With just one variable there is only one choice between the alternative Var expansion rules, giving rise to two derivations. Assigning TRUE to the positive literal produces f-structure (44a) and (44b) results if the negative literal is selected. Neither of these is complete for all the attributes and values of (43a) and thus string (43b) (and any other string that corresponds to the problem substructure) does not belong to $Gen_{G'}(f)$.

(44) a.
$$\begin{bmatrix} \textsc{sol} & \begin{bmatrix} 1_c & [\textsc{val true}] \\ 2_c & \end{bmatrix} \\ \\ \textsc{prob} & \begin{bmatrix} 1_p & \begin{bmatrix} + & \begin{bmatrix} 1_c & [\textsc{val true}] \end{bmatrix} \\ - & \begin{bmatrix} 2_c & \end{bmatrix} \end{bmatrix} \end{bmatrix} \end{bmatrix}$$

b.
$$\begin{bmatrix} \textsc{sol} & \begin{bmatrix} 1_c & \\ 2_c & [\textsc{val true}] \end{bmatrix} \\ \\ \textsc{prob} & \begin{bmatrix} 1_p & \begin{bmatrix} + & \begin{bmatrix} 1_c & \end{bmatrix} \\ - & \begin{bmatrix} 2_c & [\textsc{val true}] \end{bmatrix} \end{bmatrix} \end{bmatrix} \end{bmatrix}$$

Any Boolean satisfiability problem can thus be reduced to the realization problem for the simple LFG grammar G' if the problem is translated to an input f-structure that encodes the problem and the requirement of truth for all clauses. A derivation for G' will map a string to that f-structure if and only if the Boolean problem is satisfiable. As for recognition, realization is intractable because the number of derivations whose f-structures must be compared to the input is exponential in the size of the problem, in this case the number of variables it contains.

7 *k*-bounded LFG grammars and tractability

These intractability results for the conservative, properly anchored derivations of arbitrary grammars raise the question whether there are other formal restrictions that will guarantee that the computationally important problems of recognition and realization can be solved in polynomial time. Seki et al. 1993 first established the connection between a much more restricted subclass of LFG grammars and Linear Context-Free Rewriting Systems (LCFRS), formal systems that can describe only mildly context-sensitive dependencies and for which the recognition problem is tractable (Kallmeyer 2010). The Seki et al. *finite-copying grammars* permit rules with the very limited functional annotations in (45a) provided that all their derivations also satisfy the bounding condition (45b).

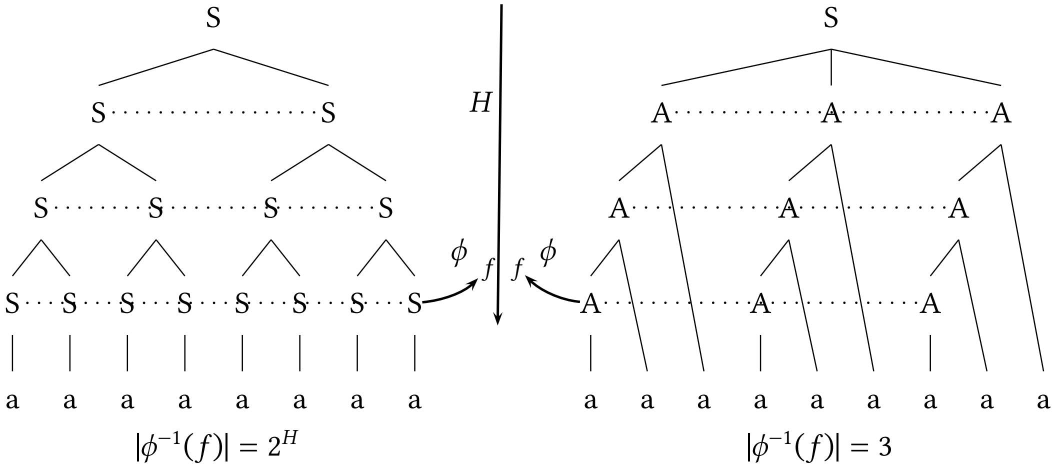
(45) a. Each category on the right-side of a rule can be annotated with at most one function assignment of the form $(\uparrow \textsc{f}) = \downarrow$ and any number of atom-value assignments only of the form $(\uparrow \textsc{a}) = \textsc{v}$.
b. There is a constant k such that no more than k nodes map to the same f-structure element f in any derivation. That is, $|\phi^{-1}(f)| \leq k$ for every f.[19]

Structure sharing in finite-copying grammars can only be achieved through instantiated function-assigning annotations. This specific type of structure sharing is occasionally referred to as "zipper" unification. That is, if two distinct nodes n_1 and n_2 map to the same f-structure in a derivation, then there must always be a node $\hat{n}$ dominating these nodes such that the sequences of function-assigning annotations on the paths from $\hat{n}$ to n_1 and n_2, respectively, must be identical, that is, form a "zipper".

The bounding condition (45b) limits the number of non-local dependencies that can arise through structure sharing and thus proscribes c-structure recursions that give rise to zippers of size greater than the constant k. Indeed, Seki et al. have shown that the recognition problem is NP-complete for grammars

---

[19] This condition can also be expressed in terms of an extended-head formulation: $|\phi^{-1} \circ \phi(n)| \leq k$ for every c-structure node n. The parameter k may also be regarded as a formal characterization of the linguistic notion *degree of discontinuity* (Chomsky 1953).



a. C-structure for grammar (46a)   b. C-structure for grammar (46b)

Figure 5: Zipper nodes in depth-balanced c-structures

that meet the notational restrictions (45a) but do not satisfy the bounding condition (45b). Thus the bounding condition is crucial for tractable performance even with the severe notational restrictions of the finite-copying formalism.

Grammars with these limited annotations are expressive enough to specify the kinds of derivations depicted in Figure 5. The derivation on the left is produced by the simple recursive rules in (46a) while the one on the right is derived with the grammar (46b).

(46) a. $\text{S} \rightarrow \underset{(\uparrow \textsc{l}) = \downarrow}{\text{S}} \quad \underset{(\uparrow \textsc{l}) = \downarrow}{\text{S}}$ $\qquad$ $\text{S} \rightarrow \underset{(\uparrow \textsc{l}) = \#}{\text{a}}$

b. $\text{S} \rightarrow \underset{(\uparrow \textsc{l}) = \downarrow}{\text{A}} \quad \underset{(\uparrow \textsc{l}) = \downarrow}{\text{A}} \quad \underset{(\uparrow \textsc{l}) = \downarrow}{\text{A}}$ $\qquad$ $\text{A} \rightarrow \underset{(\uparrow \textsc{l}) = \downarrow}{\text{A}} \ \text{a}$ $\qquad$ $\text{A} \rightarrow \underset{(\uparrow \textsc{l}) = \#}{\text{a}}$

These grammars both meet the finite-copying notational restrictions (45a), and the derivations of both grammars have nodes that share structure in the zipper configurations indicated by the dotted lines. But the difference in these structure-sharing configurations corresponds to a difference in computational complexity. For all derivations of grammar (46a) the number of nodes in the set $\phi^{-1}(f)$ is an exponential in the height H of those nodes, as indicated in Figure 5a. In contrast, for all derivations of grammar (46b) the number of nodes in a structure-sharing set is bounded by a constant (3 in this case) that is independent of their height (Figure 5b). Grammar (46b) but not (46a) meets the finite-boundedness property

(45b), and this is a decidable property for all derivations of such notationally restricted grammars. Note that the string and f-structure sizes are correlated in the derivations of both grammars. They are thus not distinguished by the conditions of proper anchoring.

The restrictions (45a) are obviously too severe for linguistic description. The notation disallows, for example, the trivial ↑ = ↓ annotations that mark the heads and coheads in the functional domain of a predicate, the (↑ xcomp subj) = (↑ obj) equations of functional control, and all other ways of relating the f-structures of different nodes. They also exclude multi-attribute value specifications, such as (↑ subj num) = sg, that encode agreement requirements, and any direct specification of feature values on daughter nodes, as in (↓ case) = nom.

Wedekind & Kaplan 2020 take the Seki et al. 1993 finite-copying grammars as the starting point for developing a subclass of LFG grammars that are more suitable for linguistic description but are similarly limited in their expressive power. The *k-bounded* LFG grammars of Wedekind and Kaplan allow the richer set of annotations in (47).

(47)

Basic annotations	
↑ = ↓	(co)head identifier
(↑ f) = ↓	function assignment
(↑/↓ a b c ⋯) = v	general atom-value assignments
Reentrancies	
(↑ f) = (↑ h)	local-topic link
(↓ g) = (↑ h)	daughter-mother control
(↓ g) = (↓ h)	daughter sharing
(↓ g) = ↑	promotion
(↑ f) = ↑	mother cycle
(↓ g) = ↓	daughter cycle
(↑ f g) = (↑ h)	functional control

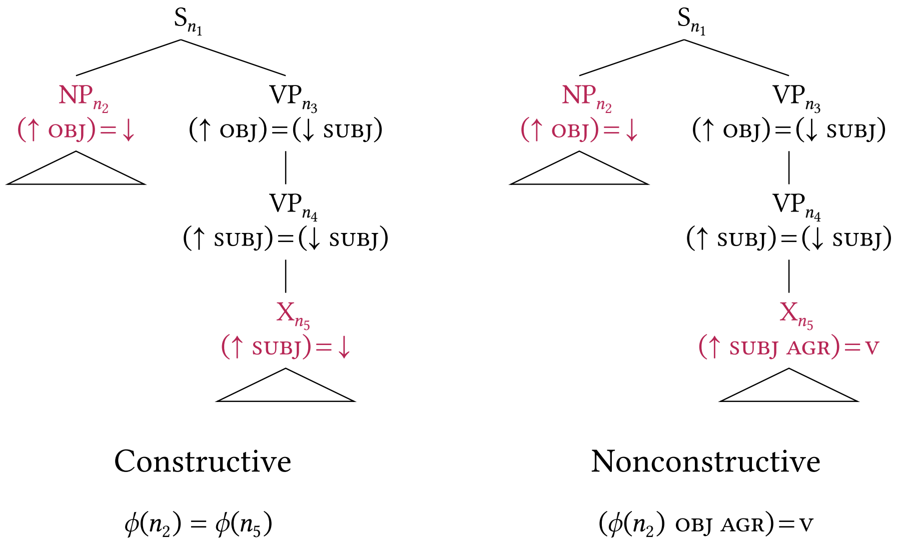
The annotations in this enlarged set include those that are commonly used in natural language grammars and that remain compatible with theoretical conventions such as the Principle of Functional Locality (Kaplan & Bresnan 1982). In *k*-bounded grammars these more flexible annotations are accompanied with additional conditions that also limit the number of non-local dependences that can arise through structure sharing. The *k*-bounded LFG grammars thus enjoy the same mathematical and computational properties that Seki et. al identified: They characterize only mildly context sensitive languages for which recognition is tractable. The additional conditions that a *k*-bounded grammar *G* must meet are listed in (48).

(48)
a. Each right-side category is annotated with at most one function assignment ($(\uparrow \text{F}) = \downarrow$), and (co)head identifiers $\uparrow = \downarrow$ and function assignments always appear in complementary distribution (to keep separate the properties of heads and their complements).
b. The *functional domains* of G (the collections of $\uparrow = \downarrow$-annotated nodes that map to the same f-structure) are bounded by a grammar-dependent constant h (so G can be converted to an equivalent grammar $G^{\backslash\uparrow=\downarrow}$ that is free of $\uparrow = \downarrow$ annotations).
c. The derivations of the grammar formed by removing all reentrancies from $G^{\backslash\uparrow=\downarrow}$ are bounded by a grammar-dependent constant k, as in (45b). (Wedekind & Kaplan 2020 call this the *reentrancy-free kernel* of G.)
d. Reentrancies are nonconstructive.

Nonconstructivity is an implicit property of derivations in broad coverage LFG grammars that has been mentioned (but not well formalize) in the LFG literature as a requirement for functional uncertainty and off-path constraints (Crouch et al. 2011, Zaenen & Kaplan 1995) (Dalrymple et al. 1995: page 133). The reentrancies of a grammar are nonconstructive if they cannot extend the ϕ mapping from c-structure nodes to f-structure units beyond the correspondences established by simple function assignments (the zipper-forming annotations of finite-copying grammars).

The difference between constructive and nonconstructive reentrancies is illustrated in Figure 6. On the left side the reentrancies are constructive because they cause the nodes n_2 and n_5 to map to the same f-structure element. If reentrancies are nonconstructive, as in the derivation on the right side, they do not introduce node-to-f-structure mappings that are not entailed by function assignments alone, and thus they do not affect the bounds that function assignments establish on the ϕ^{-1} node classes. Nonconstructive reentrancies only propagate the limited atom-value information that the grammar attaches to individual nodes and not the unregulated amount of information that might be associated recursively with entire subtrees.

Wedekind & Kaplan 2020 have shown that the nonconstructivity condition (48d) is decidable if the ϕ^{-1} node classes of a grammar are k-bounded and if any two-attribute functional control annotations can be reduced to shorter ones (e.g. shrinking $(\uparrow \text{XCOMP SUBJ}) = (\uparrow \text{OBJ})$ to $(\downarrow \text{SUBJ}) = (\uparrow \text{OBJ})$ when conjoined with $(\uparrow \text{XCOMP}) = \downarrow$). While it is undecidable in general whether every functional control annotation can be shortened (see example (52c) in Appendix A), they can



Constructive

$\phi(n_2) = \phi(n_5)$

Nonconstructive

$(\phi(n_2)\ \textsc{obj agr}) = \textsc{v}$

Figure 6: Constructive and nonconstructive reentrancies.

always be reduced to daughter-mother controls in derivations that meet the requirements of the Coherence Condition. Wedekind & Kaplan 2020 provide a formal specification of nonconstructivity, this expected consequence of Coherence, and other technical requirements that are sufficient to decide whether an arbitrary LFG grammar belongs to the k-bounded subclass and therefore describes only mildly context-sensitive languages.

Wedekind & Kaplan 2020 also prove that for any LFG grammar G with the properties defined in (47) and (48) there is a linear context free rewriting system that accepts all and only the strings in $L(G)$ and allows recovery of the f-structures that G assigns to each such string. The tractability of LCFRS recognition thus establishes for k-bounded LFG grammars that recognition of individual input strings can be accomplished in time polynomial in their length. Here we sketch a simpler demonstration that is framed entirely within the LFG formalism. This is based on a line of argument that Lang 1994 and others have developed for the recognition problem of context-free grammars.

On this approach to context-free recognition the solution is partitioned into two phases. Given an input string s and an arbitrary context-free grammar G with $|G|$ rules, the first step is to specialize G to a context-free grammar G_s with the property that $s \in L(G)$ if and only if $L(G_s) \neq \emptyset$. The second step then is to determine whether or not the language $L(G_s)$ is empty. In the context-free case the procedure for specializing G to s and the size of the resulting grammar are both polynomial in the length of the input, and for context-free grammars the emptiness problem is bounded by a polynomial in grammar size. It follows on this particular argument (among many others) that context-free recognition is bounded by a polynomial in $|s|$.

This two-part strategy immediately carries over to LFG recognition. The specialization of an arbitrary LFG grammar G to a given input s can be extracted from the chart data structures provided by any number of context-free parsing algorithms modified to keep track of the annotations of matching c-structure categories (equivalently, to operate unmodified on left-side annotated rules as in (6) above). This is a polynomial process that results in an annotated LFG grammar G_s of size also polynomial in $|s|$ that assigns to s all and only the f-structures that G assigns to s. In particular, $Par_G(s) = \emptyset$ if and only if $Par_{G_s}(s) = \emptyset$, and this is equivalent to the question whether $L(G_s) = \emptyset$.

We noted above that the emptiness problem for arbitrary LFG grammars remains undecidable even if only properly anchored derivations are taken into account. However, if G belongs to the subclass of k-bounded grammars then so does G_s, and the emptiness problem for arbitrary k-bounded grammars is not only decidable but solvable with worst-case complexity that is polynomial in grammar size. A proof of this property is outlined in Appendix B. Thus, following the context-free argument, for any input string s and k-bounded LFG grammar G, in time polynomial in $|s|$ it can be determined whether $s \in L(G)$.

Wedekind & Kaplan 2012 applied a similar two-phase strategy to prove that the realization problem is decidable for an arbitrary LFG grammar G and an arbitrary acyclic input f-structure f (see also Kaplan & Wedekind (2000)). They specialized G to a grammar G_f with the property that the string-set $Gen_G(f) = \emptyset$ if and only if $L(G_f) = \emptyset$. The grammar G_f is context-free and its emptiness is therefore decidable. In the general case the specialization phase is not tractable and the resulting G_f may be exponentially larger than G. If G is k-bounded, however, the consistency and completeness of all LFG derivations for any f, even cyclic ones, can be simulated with an annotation-free polynomial expansion of the categories and rules of G.

Thus the recognition and realization problems for k-bounded grammars can be solved in polynomial time: for arbitrary inputs it can be determined whether the sets $Par_G(s)$ and $Gen_G(f)$ are empty. But the k-bounded restrictions are not sufficient to guarantee that those sets contain only a finite number of elements. The context-free grammar G_f, for example, can describe a language with arbitrarily long strings, if G allows for unlimited morphological markers in subtrees with nodes that are not in the domain of the ϕ projection. And the f-structures for a given string can also be arbitrarily large, if the grammar permits stacked recursive subderivations. If useless rules are removed from G_f and if annotations are carried along in the grammar G_s^* as described in Appendix B, then the generation algorithm for context free grammars can be used to enumerate the elements of $Gen_G(f)$ and $Par_G(s)$, one after the other and each in linear time. But obviously the generation and parsing enumerations will never terminate in the face of infinite ambiguity. The derivations for a k-bounded grammar are not necessarily conservative in the sense of (25), even though the emptiness tests for recognition and realization have tractable solutions.

The proper-anchoring/conservation and k-bounded restrictions target different sources of mathematical and computational complexity. Proper anchoring limits the height of recursive subderivations in a stack but imposes no constraint on the number of stacks in a single derivation. The k-bounded restrictions limit the degree of discontinuity but say nothing to relate the sizes of strings and f-structures. The combination of constraints provides for conservative, finitely-ambiguous, derivations with tractable recognition and realization. We have suggested above that conservation is a plausible pretheoretic property of natural communication, and we have also argued that the k-bounded patterns of information flow are compatible with other linguistic principles (Kaplan & Wedekind 2019, Wedekind & Kaplan 2020). The k-bounded restrictions (47-48) and the proper anchoring condition (29) are different ways of moderating the excessive mathematical and computational power of the basic LFG formalism while preserving in different ways its suitability for linguistic description.

8 Summary

Lexical-Functional Grammar is equipped with a simple architecture that formalizes a piecewise correspondence between structures of different types, the phrase-structure trees of the constituent structure and the attribute-value matrices of the functional structure. We have shown that f-structure encodings of the strings of arbitrary context-free grammars can be produced by straightforward application of the formalism's most primitive annotations. From that it follows that recognition/parsing, realization/generation, and other mathematical and computational questions are easily proved to be undecidable.

One source of this excessive power, at least for the recognition and realization problems, is the fact that an unrestricted grammar may establish no systematic relationship between the sizes of input strings and the sizes of corresponding f-structures. This is inconsistent with the Principle of Conservation (22) that we suggest is a pretheoretic property of language as a medium of communication: the derivational machinery that maps in both directions between strings and their f-structures does not add or subtract arbitrary amounts of information.

Problems that relate to specific inputs, including recognition/parsing and realization/generation, become decidable if unconservative derivations are excluded from consideration.

The annotated c-structure is the generative component of the LFG formalism and serves as the intermediary between strings and f-structures. Thus we have proposed a condition on recursive c-structure subderivations that ensures that strings and f-structures stand in a conservative relationship. A derivation is properly anchored if each recursive subderivation is anchored in elements of both the string and f-structure and recursive subderivations in a stack do not share the same anchors. For parsing this condition improves on the original prohibition of derivations with nonbranching dominance chains but applies to the generation problem as well.

The proper anchoring condition is strong enough to ensure decidability but we show that it is not strong enough to guarantee tractability. Tractability for recognition and realization is the computationally important property of the k-bounded LFG grammars and derivations. These grammars are in the class of mildly context-sensitive grammars, even though their derivations are not necessarily conservative. The subclass of LFG grammars and derivations that meet the conditions of both proper anchoring and k-boundedness has attractive mathematical and computational properties and may serve as a better foundation for a formal theory of natural language syntax.

Appendix A: Other undecidable questions

In Section 4 we used the descending attribute-chain string encoding (17) for arbitrary Chomsky Normal Form context-free grammars to prove the undecidability of the realization problem. We apply that same encoding here to show that several more specific properties are undecidable for unrestricted LFG grammars. The start rule (49) follows the pattern laid out earlier in (19). It denotes the ends of the S_1 and S_2 substrings as E_1 and E_2 respectively and includes a place-holder P for grammatical fragments that we will use to encode other decision problems. As noted before, there are no atomic values and therefore no atom-value clashes in the attribute-chain string encodings, and the set of derivations can only be filtered by properties spelled out in P.

(49)
$$\begin{array}{llccc}
\mathrm{S} & \rightarrow & \mathrm{S}_1 & \mathrm{S}_2 & P \\
 & & (\uparrow \textsc{l}) = \downarrow & (\uparrow \textsc{r}) = \downarrow & \\
 & & (\downarrow \textsc{b}) = (\uparrow \textsc{b}) & (\downarrow \textsc{b}) = (\uparrow \textsc{b}) & \\
 & & (\downarrow \textsc{e}) = (\uparrow \textsc{e}_1) & (\downarrow \textsc{e}) = (\uparrow \textsc{e}_2) &
\end{array}$$

If any realization of P expresses a particular property that is satisfied only if $F(G)$ contains f-structures with equal E_1 and E_2 values, then that property must be undecidable.

As a first example, the alternative annotations on the terminal # in (50) shows that it is undecidable whether a minimal model satisfies either defining or constraining equalities between two f-structure units.

(50)
$$\mathrm{S} \rightarrow \quad \begin{array}[t]{c} \mathrm{S}_1 \\ (\uparrow \textsc{l}) = \downarrow \\ (\downarrow \textsc{b}) = (\uparrow \textsc{b}) \\ (\downarrow \textsc{e}) = (\uparrow \textsc{e}_1) \end{array} \quad \begin{array}[t]{c} \mathrm{S}_2 \\ (\uparrow \textsc{r}) = \downarrow \\ (\downarrow \textsc{b}) = (\uparrow \textsc{b}) \\ (\downarrow \textsc{e}) = (\uparrow \textsc{e}_2) \end{array} \quad \begin{array}[t]{c} \# \\ \left\{ \begin{array}{c} (\uparrow \textsc{e}_1) = (\uparrow \textsc{e}_2) \\ (\uparrow \textsc{e}_1) =_c (\uparrow \textsc{e}_2) \\ (\uparrow \textsc{e}_1) \neq (\uparrow \textsc{e}_2) \end{array} \right\} \end{array}$$

The function assignments on X and Y in (51) show that it is in general undecidable whether there are derivations with nodes that ϕ maps to the same f-structure.

(51)
$$\mathrm{S} \rightarrow \quad \begin{array}[t]{c} \mathrm{S}_1 \\ (\uparrow \textsc{l}) = \downarrow \\ (\downarrow \textsc{b}) = (\uparrow \textsc{b}) \\ (\downarrow \textsc{e}) = (\uparrow \textsc{e}_1) \end{array} \quad \begin{array}[t]{c} \mathrm{S}_2 \\ (\uparrow \textsc{r}) = \downarrow \\ (\downarrow \textsc{b}) = (\uparrow \textsc{b}) \\ (\downarrow \textsc{e}) = (\uparrow \textsc{e}_2) \end{array} \quad \begin{array}[t]{c} \mathrm{X} \\ (\uparrow \textsc{e}_1) = \downarrow \\ (\uparrow \textsc{e}_1) = (\uparrow \textsc{e}_2) \end{array} \quad \begin{array}[t]{c} \mathrm{Y} \\ (\uparrow \textsc{e}_2) = \downarrow \end{array}$$

It follows from this that any other property that depends on nodes mapping to the same f-structure is also undecidable.

Thus, expanding the nonterminals X and Y with the rules (52a) shows that the satisfiability of existential constraints or constraints between atomic values is undecidable and, as a consequence, that Completeness and Coherence are also undecidable. The annotations (52b) establish that it is undecidable whether an arbitrary LFG grammar gives rise to cyclic f-structures, and (52c) shows that functional control annotations cannot decidably be reduced to combinations of function assignments and daughter-mother controls.

(52) a.
$$\mathrm{X} \rightarrow \begin{array}[t]{c} x \\ (\uparrow \textsc{f}) = \textsc{v} \end{array} \qquad \mathrm{Y} \rightarrow \begin{array}[t]{c} y \\ \left\{ \begin{array}{c} (\uparrow \textsc{f}) \\ \neg(\uparrow \textsc{f}) \\ (\uparrow \textsc{f}) =_c \textsc{v} \\ (\uparrow \textsc{f}) \neq \textsc{v} \end{array} \right\} \end{array}$$

b.
$$\mathrm{X} \rightarrow \begin{array}[t]{c} x \\ (\uparrow \textsc{f g}) = (\uparrow \textsc{h}) \end{array} \qquad \mathrm{Y} \rightarrow \begin{array}[t]{c} y \\ (\uparrow \textsc{f}) = (\uparrow \textsc{h}) \end{array}$$

c.
$$\mathrm{X} \rightarrow \begin{array}[t]{c} x \\ (\uparrow \textsc{f g}) = (\uparrow \textsc{h}) \end{array} \qquad \mathrm{Y} \rightarrow \begin{array}[t]{c} y \\ (\uparrow \textsc{f}) = \downarrow \end{array}$$

Appendix B: Emptiness of k-bounded LFG grammars

We sketch here the proof that the complexity of the emptiness problem for an arbitrary k-bounded LFG grammar G is polynomial in $|G|$, the size of its rule set. The argument makes use of the three grammar transformations listed in (53). Each of these can be carried out in polynomial time, as indicated below, and each guarantees that G and the transformed grammar G' are *co-empty*, that is, that the set of derivations $\Delta_G = \emptyset$ if and only $\Delta_{G'} = \emptyset$.

(53)
a. $\uparrow = \downarrow$ removal: For any k-bounded LFG grammar G there is a co-empty $\uparrow = \downarrow$-free k-bounded grammar $G^{\backslash\uparrow=\downarrow}$.
b. Zipper removal: For any $\uparrow = \downarrow$-free k-bound LFG grammar G there is a co-empty 1-bounded (zipper-free) LFG grammar G^{z}.[20]
c. Annotation removal: For any 1-bounded LFG grammar G there is a co-empty annotation-free grammar G^{a}, and G^{a} is context-free.

Applying these transformations in sequence to an arbitrary k-bounded LFG grammar G results in a co-empty context free grammar $G^{*} = G^{\backslash\uparrow=\downarrow,z,a}$ whose size $|G^{*}|$ is a polynomial function of $|G|$. The string-set $L(G) = \emptyset$ if and only if the context free language $L(G^{*}) = \emptyset$, and this can be determined by the well-known emptiness algorithm for context free grammars, which is polynomial in the size of the grammar.

For (53a), the $\uparrow = \downarrow$ annotations in an arbitrary k-bounded grammar G are eliminated by replacing each $\uparrow = \downarrow$-annotated category in one rule with the right-side of each of the rules that expand that category. Let R be the smallest set that includes the rules of G and is closed under the convention (54). In this template δ, θ, and ψ are strings of annotated categories, and α may be a set of annotations with $\uparrow$ substituted for $\downarrow$.

(54) If R contains rules of the form

$$\mathrm{A} \rightarrow \delta \underset{\alpha}{\underset{\uparrow=\downarrow}{\mathrm{B}}} \theta \quad \text{and} \quad \mathrm{B} \rightarrow \psi$$

then R also contains the rule $\mathrm{A} \rightarrow \delta \underset{\alpha}{\psi} \theta$

The $\uparrow = \downarrow$-free grammar $G^{\backslash\uparrow=\downarrow}$ is constructed by removing from R any rules with $\uparrow = \downarrow$ annotations. Note that a replacement sequence can never be longer than the

---

[20] Unlike the transformations that are often used in proofs of other formal-language properties, zipper removal does not preserve the language $L(G)$: the grammars G and G' generally are not weakly equivalent.

limit on the number of nodes in a functional domain, the parameter h of condition (48b). As a consequence, the growth of the grammar is bounded by a polynomial in $|G|$. Moreover, the resulting grammar $G^{\backslash\uparrow=\downarrow}$ accepts exactly the same strings as G and assigns them the same f-structures, although with c-structures that are not as deep.

For (53b), the rules of a zipper-free 1-bounded grammar are created from sets of up to k rules of a $\uparrow=\downarrow$-free k-bounded grammar G. The zipper daughters, occurrences of right-side categories with the same function assignments, are replaced with a single new daughter labeled by the concatenation (notated with $\cdot$) of the labels of the zipper daughters and annotated with the union of the zipper-daughter annotations. Let R now be the smallest set that includes the rules of a $\uparrow=\downarrow$-free grammar G and is closed under the following:

(55) a. If $\mathrm{A}_1 \rightarrow \delta_1,\ \ldots,\ \mathrm{A}_j \rightarrow \delta_j\quad (1 \leq j \leq k)$ are rules in R,

then R also contains the rule $\mathrm{A}_1 \cdot \ldots \cdot \mathrm{A}_j \rightarrow \delta_1 \ldots \delta_j$

b. If R contains a rule of the form

$$\begin{array}{ccccccc} \mathrm{A} & \rightarrow & \delta & \mathrm{B}_1 & \theta & \mathrm{B}_2 & \psi \\ & & & (\uparrow \text{F}){=}\downarrow & & (\uparrow \text{F}){=}\downarrow & \\ & & & \alpha_1 & & \alpha_2 & \end{array}$$

then R also contains the rule $$\begin{array}{cccc} \mathrm{A} & \rightarrow & \mathrm{B}_1 \cdot \mathrm{B}_2 & \delta\ \theta\ \psi \\ & & (\uparrow \text{F}){=}\downarrow & \\ & & \alpha_1\ \alpha_2 & \end{array}$$

The zipper-free grammar G^z is then created by removing from R any rule with multiple assignments for the same function or with annotations that are locally unsatisfiable. Local (within-rule) satisfiability of a rule with n daughters is tested by instantiating all metavariables with distinct constants $b_0, b_1, \ldots, b_n$ that stand for a putative mother node and its daughters. b_0 is substitute for $\uparrow$ in all annotations and b_i is substituted for $\downarrow$ in the annotations of the i^{th} daughter. The local f-description thus created is then solved using standard deductive-closure techniques.

The size of a zipper-free grammar G^z is exponential in k but polynomial in $|G|$, because there are at most $|G|^k$ rule combinations that must be considered. For every derivation in G of a string s with discontinuous subtrees for a particular grammatical function there is a corresponding derivation in G^z that assigns the same f-structure to a string s^z. The two strings contain the same words but not necessarily in the same order: the words are permuted so that the words of discontinuous subtrees for s are contiguous in s^z.

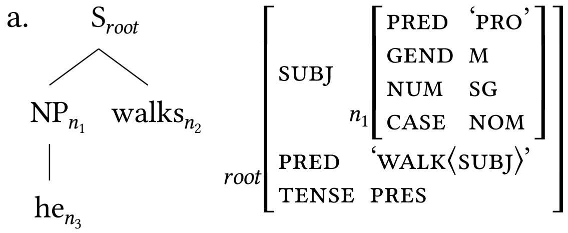
The annotation-removal transformation (53c) is based on the fact that atomic values in a 1-bounded grammar can only propagate between mothers and daughters within a single subtree. This is because, by definition, there are no nodes n and n' in separate subtrees with $\phi(n) = \phi(n')$. Atomic values in sister subtrees may have different values for a particular feature, but that can only result in an overall unsatisfiable f-description if annotation chains relative to a common mother put them in contact. Chains of atom-value annotations carried by the categories of a 1-bounded LFG derivation can be simulated by an elaborated set of refined c-structure categories in a corresponding annotation-free derivation. An annotation-free derivation is context-free and will fail if and only if the f-description for the 1-bounded LFG derivation is unsatisfiable.

The ↑ = ↓-free and zipper-free rules in (56) provide the derivation (57a) for the sentence *He walks.*

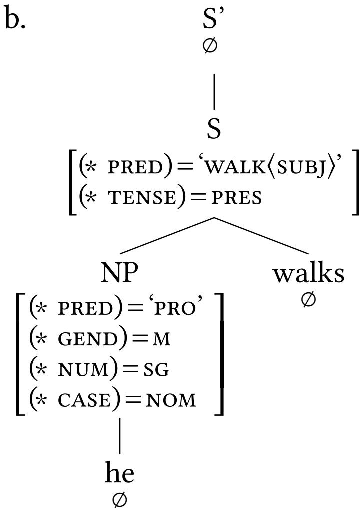
(56)	S →	NP	walks	NP →	he
		(↑ SUBJ) = ↓	(↑ PRED) = ‘WALK⟨SUBJ⟩’		(↑ PRED) = ‘PRO’
		(↓ CASE) = NOM	(↑ TENSE) = PRES		(↑ GEND) = M
			(↑ SUBJ NUM) = SG		(↑ NUM) = SG
					(↑ CASE) = NOM

The f-description is satisfiable because the case assigned to the subject NP matches the case of *he*, and the subject's number, entailed by the combination (↑ SUBJ) = ↓ and (↑ SUBJ NUM) = SG, also matches the number of *he*. The connection between the S and NP feature annotations is simulated by the refined NP category in (57b).

(57) a.



b.



Starting from a new category S’, tree (57b) is the context free derivation provided by the category-refined, annotation-free rules in (58).

(58)

$$\underset{\varnothing}{\text{S'}} \rightarrow \underset{\left[\begin{array}{l}(*\ \textsc{pred})=\text{‘}\textsc{walk}\langle\textsc{subj}\rangle\text{’}\\ (*\ \textsc{tense})=\textsc{pres}\end{array}\right]}{\text{S}}$$

$$\underset{\left[\begin{array}{l}(*\ \textsc{pred})=\text{‘}\textsc{walk}\langle\textsc{subj}\rangle\text{’}\\ (*\ \textsc{tense})=\textsc{pres}\end{array}\right]}{\text{S}} \rightarrow \underset{\left[\begin{array}{l}(*\ \textsc{pred})=\text{‘}\textsc{pro}\text{’}\\ (*\ \textsc{gend})=\textsc{m}\\ (*\ \textsc{num})=\textsc{sg}\\ (*\ \textsc{case})=\textsc{nom}\end{array}\right]}{\text{NP}} \quad \underset{\varnothing}{\text{walks}} \qquad \underset{\left[\begin{array}{l}(*\ \textsc{pred})=\text{‘}\textsc{pro}\text{’}\\ (*\ \textsc{gend})=\textsc{m}\\ (*\ \textsc{num})=\textsc{sg}\\ (*\ \textsc{case})=\textsc{nom}\end{array}\right]}{\text{NP}} \rightarrow \underset{\varnothing}{\text{he}}$$

Note that the c-structure derivation for the string *Him walks* would have an unsatisfiable f-description. The corresponding category mismatch excludes a derivation with refined categories.

For an arbitrary 1-bounded grammar G the co-empty annotation-free grammar G^a produces derivation trees whose nodes are labeled with refined categories of this form. A refined category is a pair $c{:}m$ consisting of a c-structure category label c of G together with a refinement matrix m of atom-value feature specifiers $(*\ \textsc{p q r} \ldots)=\textsc{v}$. The feature specifiers simulate in a G^a derivation the possible interactions of atomic values in the f-description of a corresponding G derivation, as illustrated. Importantly, Wedekind & Kaplan 2020 show that a finite set of specifiers is sufficient to simulate all possible atom-value interactions. These are the specifiers containing no more than ℓ of G's attributes, where ℓ is the number of attributes in the longest atom-value assignment in G.

Let N be the smallest set of refined categories and let R be the smallest set of refined rules, rules with refined-category labels, that are closed under the following conditions (see Wedekind & Kaplan 2020 for additional technical details).

(59)
a. If S is the start symbol of G and S' is a category distinct from other G categories, N contains S:∅ and S':∅ and R contains S':∅ → S:∅.
b. If *term* is a terminal symbol of G, N contains *term*:∅.
c. If r is a refinement of a rule $A_0 \rightarrow \underset{\alpha_1}{A_1} \ldots \underset{\alpha_n}{A_n}$ of G with a sequence of refined categories $A_0{:}m_0, \ldots, A_n{:}m_n$ in N, then R contains r and N contains the refined categories of r.

The refinement of a rule $A_0 \rightarrow \underset{\alpha_1}{A_1} \ldots \underset{\alpha_n}{A_n}$ of G with a sequence of refined categories $A_0{:}m_0, \ldots, A_n{:}m_n$ is produced by instantiating the ↑ and ↓ metavariables with distinct mother-daughter constants $b_0, b_1, \ldots, b_n$, as above, but also including in the local f-description atom-value equations instantiated from the feature-specifier matrices. The additional equations are created by substituting b_i for all of the asterisks in each m_i. A refined rule r is constructed if this augmented f-description is satisfiable. Each category A_i in the original G rule (including the mother category) is replaced by a refined category $A_i{:}m_i'$ where the feature specifiers of m_i' are formed by substituting * for b_i in each length-limited atom-value equation (b_i P Q R...) = V that the f-description entails. The newly refined categories are added to N.

The annotation-free grammar G^a is then constructed in the following way. S':∅ is its starting category, its terminals categories are of the form *term*:∅ for each terminal *term* of G, and its context-free rules are constructed from the refined rules in R by using standard context-free algorithms to eliminate useless rules, those that cannot participate in successful derivations, and then removing their functional annotations. The context-free derivations in G^a correspond to all and only the c-structures of G with satisfiable f-descriptions. Because the feature specifiers in a refined category are limited in length by the grammar parameter ℓ, $|G^a|$ is only polynomially larger than $|G|$ and its emptiness can be determined in polynomial time. We also note that if the annotations are not removed from the useful rules of R, the set of f-structures for a grammar with those still-annotated rules will be exactly the f-structures of G.

Acknowledgments

Chapter 23

Computational implementations and applications

Martin Forst
Cerence Inc.

Tracy Holloway King
Adobe Inc.

Computational implementations of LFG are computer programs composed of LFG annotated c-structure rules and lexical entries. LFG was designed to be computationally tractable and has a strong history of broad-coverage grammar implementations for diverse languages. As with theoretical LFG, implemented grammars primarily focus on c-structure and f-structure, but the resulting f-structures are used as input to semantics and abstract knowledge representation, and some work has focused on the integration of morphological and phonological information as well as argument structure. From a theoretical linguistic perspective, implemented grammars allow the linguist to test analyses and to see interactions between different parts of the grammar. From an application perspective, applications such as machine translation and question answering take advantage of the abstract f-structures and the ability of LFG grammars to parse and generate as well as to detect (un)grammaticality.

Computational implementations of LFG are computer programs composed of LFG annotated c-structure rules and lexical entries. When parsing, they take as input a natural language sentence and output c-structures and f-structures and potentially other projections such as semantics. When generating, they take as input an f-structure and generate a grammatical natural language sentence. As with theoretical LFG, these implemented grammars obey the fundamental premises of LFG such as completeness, coherence, and uniqueness.[1] LFG was de-

---

[1] This contrasts with approaches which produce f-structure-like representations but do not use LFG principles or machinery. See Section 3 and Cahill et al. 2002.

Martin Forst & Tracy Holloway King. 2023. Computational implementations and applications. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 1083–1123. Berlin: Language Science Press. DOI: 10.5281/zenodo.10185986

signed from the outset to be computationally tractable and has a strong history of broad-coverage implementations for multiple languages, primarily through the ParGram project (Butt, King, et al. 1999) which is built on the XLE grammar development platform (Crouch et al. 2011).

Grammar engineering involves the implementation of linguistically-motivated grammars so that natural language utterances and text can be processed to produce deep syntactic, and sometimes semantic, structures. As with theoretical LFG, implemented grammars primarily focus on c-structure and f-structure. The resulting f-structures have been used extensively as input to semantics and abstract knowledge representation. Other work has focused on the integration of morphological and phonological information, as well as argument structure, but in general these areas have lagged behind the proposals in the theoretical literature. In addition, implemented LFG grammars have been used to create large-scale tree and dependency banks, mapping a corpus of sentences to a set of f-structures or related dependency structures.

We first introduce the computational implementations of LFG, presenting specific platforms and touching upon aspects such as core components, grammar development tools, modularity, and runtime performance (Section 1). We then discuss implications for theoretical issues (Section 2) and the ParGram grammar resources (Section 3). Finally, we outline existing and potential applications for LFG implemented grammars (Section 4).

1 Computational implementations

Computational implementations of LFG grammars focus on annotated phrase structure rules and lexical entries. These implementations concentrate on creating high-quality f-structures since most applications use f-structures as their input (Section 4). This section first introduces the major platforms that support LFG implementations. The core components provided by these platforms are then outlined, followed by some specific grammar development tools. Finally two computational notions, modularity and performance, are discussed.

1.1 Platforms

Since the inception of LFG as a grammar framework several platforms aimed at processing text according to the LFG formalism have been created. These platforms range from an M.Sc. project (Minos 2014) and introductory French implementation (Zweigenbaum 1991) to an industrially funded grammar development and processing platform which was actively developed for over two decades: the Xerox Linguistic Environment (XLE). In between those in terms of breadth of applicability and technical maturity are systems developed in academic research institutions, in particular XLFG, SxLFG, and the Free Linguistic Environment (FLE). Active development on many of these systems is limited: for current status and documentation the platform owners should be consulted.

1.1.1 XLFG and Elvex

XLFG (Clément & Kinyon 2001) is a parsing platform that was first implemented for didactic purposes.[2] It has been used to verify the soundness of several proposals to handle a variety of linguistic phenomena (Section 2), e.g. zeugmas, particle verbs, and non-constituent coordination (Clément 2019).

XLFG uses an Earley parser (Earley 1970) for context-free parsing, and then resolves the f-structure constraints on packed c-structure representations (Maxwell & Kaplan 1989, 1993). It expects tokenized sentences as input and uses full-form lexicons for lexical lookup (Section 1.2). XLFG does not facilitate the use of external components like finite-state transducers for preprocessing tasks such as tokenization or morphological analysis (Section 1.2). It has primarily been applied to parsing French and English, i.e. analyzing French or English text into f-structures. Recently, work was started on a generator, i.e. mapping f-structures to text, using XLFG-style grammars for the production of surface realizations from f-structures. This generator is named Elvex.[3]

1.1.2 SxLFG

SxLFG (Boullier & Sagot 2005) was also developed with the participation of Lionel Clément, but its main authors are Pierre Boullier and Benoît Sagot of INRIA. The primary focus of SxLFG is on the deep non-probabilistic parsing of large corpora (Sagot & Boullier 2006) by means of robustness techniques for input sentences for which no spanning c-structure can be produced. The underlying context-free parser is the Earley parser of the SYNTAX project. Like XLFG and XLE, SxLFG resolves f-structure constraints on packed c-structure representations. The French broad-coverage LFG implementation that has been used extensively with SxLFG includes a large full-form lexicon for French, the Lefff 2 (Sagot et al. 2006). Like XLFG, SxLFG does not facilitate the use of external components

---

[2] XLFG is available at http://www.xlfg.org

[3] Elvex is available at https://github.com/lionelclement/Elvex

like finite-state transducers for preprocessing tasks such as tokenization or morphological analysis (Section 1.2). SxLFG was developed for parsing. Generation has not been in the scope of SxLFG.

1.1.3 XLE (and GWW as precursor) and XLE-Web

The Xerox Linguistic Environment (XLE) was developed by the Natural Language Theory and Technology (NLTT) group at the Xerox Palo Alto Research Center (PARC). It started as a reimplementation in C of the earlier Grammar Writer's Workbench (GWW) (Kaplan & Maxwell 1996), which was implemented in Lisp and is still available. XLE was used by several academic and industry teams for the development of LFG implementations for more than a dozen languages (see Section 3 on the ParGram project). XLE, in conjunction with a customized broad-coverage grammar, was used to parse the English Wikipedia in the Powerset search engine (Kaplan 2009).

XLE has mostly been used for parsing, but it includes a generator that can efficiently produce surface realizations from f-structures and even packed f-structure charts (Maxwell 2006). Thanks to this bidirectionality, it has powered applications such as machine translation and sentence condensation (Section 4), and it has been used in research projects on stochastic realization ranking (Cahill & Forst 2009).

From its inception, XLE was designed to use finite-state transducers for low-level processing steps such as (de)tokenization and morphological analysis and generation (Section 1.2). The interface can readily be used with transducers in Xerox's finite-state transducer format including ones converted from the Foma finite-state transducers, and with relatively little programming effort, other external components can be integrated into an XLE grammar (e.g. see Fang & King 2007 on integrating a non-finite state Chinese word breaker into an XLE Chinese grammar).

In addition to the ϕ-projection from c-structures to f-structures, the XLE parser supports further projections from either of those representations. One of them, the optimality structure, is hard-coded to guide the parsing and generation process on the basis of optimality marks (Section 1.5). The use of optimality marks as a robustness mechanism is one of the many extensions of XLE born out of a joint effort of the group at PARC and its ParGram partners.

Other extensions of the parser and generator are aimed at reducing latency and at ranking the (top n) parses or realizations. For the former, the most notable mechanism is c-structure pruning (Cahill et al. 2008). C-structure pruning relies on corpus data annotated with (partial) constituent bracketing and learns to eliminate highly unlikely c-structures before the computationally expensive resolution of f-annotations. For the latter, a component for training[4] and applying maximum-entropy models based on a large variety of features is provided as part of XLE (Riezler et al. 2002).

Beyond the parser and the generator, XLE also contains a term-rewriting component which was first developed for transfer-based machine translation but has been used for a number of other purposes: identifying and deleting modifiers in f-structures that can be deleted without changing the meaning of the corresponding sentences too much (Riezler et al. 2003); treebank (Rosén 2023 [this volume]) conversion from one dependency-oriented format into another (Forst 2003); further normalization of f-structures and/or construction of semantic representations (Crouch & King 2006, Bobrow et al. 2007); extraction of features for parse ranking (Forst 2007) and realization ranking (Cahill & Forst 2009).

Currently XLE is used by the academic members of the ParGram initiative (Section 3) as well as by individual researchers. It can be used online with LFG implementations for a number of languages via XLE-Web,[5] a web interface for XLE developed at the University of Bergen, and is used as part of the INESS infrastructure developed there (Rosén et al. 2009, 2012). See Rosén 2023 [this volume] for details on using INESS for parsebanking and more generally the uses of LFG parsebanks. XLE is available for non-commercial research purposes.[6] Uses beyond that require a license agreement with PARC and Xerox.

1.1.4 FLE

The Free Linguistic Environment (FLE) (Ćavar et al. 2016) aims to create an LFG-oriented grammar-development and parsing environment with a license less restrictive than XLE's. It is implemented in C++ and uses the same grammar syntax as XLE, but it is subject to the Apache 2.0 license. In addition to the context-free grammar format of XLE, it supports two probabilistic context-free grammar formats. For tokenization and morphological analysis, FLE provides an interface to Foma transducers.[7] FLE uses open-source components when possible. FLE provides basic parsing functionality but does not contain a generator capable of producing surface strings for input f-structures.[8]

---

[4] Training data comprises sentences with labeled bracketing, which can be derived from treebanks or created manually (Riezler et al. 2002).

[5] XLE-Web is available at http://clarino.uib.no/iness/xle-web

[6] XLE is available at https://ling.sprachwiss.uni-konstanz.de/pages/xle/redmine.html

[7] Foma supports the import from and the export to XFST formats and XFST supports Foma transducers.

[8] FLE is available at https://gorilla.linguistlist.org/fle/

1.2 Core components

The LFG systems described above allow grammar writers to implement LFG grammars with annotated phrase structure rules and lexical entries similar to those in theoretical LFG. The main difference is that the formatting is specified with easier-to-type variants, e.g. symbols like ↑ and ↓ are replaced with ^ and !.

(1) Example theoretical and implemented annotated c-structure rules:

Theoretical notation:			Implementation (XLE system) notation:	
S ⟶	NP	VP	S -->	NP: (^ SUBJ)=!;
	(↑ SUBJ)=↓	↑=↓		VP: ^=!.

1.2.1 Preprocessing

In order to implement an LFG grammar, it is necessary to preprocess the text that the grammar will parse. Minimally the preprocessing contains a tokenizer which breaks the text into tokens (i.e. words) and canonicalizes the capitalization if necessary (e.g. lowercasing sentence initial capitalized words in English unless they are proper nouns). These canonicalized tokens are then looked up in the lexicon. Implemented lexicons are similar to their theoretical counterparts, comprising the word, its part of speech, and f-structure annotations such as PRED, CASE, and NUMBER. This information is integrated into the grammar via the annotated c-structure rules, as in theoretical LFG. Many implementations integrate a morphological analyzer which associates inflected forms of words with their lemma and morphological information. When using a morphological analyzer, the text is first tokenized and canonicalized for capitalization and then processed by the morphology. The output of the morphology (lemmata and morphological tags) are looked up in the lexicon. This simplifies the lexicon which only has to contain the lemmata and the morphological tags instead of containing all the inflected forms. These morphologies are often finite-state transducers (FSTs; Beesley & Karttunen 2003) which can be used for both parsing and generation.[9] For more details on using FSTs for preprocessing for LFG grammars see Kaplan et al. 2004 and Bögel et al. 2019, for integration of externally developed morphologies and lexicons within LFG grammars see Kaplan & Newman 1997.

A given inflected form can have multiple morphological analyses. Often all the analyses are provided as input to the LFG grammar, and the c-structure rules

---

[9] Parsing goes from a string (e.g. a natural language sentence) to a c- and f-structure. Generation goes from an f-structure to a natural language string. Most theoretical LFG focuses on parsing, although some accounts, especially OT-LFG ones (see papers in Sells 2001), discuss generation.

Original text:	Dogs barked.		
Tokenization:	Dogs	barked	.
	dogs		
Morphology:	dog +Noun +Pl	bark +Verb +Past	. +Punct
	dog +Verb +3Sg		

Figure 1: Example preprocessing: Tokenization and morphological analysis

and f-structure constraints are used to eliminate analyses which are not feasible in the context of the sentence (e.g. the verbal analysis of *dogs* in figure 1). Preprocessing with a part-of-speech (PoS) tagger marks each word with its part of speech, as in (2). This information can be used to prune the morphological analyses and thus constrain the c-structure built over the sentence. Since PoS taggers are not perfect even for well-edited text, only certain tags are kept, or fall-back techniques are used when no analysis is found. See Kaplan & King 2003 and Dalrymple 2006 for more details on integrating PoS taggers into LFG and other symbolic grammars.

(2) Dogs/Noun barked/Verb and/Conj the/Det cat/Noun left/Verb ./Punct

1.2.2 Projections

Theoretical LFG posits projections beyond the original lexicon, c-structure and f-structure. The exact number and combination of these projections is a subject of lively debate (Belyaev 2023 [this volume]). These include Lexical Mapping Theory (LMT) to map between underlying argument structure and grammatical functions in the lexicon (Findlay et al. 2023 [this volume]), phonological and prosodic projections (Bögel 2023 [this volume]), semantics and semantic structure (Asudeh 2023 [this volume]), and information structure for discourse function information (Zaenen 2023 [this volume]). Most LFG implemented grammars do not include these additional projections because f-structures are sufficient for the applications they target. Even when other projections are included, they are often different from their theoretical counterparts both in their format and in how they are projected or derived. The primary additional component that is included is the semantic component. This component is based on the f-structure and is generally not a projection but instead is a separate post-processing step, although in some stages of its development the Norwegian ParGram grammar NorGram (Dyvik et al. 2016, 2019) included a semantic projection (Halvorsen 1983, Kaplan 1987, Halvorsen & Kaplan 1995) whose representations were in Minimal

Recursion Semantics (Copestake et al. 2005). Semantic components include Glue semantics (Dalrymple et al. 1993, Meßmer & Zymla 2018) and ordered rewriting rules (Crouch & King 2006). The ordered rewriting rules have been extended into abstract knowledge representations (Bobrow et al. 2007). XLE-based implementations have been created for morphological structure (Butt et al. 1996) and prosodic structure and information structure (Butt & King 1998), although none of these are used in large-scale grammars. Instead, they focus on testing theoretical hypotheses and determining the complex interactions among different grammar components (Section 2). The lack of an implementation of LMT has resulted in issues for the parsing of morphologically rich languages like Turkish and Urdu, where interactions between passive and causative constructions cannot be easily captured in LFG implementations (Section 2; Çetinoğlu et al. 2009).

1.2.3 Ambiguity

Implemented grammars often include components to handle ambiguity (see Section 1.5). There are three broad areas around managing ambiguity: computing all the analyses efficiently; representing the ambiguities compactly; resolving the ambiguity so that it does not need to be computed and represented. The first two are discussed in Kaplan & Wedekind 2023 [this volume] and Rosén 2023 [this volume]. Within the grammar writer's control are components including preprocessing by PoS taggers and named entity recognition systems, Optimality-Theory marks to prefer some constructions over others, and stochastic ranking of analyses.

1.2.4 Configuration

The determination of which components (e.g. which tokenizer, morphology, lexicons, and annotated c-structure rules) to use in an implemented grammar need to be specified in a configuration (see Crouch et al. 2011 on how this is done in XLE). These may have default values, e.g. a tokenizer which simply splits sentences at spaces and does not deal with capitalization or punctuation, but large-scale grammars require customized components for the specific language and often the type of text (e.g. newspaper text, tweets). In addition, to allow for rapid extension to specific applications which may have new vocabulary and unusual constructions, these configurations allow the grammar writer to specify lexicons and rules that add to or override those in a standard base grammar (King & Maxwell 2007). For example, to parse English academic biology papers, special lexicons of biological terms as well as special c-structure rules for section titles might be added to a grammar of standard written English.

1.3 Grammar development tools

To aid the grammar writer in managing a large-scale, broad-coverage LFG grammar, specialized variants of standard software development tools are needed. These grammar development tools are part of any LFG platform (Section 1.1). Throughout this chapter we rely on examples from XLE (Crouch et al. 2011), which is the most broadly adopted LFG grammar development framework and is used in the ParGram project (Section 3).

1.3.1 Grammar writer interface

Grammar-development tools for the creation of LFG implementations facilitate the creation of c-structure rules and lexicon entries that are annotated with LFG functional annotations. Some platforms, e.g. Xerox's Grammar Writer's Workbench and XLFG, provide special interfaces for rules and lexicon entries. Others, e.g. XLE, use editors such as Emacs or the Eclipse-based eXLEpse (Rädle et al. 2011). The interfaces provide a way to apply the rules (i.e. the grammar) to a given input string and to output a c-structure and an f-structure graph in human-readable and machine-readable formats. They also generally provide tools to help debug issues such as why a well-formed input sentence does not receive an analysis or why the analysis is incorrect.

1.3.2 Macros and templates

Since grammar engineers want to efficiently encode patterns across lexicon entries and grammar rules, some platforms support additional notations. XLE, for example, supports regular-expression macros that can expand to anything from a piece of f-annotation to an entire rule as well as f-annotation templates, e.g. to allow for like-category coordination over any c-structure category. Using a shared definition of templates across parallel LFG implementations for various languages and domains considerably facilitates the adherence to the agreed-upon f-structure conventions (King et al. 2005). For example, using a template NUMBER wherever number on nouns is assigned ensures that the same attribute (e.g. NUMB) is used and that it only needs to be changed in one place if later another name of the attribute is used (e.g. NUM instead of NUMB). See Section 2 for discussion of the role of macros and templates in theoretical LFG.

1.3.3 Feature table and feature space

In a grammar formalism with untyped attribute-value matrices such as LFG, it is not strictly necessary to declare the valid values for the attributes used in f-structures and potential other levels of representation. However, from an engineering standpoint, it is highly desirable to make sure that only valid values are used; this way, unintended deviations due to typos can be caught easily (Crouch & King 2008). This need to enforce the adherence to a set of conventions is heightened in efforts to develop parallel LFG implementations for various languages such as ParGram (Section 3). XLE therefore supports feature declarations which state all the features, i.e. attributes, and their values that are allowed in the grammar. Multiple feature declarations can be combined to check the grammar code for adherence to them. In ParGram, each grammar combines the common feature declaration with a language-specific one which adds additional language-specific features and declares which subset of values are allowed, e.g. for English the *dual* value of the NUM attribute is removed.

1.3.4 Treebanks as test suites

Treebanks, and more specifically f-structure banks (Rosén 2023 [this volume]), can be used as a form of detailed, LFG-specific test suite for the grammar's coverage. Creating the treebank highlights missing constructions and vocabulary in the grammar. The INESS-based Parsebanker (Rosén 2023 [this volume]) provides infrastructure for rapidly selecting the best parse from an XLE analysis by making use of c- and f-structure discriminants (Rosén et al. 2007). These discriminants are stored as part of the parsebanking to allow for rapid updating as the grammar evolves. The grammar is then enhanced to account for these and the treebank is reparsed with the updated grammar and the new version of the treebank is inspected. This aids both in improving coverage and in ensuring that changes to the grammar do not break constructions that were previously covered. This approach has been used extensively in the development of the Norwegian (Dyvik et al. 2016), Polish (Patejuk & Przepiórkowski 2012), and Wolof (Dione 2014) grammars.

1.3.5 Version control

Version control is used in software development to track changes to the software being developed. As with software development more generally, version control in grammar development allows the grammar writer to compare two versions of a rule, lexical entry, or any other part of the grammar, to revert to a previous version if needed, and to view conflicting changes. Version control systems also record who made a particular change, which makes it easier for multiple people to work on a grammar simultaneously by highlighting recent changes, especially conflicting ones. To our knowledge, eXLEpse (Rädle et al. 2011) is the only LFG-oriented editor that offers support for a variety of version-control systems. Since eXLEpse is based on Eclipse, all version-control plugins for Eclipse can be used. However, although XLE does not provide a version control system, most large scale grammars use a standard software version control system such as SVN or Git. In addition, regression testing by providing sentences and analyses known to be parsable by the grammar help in determining whether new versions of a grammar function properly (Chatzichrisafis et al. 2007, de Paiva & King 2008).

1.3.6 Documentation

As with any software development project, it is important to document what each part of the implemented grammar does. This takes the form of comments in the lexicon and annotated phrase structure rules, including examples of sentences which that part of the grammar can parse. Dipper 2003 designed a self-documenting grammar system whereby the comments are extracted into proper, stand-alone documentation and example test suites of constructions covered by the grammar.

1.4 Modularity and integration of systems

LFG is an inherently modular linguistic theory, with different representations and components for the lexicon, phrase (constituent) structure, functional structure, semantics, etc. This is highlighted in implemented systems which introduce two other types of modularity: modularity for the grammar components, which correlates with the linguistic modularity, and modularity within those components, which enables better grammar engineering practices. LFG implementations are software systems and hence modularity of the different components is important for developing, scaling, maintaining and debugging the system. This section describes how the modularity of the grammar components helps with grammar implementation.

A core tenet of LFG is that different parts of the grammar require different types of representations. This is echoed in the implementations where the different modules can be created by different people and use different types of technology. As with theoretical LFG, the c-structure is a tree and the f-structure an attribute-value matrix, and the two are related via annotated phrase-structure rules. These phrase-structure rules form one module of the grammar. Similarly, lexicons comprise word forms, parts-of-speech, and f-annotations. These form another module. These lexicons can be custom-created for the LFG grammar or converted from other lexical resources (Kaplan & Newman 1997, Sheil & Ørsnes 2006, Przepiórkowski et al. 2014, Patejuk & Przepiórkowski 2014). The morphological component is often implemented as a finite-state transducer (Kaplan et al. 2004, Bögel et al. 2019) but can be of any form.[10] For example, the ParGram Chinese grammar uses a combined tokenizer and part-of-speech tagger that was externally developed for non-LFG purposes (Fang & King 2007). The importance of modularity is highlighted by the treatment of semantics: there have been many implementational approaches to semantic representations based on the LFG f-structure analyses. These include projecting the semantics as an attribute-value matrix (Halvorsen 1983, Halvorsen & Kaplan 1995, Asudeh 2006, Dyvik et al. 2016, 2019), implementing Glue Semantics (Dalrymple et al. 1993, Meßmer & Zymla 2018), and using ordered rewrite rules (Crouch & King 2006). Without a modular system, this exploration of the best way to capture the semantics would be difficult.

There are three additional reasons to maintain modularity in an implemented grammar. The first is that large scale grammars often have multiple grammar writers. By having different files for the lexicon, templates, and annotated phrase structure rules, the efforts can be divided in such a way that changes can be easily merged. To further aid this, the lexicons and phrase-structure rules often comprise multiple files, e.g. the lexicon might be divided into verbs, closed-class items, and all other entries, and the phrase-structure rules might be divided into clausal and nominal. The second reason is that debugging, i.e. the process of finding and fixing errors in the grammar, is simpler in a more modular system. By having different components and different files within those components, the structure of the grammar is easier to see and the individual rules easier to locate. This debugging is further aided by the use of test suites (Chatzichrisafis et al. 2007, de Paiva & King 2008), including ones based on examples in comments in the grammar rules (Dipper 2003). Even with modularity, the inclusion of OT marks (Section 1.5) can make debugging more complex since an analysis may not surface due to competition with another analysis. A third reason is that as described in Section 1.2 and Section 1.3, in addition to a lexicon and annotated phrase structure rules, LFG implementations can have tokenizers, morphologies, templates, feature tables, etc. These are combined via configuration files that encode the different modules of the system and the way they interact.

---

[10] The non-FST morphologies are referred to as library transducers in XLE.

1.5 Runtime performance

When implemented grammars are used to test linguistic hypotheses and analyses (Section 2), how quickly the grammar provides an analysis for a sentence, i.e. its latency, is generally not important. However, almost all other uses for implemented grammars (Section 4) have latency considerations. LFG implementations have provided a number of techniques to improve latency, sometimes at the cost of accuracy and coverage, e.g. certain analyses may be lost due to early elimination of possible structures (Kaplan et al. 2004). There are two main issues with runtime performance of LFG grammars: ambiguity and latency. These considerations hold for both parsing and generation; we focus on parsing here.[11]

Ambiguity concerns the multiple analyses (i.e. c- and f-structures) that are assigned to a given sentence. The ambiguity problem is accentuated when there is no semantic or pragmatic processing to guide the choice among the different analyses. The ambiguities fall into three broad categories. First, sentences can have multiple analyses, all of which are correct and equally plausible out of context, e.g. in *I saw her duck* either I saw a bird or I saw a person ducking down. Second, sentences can have correct analyses but even out of context some of them are highly improbable, e.g. in *I saw the child with the telescope* there are two plausible readings where *saw* is the past tense of the verb *see* and one implausible one where *saw* is the present tense of the verb meaning to cut with a saw, which is only plausible in a bizarre magic show. Third, ambiguities can arise when the grammar allows ungrammatical analyses, either intentionally as a fall-back mechanism or unintentionally due to an error in the implementation. Copperman & Segond 1996 provide one of the first detailed expositions of ambiguity in LFG grammars, comparing the ambiguity discussed in the theoretical linguistics literature with that in implemented grammars. King et al. 2004 discuss ambiguity in LFG grammar writing in detail, focusing on the XLE-based LFG implementations.

Language contains ambiguities at many levels, from determining word boundaries in tokenization, to morphological analysis, to syntactic attachment ambiguities, to semantic quantifier scope and beyond. This can result in thousands of analyses even for short sentences and long processing times to compute each analysis. There are two main ways to handle this ambiguity efficiently. One is to handle the ambiguity by "packing" (Maxwell & Kaplan 1989, 1993, Shemtov 1997) and operating at each level efficiently over the packed representations. Packing allows operations to apply just once to shared parts of the representation instead

---

[11] See Kaplan & Wedekind 2023 [this volume] on the inherent formal and computational properties of LFG.

of enumerating all of the possibilities and processing each of them separately. For example, XLE is designed to maintain packed structures from the tokenization and morphology to the syntactic c- and f-structures and then into an ordered rule writing system that can be used to create semantic representations (Crouch & King 2006). The other way to handle ambiguity is to choose the most likely analysis at each level. For example, if there are multiple morphological analyses for a word (e.g. English *leaves*), the system can choose the most likely one given the information it has at that time (e.g. the words adjacent to *leaves* and their potential morphological analyses). This has the downside that the correct analysis may be lost due to removing information early (Dalrymple 2006).

Optimality Theory (OT) (Kuhn 2023 [this volume]) can be used to allow the grammar writer to prefer certain analyses and even to control which grammar rules are active. Frank et al. 1998, 2001 propose an extension of the classical LFG projection architecture to incorporate a constraint ranking mechanism inspired by OT. A new projection, the o-projection, specifies violable constraints, which are used to determine a “winner” among competing, alternative analyses. Many ambiguities can be filtered from the set of possible analyses for a given sentence by using this constraint ranking mechanism in the XLE system. For example, OT marks can be used to prefer verbal analyses over adjectival ones in copular clauses with passives like *They were eaten*. XLE further provides a way to cut down the search space in parsing, allowing for potentially fewer parses to search through. This is done via a special STOPPOINT feature, which is part of the Optimality Theory preference mechanism incorporated into XLE (King et al. 2000). The OT marks can be grouped with certain groups only applying if no parse is found with the original set of OT marks. That is, XLE will process the input in multiple passes, using larger and larger versions of the grammar in subsequent reparsing phases. These groupings are referred to as STOPPOINTS. STOPPOINTS are useful for eliminating ungrammatical analyses when grammatical analyses are present and for speeding up the parser by only using expensive and rare constructions when no other analysis is available. If a solution can be found with the smaller, restricted grammar, XLE will terminate with this solution. Otherwise, a reparsing phase is triggered. This approach can be used to prefer multi-word expressions, for instance so that XLE will only consider analyses that involve the individual components of the multi-word expression if there is no valid analysis involving the multi-word expression. In addition to the OT marks, c-structure pruning (Cahill et al. 2008) and part-of-speech tagging and named entity recognition (Kaplan & King 2003, Dalrymple 2006, Krasnowska-Kieraś & Patejuk 2015) can be used to eliminate unlikely c-structures before unification.

Even with the use of OT marks, a sentence may have many valid parses. However, downstream applications often expect a single analysis, i.e. a single f-structure, as input. To use LFG grammars as input to such applications, statistical methods can be used to choose the most probable analysis (Riezler et al. 2002). These stochastic models are trained on treebanks or dependency banks of known correct analyses. As a variant of this, Dalrymple 2006 and Krasnowska-Kieraś & Patejuk 2015 investigated using a stochastic part-of-speech tagger to trim potential analyses before constructing the c- and f-structure.

2 Implications for theoretical issues

LFG and HPSG (Pollard & Sag 1994 and, for an implementational perspective, Bender & Emerson 2019) are in the privileged position of having not only a community of theoretical linguists but also of grammar engineers, with significant crossover between the theoretical and grammar-engineering communities. There are four areas in which grammar engineering interacts with theoretical linguistics (King 2011, 2016). These include: using grammar engineering to confirm linguistic hypotheses; linguistic issues highlighted by grammar engineering; implementation capabilities guiding theoretical analyses; and insights into architecture issues. The positive feedback loop between theoretical and implementational efforts is a domain in which LFG and HPSG have a distinct advantage compared to many other linguistic theories, given the strong communities and resources available.

2.1 Confirming linguistic hypotheses

Grammar engineering can be used to confirm linguistic hypotheses (Bierwisch 1963, Müller 1999, Butt, Dipper, et al. 1999, Bender 2008, Bender et al. 2011, King 2011, Fokkens 2014, King 2016, Müller 2015). Encoding the hypothesis in an implemented grammar not only highlights details of the analysis that might be missed in a pencil-and-paper version but can also bring to light interesting interactions with other linguistic phenomena, especially when the hypothesized analysis is encoded in a broad-coverage grammar. Two examples of this type include the analysis of determiner agreement systems and the prosody-syntax interaction.

King & Dalrymple 2004 provide an LFG analysis of determiner agreement and noun conjunction, looking particularly at indeterminacy of agreement features. In order to test the proposed system, they implemented a toy grammar with lexical entries of each type and enough syntactic structure to encompass determiner, adjective, and verb agreement with conjoined and non-conjoined nouns. As a result, the authors were able to confirm that their analysis was formally sound and accounted for the known data. This toy grammar was relatively easy to implement in XLE because all of the necessary components, e.g. distributive features, were already available.

Implementing proposals for the prosody-syntax interaction in LFG is more challenging because not all of the mechanisms that have been proposed in the literature are available in systems like XLE. Butt & King 1998 used an existing, non-LFG analysis of Bengali clitics and implemented it in order to test whether p(rosodic)-structure could be used to capture the generalizations proposed in the theoretical analysis, focusing on where mismatches between prosodic and syntactic structure occur. A much different interface approach was pursued in Bögel et al. 2009, which built upon the finite-state transducers used for tokenization and morphological analysis within the grammars (Section 1.2). Finally, a large-scale implementation of certain phonology-syntax interactions was completed for Welsh (Mittendorf & Sadler 2006).

2.2 Implementational devices

Writing large-scale grammars highlights the interaction of different parts of the grammar and the need to be able to formally state certain types of generalizations. These needs have led to the creation of formal devices, some of which have become part of theoretical LFG analyses while others remain implementational devices. Implementation capabilities that guided theoretical analysis include the use of complex categories for auxiliary analysis in English and German, the analysis of Welsh phonology-syntax interactions through the interaction of morphological analysis via finite-state transducers and the LFG c-structure, and the introduction of templates and macros.

Complex categories (Crouch et al. 2011) are a formal c-structure device. They allow for generalizations over c-structure categories by having the category be composed of a fixed component and a variable, where the variable can pass its value to other complex categories on the right-hand side of the rule. In this way, they allow the grammar writer to capture generalizations through notation. This notation is then automatically compiled into standard c-structure rules. Complex categories are used to constrain the order and form of auxiliaries and main verbs in English (e.g. *They will have been promoted.*) by having each auxiliary state its meaning and its form (e.g. *have* is an AUX[perf,base] with perfective meaning and base form while *been* is an AUX[pass,perf] with passive meaning and pefective form) and the VP rules themselves are complex categories that reflect their head and based on that put requirements on their complement.

Welsh consonant mutations are a phenomenon whereby the initial consonant of certain words changes based on its phonological and syntactic environment (Graver 2023 [this volume]). To capture the joint requirements on the morphophonology and the syntax which trigger mutations, Mittendorf & Sadler 2006 used the finite-state morphology capabilities integrated in XLE to control where Welsh consonant mutations occur by encoding the boundary conditions in the morphological tag sequences. The modular nature of LFG combined with the implementational device of finite-state morphology provided a clean solution to the different types of triggers for the mutations.

A long standing debate in the linguistic literature, especially for constraint-based formalisms like HPSG and LFG, is whether a comprehensive and efficient grammatical theory should include a type hierarchy and what role it should play. Historically HPSG has had types as foundational to the theory while LFG has not. However, in grammar engineering, it is important to be able to efficiently capture generalizations as well as exceptions to those generalizations. The introduction of templates into the formal devices available to LFG allows for generalizations and inheritance via notation, without introducing a full type hierarchy into the formalism (Dalrymple, Kaplan & King 2004, Crouch & King 2008) and as a result, the concept of templates has become part of theoretical LFG analyses. Similar to complex categories, templates and macros allow the grammar writer to capture generalizations through notation, which is then automatically compiled into standard LFG c- and f-structure rules.

Two more minor formal devices which are gaining traction in theoretical analyses are instantiation and local variables (a third is the restriction operator discussed in the next section). Since the beginning, predicates (PRED) in LFG have not been unifiable with one another due to their unique lexical index (Kaplan & Bresnan 1982). Certain non-PRED features also need to be non-unifiable (Dalrymple 2001). This can be captured by instantiation, represented by having the value of the feature be followed by an underscore. For example, instantiating the form values of English particles blocks their occurring multiple times in a sentence (e.g. **they threw out the garbage out*) (see Figure 2 for an English example and Forst et al. 2010). Finally, local variables anchor a functional uncertainty equation to a particular f-structure and then refer to that f-structure in other annotations (Dalrymple 2001, Crouch et al. 2011). This is needed when making a set of statements about a particular element of a set or a particular type of governing element. For example Szűcs 2019 uses local variables to state constraints on topic left dislocation constructions in Hungarian.

2.3 Architectural issues

Implementing a wide variety of phenomena, as is necessary for broad-coverage grammars, brings to light architectural issues with the theory. Çetinoğlu et al. 2009 and Bögel et al. 2019 describe issues with the interaction of the passive and causative in Turkish and Urdu. These issues are the result of how lexical rules in LFG interact with complex predicate formation, where the passive is traditionally analyzed as involving a lexical rule while the causative is often analyzed as a complex predicate. The Urdu and Turkish grammars use the restriction operator (Kaplan & Wedekind 1993) in the annotated c-structure rules to model complex predication, including causatives. The restriction operator allows for features of f-structures to be restricted out, i.e. to cause the grammar to function as if these features did not exist. This allows complex predicate-argument structures to be built dynamically (Butt et al. 2003, 2010). In contrast, the passive is handled by lexical rules which apply to the predication frames in the lexicon. This predicts that passivization applies before causativization and that it is not possible to passivize a causative by demoting or suppressing the subject of the causative. However, this is the reverse of the Urdu and Turkish facts. To solve this problem in the ParGram grammars of Urdu and Turkish, both the causative and the passive are handled via restriction in the annotated phrase structure rules. In the theoretical literature, this issue had not been highlighted because for Turkish and Urdu style morphosyntax, the causative was handled in argument-structure, but the interaction between causativization and passives at the morphology-syntax interface highlighted that traditional lexical rules do not allow for the right order of application when causativization is morphological but passivization is part of the syntax.

To conclude this section, the interaction of grammar engineering and theoretical linguistics helps to confirm linguistic hypotheses, to highlight complex linguistic issues, to posit new formal capabilities, and shed light on architecture issues. The positive feedback loop between theoretical and implementational efforts is a domain in which LFG and HPSG have a distinct advantage.

3 Grammar resources: ParGram

The systems described above are used to create small- and large-scale LFG grammars. These can be used as input to applications (Section 4) or to explore theoretical hypotheses (Section 2). The Parallel Grammar (ParGram) project is a consortium of LFG researchers implementing grammars for a typologically varied set of languages in a parallel fashion (Butt, King, et al. 1999, Butt et al. 2002) using the

XLE LFG parser, generator, and grammar development platform. The parallels are most notable in the f-structure space, where common features and analyses are used wherever possible, but differ when required by the syntax of the languages. This parallelism is enabled by LFG theory, by grammar engineering components such as feature declarations, and by semi-annual meetings between the grammar writers.[12]

ParGram began with three languages: English (Riezler et al. 2002), French (Frank 1996), and German (Dipper 2003, Rohrer & Forst 2006). They developed aligned f-structure analyses for a tractor manual which existed as an aligned corpus in all three languages. Even with three closely related languages, it was clear that full f-structure alignment was not possible (Butt, Dipper, et al. 1999) due to fundamental syntactic differences in the languages. Later, the Fuji Xerox Corporate Research Group and the University of Bergen joined the initiative with a Japanese (Masuichi et al. 2003) and a Norwegian grammar (Dyvik et al. 2016, 2019) respectively. Other longer-term academic efforts participating in ParGram concern the development of Urdu (Butt & King 2002, 2007) and Polish (Patejuk & Przepiórkowski 2012) LFG implementations. Finally, further ParGram efforts have given rise to computational LFGs for Arabic (Attia 2006, 2012), Chinese (Fang & King 2007), Danish (Ørsnes 2006), Georgian (Meurer 2009), Hungarian (Laczkó & Rákosi 2008–2019), Indonesian (Arka et al. 2009, Arka 2012), Korean (Kim et al. 2003), Malagasy (Dalrymple et al. 2006), Tamil (Sarveswaran & Butt 2019), Tigrinya (Kifle 2011), Turkish (Çetinoğlu & Oflazer 2018), Welsh (Mittendorf & Sadler 2006), and Wolof (Dione 2014).

The project resulted in the creation of LFG grammars in these multiple languages and hence a greater understanding of the parallelism (or lack thereof) for the LFG analyses of particular constructions. Major issues in LFG analysis and architecture highlighted by the ParGram project included: Copular constructions and in particular whether there is a copular *be* predicate and whether the predicated argument has a subject (xcomp-like) or not (predlink) (Dalrymple, Dyvik, et al. 2004, Attia 2008); how to handle argument-changing relations such as the passive, causative, benefactives, complex predicates, and interactions thereof, including morphological and syntactic interactions (Bögel et al. 2019; see Section 2); whether auxiliaries have predicates or just supply tense and aspect features to the f-structure (Butt et al. 1996, Dyvik 1999); the interaction of tokenization and morphology with the c- and f-structures, especially around features like Welsh mutations (Mittendorf & Sadler 2006) and Urdu complex predicates (Bögel et al.

---

[12] A similar approach was subsequently adopted by the HPSG DELPH-IN consortium (Bender et al. 2002).

2019). In addition, the ParGram project resulted in improvements to the grammar development platform (Section 1.2, Section 1.3 and Section 1.5) and in best practices for distributed parallel grammar development.

In addition to the traditional LFG-style ParGram grammars which use annotated phrase structure rules to create the c- and f-structure representations, the ParGram project also includes several automatically induced grammars that create ParGram compatible f-structures, i.e. f-structures using the same feature space as the grammars described above, but which are learned from tree and f-structure banks (Cahill et al. 2002). These grammars are robust in that they produce f-structures for nearly any sentence, at the cost of producing structures which sometimes violate core LFG principles such as completeness and coherence. See Section 4 for applications which require such robustness.

An influential initiative that resembles ParGram is the Universal Dependencies (UD) initiative (McDonald et al. 2013; see also Haug 2023 [this volume]). Like ParGram, it aims at parallel representations across languages, and UD follows LFG concerning many of the distinctions made at the level of syntactic dependencies and grammatical functions respectively (de Marneffe et al. 2014). This being said, surface-oriented dependency structures as used in UD cannot be as parallel as the more abstract f-structures of ParGram. Korsak 2018 and Przepiórkowski & Patejuk 2020 discuss the similarities between LFG and UD and investigate mapping between LFG f-structures and UD. Another noteworthy difference between ParGram and UD is that ParGram has been developing reversible XLE grammars whereas UD focuses solely on parsing.

4 Applications

Some applications integrating natural language processing only require parsing. For these applications, parsing should be robust to typos and grammatical errors, unusual constructions, unknown words, etc. In addition, minor issues in parsing may be unimportant for these applications because systematic errors can be compensated for within the system. Semantic search is an application that requires only parsing, needs to be robust, and can tolerate certain parsing errors.

Other applications, e.g. sentence condensation, transfer-based machine translation (MT) and conversational agents, require both parsing and generation. Applications using generation generally require highly grammatical output since users are sensitive to malformed natural language such as incorrect subject-verb agreement. Since corpus-induced grammars do not lend themselves to refinement in order to control generation, hand-crafted grammar implementations such as LFG grammars are still the means of choice for the generation of high-quality text.

Finally, there are applications that require grammaticality judgments. This is the case of grammar checkers, both general-purpose ones and grammar checkers for computer-assisted language learning (CALL). Parsers trained on general-purpose treebanks cannot be used for this purpose, so these applications are another natural fit for hand-crafted grammar implementations. In our opinion, LFG suits this purpose particularly well because its terminology is relatively close to that used in language instruction.

4.1 Applications requiring deep features and robustness

For applications that require mainly natural language understanding, parsing needs to be robust to unexpected words and constructions. To provide the robustness necessary for these applications, domain-specific grammars can be created based on a general large-scale grammar (Kim et al. 2003, King & Maxwell 2007). However, this is often not enough to cover all use cases. LFG grammars can use morphological guessers to cover unknown vocabulary (Dost & King 2009, Bögel et al. 2019), can parse fragments of the structure, e.g. provide f-structures for all the noun phrases even if they cannot be formed into a sentence (Riezler et al. 2003), and can include fall-back rules (mal-rules Schneider & McCoy 1998, Reuer 2003, Khader 2003, Fortmann & Forst 2004, Bender et al. 2004) explicitly accounting for certain types of ungrammaticality, e.g. incorrect subject-verb agreement.

Semantic search is one application which benefits from the deep LFG representations. As a search application, the goal is to find documents which are relevant to the query and, ideally, to highlight the passage in the document most relevant to the query. Semantic search moves beyond keyword matching to match the relationships between entities in the query. It can include queries that are full interrogatives as well as ones that are phrases. The ParGram XLE English grammar was used in the Powerset Inc. semantic search engine for searching Wikipedia articles. By using LFG representations for the query and the documents it can differentiate between *who acquired PeopleSoft* and *who did PeopleSoft acquire*, where PeopleSoft is the object in the first question and the subject in the second. By using a fragment grammar as a backup, longer sentences could be partially parsed, e.g. the first conjunct of a coordinated sentence could be parsed even if the second failed. This combined with the redundancy across the articles made using an LFG grammar feasible for moving beyond keyword search. The f-structures were mapped to abstract knowledge representations which went beyond grammatical functions to semantic rules, e.g. mapping *Oracle acquired PeopleSoft* and

PeopleSoft was acquired by Oracle and even *Oracle's acquisition of PeopleSoft* to the same abstract representation.

A more complex application than semantic search is question answering. Unlike search, question answering uses a document collection to find the answer to the query, which is generally in the form of a natural-language question, and present it to the user. The PARC Bridge system (Bobrow et al. 2007) used the XLE ParGram English grammar as its base and mapped the query and documents to an abstract knowledge representation using ordered rewrite rules, deep lexical resources such as WordNet (Fellbaum 1998) and VerbNet (Kipper et al. 2000, Levin 1993), and knowledge resources such as Cyc (Lenat 1995). The queries and documents were then matched against one another with a graph-based algorithm. An interesting extension of this was to perform entailment and contradiction detection (ECD) (Bobrow et al. 2007) with a graph-based module that determined whether one sentence entailed or contradicted (or neither) the other. ECD depended on understanding the roles between the entities as determined by the LFG grammar as well as detailed lexical knowledge.

Burton 2006 describes a tutorial system which uses the XLE English grammar for its language-understanding component. The tutorial system is provided by Acuitus and teaches network administration. The coursework includes a set of troubleshooting exercises where students find and fix problems. During these exercises the computer helps the students when they ask for help or based on their actions. The system asks the student a mix of multiple-choice, short-answer, and natural-language questions. The idea behind using natural-language interactions is to encourage students to think beyond what multiple-choice questions provide and to allow more complex questions and answers. The system converts the f-structures from the student input to semantic interpretations via the transfer rule system (Crouch 2006). Both the syntactic parsing and the semantics are adapted to the domain to provide more accurate and robust results.

Historically, hand-crafted LFG implementations have had a hard time competing with machine-learned constituency or dependency parsers in terms of robustness, i.e. providing a parse for all input, and speed for purely understanding-oriented applications, even though they are often superior in terms of systematicity and detail of analysis and despite the fact that machine-learned parsers often produce illogical parses for input where LFG grammars would fail to produce a parse. Because of this speed and perceived robustness, machine-learning-based dependency parsers have become increasingly popular, as is evident from the shared tasks of the Conference on Computational Natural Language Learning (CoNLL) series. Interesting though, the CoNLL tasks now often integrate UD representations (McDonald et al. 2013), which can be seen as less fine-grained f-structures (see Section 3 for more details on UD). The combination of handcrafted grammars, fall-back techniques, and statistical parser selection as described in this chapter allow LFG and other rule-based grammars to be used in applications requiring robustness (see also Ivanova et al. 2016).

4.2 Applications requiring grammaticality

Certain applications not only aim to map text to representations more amenable to the computation of meaning, but they also take abstract meaning representations, including f-structures, as input and map them to text. Among such applications are sentence condensation and transfer-based machine translation, both applications for which LFG implementations have been used because f-structures are abstract enough to facilitate transformations like the removal of certain adjuncts or the transfer from a source to a target language. Furthermore, since corpus-induced grammars do not lend themselves to refinement in order to control generation, hand-crafted grammar implementations are still the means of choice for the generation of high-quality text.

Sentence condensation is a form of summarization (Knight & Marcu 2000, Jing 2000). It takes a long sentence and produces a shorter sentence which preserves the core meaning of the original sentence. This requires the ability to identify the core part of the original sentence and to generate a grammatical shorter sentence. Riezler et al. 2003 and Crouch et al. 2004 used the ParGram XLE grammar to create a sentence condensation system for English. The LFG f-structure was used to identify the core meaning, e.g. by removing adjuncts other than negation. A new f-structure was created which contained only this core meaning. This new f-structure was then run through the grammar in the generation direction to generate the shorter, condensed sentence. This sentence was guaranteed to be grammatical since it met the well-formedness conditions of the grammar. Since multiple strings (e.g. sentences) can map to the same f-structure, more than one condensed sentence can often be generated from a single f-structure. This can be partially controlled by Optimality-Theory marks in the grammar in XLE (Frank et al. 1998). The choice between the remaining sentences can be done with a language model (Riezler et al. 2003). A related application is note taking where longer texts are condensed into legible notes (Kaplan et al. 2005).

Machine translation (MT) involves automatically translating a text from one language (the source) to another (the target). The resulting translation has to preserve the meaning and to be grammatical. LFG f-structures have been used for MT (Oepen et al. 2004, Riezler & Maxwell 2006, Avramidis & Kuhn 2009, Graham et al. 2009, Graham 2012, Graham & van Genabith 2012, Homola & Coler

2012). The idea is that the f-structure encodes the meaning of the sentence more abstractly than the surface form of the text and so can be used as the level for translation. That is, f-structure enables translation by transfer across structures and not just an interlingua across words (Kaplan et al. 1989). In theory, simply substituting the PRED values in the f-structure could produce an f-structure in the target language and the LFG grammar can then be used to generate the translation. In practice, f-structures still encode enough language-specific syntactic information that additional transfer rules need to be applied before the generation step. For example, one language may use indefinite singular determiners (e.g. English *a*) while the other may not, in which case the determiner would have to be deleted (in the source language) or inserted (in the target language). The LOGON MT project (Oepen et al. 2004) provides an interesting approach with parsing via the LFG Norwegian NorGram grammar, transfer to semantic MRS (Copestake et al. 2005) and generation via an HPSG English grammar. Although LFG-based MT systems can be brittle since there has to be a successful parse, transfer, and generation, when a translation is produced it is generally of high quality both in terms of preserving the meaning and of being grammatically well-formed.

Consider the English and German sentences in (3) and (4), for which the corresponding f-structures are displayed in Figure 2.

(3) Across the city, monuments to prosperity have sprung up.

(4) In der ganzen Stadt sind Denkmäler des Wohlstands entstanden.
in the whole city be monuments of.the prosperity up.spring
Across the city, monuments to prosperity have sprung up.

Apart from the fact that the German analysis of adjunct NPs in the genitive is not parallel to other ParGram implementations and that the German finite-state morphology decomposes the word *Wohlstand*, which gives rise to a MOD dependency under the Subj Adj-Gen, the f-structures are surprisingly parallel. (At first sight, this is obscured by the fact that in the German f-structure, the sub-f-structures under Topic and in the Adjunct set are the same.) Even though the English sentence is headed by a particle verb while the German one is not, there is a single PRED value for the head verb on either side; even though the subject of the English sentence precedes the verb while the one of the German sentence follows the verb, both appear in the respective f-structure under SUBJ; even though the auxiliary in the English sentence is *have* while the German verb *entstehen* requires the auxiliary *sein* (‘to be’) for perfect tenses, the auxiliaries contribute the same value for TNS-ASP PERF. As a result, the transfer component can concentrate on word-to-word translation equivalencies while letting the language-specific grammars take care of well-formedness conditions independent of the language pair under consideration. An example of a non-trivial translation equivalency is the one between *across the city* and *in der ganzen Stadt* (literally 'in the entire city'), as the English phrase might also correspond to *durch die Stadt* (literally 'through the city') in other contexts (especially in combination with motion verbs).

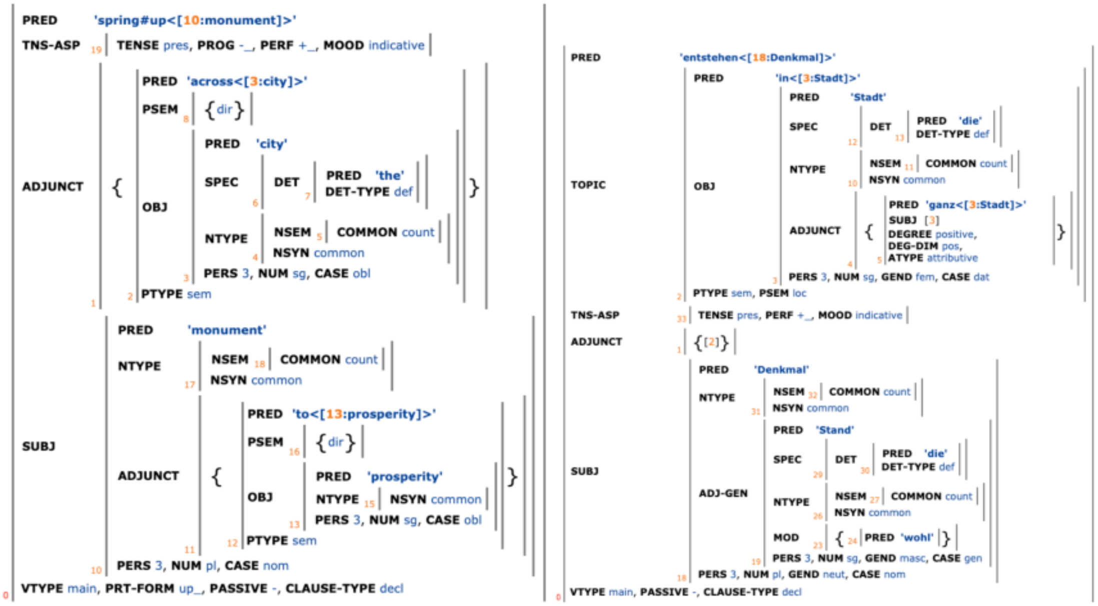

Figure 2: F-structures for English and German translation equivalents

Certain other applications do not require semantic representations or grammatical text output but do require the system to have a notion of grammaticality as their purpose is to highlight ungrammatical (or otherwise undesired) passages in text. Such systems can be directed to a general public of people producing texts or explicitly target second-language learners, sometimes even second-language learners with a specific first-language background. The latter application, in the context of Intelligent Computer-Assisted Language Learning (ICALL), has used LFG implementations, typically augmented with mal-rules (Rypa & Feuerman 1995, Reuer 2003, Khader 2003, Fortmann & Forst 2004). Mal-rules are rules or rule extensions that cover ungrammatical constructions typically produced by second-language learners, e.g. NPs where determiners or adjectives do not agree with the head noun, NPs with countable head nouns in the singular that are not preceded by a determiner, or sentences with an ungrammatical order of constituents or a violation of subject-verb agreement. As typical mistakes made by second-language learners depend significantly on their native language as well as on other languages they know, mal-rules can be optimized with respect to their coverage more easily when the linguistic background of the audience is known. A machine-learning-based approach to ICALL exploiting features provided by the English ParGram LFG implementation is described by Berend et al. 2013.

A final application we discuss is natural language understanding (NLU) components used in car computers or in personal assistants on mobile devices. Those components often combine grammar-based analysis and deep-learning-based neural networks or statistical models learned from annotated data. Moreover, machine-learning-based NLU models depend on large amounts of training data from the relevant domain. Since such data is hard to collect and costly to annotate, much of it is generated by means of grammars. For the most part, the grammars used to this end are simple, largely context-free grammars. However, as the semantic representations used for NLU become increasingly sophisticated, the use of more powerful grammar formalisms such as LFG can be used for the generation of high-quality grammatical training data.

5 Conclusion

This chapter provided an overview of computational implementations of LFG. LFG was designed from the outset to be computationally tractable and has a strong history of broad-coverage implementations for multiple languages, primarily through the ParGram project which is built on the XLE grammar development platform. As with theoretical LFG, implemented grammars primarily focus on c-structure and f-structure, but extensive work has been done on using the resulting f-structures as input to semantics and abstract knowledge representation, and some work has focused on the integration of morphological and phonological information as well as argument structure. The ParGram project is based on the theoretical LFG hypothesis that languages are more similar at f-structure, which encodes grammatical functions, than at c-structure. This f-structure similarity can then be exploited in applications such as machine translation. Other applications which take advantage of the more abstract f-structures and the ability of LFG grammars to parse and generate as well as to detect (un)grammaticality include computer-assisted language learning, question answering, and sentence condensation. From a theoretical linguistic perspective, implemented grammars allow the linguist to test analyses and to see interactions between different parts of the grammar.

Chapter 24

Treebank-driven parsing, translation and grammar induction using LFG

Aoife Cahill

Educational Testing Service

Andy Way

ADAPT Centre, School of Computing, Dublin City University

This chapter provides a summary of a range of work on probabilistic models of Lexical Functional Grammar (LFG). LFG grammars as originally conceived in Kaplan & Bresnan (1982) were defined by grammatical rules and constraints, so could not describe ill-formed strings, and they failed if confronted with well-formed strings outside their coverage. In contrast, the hybrid LFG-DOP model of Bod & Kaplan 1998 and Bod & Kaplan 2003 could generalize well-formed analyses via the *Discard* operation to allow ill-formed and previously uncovered well-formed strings to be handled. Way (1999) and Way (2001) extended LFG-DOP to handle translation, and demonstrated two advantages of his LFG-DOT models: (i) being probabilistic, LFG-DOT was able to handle a range of translation phenomena that were problematic for the description of LFG-MT (Kaplan et al. 1989); and (ii) having f-structure constraints enabled LFG-DOT to overcome problems for DOT (Poutsma 2000), a model of translation based on DOP (Bod 1992, Sima'an 1997, Bod 1998). Like most probabilistic models, LFG-DOP (and LFG-DOT) require large amounts of annotated data. In a range of seminal work on grammar induction – now a research field in its own right, but at the time quite a novelty – it was demonstrated how strings could be automatically annotated with both LFG c- and f-structure information (Sadler et al. 2000, Cahill et al. 2002a). These were then used for multilingual probabilistic parsing (Cahill et al. 2005, Cahill, Burke, O'Donovan, et al. 2008) and lexicon induction experiments (O'Donovan 2006), which we describe here.

1 Introduction

In this chapter we summarize work on extensions to the core LFG formalism that facilitate large-scale probabilistic LFG parsing and translation models. Traditional LFG grammars (Kaplan & Bresnan 1982) are defined in terms of well-formed grammatical rules and constraints. This has two main limitations: (i) ill-formed input cannot be handled easily;[1] and (ii) when a grammar produces multiple analyses for an input, there is no inherent way of ranking the competing solutions.

We describe LFG-DOP (Bod & Kaplan 1998), a hybrid model of Data-Oriented Parsing (DOP: Bod 1992, Sima'an 1997, Bod 1998) and LFG that allows for probabilistic tree parsing, and which is beyond context-free in its generative power. We describe how this work led to the LFG-DOT framework (Way 1999, 2001) for machine translation (MT) with LFG.

Large-scale probabilistic parsing typically requires substantial amounts of annotated training data. We describe techniques developed to automatically generate large-scale LFG-annotated treebanks that provide the training data needed for probabilistic LFG parsing. We describe how this work was not only applied to English, but also several other languages including German (Cahill et al. 2005, Rehbein & van Genabith 2009), French (Schluter 2011), Spanish (O'Donovan et al. 2005, Chrupała & van Genabith 2006), Chinese (Burke, Cahill, et al. 2004, Guo 2009), Japanese (Oya & van Genabith 2007) and Arabic (Tounsi et al. 2009a). A related field of work was the automated extraction of large-scale lexical resources from these LFG-annotated treebanks (O'Donovan 2006). Although large-scale LFG-DOT experimentation has not been conducted to date,[2] these grammars and semantic forms (i.e. subcategorisation frames) are exactly what LFG-DOT requires to build its models. Accordingly, we sketch what would need to be done to conduct such experiments.

Finally, we compare this semi-automatic approach to lexicon and grammar induction to that based on the hand-crafted XLE grammars.

2 LFG-DOP

This section describes how LFG was combined with Data-Oriented Parsing (DOP) models to create a more robust, probabilistic model of language processing, LFG-

---

[1] This applies equally to legitimate strings which are not covered by the grammar.

[2] Bod (2000) acknowledges that Cormons (1999) "accomplished [the] first simple experiment with LFG-DOP". Bod & Kaplan (2003) includes a large-scale evaluation of LFG-DOP against a DOP baseline. Hearne (2005) extends these experiments for DOP, demonstrating higher accuracy for the exact match metric using improved sampling techniques.

DOP. In later sections, we will show how both DOP and LFG-DOP were used to build powerful, robust models of MT.

2.1 Data-Oriented Parsing

DOP models (Bod 1992, Sima'an 1997, Bod 1998) assume that past experiences of language are significant in both perception and production. DOP prefers performance models over competence grammars, in that abstract grammar rules are eschewed in favour of models based on large collections of previously occurring fragments of language. Previously uncovered sentences are processed with reference to existing fragments from the treebank, which are combined using probabilistic techniques to determine the most likely analysis for the new fragment.

The general DOP architecture stipulates four parameters on which particular models are instantiated:

1. A formal definition of *well-formed representations* for sentence analyses;
2. A set of *decomposition* operations for splitting sentence analyses into a set of fragments;
3. A set of *composition* operations for recombination of such fragments in order to derive analyses of new strings;
4. A definition of a *probability model* indicating the likelihood of a sentence analysis based on the probabilities of its constituent parts.

DOP models typically assign a surface phrase-structure (PS) tree to strings (hence 'Tree-DOP', or 'DOP1' in Bod (1992)). However, context-free models are insufficiently powerful to deal with all aspects of human language. LFG, on the other hand, is known to be beyond context-free, and can capture and provide representations of linguistic phenomena other than those occurring at surface structure.[3]

---

[3] Note that the question of what grammar type in the Chomsky Hierarchy (Chomsky 1956) was capable of processing human language was a significant one when LFG was first proposed, but appears to be less of a concern nowadays. This was relevant for Chomsky's claims of Universal Grammar (Chomsky 1981), of course, but different languages have been demonstrated to require different grammar types; for example, Dutch cross-serial dependencies can only be handled by a context-sensitive grammar, whereas English is arguably context-free. Note that Futrell et al. (2016) claim the Amazonian language Pirahã to be finite-state, so the Chomsky Hierarchy no longer seems to be particularly helpful as a characterisation of human languages in general. Nonetheless, the fact that LFG is beyond context-free would allow it to claim that it is a general enough model to cope with languages like Dutch. Note too that a grammar formalism should be sufficiently constrained to ensure that parsing can be done in polynomial time.

2.2 Combining DOP with LFG: LFG-DOP

Accordingly, Bod & Kaplan (1998) augmented DOP with the syntactic representations of LFG to create a new, more powerful hybrid model of language processing – LFG-DOP – which adds a level of robustness not available to models based solely on LFG.

LFG-DOP is defined using the same four parameters as in Tree-DOP. We describe each of these in the next sections.

2.2.1 Representations in LFG-DOP

The LFG-DOP **representations** are those traditionally used in LFG, where each string is annotated with a c-structure, an f-structure, and a mapping ϕ between them. Well-formedness conditions operate solely on f-structure, as usual.

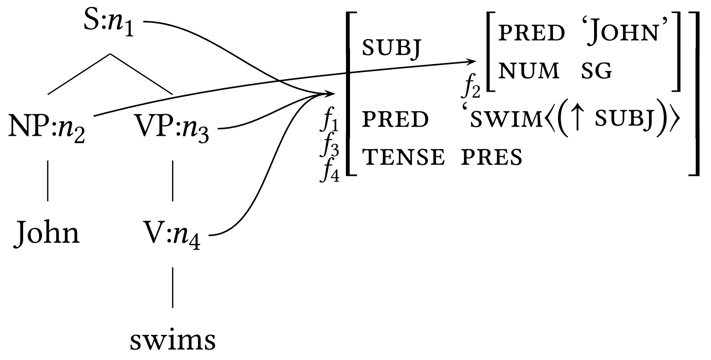
2.2.2 Decomposition in LFG-DOP

Since we are now dealing with $\langle c, f\rangle$ pairs of structure, the *Root* and *Frontier* **decomposition** operations of DOP need to be adapted to stipulate exactly which c-structure nodes are linked to which f-structure fragments, thereby maintaining the fundamentals of c- and f-structure correspondence. As LFG c-structures are little more than annotated PS trees, we can proceed very much on the same lines as in Tree-DOP. *Root* erases all nodes outside of the selected node, and in addition deletes all ϕ-links (informally, parts of the f-structure linked to a c-structure node) leaving the erased nodes, as well as all f-structure units that are not ϕ-accessible from the remaining nodes. Bod & Kaplan (1998) define ϕ-accessibility as follows:

> "An f-structure unit f is ϕ-accessible from a node n iff either n is ϕ-linked to f (that is, $f = \phi(n)$) or f is contained within $\phi(n)$ (that is, there is a chain of attributes that leads from $\phi(n)$ to f)." (Bod & Kaplan 1998: 146)

As an example, consider (1):

(1)



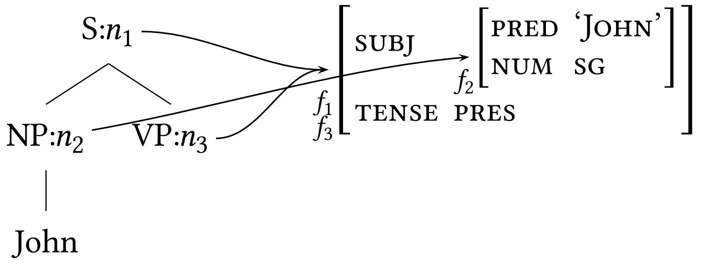
The ϕ-links are shown in (2):

(2) $\phi(n_1) = \mathrm{f}_1$, $\phi(n_2) = \mathrm{f}_2$, $\phi(n_3) = \mathrm{f}_3$, $\phi(n_4) = \mathrm{f}_4$, $\phi(n_1) = \phi(n_3) = \phi(n_4)$

ϕ-accessibility reflects the intuitive notion that nodes in a tree carry information only about the f-structure elements to which the root node of the tree permits access, as in (1). Note that all f-structure units are ϕ-accessible from the S, VP and V nodes, but TENSE and the top-level PRED (the main verb *swim*) cannot be accessed via ϕ from the subject NP node.

Frontier operates as in Tree-DOP, deleting all subtrees of the selected frontier nodes. It also deletes all ϕ-links of these deleted nodes together with any semantic form (e.g. in (1), 'SWIM⟨(↑ SUBJ)⟩') as is the case if the V:swims node is deleted in (3):

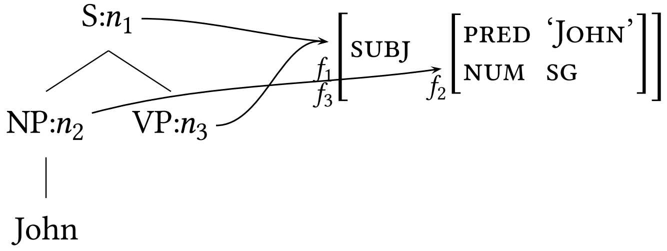
(3)



This illustrates the ability of *Root* nodes to access certain f-structure features even after subnodes have been deleted. Even though the V:swims node is deleted in the c-structure tree, only the semantic form 'swim⟨(↑ SUBJ)⟩' is deleted from the f-structure, and the TENSE feature remains.[4]

It is, however, possible to prune (3) still further, as (4) illustrates:

(4)



This is achieved by applying a third, and new operation, *Discard*, to the TENSE feature in (3).[5] The *Discard* operation adds considerably to LFG's robustness by

---

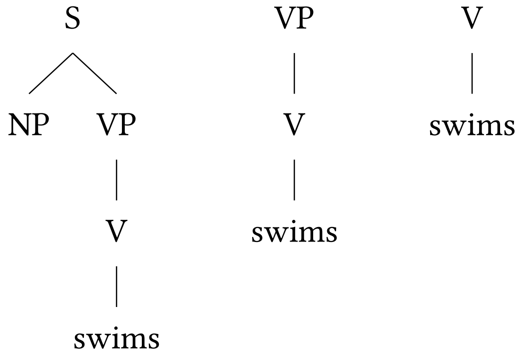
[4] Note that subject-tense agreement *is* seen in some languages e.g. Hindi. Accordingly, there is no universal principle which should rule out fragments such as (3).

[5] This function generates appropriate fragments for English which have no subject-tense dependency; accordingly, we would expect more fragments like (4) in English treebanks, but fewer such fragments for Hindi, say, given the point made in fn. 4.

providing generalized fragments from those derived via *Root* and *Frontier* by freely deleting any combination of attribute-value pairs from an f-structure except those that are ϕ-linked to some remaining c-structure node, or that are governed by the local predicate (i.e. required to be present). Its introduction also necessitates a new definition of the grammaticality of a sentence *with respect to a corpus*, namely any sentence having at least one derivation whose fragments are produced only by *Root* and *Frontier* and not by *Discard*. Way (1999) splits fragments into separate bags of *Discard* and non-*Discard* fragments in order "to facilitate the consideration of grammaticality." Bod (2000) demonstrates that this is helpful for LFG-DOP, too, on experiments with the Verbmobil and Homecentre corpora, which compare favourably with the original model of Bod & Kaplan (1998). In contrast, Hearne & Sima'an (2004) present an improved back-off estimation method where non-*Discard* fragments are naturally preferred.

We omit here the complete LFG-DOP treebank (ignoring the effects of the *Discard* operator) for the sentence *John swims*, but refer the interested reader to Figure 4.1 in Way (2001: 114). Nonetheless, as he does, we point out that each c-structure fragment in an LFG-DOP corpus is not necessarily linked to a unique f-structure fragment. From his Figure 4.1, consider the three fragments in (5):

(5)



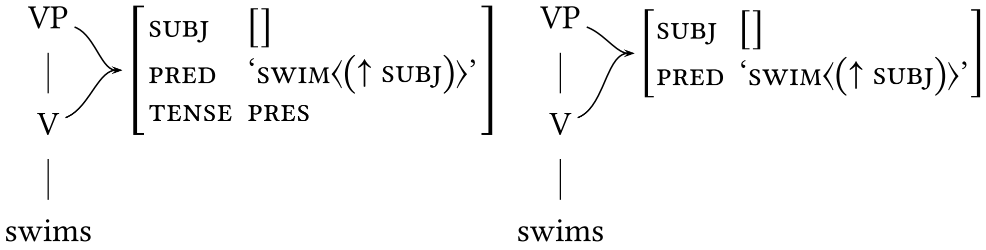
These three c-structure fragments all map to the same f-structure fragment in (6) because of equations such as $\phi(n_1) = \phi(n_3) = \phi(n_4)$ in (2):

(6)
$$\left[\begin{array}{ll} \textsc{subj} & \left[\textsc{num sg}\right] \\ \textsc{pred} & \text{`}\textsc{swim}\langle(\uparrow \textsc{subj})\rangle\text{'} \\ \textsc{tense} & \textsc{pres} \end{array}\right]$$

This f-structure shows that *swims* being singular requires a singular subject. Of course, to be completely accurate, we should add in a subj:pers:3 constraint too, to prevent strings such as *I swims* and *you swims* from being deemed grammatical.

We can illustrate the effect of *Discard* in relaxing the SUBJ:NUM:SG constraint with *swims* in (7):

(7)



Accordingly, if the ill-formed string *The men swims* were input, it could be processed by LFG-DOP because of generalised fragments like these, but would be ruled out as ungrammatical in LFG, given f-structures like (6). Note that *Discard* has been applied to the rightmost f-structure in (7).

2.2.3 Composition in LFG-DOP

Composition in LFG-DOP is also a two-step operation. C-structures are combined by leftmost substitution, as in Tree-DOP, subject to the matching of their nodes. F-structures corresponding to these nodes are then recursively unified, and the resulting f-structures are subjected to the grammaticality checks of LFG.

2.2.4 Probability models for LFG-DOP

$CP(f \mid CS)$ denotes the probability of choosing a fragment f from a competition set CS of competing fragments. In Tree-DOP, we wanted to select a tree t from a treebank, whereas in LFG-DOP we are interested in selecting a $\langle c, f \rangle$ pair from a corpus. The probability of an LFG-DOP derivation is the same as in Tree-DOP; it is just the derivation itself which changes. As in DOP, then, an LFG-DOP derivation $D = \langle f_1, f_2 ... f_n \rangle$ is produced by a stochastic branching process which at each stage in the process randomly samples from a competition set CS of competing samples, as in (8) (cf. example (10) in Bod & Kaplan 1998: 148):

(8)
$$P(\langle f_1, f_2 ... f_n \rangle) = \prod_{i=1}^{n} CP(f_i \mid CS_i)$$

This competition probability $CP(f \mid CS)$ is expressed in terms of fragment probabilities $P(f)$ in (9) (cf. example (11) in Bod & Kaplan 1998: 148):

(9) $$CP(f \mid CS) = \frac{P(f)}{\sum_{f' \in CS} P(f')}$$

Taking (8) and (9) together, the probability of a derivation f is calculated by multiplying together the probabilities of the fragments f_i which are composed together to form that fragment; this is analogous to how derivations are computed in Tree-DOP: there, we just have tree fragments, whereas in LFG-DOP, we have tree fragments together with their associated f-structure fragments.

In Tree-DOP, apart from the *Root* and *Frontier* operations, there are no other well-formedness checks. LFG, however, has a number of grammaticality conditions, some of which – the Completeness check at least – cannot be evaluated during the stochastic process. Accordingly, probabilities for valid representations can only be defined by sampling *post hoc* from the set of representations which are output from the stochastic process. The probability of sampling a valid representation is (10) (cf. example (12) in Bod & Kaplan 1998: 148):

(10) $$P(R \mid R \text{ is valid}) = \frac{P(R)}{\sum_{R' \textit{ is valid}} P(R')}$$

Bod & Kaplan (1998) note that (10) assigns probabilities to valid representations whether or not the stochastic process guarantees validity. The valid representations for a particular utterance *u* are obtained by a further sampling step, with their probabilities given by (11) (cf. example (13) in Bod & Kaplan 1998: 148):

(11) $$P(R \mid R \text{ is valid and yields } u) = \frac{P(R)}{\sum_{R' \textit{ is valid and yields } u} P(R')}$$

Comparing (10–11) with the equivalent formula for calculating the probability of a particular analysis for a Tree-DOP representation, Way (2001) observes that the LFG-DOP formulae contain references to *valid* structures. In Tree-DOP, apart from the root-matching criterion, there are no other validity conditions; in LFG-DOP, depending on the competition set chosen, there may be several.

Omitting the details for reasons of space, Bod & Kaplan (1998) give three different competition sets depending on the stage at which the LFG grammaticality checks are carried out, which affect the the **probability models** for LFG-DOP:

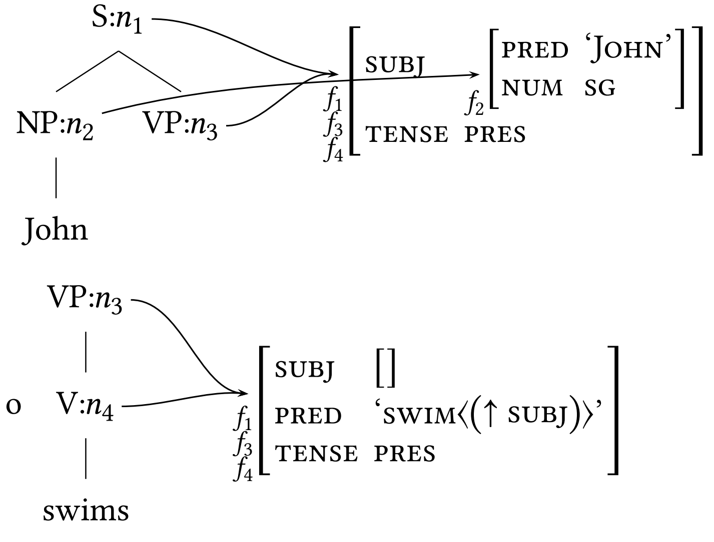
1. A straightforward extension of the Tree-DOP probability model, where the choice of a fragment depends only on its *Root* node (i.e. c-structure matching category) and not on the Uniqueness, Completeness or Coherence conditions of LFG, which are enforced off-line.

2. *Root* nodes must match, and f-structures must be unifiable if two LFG fragments are to be combined. This model takes the LFG Uniqueness condition (namely that each attribute has only one value) as well as the *Root* category into account. As the resultant fragments produced vary depending on the derivation followed, unifiability must be determined at each step in the process.

3. In addition to the previous two steps, the LFG Coherence check is enforced at each step, ensuring that each grammatical function (SUBJ, OBJ etc.) present in the f-structure is governed by a PRED. This means that in this model, we are dealing only with well-formed c-structures which correspond to coherent and consistent f-structures, i.e. structures which satisfy LFG's Uniqueness check, thereby permitting unification only where exactly appropriate. As we have noted already, the LFG Completeness check can only be enforced after all other validity sampling has taken place.

Let us now return to the sentence *John swims*, and show one possible derivation of the $\langle c, f\rangle$ pair in (1). A straightforward way of doing this would be to compose (via the 'o' operator in (12)) the $\langle c, f\rangle$ fragment in (3) with the leftmost fragment in (7), which we include in full in (12):

(12)



This is possible given that the VP node in the upper tree is vacant, so the lower VP tree can be substituted for this node. The respective f-structures are then unified to give the $\langle c, f\rangle$ fragment in (1). Throughout the derivation of this $\langle c, f\rangle$ pair, we have satisfied DOP's *Root* condition (leftmost substitution of 'like' categories only), as well as the Uniqueness, Completeness and Coherence grammaticality conditions of LFG. As a consequence, the resultant structures in (1) are valid. This is equivalent to using the third option given above for possible competition sets.

Of course there will be many other possible derivations which contribute to the overall probability of the sentence *John swims.* Note that if we enforce LFG's grammaticality checks on-line, leftmost substitution of non-*Discard* fragments reduces the size of the competition set for future iterations of the composition process. In (12), for instance, enforcing the Uniqueness condition on-line (models 2 or 3 above) prevents any fragment other than a singular intransitive VP from being substituted into the VP slot. In Tree-DOP, *any* VP could be substituted at this node.

3 LFG-DOT

In this section, we demonstrate that problems with the LFG-MT (Kaplan et al. 1989) and Data-Oriented Translation (DOT: Poutsma (2000)) models of translation can be solved by LFG-DOT.[6] As the LFG-DOT models proposed by Way (1999) and Way (2001) are based on LFG-DOP, they have the same advantages as shown in the previous section, albeit now for translation:

1. Being a probabilistic model, LFG-DOT can overcome problems encountered by LFG-MT which is based solely on LFG's constraints; and
2. By appealing to LFG's f-structure constraints, LFG-DOT can overcome problems encountered by DOT which is based solely on trees.

3.1 LFG-MT

A translation model based on LFG was first presented in Kaplan et al. (1989). This original model introduces the τ-correspondence as a mapping between source

---

[6] Hearne (2005) demonstrates that reasonably large-scale models can be built with DOT that considerably outperform SMT. Bod (2007) contains results which demonstrate similar improvements over SMT, but for *really* large-scale models at the time. Given the massive time and space constraints involved in processing DOP models, it is noteworthy that Bod was able to build DOT models trained on more than 750K sentence-pairs of German-English Europarl data (Koehn 2005).

and target f-structures. For *swim*, we would need a transfer lexicon entry such as (13) for translation between English and French:

(13) *swim*:
$(\tau\uparrow \text{PRED}) = \text{nager}$
$(\tau\uparrow \text{SUBJ}) = \tau(\uparrow \text{SUBJ})$

Being a straightforward translation example, this entry demonstrates two things: (i) that the translation of the verb *swim* is *nager*, and (ii) that the translation of the subject of *swim* is the subject of *nager*.

This model is very elegant, and allows for some difficult translation problems to be handled by the LFG-MT formalism. For example, verbs with different semantic forms can be handled relatively straightforwardly. Assume the translation case in (14):

(14) The student answers the question ⟷ L'étudiant répond à la question.

This case can be dealt with as in (15):

(15) *answer*:
$(\tau\uparrow \text{PRED}) = \text{répondre}$
$(\tau\uparrow \text{SUBJ}) = \tau(\uparrow \text{SUBJ})$
$(\tau\uparrow \text{OBL OBJ}) = \tau(\uparrow \text{OBJ})$

This states that *répondre* is the corresponding French predicate of *answer*, that the translation of the SUBJ is straightforward, and that the translation of the OBJ of *answer* is the OBL OBJ of *répondre*.

The LFG-MT model of Kaplan et al. (1989) can also deal correctly with the *like–plaire* relation-changing case, as (16) demonstrates:

(16) *like*:
$(\tau\uparrow \text{PRED}) = \text{plaire}$
$(\tau\uparrow \text{OBL}_{)} = \tau(\uparrow \text{SUBJ})$
$(\tau\uparrow \text{SUBJ}) = \tau(\uparrow \text{OBJ})$

That is, the subject of *like* is translated as the oblique argument of *plaire*, while the object of *like* is translated as the subject of *plaire*.

However, a line of work showed that while the τ-equations of Kaplan et al. (1989) are by and large able to link exactly those source–target elements which are translations of each other, there are a number of cases where this machinery is unable to cope with a set of translation cases, in particular embedded headswitching examples and the correct translation of adjuncts (cf. Arnold et al. 1990, Sadler & Thompson 1991, Way 2001).[7]

It is worth noting that an updated version of LFG-MT was described in Kaplan & Wedekind (1993) which used the concept of *Restriction* to try to overcome some of the problems in mapping between flat syntactic f-structures to hierarchical semantic ones. However, as well as receiving criticism from a monolingual perspective (cf. Butt (1994) and complex predicates in Urdu), Way (2001) demonstrates this new approach failed to ensure that only the correct translations ensued; rather, it was left to a human expert to select the correct translation from a set of alternatives, many of which were incorrect. Despite being an improvement on the original model of Kaplan et al. (1989), it is still open to criticism as a general model of translation.

Another solution proposed around this time involved using linear logic (van Genabith et al. 1998), but this involved adding massive redundancy in the transfer lexicon, cf. Way (2001: 92–96).

Note too that work continued on using LFG as a basis for MT after LFG-DOT was introduced. One such model was that of Riezler & Maxwell (2006). Note that their paper is not a comparison of LFG-MT, but rather with SMT (Koehn et al. 2003). Note that they add a 'fragment grammar' which "allows sentences that are outside the scope of the standard grammar to be parsed as well-formed chunks" (p.251), but they do not compare this with the bag of *Discard*-generated fragment-pairs in LFG-DOT. This work is extended by Graham & van Genabith (2012), who incorporate a deep syntax language model directly into the decoder, as opposed to using it *post hoc* to improve the grammaticality of the target translations. Note that neither approach shows how their models handle any of the traditional 'hard' translation cases. For the approach of Riezler & Maxwell (2006), being based on transfer rules – albeit automatically extracted ones – it will surely fail in similar ways to LFG-MT. As to the model of Graham & van Genabith (2012), and approaches based on SMT in general, it is doubtful whether the system designers can answer the question how such translational phenomena are handled, as SMT does not work in this way. Of course, test sets can be designed which include such 'hard' cases, and the translation output inspected, but SMT systems

---

[7] To give the reader some insight into the first-mentioned issue without having to consult the primary literature, LFG-MT can cope with 'straightforward' headswitching examples like *The baby just fell* ⟷ *Le bébé vient de tomber*. However, when such examples appear in embedded clauses, as in *I think that the baby just fell* ⟷ *Je pense que le bébé vient de tomber*, *ad hoc* solutions are required to avoid target f-structures being doubly rooted, i.e. two τ-equations result in inconsistent solutions where one piece of f-structure is required to simultaneously fill two different slots.

by their very nature are far less inspectable than systems which include syntactic constraints, so even if such sentences were translated correctly, it would be hard to know why exactly. Of course, this problem is worse again with today's state-of-the-art neural models; despite the improved quality that can be derived, our knowledge as to what is going on internally inside the systems is less than it's ever been.

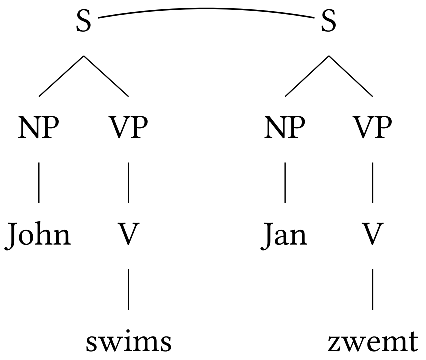
3.2 Data-Oriented Translation

Poutsma (2000) produced two models of tree-based translation, DOT1 and DOT2. These models were formulated along the same lines as DOP and LFG-DOP, with definitions of the representations to be used, how these were to be decomposed, recomposed, and a probability model.

In DOT, the latter determined the likelihood of a target translation given a source string. The representations used were PS trees, decomposition described how to extract well-formed subtree-pairs from these representations,[8] and the composition operator used was leftmost substitution (to ensure unique derivations) of matching *Root* labels.

We illustrate a linked translation pair in DOT in (17) for the the sentence pair ⟨ *John swims*, *Jan zwemt* ⟩:[9]

(17)



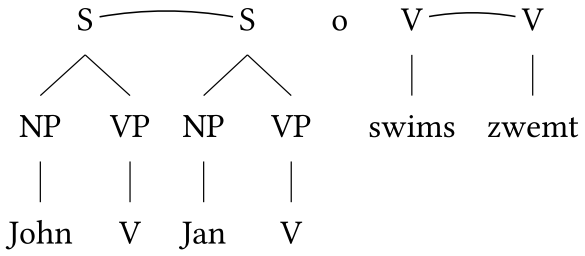
If we assume that the sentential fragment in (17) is unseen in our DOT treebank, one derivation of the translation *Jan zwemt* given the source sentence *John swims* might be (18):

---

[8] In his thesis, Way 2001 introduces the label γ to refer to the function that links DOT source and target subtree fragments. See Section 3.3.2 for models which use the γ function in LFG-DOT, and Poutsma 2000: Sect. 2.1 for a description of how linked subtrees like the V-labelled fragments in (18) are extracted from tree pairs such as (17).

[9] Here we 'translate' names to indicate that the translation process has been successful, as opposed to merely passing over a source word as untranslated – an out-of-vocabulary item – into the target side.

(18)



Way (1999) showed that the DOT1 model could not always explicitly relate parts of the source-language structure to the corresponding, correct parts in the target structure, so fails to translate correctly where source and target strings differ with respect to word order (e.g. the *like* ⇔ *plaire* relation changing case – which LFG-MT can handle, cf. (16) – plus many more 'hard' translation cases described in Way et al. (1997)).

DOT2 was developed as a consequence of these failings, and improves over DOT1 by not restricting the composition operation to left-most substitution on *both* sides. With that change, DOT2 manages to overcome cases of word-order difference by and large. However, Way (2001) notes that:

> "this is compromised by a lesser amount of compositionality in the translation process. Given the small number of fragments playing a role in the derivation of some translations involving complex phenomena, almost the exact linked sentence pair may need to be present in order for a translation to be possible. Furthermore, any such translations produced have extremely small probabilities with respect to the corpus. Finally, of course, translation systems which are based purely on PS trees will ultimately not be able to handle certain linguistic phenomena." (Way 2001: 190)

To illustrate the 'limited compositionality' problem in DOT2, Way (2001) appeals to the translation pair in (19):[10]

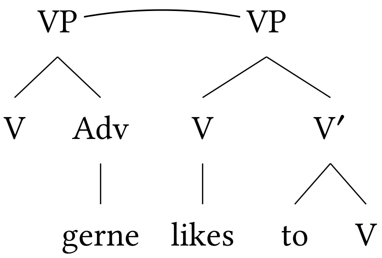
(19) DE: Johannes schwimmt gerne ⇔ EN: John likes to swim.

Essentially, the VPs cannot be broken down further; *schwimmt* and *swim* are not translationally equivalent – one is inflected and the other is in the infinitive form – so in their source–target tree pairs, links cannot be drawn between the fragment-pair in (20), as we might otherwise wish to do, in order to describe the basic translation relations in (19):

---

[10] Given that other similar cases exist, e.g. DE: Josef läuft zufällig ⇔ EN: Joseph happens to run, the redundancy in the DOT2 approach really shows itself to be problematic when such cases are combined, as in strings such as *John likes to happen to swim* (i.e. John likes to swim by chance, rather than planning ahead), and *John happens to like to swim.*

(20)



Accordingly, while it is possible for DOT2 to cope with such examples in contrast to DOT1, which couldn't handle them at all, the exact VPs (*likes to swim*, here) have to exist *a priori* in the treebank. This is because these linked VP pairs are handled non-compositionally in DOT2 between German and English, but the monolingual VPs are treated compositionally in DOP. As can be seen, DOT2 approximates to a translation dictionary for such cases – as *likes to* can be followed by pretty much any verb in English, and *gerne* can modify pretty much any verb in German – which is clearly impractical, and so can be disregarded as a general model of translation.

3.3 Combining DOT and LFG-MT: the best of both worlds

In his thesis, Way (2001) provides four LFG-DOT models which solve all these 'hard' cases:

1. Model 1: Translation via τ
2. Model 2: Translation via τ and γ
3. Model 3: Translation via γ with Monolingual Filtering
4. Translation via γ and 'Extended Transfer'

3.3.1 LFG-DOT1

Way (2001) describes this as a simple linear model, as in (21):

(21)

$$\begin{tikzcd}
c \arrow[r, dash, "\text{LFG-DOP-}\phi"] & f \arrow[d, dash, "\tau"] \\
c' \arrow[r, dash, "\text{LFG-DOP-}\phi'"'] & f'
\end{tikzcd}$$

The different components needed are:

- a source language LFG-DOP model;
- the τ mapping;
- a target language LFG-DOP model.

Way (2001: 193) notes that "LFG-DOT1 contains two monolingual LFG-DOP language models … [so] *Discard* can be run on both source and target sides. This means that LFG-DOT1 can cope with ill-formed or previously uncovered input which LFG-MT would not be able to handle at all". Despite this advantage, LFG-DOT1 unsurprisingly suffers from the same problems as LFG-MT, as its translation function is described by the same operator τ.

3.3.2 LFG-DOT2

Given that τ is an insufficient operator to define all translation problems (cf. fn. 7, for example), Way (2001) describes the translation relation using both the γ and τ functions in his LFG-DOT2 model, summarised in (22):

(22)

$$\begin{tikzcd}
c \arrow[r, dash, "\text{LFG-DOP-}\phi"] \arrow[d, dash, "\gamma"'] & f \arrow[d, dash, "\tau"] \\
c' \arrow[r, dash, "\text{LFG-DOP-}\phi'"'] & f'
\end{tikzcd}$$

This is clearly a more complex model than LFG-DOT1, necessitating:

- a source language LFG-DOP model;
- the γ mapping (i.e. the DOT2 model of translation, cf. fn. 8);
- a target language LFG-DOP model;
- a probabilistic transfer component.

Way (2001) provides a number of ways in which the γ and τ functions might co-operate in his LFG-DOT2 model. He notes that using LFG-DOP as the source and target language models overcomes the shortcomings of both Tree-DOP and LFG, and that including τ allows certain 'hard' cases (like relation-changing) to be handled correctly, unlike the DOT1 model.

Furthermore, Way (2001) notes that LFG-DOT2 is more robust than LFG-MT, in that *Discard* can produce generalized fragments which may be able to deal with input for which LFG-MT cannot offer any translation.

Ultimately, as the τ mapping cannot always produce the desired translation, Way jettisons this function in his LFG-DOT3 and LFG-DOT4 models, to which we turn next.

3.3.3 LFG-DOT3

LFG-DOT3 relies solely on γ to express the translation relation. The architecture of LFG-DOT3 is shown in (23):

(23)

$$\begin{tikzcd}
c \arrow[r, dash, "\text{LFG-DOP-}\phi"] \arrow[d, dash, "\gamma"'] & f \\
c' \arrow[r, dash, "\text{LFG-DOP-}\phi'"'] & f'
\end{tikzcd}$$

Way (2001) demonstrates that contrary to other models described here, embedded headswitching cases in LFG-DOT3 are handled in the same manner as non-embedded headswitching cases, exactly as required (cf. fn. 7). He also shows that LFG-DOT3 can cope with certain cases of combinations of exceptional phenomena which prove problematic for other formalisms. However, like DOT2 (cf. Section 3.2), LFG-DOT3 also suffers from the problem of limited compositionality.

3.3.4 LFG-DOT4

To overcome this problem, Way (2001) uses a restricted form of *Discard* in an 'extended transfer' phase in LFG-DOT4 to generalize the translation relation appropriately. Essentially, in LFG-DOP (and consequently LFG-DOT), fragments generated by *Discard* occupy an unjustifiably large proportion of the probability space. Accordingly, Way (1999) proposes to split fragments into two bags: those generated by *Root* and *Frontier*, and those generated by *Discard*. In LFG-DOT4, Way (2001) allocates a small amount of the probability space to lemmatized translation pairs produced by a second application of *Discard*.[11] To revisit

---

[11] Another way of mitigating this problem is suggested by Way (2001: 112), namely to adopt the approach of Zaenen & Kaplan (1995), which cuts down on the possible number of LFG-DOP fragments compared to the description of LFG in Kaplan & Bresnan (1982). In Zaenen & Kaplan (1995), lexical heads are ϕ-linked only to semantic forms and not to their enclosing f-structures, while other primitive feature values remain unlinked.

the problematic example in (19), if *Discard* is used to relax the TENSE constraint, then the V nodes in (20) can be linked; they couldn't before as the V in German was a finite verb, while the V in English was an infinitive. Accordingly, Way (2001: 190) suggests that "this model describes the translation relation exactly as required, and furthermore overcomes the problems of LFG-MT … and DOT models of translation". See Table 1 for a summary of the comparative advantages and disadvantages of each of the models covered in this chapter.[12]

Table 1: A comparison of the advantages and disadvantages of the MT models described in this work

Model	Ill-formed input	Word order	Embedded headswitching	All 'hard' cases	Avoids limited compositionality
LFG-MT	N	Y	N	N	N
DOT1	Y	N	N	N	N
DOT2	Y	Y	Y	N	N
LFG-DOT1	Y	Y	N	N	N
LFG-DOT2	Y	Y	Y	N	N
LFG-DOT3	Y	Y	Y	Y	N
LFG-DOT4	Y	Y	Y	Y	Y

4 Automatic derivation of f-structures from treebanks

In this section we consider how the resources needed for large-scale LFG-DOP and LFG-DOT models can be generated. We also explain the two different ways in which f-structures can be derived from a tree.

4.1 Towards large-scale resources for LFG-DOP and LFG-DOT

LFG-DOP needs large collections of monolingual annotated data (treebanks) in order to parse monolingual input, and LFG-DOT needs large collections of bilingual annotated data. At the time LFG-DOP and LFG-DOT were being developed, no such large f-structure annotated data existed. Constituency treebanks had

---

[12] See Way (2003) for more details on these models, and Hearne (2005) for an alternative LFG-DOT model based on LFG-DOT3 but which incorporates a different probability model and fragmentation procedure.

been available for several years, and large-scale hand-crafted LFG grammars were available only for a few languages. However, neither could provide the input needed to support the training of LFG-DOP or LFG-DOT models. Constituency treebanks alone could not provide the linguistic detail needed, and hand-crafted grammars were unable to select the most likely parse from a (sometimes) large number of possible solutions.

To address these shortcomings, van Genabith, Way, et al. (1999b) and van Genabith, Sadler, et al. (1999) proposed initial methods to automatically derive the LFG-treebank resources required to support training LFG-DOP and LFG-DOT models, although this was not the main driving force behind this work.

Initially, the work conducted produced grammars and lexicons for English, which seeded high-performing probabilistic parsers (see Section 5). Later, related methods were used to extract similar resources for a range of other languages (cf. Section 6). Once the general approach had been validated for different languages and treebanks, it is possible to sketch a research project which could generate the resources needed for large-scale LFG-DOP and LFG-DOT experimentation.

Taking a large-scale parallel corpus such as Europarl (Koehn 2005), we would need to:

1. Parse source and target sides to generate c-structure trees for the two languages;
2. Run the f-structure annotation algorithm(s) over each side;
3. Apply the *Root* and *Frontier* operations to extract the separate bags of fragments.

After step 2, we have $\langle c, f\rangle$ pairs of structure for all sentences on both sides of the corpus, so we can build LFG-DOP models for the individual source and target sides by running *Root* and *Frontier* operations on each side, and start producing $\langle c, f\rangle$ pairs for new monolingual input. To generate resources for the better of the four models, LFG-DOT4, we need to align each source tree generated in step 1 with each target tree generated in the same step. Fortunately, Europarl contains information regarding which sentences in one language map to which sentences in another, so we can now apply *Root* and *Frontier* operations on both sides to extract the separate bags of fragments that are needed, and start translating new input strings. This experiment remains for future work.

4.2 Direct transformation vs. indirect annotation

The initial approaches of van Genabith, Way, et al. (1999b) and van Genabith, Sadler, et al. (1999) focused on deriving f-structure annotations from PS trees. The intuition was that there were already reasonably reliable tools for automatically producing a tree from an input sentence, and so it would be easier to scale a tree-annotation plus f-structure derivation approach, compared to automatically deriving c- and f-structure simultaneously from raw input.

There are two ways to derive an f-structure from a tree: **direct** transformation or **indirect** annotation. The direct method recursively and destructively transforms a treebank tree into an f-structure. The indirect method only ever adds information: it annotates the treebank tree with f-structure annotations (equations). These annotations are then collected and passed to a constraint solver which resolves the equations and, if the equations are consistent, outputs an f-structure.

Examples (24)–(26) illustrate the indirect method: all nodes in the tree in (24) are annotated with equations in (25), which are collected and resolved into an f-structure in (26).

```

The earliest approach to automatically identifying functional grammatical categories such as subj, obj, etc in PS trees is probably that of Lappin et al. (1989). Nodes in trees are linked to their corresponding grammatical functions. Their motivation was to generate a set of grammatical function-based transfer rules as part of an MT project.

A regular expression-based, indirect automatic annotation method is described in Sadler et al. (2000). This involves extracting a context-free PS grammar (CFG) from a treebank fragment. F-structure annotation principles are stated in terms of regular expressions matching CFG rules. By applying regular expression-based annotation principles to the rules that are extracted, and using these annotated rules to re-match the original trees, f-structures can be generated for these trees. The number of annotation principles is appreciably smaller than the number of extracted CFG rule types since the regular expression-based annotation principles capture linguistic generalisations.

The flat, set-based tree description rewriting method of automatically annotating trees with f-structure descriptions developed by Frank (2000) can be seen as a generalisation of the regular expression-based technique of Sadler et al. (2000). Here the idea is that each tree is translated into a flat description using terms from a tree description language (e.g. *lex, arc, phi* etc.). Annotation principles are then defined in terms of rules employing a rewriting system originally developed for transfer-based MT architectures (Kay et al. 1994). In certain circumstances, the principles can be applied order-independently, or in a particular cascading order. One of the advantages of this method is that tree fragments of arbitrary depth can be considered, whereas in the regular expression-based method, tree depth is limited to 1 (i.e. CFG rules).

The earlier approaches were limited in scale to corpora in the order of hundreds of trees. In Cahill et al. (2002a), a first version of a large-scale indirect annotation algorithm was described. This algorithm was scaled to a corpus containing tens of thousands of trees. The algorithm recursively traverses a PS tree and annotates f-structure information on each node. McCarthy (2003) and Burke (2006) continued to expand this algorithm in terms of linguistic coverage. The algorithm itself is modular and separates the linguistic data from the traversal algorithm. There are two stages to the algorithm: (i) “proto”-f-structures are generated which contain unresolved long-distance dependencies (LDDs); and (ii) trace information encoded in the treebank is used to correctly link moved constituents to where they should be interpreted semantically. Given a PS tree with f-structure-annotated nodes, a constraint solver based on the one described in Gazdar & Mellish (1989) was used to produce the final f-structure representation for the tree. This body of work yielded the first large-scale algorithm for converting a treebank into a corpus of f-structures. This was a prerequisite for the parsing work that built on this corpus as described in Section 5.

Similar efforts to automatically acquire wide-coverage grammars for TAG (Xia 1999), HPSG (Miyao et al. 2003), and CCG (Hockenmaier & Steedman 2002) appeared around the same time as the work on LFG.

5 Probabilistic parsing & lexicon induction using LFG

With the availability of large-scale f-structure-annotated treebanks, it was now possible to train probabilistic LFG parsers.

The initial parsing experiments of Cahill et al. (2002b) were conducted on the Penn Treebank (Marcus et al. 1994). Two main approaches were compared:

1. Parse with a standard CFG parser and then automatically annotate the resulting tree (*pipeline* architecture)

2. Automatically annotate the nodes in the trees of a large corpus with f-structure information and train a probabilistic parser on it (*integrated* architecture)

Both approaches yielded c-structures whose node labels included f-structure annotations. These f-structure annotations were then collected and resolved to generate a final f-structure. Initial parsers generated what were called "proto"-f-structures which did not include any LDD resolution. It should be noted that since these techniques were probabilistic, a set of n-best trees (and therefore f-structures) could also straightforwardly be produced. This was not possible with hand-crafted grammars which output all possible f-structure solutions for a given sentence without any way to sort them. Riezler et al. (2002) showed that it was possible to *post hoc* rank the output of such a parser, however.

In Cahill (2004) and Cahill et al. (2004), additional functionality was added to the original algorithm to allow for LDD resolution. This yielded more complete f-structures. There were two main components to the algorithm: (i) a set of possible functional uncertainty paths, and (ii) a subcategorisation lexicon.

In order to obtain the set of possible functional uncertainty paths, all observed paths between co-indexed material were extracted from the f-structures automatically derived from the Penn Treebank. These paths were associated with probabilities. O'Donovan et al. (2004) and O'Donovan (2006) describe an approach for automatically acquiring a large-scale subcategorisation lexicon from the Penn

Treebank. This relies on the intuition that if the original conversion of the treebank into f-structures is of high enough quality, then the lexical entries for all predicates can be reverse-engineered (van Genabith, Way, et al. 1999a). Frames are not predefined, yet the frames that are automatically acquired fully reflect LDDs in the source data-structures, discriminate between active and passive frames, and conditional probabilities are associated with each frame.

Given a set of semantic forms s with probabilities $P(s|l)$ (where l is a lemma), a set of paths p with $P(p|t)$ (where t is either TOPIC, TOPICREL or FOCUS) and an f-structure f, the core of the algorithm to resolve LDDs recursively traverses f to identify the most likely location of co-indexed material.

Evaluation of the f-structures produced by both parsing approaches was carried out against several corpora over time: the DCU-105 corpus (Cahill et al. 2002a), the automatically converted Section 23 of the Penn Treebank, the PARC 700 corpus (King et al. 2003) and the CBS 500 (Carroll et al. 1998). F-structures were converted into dependency triple format and compared to the gold-standard triples to give results in terms of precision, recall and f-score. Results demonstrated state-of-the-art results compared to other 'deep' parsers available at the time. Cahill, Burke, O'Donovan, et al. (2008) summarize a large set of parser comparisons, and show that the f-structures produced by the automatic processes described above were able to outperform two hand-crafted parsers: RASP (Carroll & Briscoe 2004) and the the English ParGram LFG run on XLE (Riezler et al. 2002). Rimell et al. (2009) conduct a comparison of several "deep" parsers on a specialized corpus of sentences containing only LDDs. They find that the HPSG and CCG parsers perform better than the DCU LFG parser on this set of difficult sentences.

6 Multilingual probabilistic LFG induction

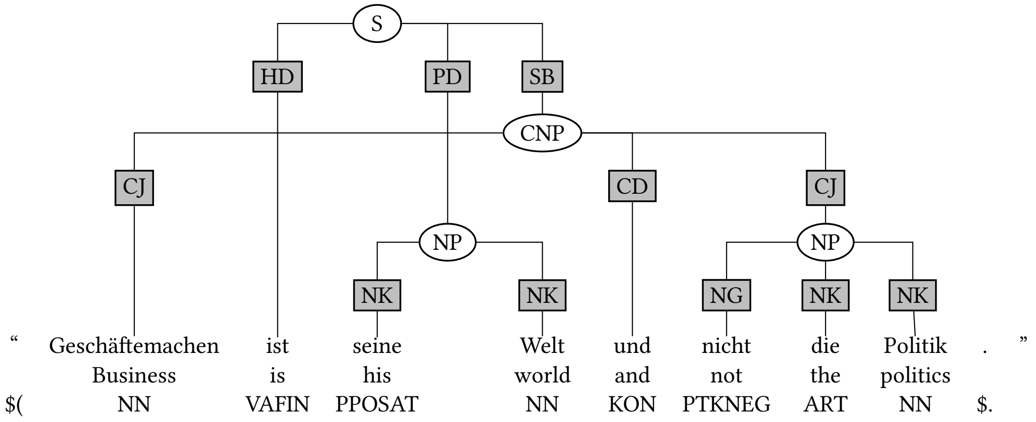
The approach developed for English was language-independent. Given a large enough and detailed treebank, one could theoretically follow the same framework to generate parsers and lexicons for other languages. Indeed, given that comparable treebank existed for some languages other than English, a large body of work ensued in this direction.

Cahill et al. (2003) first attempted this for German using the TiGer Treebank (Brants et al. 2002). This treebank differs from the Penn Treebank in that it encodes parses in terms of labeled graphs that allow crossing edges. In Cahill et al. (2003), the graphs are first converted to trees similar to those found in the Penn Treebank with trace information added to account for moved constituents.

A set of rules was then developed that automatically assigned f-structure equations to the nodes in the trees, and the same techniques described in Cahill et al. (2002b) were used to automatically acquire the first large-scale probabilistic LFG for German.

We provide an example graph from the TiGer treebank in (27) for the German sentence “Geschäftemachen ist seine Welt und nicht die Politik” (“Business is his world, not politics”).

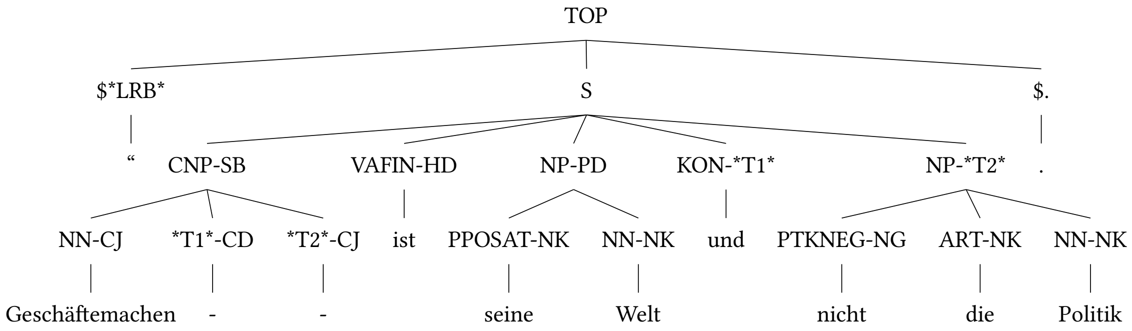
(27)



‘Business is his world, not politics.’

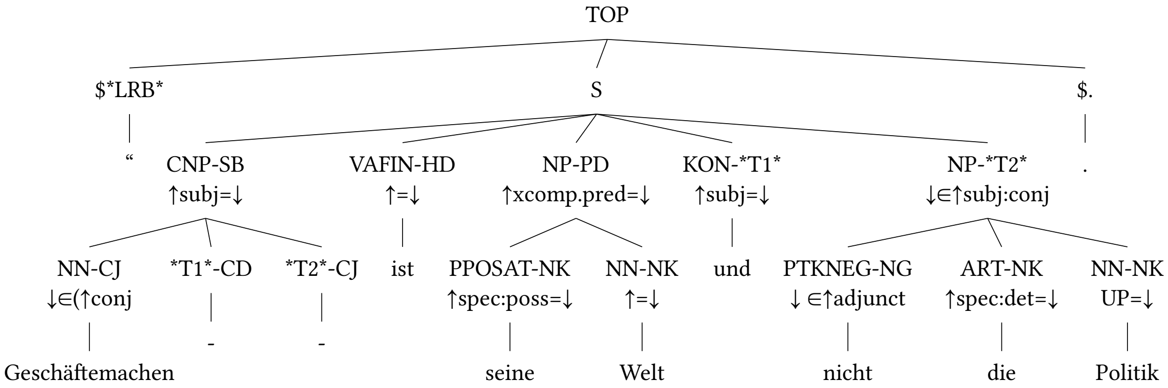
In (28), the graph in (27) is first automatically converted into a PS tree with traces and coindexation to indicate linked elements, analogous to how this kind of information is encoded in the English Penn-II treebank.

(28)



In (29), the tree in (28) is then annotated with f-structure equations. The annotation algorithm relies heavily on the functional component of the tree node labels (e.g. that SB indicates a SUBJECT).

(29)



Finally, the equations in (25) are collected and passed through a constraint solver to generate the f-structure in (30), using the same procedure as for English.

(30)
$$\left[\begin{array}{ll} \textsc{xcomp.pred} & \left[\begin{array}{ll} \textsc{spec} & \left[\textsc{poss}\ \left[\textsc{pred}\ \textsc{pro}\right]\right] \\ \textsc{pred} & \textsc{Welt} \end{array}\right] \\ \textsc{subj} & \left[\begin{array}{ll} \textsc{conj} & \left\{\begin{array}{l} \left[\textsc{pred}\ \textsc{Geschäftemachen}\right] \\ \left[\begin{array}{ll} \textsc{pred} & \textsc{Politik} \\ \textsc{spec} & \left[\textsc{det}\ \left[\textsc{pred}\ \textsc{die}\right]\right] \\ \textsc{adjunct} & \left\{\left[\textsc{pred}\ \textsc{nicht}\right]\right\} \end{array}\right] \end{array}\right\} \\ \textsc{coord-form} & \textsc{und} \end{array}\right] \\ \textsc{pred} & \textsc{ist} \end{array}\right]$$

Rehbein & van Genabith (2009) continued this work and explored the effect of the design of the treebank on the success of the technique. They compared extracting a probabilistic LFG from both TiGer and TüBa-D/Z (Telljohann et al. 2006) and found (1) that automatically inducing linguistic resources from (semi-) free word order languages such as German is much harder than for more configurational languages like English, and (2) that the the treebank encoding can have a significant effect on the success of the automatic f-structure annotation approach. Rehbein & van Genabith (2009) found that the encoding of linguistic structures in the TiGer treebank was better suited for automatic induction of LFG resources, because it was more difficult to automatically learn the grammatical function relations as they were encoded in the TüBa-D/Z.

For Chinese, Burke, Lam, et al. (2004) first applied the approach to the Penn Chinese Treebank (Xue et al. 2002). We provide in (31) an example tree from this treebank.

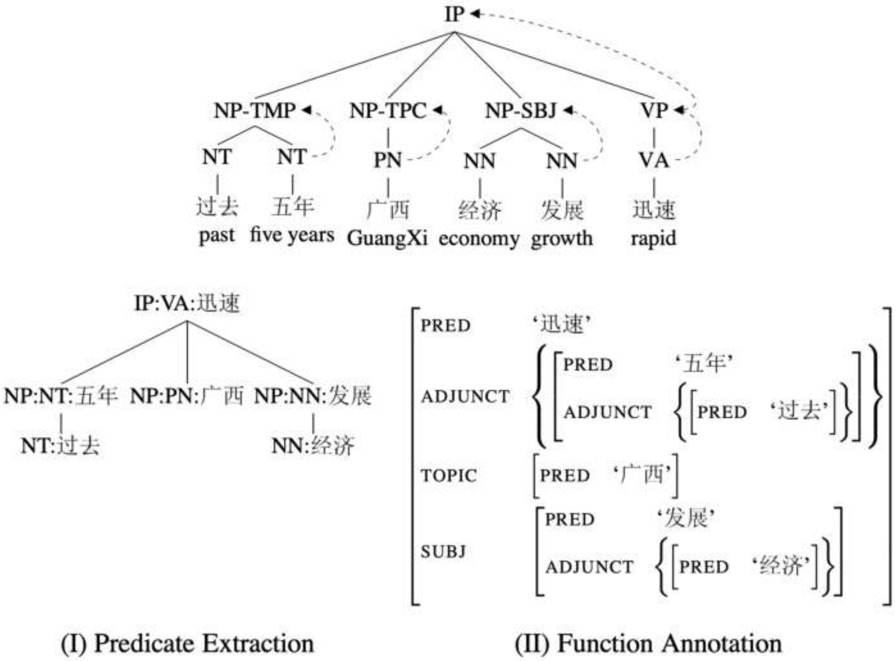
Guo et al. (2007) and Guo (2009) extended this work in terms of coverage, robustness, quality and fine-grainedness of the resulting LFG resources. They propose a more general two-stage annotation architecture, avoiding some of the limitations of the PS annotation-based method. They argue that this approach may be more suitable for less configurational languages. This algorithm works by transducing the tree into an f-structure by means of an intermediate dependency structure.

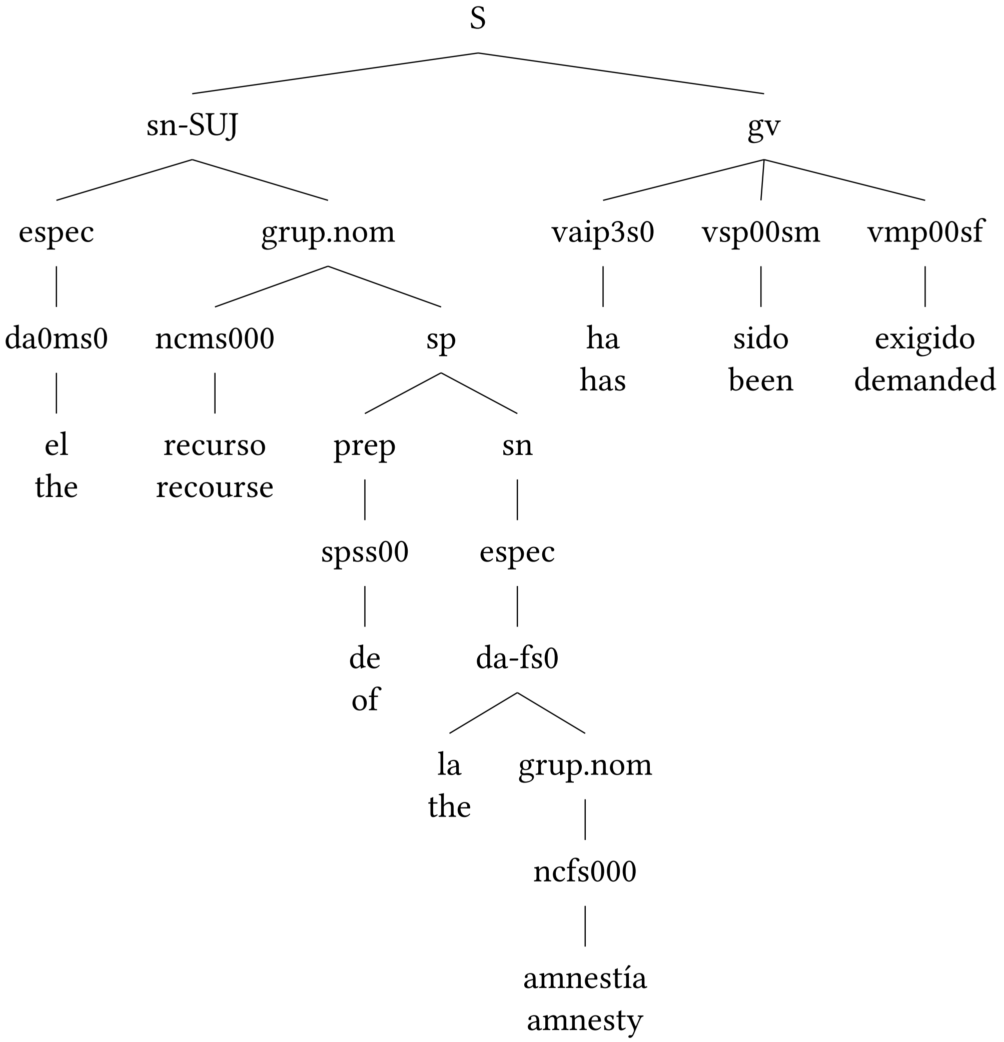
In (33), we show an example where predicate information is first extracted from the tree, and then a simpler set of function-based annotations converts the intermediate structure into an f-structure. The advantages of this approach are that it guarantees a single connected f-structure, as well as simplifying the process of taking LDDs into account.

(33)



O'Donovan et al. (2005) proposed an adaptation of the original approach for Spanish using the CAST3LB treebank (Civit 2003). In (34), we provide an example from the CAST3LB treebank.

(34)



The tree in (34) is then annotated with equations, as illustrated in (35). The equations are then resolved into the f-structure in (36).

This was extended in Chrupała & van Genabith (2006) where three main issues were addressed: (i) new constructions that had standard LFG analyses (e.g clitic doubling and null subjects); (ii) new constructions where no LFG analysis was available (e.g. periphrastic constructions in Spanish, see Figure 1); and (iii) limitations of the previous approach due to treebank- and language-specific assumptions which did not hold for Spanish and the CAST3LB treebank. Similar to what Guo et al. (2007) and Rehbein & van Genabith (2009) had found in their adaptations, the original approach assumed that the functional information could easily be derived from the tree configuration, but this proved not to be the case for many languages. Therefore, the functional tags in the parser output were critical for the success of these annotation algorithms. As a result, Chrupała & van Genabith (2006) outlined an improved method for tagging functions in parse trees, not only for Spanish, but for English, too. This was an important step in the development of a probablistic Spanish LFG parser based on the CAST3LB treebank.

In the case of French, no suitable treebank was immediately available. Therefore, Schluter & van Genabith (2007) first modified the Paris 7 Treebank (Abeillé et al. 2004), as this was the closest in format to what would be needed. A subset of the original treebank was transformed to yield a leaner, more coherent, treebank with several transformed structures, and new linguistic analyses. In Schluter & van Genabith (2008), it was shown that a probabilistic parser trained on the cleaner, modified treebank performed better than a parser trained on the

\end{array}\right]
\end{array}\right]
\end{array}\right]$$

Figure 1: Treatment of periphrastic constructions outlined in Chrupała & van Genabith (2006)

much larger, but noisier, original treebank. In addition, Schluter & van Genabith (2008) and Schluter (2011) showed that the techniques for automatically acquiring LFG resources from treebanks could successfully be adapted to the French case. Thanks to a rich morphological and functional annotation in the treebank, the automatic annotation algorithm can rely on node labels rather than inferring functional labels via tree configurations. This leads to fewer incomplete f-structures, and fewer cases where LDDs have not been resolved.

Oya & van Genabith (2007) showed that the approach can also be adapted for Japanese using the Kyoto Text Corpus (Kurohashi & Nagao 1997). The Japanese corpus encodes syntactic units in addition to rich morphological information. The automatic annotation algorithm adds f-structure equations at the level of syntactic unit. Figure 2 shows how the f-structure equations are added to each syntactic unit of the sentence "Taro went to Seoul". In the case of Japanese LFG parsing, the key to successful parsing results was in zero pronoun identification.

Finally, Tounsi et al. (2009a) and Tounsi et al. (2009b) demonstrated that the approach was also possible for Arabic using the Penn Arabic Treebank (Maamouri & Bies 2004). The annotation algorithm was able to take advantage of rich morphological tags in the treebank to support the fact that Arabic is a morphologically rich language.

In most cases we observe that the original reliance on tree configurations to identify functional properties worked best for English. For the other languages, relying on functional information already in the original treebank, and then ensuring that the CFG parser also contains that information, yielded the most accurate f-structure parsers. Evaluation of LFG parsing for the other languages followed roughly the same procedure as for English, using a small manually annotated corpus of sentences from the treebank used to derive the algorithm and parser.

7 Related approaches to grammar induction

A natural evaluation of this approach to creating large-scale probabilistic LFG parsers is to compare large-scale grammars created manually using the XLE platform.

The method proposed in Riezler et al. (2002) provides a mechanism for ranking all possible solutions generated by the hand-crafted grammar, relying on the same kinds of treebank resources as the methods described above. Kaplan et al. (2004) show that the accuracy of the hand-crafted grammar is more accurate than the Collins (1999) parser (f-score of 77.6 vs 74.6), while only slightly slower

(a) The automatically annotated sentence

$$\begin{bmatrix} \text{subj} & \begin{bmatrix} \text{pred} & \text{`Taro'} \\ \text{case} & \text{ga} \end{bmatrix} \\ \text{obl} & \begin{bmatrix} \text{pred} & \text{`Seoul'} \\ \text{case} & \text{ni} \end{bmatrix} \\ \text{pred} & \text{`iku}\langle\text{subj, obl}\rangle\text{'} \\ \text{stmt} & \text{'decl'} \\ \text{style} & \text{'plain'} \\ \text{tense} & \text{pst} \end{bmatrix}$$

(b) The resulting f-structure

Figure 2: An example from the Kyoto Text Corpus: from syntactically annotated sentence to f-structure

(total 299 CPU seconds vs 200 CPU seconds to parse 560 sentences). The two approaches have the same goal: to provide a ranked list of LFG parses for a given input. The difference is in how this ranked list is derived, and how much manual effort is required. Furthermore, in Cahill, Maxwell, et al. (2008) it was shown that a simple pruning mechanism on the c-structure forests generated by the XLE parser could significantly reduce parsing time, while maintaining comparable accuracy.

8 Conclusion

This chapter has described methods based on LFG that permit accurate, robust, scalable, probabilistic LFG parsers and MT systems to be built from large collections of automatically annotated data. While this is commonplace nowadays, it was much less so 20–25 years ago.

LFG-DOP extends LFG by generalizing well-formed analyses to allow ill-formed and previously uncovered strings to be handled. LFG-DOT, a robust, hybrid model of translation based on LFG-DOP, was demonstrated to be able to solve 'hard' cases of translation that proved difficult for DOT and LFG-MT.

The range of work on automatic annotation of LFG grammars summarised here was an important step in ensuring scalability and robustness that is commonplace nowadays. Once large-scale treebanks could be generated via these techniques, competitive probabilistic parsers were built, and large-scale lexical resources were induced. However, most experiments carried out using LFG-DOP (and LFG-DOT) were relatively small-scale, but we sketch here a method for large-scale experimentation using the resources created via the techniques described in this paper.

As well as the important extension of the core LFG framework to account for probabilistic parsing, this seminal work also provided the foundations for the now commonplace task of large-scale deep linguistic LFG annotation. In sum, the work described in this chapter laid the foundations for multilingual annotation of treebanks, which in turn allowed competitive scalable parsing and MT models to be developed that are accepted as best practice today.

Chapter 25

LFG treebanks

Victoria Rosén
University of Bergen

Treebanks are syntactically annotated corpora. LFG treebanks are collections of LFG analyses, usually created by parsing a corpus with an LFG grammar. This chapter provides an overview of existing LFG treebanks and explains how they are created, how they may be searched, and what their potential use may be to the LFG and other communities.

1 Introduction

Annotated corpora are important resources for many branches of linguistics, language studies and natural language processing. A common form of corpus annotation consists of labeling words with their parts of speech, lemmas and morphosyntactic features, such as number, person, tense, etc. Using only annotation at the word level limits the potential to search for important grammatical information, such as syntactic constructions, grammatical functions and predicate–argument relations. The usefulness of corpora is therefore greatly enhanced if they also include syntactic annotation, such as phrase structure and functional relations. Syntactically annotated corpora are usually called treebanks; if they are created by parsing, they may also be called parsed corpora or parsebanks.

LFG treebanks are treebanks annotated according to the LFG formalism. They are usually created as parsebanks, by parsing a corpus with an LFG grammar and disambiguating the parse results. An LFG parsebank is thus essentially a collection of analyses according to a grammar. LFG parsebanks encode a wealth of morphological, syntactic and semantic information in their c- and f-structure representations, and tend to be more detailed than treebanks adhering to other

Victoria Rosén. 2023. LFG treebanks. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 1169–1206. Berlin: Language Science Press. DOI: 10.5281/zenodo.10185992

formalisms. The term treebank is well established even if the treebank may contain f-structures, which are directed graphs rather than trees.

This chapter is aimed at two audiences. The first target group consists of linguists who may wish to learn to use LFG treebanks in order to find data for their research. The second target group is linguists who may wish to build LFG treebanks as part of a grammar development project.

A major platform for LFG treebanking is INESS (Infrastructure for the Exploration of Syntax and Semantics) at the CLARINO Bergen Center (University of Bergen, Norway).[1] This infrastructure will be further introduced below and will be used throughout the chapter to illustrate the various possibilities of LFG treebanking.

Section 2 describes how LFG treebanks can be created through parsing with the Xerox Linguistic Environment and further processed with the LFG Parsebanker. In Section 3 the LFG treebanks in the INESS treebanking infrastructure are presented. Section 4 demonstrates how LFG treebanks may be queried with INESS Search. Finally, Section 5 describes approaches to conversion between LFG treebanks and treebanks adhering to other formalisms.

2 Building LFG treebanks

2.1 Basic requirements

A parser, an implemented grammar and lexicon, and efficient disambiguation tools are prerequisites for creating a parsebank. A useful set of tools in this respect is the Xerox Linguistic Environment (XLE), developed at the Palo Alto Research Center and the Xerox Research Centre Europe in Grenoble. XLE includes both a parser and a generator for LFG grammars, and it is suitable for grammar implementation on a small or large scale (Crouch et al. 2011, Maxwell & Kaplan 1993). For detailed information on XLE, see Forst & King 2023 [this volume].

A grammar and lexicon with wide coverage are essential for building a large treebank of authentic texts, as well as for other applications. Grammar development is however a process which typically starts with a small set of rules which is successively expanded. In this development, the grammar must constantly be tested to see whether all the old rules still work in addition to the new rules. In this incremental process, a corpus, even a small one initially, may be useful as a

---

[1] https://clarino.uib.no/iness. INESS was built in the eponymous project (2010-2017) with funding from the Research Council of Norway and the University of Bergen (Rosén et al. 2012, Meurer et al. 2013).

test suite for parsing. As the grammar grows, it can be tested on a larger corpus and further improved. Larger grammars and lexicons do however increase the ambiguity in the analyses, so that efficient disambiguation is important.

XLE-Web[2] is a web-based implementation of XLE that was first developed in the LOGON and TREPIL projects (Rosén et al. 2005, 2006). XLE-Web uses the same parsing technology and software as XLE, but differs from the original platform in several ways. The original XLE is a standalone, integrated platform for grammar writing and debugging, whereas XLE-Web can be used through any modern browser. XLE-Web does not have tools for grammar writing, but it offers excellent tools for disambiguation.

As mentioned above, ambiguity becomes a considerable problem as the grammar grows. Therefore, XLE-Web offers *discriminant disambiguation* to efficiently select the intended analysis among possibly many alternative analyses. Discriminant analysis is a technique for identifying minimal differences between analyses and letting disambiguation proceed by resolving these differences rather than by inspecting whole structures (Rosén et al. 2007). An example of the XLE-Web display with discriminants is provided in Figure 1 for the ambiguous sentence *He saw the girl with binoculars*,[3] parsed with the English ParGram grammar.[4]

This sentence has two possible analyses due to a PP attachment ambiguity: *with binoculars* may be either an ADJUNCT of the clause or an ADJUNCT in the OBJ. Whereas XLE offers packed f-structures, XLE-Web offers packed representations for both c- and f-structures. A packed representation presents all analyses in one graph, with indices at choice points. In the middle of Figure 1 is a packed c-structure with one choice point which splits into the subtrees labeled *a1* and *a2*. A corresponding choice can be seen in the packed f-structure shown on the right in the figure. Although the disambiguated f-structure will have an ADJUNCT either on the outer level or inside the OBJ, both functions occur in the packed f-structure, labeled with *a1* and *a2* respectively.

On the left in the figure is a table with discriminants computed on the basis of these choice points. They present the user with each individual distinction between the analyses. There are two f-structure discriminants and ten c-structure discriminants.[5] F-structure discriminants describe paths through the f-structure

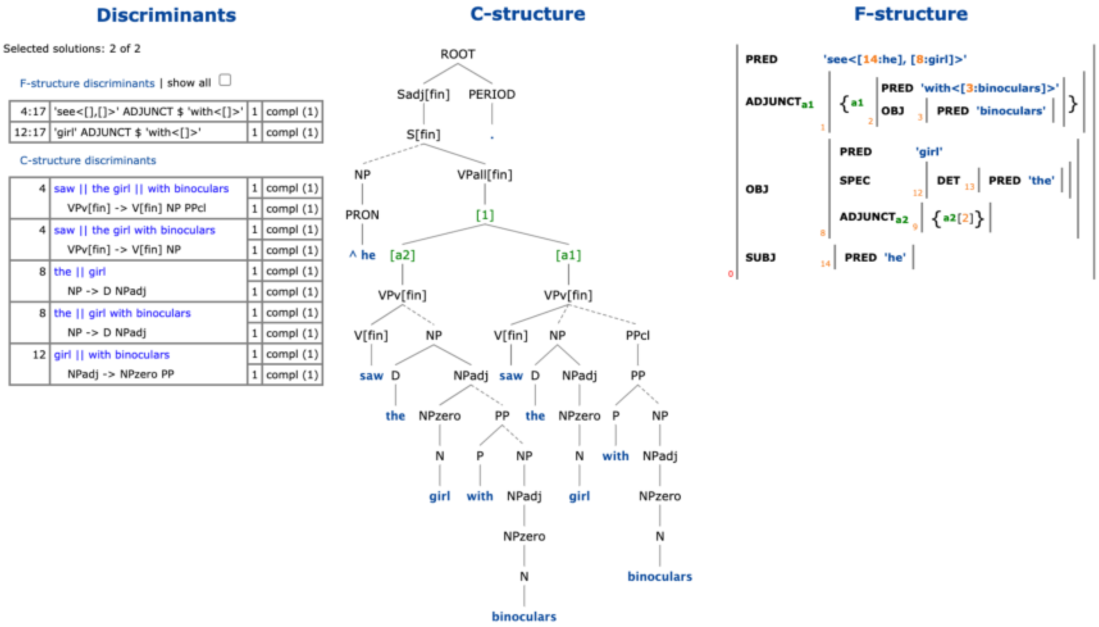
---

[2] https://clarino.uib.no/iness/xle-web

[3] In this and many subsequent f-structures, the *PREDS only* mode of display has been chosen. PREDS only mode displays only PRED values and the attribute paths which lead to them. This mode is often preferred when a full f-structure is too large to be easily legible.

[4] This grammar was developed in the Parallel Grammar (ParGram) project, see Section 3.6.2.

[5] In some cases there may also be lexical and morphological discriminants, but not for this sentence, which does not display any lexical ambiguities.



Discriminants

Selected solutions: 2 of 2

F-structure discriminants | show all ☐

4:17	'see<[],[]>' ADJUNCT $ 'with<[]>'	1	compl (1)
12:17	'girl' ADJUNCT $ 'with<[]>'	1	compl (1)

C-structure discriminants

4	saw || the girl || with binoculars	1	compl (1)
	VPv[fin] -> V[fin] NP PPcl	1	compl (1)
4	saw || the girl with binoculars	1	compl (1)
	VPv[fin] -> V[fin] NP	1	compl (1)
8	the || girl	1	compl (1)
	NP -> D NPadj	1	compl (1)
8	the || girl with binoculars	1	compl (1)
	NP -> D NPadj	1	compl (1)
12	girl || with binoculars	1	compl (1)
	NPadj -> NPzero PP	1	compl (1)

Figure 1: Analysis with discriminants and packed c- and f-structures for *He saw the girl with binoculars.*

from a PRED value to another PRED value or an atomic value. The two f-structure discriminants shown here indicate that the phrase *with binoculars* is an ADJUNCT either of the verb *see* or of the noun *girl*. The ten c-structure discriminants present the various minimal subtrees (a minimal subtree being a mother node and its daughter nodes) that make up the subtrees indexed with *a1* and *a2*. C-structure discriminants are either constituent discriminants, which show the bracketing of a substring, or rule discriminants, which show the labeled bracketing of a substring, expressed as a phrase structure rule. Rule discriminants are always displayed directly under the corresponding constituent discriminant, thus showing clearly which string of words the rule represents a bracketing of.

A discriminant may be chosen by clicking on it, or rejected by clicking on *compl* (for *complement*).[6] After a discriminant or its complement has been clicked on, it is displayed in boldface; the choice may be reversed by clicking on the boldfaced discriminant, thus resetting it. Since there are only two analyses for the

---

[6] The numbers to the left of the discriminants are anchors, which are necessary in case the same word or phrase occurs more than once in the sentence. In c-structure discriminants the anchor identifies the position of the first character in the substring. In f-structure discriminants the anchors identify the position of the first character of the words that project the PRED values in the discriminant. The number to the right of a discriminant (or its complement) indicates the number of solutions that will remain after the discriminant (or its complement) is chosen.

sentence in Figure 1, the intended one may be selected by choosing or rejecting any one discriminant. Figure 2 shows the effect of choosing the analysis in which *with binoculars* is an adjunct of the verb *see* by clicking on the first f-structure discriminant, resulting in full disambiguation. Discriminants that have not been chosen and that are no longer relevant for disambiguation, because they do not distinguish between any remaining analyses, are not displayed. This is important for efficiency, since the disambiguator then has fewer discriminants to take into consideration.

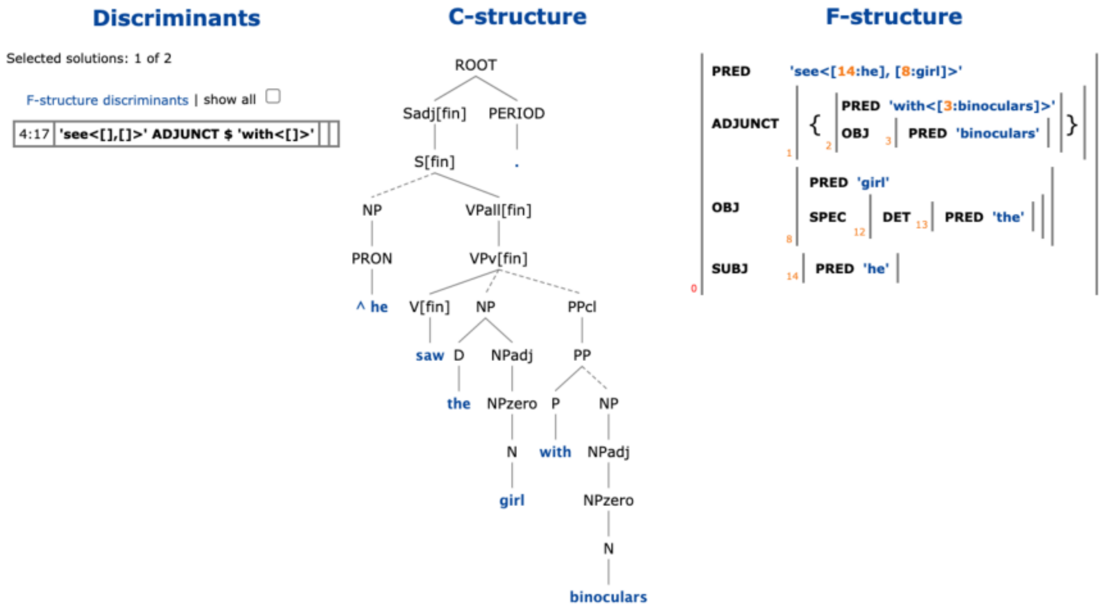


Figure 2: Fully disambiguated analysis for *He saw the girl with binoculars.*

This process may seem like overkill for this simple example which has only two readings. It becomes rewarding, however, when there are multiple ambiguities in the sentence. Even when the combination of ambiguities may give rise to a very large number of analyses, the number of discriminants does not necessarily increase as much, so that discriminant analysis remains comparatively efficient. A more detailed presentation of disambiguation with discriminants in LFG may be found in Rosén et al. (2007).

At the time of writing, the XLE-Web instance at INESS offers online parsing with the ParGram grammars of the following languages: English, French, Georgian, German, Indonesian, Italian, Malagasy, Norwegian, Polish, Tamil, Tigrinya, Turkish, Urdu and Wolof. Some of these have broad coverage, while others are more limited in scope.

2.2 The LFG Parsebanker

The LFG Parsebanker, available in INESS, is an integrated set of tools for creating and searching LFG treebanks (Rosén et al. 2009). It allows texts to be batch parsed with the XLE parser, and it stores the analyses in a database. The resulting parsebank may be disambiguated by using discriminants in the same way as described above. The LFG Parsebanker stores both the analyses and all discriminant choices that were made. This means that the grammar and lexicon may be further developed, and the treebank subsequently reparsed and at least partially redisambiguated with the stored discriminant choices. This method makes it possible to develop the grammar and the treebank in tandem, thus incrementally improving the quality of the analyses. The stored discriminants may also be used for stochastic parseranking. In this way larger parsebanks can be automatically disambiguated.

A possible drawback of constructing a treebank by parsing with an LFG (or other) broad-coverage unification grammar is that the grammar cannot hope to have full coverage for all authentically occurring sentences in a large corpus. Nevertheless, some traditional treebanks that are (at least partially) manually annotated are meant to assign an analysis to every sentence, and a variety of methods are utilized to achieve this. When a sentence is not covered by the grammar, an annotator can, for instance, manually construct an analysis to "fix" the problem. Although this provides an analysis for the treebank, it does not provide an analysis that is consistent with a grammar, and sentences that are not actually grammatical may receive analyses as if they were. In contrast, a pure parsebank does not resort to such ad hoc fixes, since it is often primarily meant to test the coverage and precision of a grammar, so that it is desirable to keep the treebank in sync with the grammar. The LFG Parsebanker therefore does not permit disambiguators to edit the automatically derived analyses, but allows them to make notes for grammar and lexicon development to solve coverage problems.

3 LFG treebanks in INESS

INESS is a treebanking infrastructure for building, hosting and exploring treebanks. It includes the above-mentioned XLE-Web and the LFG Parsebanker. It also has an elaborate infrastructure for browsing, search and visualization, as will be explained below.

INESS accommodates not only LFG treebanks, but also treebanks based on other frameworks, such as HPSG (Pollard & Sag 1994), constituency, and dependency treebanks. The infrastructure makes treebanks available online in an internet browser, eliminating the need to download treebanks and software for viewing and searching them, thus considerably facilitating access to them. Since INESS hosts many treebanks, there is an interface for treebank selection, as described in Section 3.1.

While some treebanks have completely open access, others require user authentication and authorization. Treebank owners decide under what licensing terms their treebanks are to be made available; some treebanks have restrictive licenses due to copyright of the input texts. The most open license that copyright will allow is recommended (Rosén & De Smedt 2022). INESS participates in the CLARIN Service Provider Federation (SPF), which allows researchers to authenticate themselves by logging in with their own university credentials, thus gaining access to many more treebanks than are freely available. The CLARIN SPF has participant institutions in many countries, both in Europe and beyond. Users not belonging to one of these institutions can apply for a user name and password at CLARIN.[7]

INESS hosts LFG treebanks of varying sizes. The larger treebanks TIGER, the LFG Structure Bank for Polish, and NorGramBank are presented in Section 3.2, Section 3.3 and Section 3.4, respectively. The smaller treebanks are presented in Section 3.5. INESS also hosts several parallel treebanks with LFG annotations, presented in Section 3.6. The INESS interface is described in more detail by Meurer et al. (2020).

3.1 Selecting treebanks in INESS

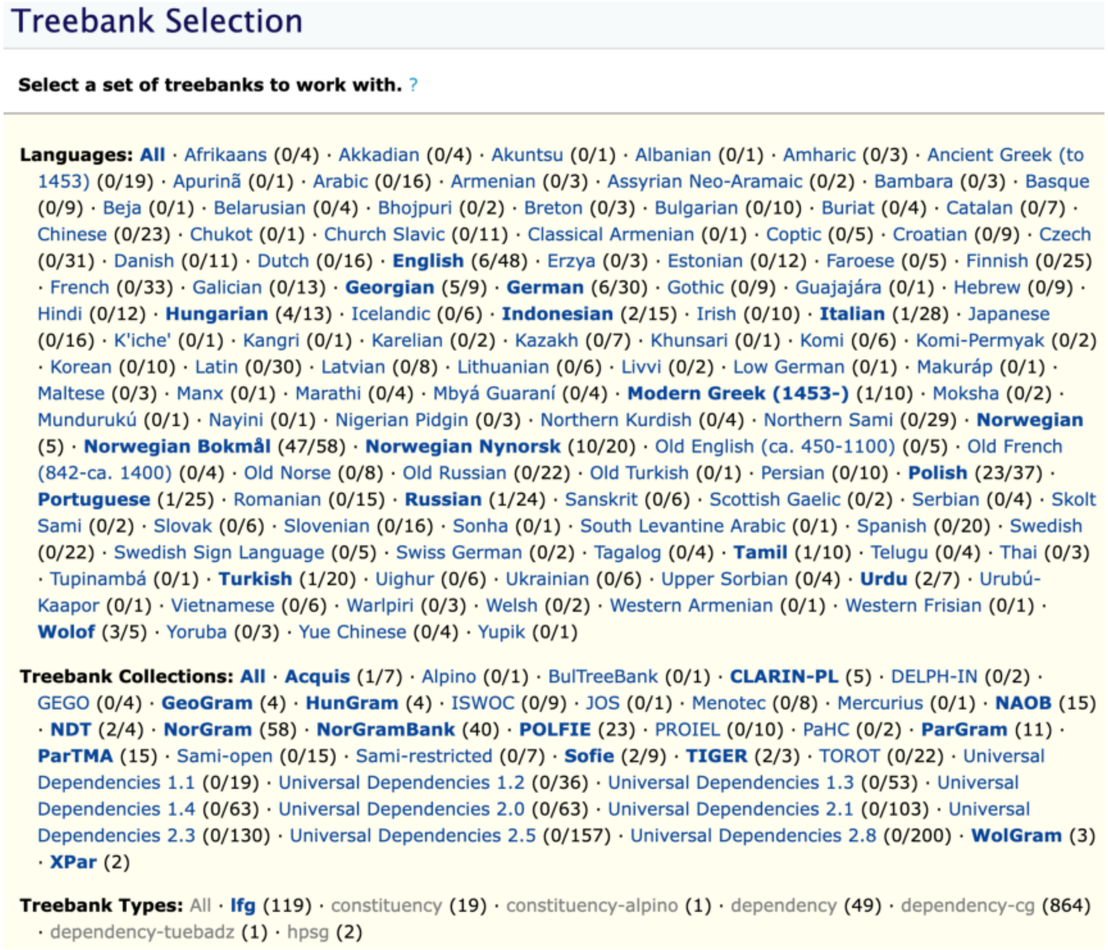
The first step in exploring treebanks involves selecting one or more treebanks. At the time of writing, INESS hosts 433[8] treebanks for 115[9] languages. The *Treebank Selection* page in INESS, shown in Figure 3, groups treebanks according to language, collection and type.

---

[7] CLARIN is a digital infrastructure offering data, tools and services to support research based on language resources (http://clarin.eu).

[8] According to Figure 3, there are 1057 treebanks in total, but this number includes all of the versions of the UD treebanks. If we only count the number of treebanks in Universal Dependencies 2.5 (200), the total number of treebanks is 433.

[9] There are 117 language names, but three of these are Norwegian, Norwegian Bokmål, and Norwegian Nynorsk, and these have been counted as one language: Norwegian. Norwegian Bokmål and Norwegian Nynorsk are the two written standards for the Norwegian language, with a good deal of lexical variation and many differences in spelling and morphology. Most treebank texts are written consistently in one variety or the other, so that users can choose which written variety to explore. Some texts, however, contain both varieties, for instance the proceedings of the Norwegian parliament 'Stortinget'; the latter are categorized simply as Norwegian.



Treebank Selection

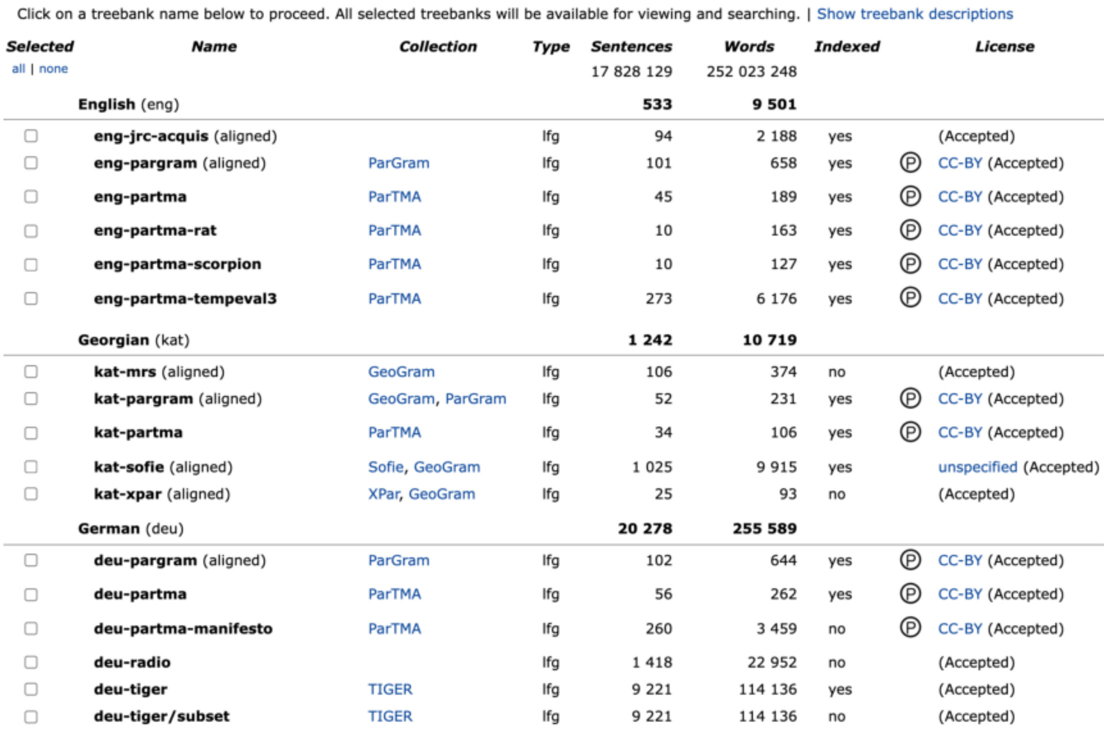
Figure 3: The INESS user interface for treebank selection, with treebank type *lfg* chosen

A collection contains several treebanks with something in common, for instance that they were developed as part of a specific project, or that they consist of translations of the same text into different languages (including the source language text). A single treebank may belong to more than one collection. Type refers to the annotation type, such as LFG, HPSG, constituency, and dependency, and includes subtypes of these. The user may click on any language, collection or type to make a first choice about which treebanks should be displayed.

In Figure 3 we see the effect of clicking on the type *lfg*; after this choice, only the languages and treebank collections that have LFG treebanks are displayed in boldface. Counting the boldfaced languages in Figure 3 shows that there are 16 languages that have LFG treebanks. After each language name, the numbers in parentheses indicate how many of the treebanks are LFG treebanks; for English, (6/48) means that six of 48 treebanks are LFG treebanks. In a similar manner, under Treebank Collections, TIGER (2/3) means that two of the three treebanks in the collection called TIGER are LFG treebanks.

Once a first choice has been made by a user, a list of all treebanks matching that choice is displayed. When LFG is chosen, a total of 119 treebanks are listed. The top of this list is shown in Figure 4.[10] For each treebank, this overview shows its name, which collections it belongs to, its annotation type, its size (in sentences and words), whether it has been indexed for search, and the type of license (if any). The user may choose one or more treebanks by ticking off the boxes to the left of the treebank name; clicking on the name of one of the chosen treebanks brings the user to that treebank. When exploring a treebank for the first time, the user is asked to accept the license conditions.

Clicking on a treebank name brings the user to the *Sentence Overview* page for that treebank; the sentences are listed one per line together with information about their disambiguation status. Clicking on a sentence displays the *Sentence* page, where the analysis for that sentence is shown including the textual context the sentence occurs in (the previous and following three sentences).



Click on a treebank name below to proceed. All selected treebanks will be available for viewing and searching. | Show treebank descriptions

Figure 4: Top of the list of treebanks after the type *lfg* has been chosen

---

[10] Treebank names in INESS begin with the three-letter ISO 639-3 code for the relevant language.

3.2 The TIGER treebank

The original TIGER treebank of German newspaper text (Brants et al. 2002, 2004) uses a hybrid annotation combining constituency and dependency information; part of it is also annotated with LFG structures. The constituency/dependency part of the treebank was constructed by two different methods. In one method a cascaded probabilistic parser was used in combination with manual annotation with the ANNOTATE tool (Brants & Plaehn 2000). The other method involved parsing with the German LFG grammar, followed by manual disambiguation; the XLE transfer system was employed to change the representations into the TIGER format (Zinsmeister et al. 2002). The LFG analyses were thus originally utilized in an experimental way to construct a more traditional treebank, but they now also constitute a useful resource as a standalone LFG treebank.

Figures 5 and 6 display the constituency/dependency and LFG analyses, respectively, for the sentence in (1). The URLs in parentheses in the captions are PIDs (persistent identifiers). They provide links to the analyses in the treebanks. Such links are persistent as long as the treebank they refer to remains available. For treebanks with certain licensing conditions, the PIDs may only work if the user is logged in and has accepted the license. For LFG treebanks, which are dynamic (they can be reparsed after changes are made to the grammar and/or lexicon), the PIDs are persistent in the sense that they provide a link to the *current* analysis of the sentence in the treebank.

(1) German
Das Angebot ist bereits groß.
the offer is already large
'The offer is already large.'

The tree in Figure 5 contains information about both phrase structure and syntactic functions. The nodes in yellow boxes are phrasal categories, while the nodes in the blue boxes under the S node are syntactic functions: sb for subject, hd for head, mo for modifier and pd for predicate complement.

The c-structure in Figure 6 displays extensive unary branching – many nodes have only single daughters – and many complex category labels, i.e., c-structure nodes subscripted with features enclosed in square brackets. The latter device moves some of the feature complexity of the LFG grammar from the f-structure space into the context-free c-structure space, which improves parsing efficiency while maintaining the simplicity of the c-structure rules. In the f-structure we see that the subj is also analyzed as the topic, the predicate complement is analyzed as an xcomp-pred, and the modifier is analyzed as an adjunct.

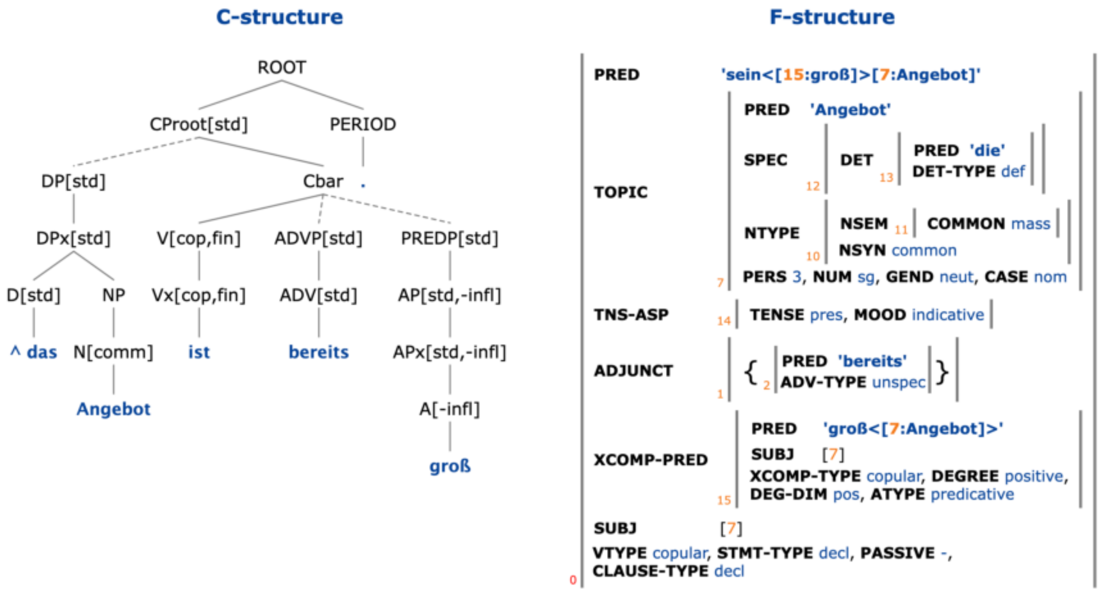

Figure 6: TIGER LFG analysis of (1) (http://hdl.handle.net/11495/D8B8-3970-851A-3@lfg41730)

3.3 The LFG Structure Bank for Polish

The LFG Structure Bank for Polish was built by parsing a corpus with the POLFIE grammar (Patejuk & Przepiórkowski 2012, 2014). This grammar was created by reusing context-free grammar rules written for another parser for Polish, Świgra, and adding annotations for building the f-structures. The corpus for the treebank is the one-million word subcorpus of the National Corpus of Polish[11] which has been manually annotated, the same subcorpus that was used for the previously annotated Składnica treebank.[12]

In INESS, the treebanks created by the POLFIE grammar are all in one large collection, also called POLFIE. This collection includes the LFG Structure Bank for Polish as well as other treebanks. The size of the POLFIE collection is 179,994 sentences and 2,022,026 words. Some of the subtreebanks in POLFIE are also in other collections: CLARIN-PL, ParGram and ParTMA.

Sample c- and f-structures from the POLFIE treebank for the sentence in (2) are given in Figure 7.

(2) Polish
Drzewo zostało ścięte wczoraj.
tree.NOM.SG.N get.3SG.N cut.NOM.SG.N yesterday
'The tree was cut down yesterday.'

[12] http://zil.ipipan.waw.pl/Składnica

In the c-structure we see some familiar categories such as A, ADV, ADVP, NP, N, I, Ibar, etc., but there are also categories which we might not immediately be able to identify, such as ILEX, PRAET and PPAS. Some terms in the f-structure may also be unfamiliar, such as NTYPE, NSEM and NSYN.[13] Treebank documentation should ideally be made available by treebank creators to assist users in exploring the treebank; unfortunately INESS lacks documentation for many treebanks.

An overview of all *indexed attributes* for each treebank may be found on the *Treebank Details* page. The indexed attributes are all labels used in the treebank annotation that can be searched for. For LFG treebanks, these attributes include *cat* (category) and *edge* (feature or attribute, in more standard LFG terminology). A screenshot of the top of this page is shown in Figure 8.

Clicking on *cat* and *edge* under *Indexed attributes* produces the lists in Figure 9. These lists are shown sorted according to frequency; we see that, for instance, the category NP occurs 236 times in this subcorpus (pol-pargram) consisting of 100 sentences.

3.4 NorGramBank: A Norwegian LFG parsebank

The INESS project had the twofold goal of building a treebanking infrastructure and of building the first large treebank for Norwegian. The result of the latter effort is the treebank collection NorGram, consisting of 15 million sentences (215

---

[13] These f-structure attributes also occur in Figure 6, and they illustrate the parallelism on the f-structure level achieved by the ParGram grammars; see Section 3.6.2.

Figure 9: Values for the *cat* and *edge* attributes in POLFIE

million words) and by far the largest LFG treebank available in INESS. It was parsed with the eponymous grammar NorGram, a wide-coverage LFG grammar developed in the LOGON, TREPIL and INESS projects. Several versions of this grammar were constructed and used for parsebanking, including versions with c-structure pruning (Cahill et al. 2008). Some material was disambiguated manually with discriminants, but the bulk of the parsebank was disambiguated automatically through stochastic parseranking, based on the stored discriminants.

The collection NorGramBank (Dyvik et al. 2016) consists of a subset of the texts parsed in the NorGram collection. NorGramBank has more than 160 million words and consists of a variety of text types; while some newspaper texts were included, edited fiction and nonfiction texts were preferred because these have a higher language quality and fewer errors. Any error in a sentence, whether typographical, orthographical or grammatical, will result in a failure to find the intended analysis on parsing. Some NorGram texts were excluded from NorGramBank because the source texts had many OCR errors.

The text selection for the corpus was partially dependent on available resources. While published texts are valued sources for treebanks and other corpora, copyright restrictions must be taken into account. It is therefore paramount to clear permissions with rights holders before starting to work on texts. In the case of NorGram, several texts were obtained through the National Library of Norway. For some of these, copyright had expired. For newer texts, exceptional permission to use these with some restrictions was obtained from the government. Every corpus must be provided with metadata, including such information as provenance and conditions for use.

The Norwegian treebanks parsed with NorGram have proved useful for lexicography (see Section 4.4). Some NorGram treebanks have been specifically added for NAOB, a dictionary project by the Norwegian Academy for Language and Literature aimed at building a large dictionary for Norwegian Bokmål. In INESS, the collection called NAOB consists of 15 treebanks with a total of over 11 million sentences (161 million words).

The Norwegian example analyses shown in Figures 10, 11, 14, 15 and 18 are all from the NorGram treebanks.

3.5 Small treebanks for grammar development

Most of the small LFG treebanks in INESS are test suites used in various projects. GeoGram, HunGram and WolGram are collections of test suites used for the development of XLE grammars for Georgian (Meurer 2009), Hungarian (Laczkó et al. 2013, Laczkó 2014) and Wolof (Dione 2014, 2019), respectively. Some of these test suites are parts of parallel treebanks (see Section 3.6). Other treebanks in these collections may only be available to their creators since they are work in progress and not at a stage where they may be useful to other researchers. Treebank developers decide whether they want to make their treebanks publicly available.

3.6 Parallel treebanks with LFG annotations

A parallel treebank is a collection of monolingual treebanks that are aligned with each other on the sentence level, and sometimes also on phrase and/or word levels. The most common type of parallel treebank involves one or more translations of a text that are aligned with the source text, but a parallel treebank can also have different annotations of the same text, for example a constituency annotation and a dependency annotation.

The user can select aligned parallel treebanks by choosing *Show only Parallel Treebanks* on the *Treebank Selection* page and selecting a collection from those that are then displayed in boldface. One of the treebanks to be examined is then chosen in the usual manner by clicking in the box next to the treebank name and subsequently clicking on the treebank name. From the *Sentence Overview* page, clicking on *Treebank Details* provides an overview of which other treebanks are aligned. Selecting one of those treebanks will start the display of parallel analyses for the two chosen languages.

The following subsections will present the XPAR Project (Section 3.6.1), the treebanks developed in the Parallel Grammar Project (Section 3.6.2), and other parallel treebanks containing LFG analyses (Section 3.6.3).

3.6.1 The XPAR Project

Language Diversity and Parallel Grammars (XPAR) was a pilot project which aimed to determine to what extent the development of parallel deep grammars for typologically diverse languages may support the automatic derivation of high-quality parallel treebanks for those languages (Dyvik et al. 2009). Principles for phrase alignment and methodology for the automatic alignment of c-structures from manually aligned f-structures were developed in the project.

A small parallel test suite of translationally equivalent Georgian and Norwegian sentences was used in developing the alignment tool. An example of aligned sentences is provided in (3), and their sentence-aligned analyses are shown in Figure 10.

(3) a. Georgian
gia-s uqvars eka.
Gia-DAT loves Eka.NOM
‘Gia loves Eka.’

b. Norwegian
Jon elsker Maria.
Jon loves Maria
‘Jon loves Maria.’

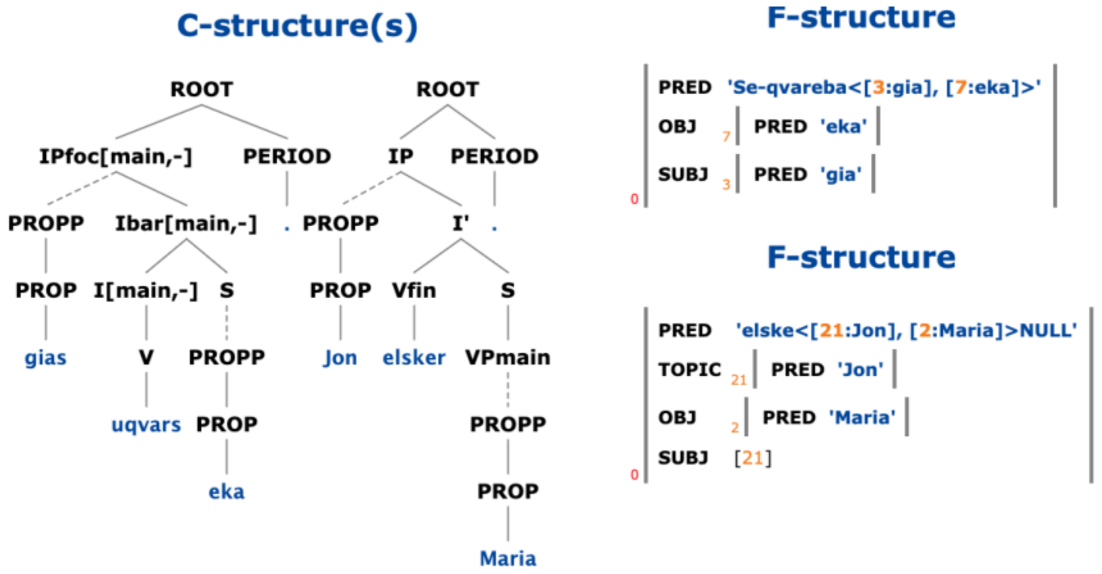

Figure 10: Sentence aligned c- and f-structures for the Georgian (http://hdl.handle.net/11495/D8B8-3970-851A-3@lfg51519) and Norwegian (http://hdl.handle.net/11495/D8B8-3970-851A-3@lfg60949) sentences in (3)

F-structures are manually aligned on the basis of translational correspondences at the level of predicate–argument structure. Subsidiary f-structures correspond if their predicates are in a translational relationship to one another. The alignment is done by dragging the index of one f-structure onto the corresponding index of the other f-structure. For instance, in Figure 10, the OBJ index 7 in the Georgian f-structure may be dragged onto the OBJ index 2 in the Norwegian one. This results in indices of the form $\boxed{n \rightarrow m}$, where n is the original index of that f-structure and m is the original index of the f-structure it is aligned with. Figure 11 shows the result of this manual alignment of f-structures, where the indices for the OBJ, SUBJ and main PRED have been aligned. Once the f-structures are aligned, the LFG Parsebanker automatically aligns the corresponding nodes

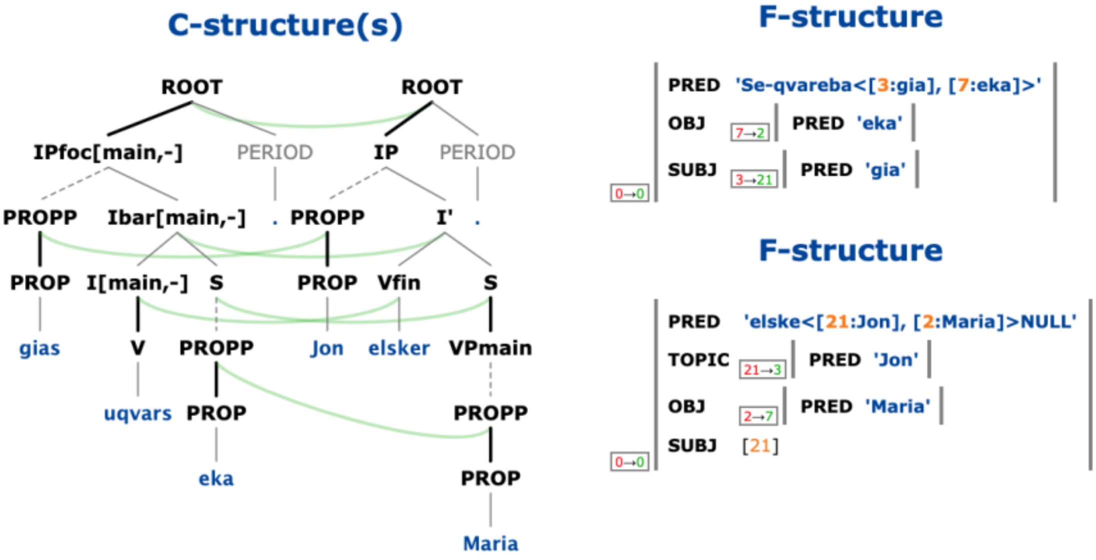

Figure 11: Word and phrase aligned c- and f-structures for the Georgian and Norwegian sentences in (3)

in the c-structures, shown by the curved green lines. We see, for example, that the OBJ alignment in the f-structures results in the alignment of the PROPP nodes dominating *Eka* and *Maria* in the c-structures.

3.6.2 The Parallel Grammar Project treebanks

The Parallel Grammar Project (ParGram) is an international cooperative effort to develop parallel LFG grammars implemented in XLE (Butt et al. 1999, 2002). Originally three languages were involved in the project: English, French and German; later, other languages joined, including Georgian, Hungarian, Indonesian, Japanese, Norwegian, Polish, Tamil, Turkish, Urdu and Wolof, among others. The main focus of the ParGram project was to develop and maintain linguistically motivated parallelism at the level of f-structure. Some of the ParGram participants have also been involved in the ParSem project, an effort to develop semantic structures based on the ParGram syntactic structures, with most of the ParSem systems using XLE's transfer system.

ParGram has created two parallel treebanks to support the aim of developing parallel LFG grammars. These treebanks consist of test suites encompassing various syntactic constructions. The English sentences were first agreed upon, and then translated into the other languages in the project. The first set of 50 sentences included such constructions as declaratives, interrogatives, imperatives, transitivity, passive, unaccusative, and subcategorized declaratives (Sulger et al.

2013). These sentences are included in the ParGram collection in INESS. Another set of sentences, concerned with tense, mode and aspect, constitutes the ParTMA collection. Figure 12 shows word and phrase aligned c- and f-structures for the English and German sentences in (4).

(4) a. What did the farmer see?

b. German
Was sah der Bauer?
what saw the farmer
'What did the farmer see?'

The f-structures for these sentences are practically identical, whereas the c-structures are quite different. This is both because the languages are different (English has *do*-support and German does not) and because the grammars for these languages have used quite different principles and techniques in writing the phrase structure rules. Still we see that most c-structure nodes are aligned. Since the XPAR principles align only translationally corresponding f-structures with PRED values, not all c-structure nodes can be aligned. The word *did* and the question marks only contribute features to the f-structure, not PRED values; these features are not shown here since the f-structures are displayed in PREDs only mode.

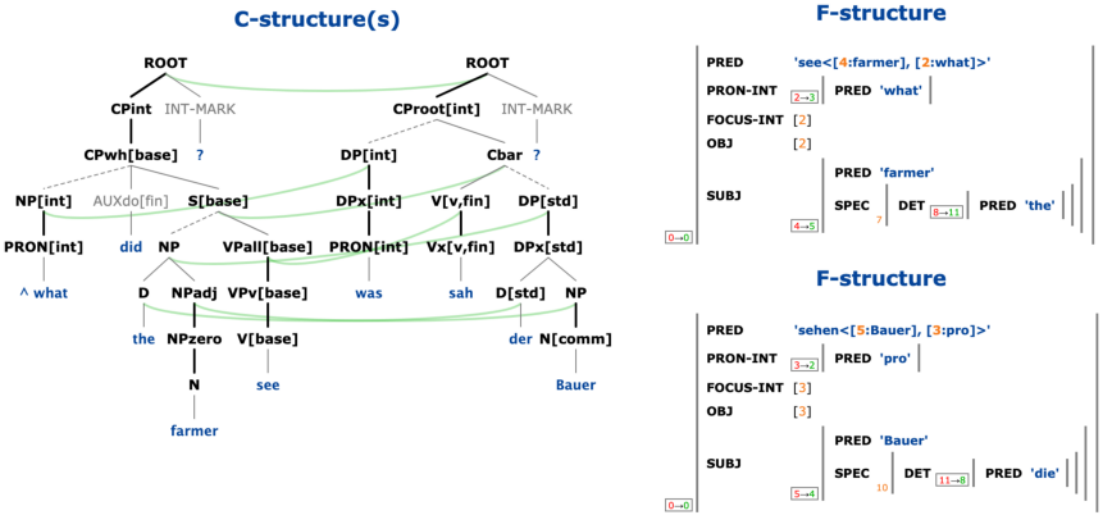

Figure 12: Word and phrase aligned c- and f-structures for the English (http://hdl.handle.net/11495/D8B8-3970-851A-3@lfg423651) and German (http://hdl.handle.net/11495/D8B8-3970-851A-3@lfg444239) sentences in (4)

3.6.3 Other parallel treebanks including LFG

Several projects have built parallel treebanks that include both LFG treebanks and treebanks of other types. Three such parallel treebanks are presented here.

The Sofie Parallel Treebank is a parallel corpus containing the first chapters of Jostein Gaarder's novel *Sofies verden* "Sophie's World". This text was chosen for treebanking because it is a well-written text that has been translated into a great number of languages. The Nordic Treebank Network developed treebanks based on these texts for Danish, Estonian, German, Icelandic and Swedish in the period 2001–2005. The META-NORD project,[14] which ran from 2011 to 2013, had as one of its goals to promote the accessibility of treebanks, including some that had not been maintained and were no longer accessible (Losnegaard et al. 2013). An English treebank, originally developed in the SMULTRON project,[15] and a Georgian treebank, developed at Uni Computing in Bergen, Norway, were added to the Sofie collection. Two treebanks for Norwegian were also developed, one an LFG treebank and the other a constituency treebank with syntactic and functional categories. Only the Georgian and one of the Norwegian treebanks have LFG annotation; the rest of the treebanks have various types of constituency annotation. In the initial version of the LFG Sofie treebank for Norwegian, 73% of sentences received analyses. An in-depth study of the sentences that received full parses that were not entirely correct showed that 29% lacked the correct analysis because of grammar problems, while lexical problems accounted for 71%, with missing multiword expressions in the lexicon being the most important of these. Subsequent grammar and lexicon updates resulted in correct analyses for more than 90% of these sentences (Losnegaard et al. 2012).

The META-NORD Acquis Parallel Treebank is a small parallel corpus of translations of a European Union directive.[16] The EU languages Danish, Estonian, Finnish, Latvian and Swedish, as well as the non-EU languages Norwegian and Icelandic, have treebanks in the collection. All language pairs are aligned at sentence level. The Norwegian treebank contains LFG analyses, while the other languages have consistency or dependency annotations.

The Norwegian Dependency Treebank was developed by the National Library of Norway (Solberg et al. 2014); it is made available in INESS as the treebanks named nob-ndt-dep (for Norwegian Bokmål) and nno-ndt-dep (for Norwegian

---

[16] Directive 2002/74/EC, from the Acquis Communautaire (AC), the total body of European Union law applicable in the member states.

Nynorsk). The treebank has also been converted to the Universal Dependencies (UD) annotation scheme (Øvrelid & Hohle 2016), creating the treebanks nob-ud-2.5-dep and nno-ud-2.5-dep. The same texts were parsed with NorGram to obtain LFG analyses, resulting in the treebanks nob-ndt-lfg and nno-ndt-lfg. The original dependency annotations were created automatically, but the analyses were then manually checked and corrected, resulting in a gold standard treebank. The dependency treebanks contain analyses for all sentences, while the LFG treebank has coverage for about 90% of the sentences. The analyses for the sentences that are covered in the LFG treebank are, however, much more detailed than those in the dependency treebanks. See Section 4.5 for more on UD treebanks, including a comparison with LFG analyses.

4 Exploring and exploiting LFG treebanks

4.1 INESS Search

Prior to the INESS project, there was no search tool that could perform search in LFG f-structures. INESS Search (Meurer 2012, 2020, Rosén et al. 2017) is a search tool that was developed in order to fill this need. It is a reimplementation and extension of TIGERSearch (Lezius 2002), a search system designed for the TIGER treebank (Zinsmeister et al. 2002, Brants et al. 2004). INESS Search retains the full functionality of TIGERSearch for querying constituency and dependency treebanks while extending its functionality in order to query fully general directed graphs like LFG f-structures; in addition, it can be used for search in HPSG treebanks. INESS Search supports almost full first-order predicate logic, including negation and existential and universal quantification, with the exception of universal quantification over disjunctions.

INESS Search is fully integrated in the INESS infrastructure and is used via its Web interface. There is extensive documentation for INESS Search online, both a walkthrough that describes how to get started searching in INESS treebanks,[17] and thorough documentation of the query language itself.[18]

In addition to extending TIGERSearch, INESS Search has implemented simplifications to the syntax of search expressions for more clarity. Suppose you want to find examples of NPs with AP modifiers that have embedded PPs, such as the German NP in (5). In TIGERSearch you could write the search expression in (6), whereas (7) is an equivalent abbreviated expression in INESS Search.

---

[17] https://clarino.uib.no/iness/page?page-id=INESS_Search_Walkthrough

[18] https://clarino.uib.no/iness/page?page-id=INESS_Search

(5) German
die von Slumbewohnern unerlaubt gebauten Lehmhütten
the by slum.dwellers illegally built mud.huts
'the mud huts illegally built by slum dwellers'

(6) `[cat="NP"] > #x:[cat="AP"] & #x > [cat="PP"]`

(7) `NP > AP > PP`

The TIGERSearch expression in (6) may be read as follows: "There is a node with the category NP that dominates a node #*x* with the category AP; this same AP node #*x* dominates a node with the category PP." Each node has a variable, but it does not always need to be expressed; in (6), it is necessary to specify through the use of an explicit variable that it is the same AP that is dominated by the NP and that dominates the PP, otherwise the search results would return all sentences where there is at least one NP dominating an AP and at least one AP dominating a PP. In the abbreviated INESS Search expression (7), this chaining is inferred, so that an explicit mention of the variable is not necessary in this case. Furthermore, as also shown in Table 1, node labels may be used directly in the search expression, lexical and terminal nodes need only be enclosed in double quotes, and atomic f-structure values only in single quotes. One of the search results for the search expression in (7) from the TIGER treebank, the NP in (5), is shown in Figure 13; the node labels mentioned in the search expression are highlighted in red in the graph.

Table 1: Some examples of abbreviated syntax in INESS Search

Expression	Abbreviation	Explanation
`[cat="NP"]`	`NP`	node labels
`[word="book"]`	`"book"`	lexical nodes in dependency treebanks; terminal nodes in LFG and phrase-structure treebanks
`[atom="sg"]`	`'sg'`	atomic f-structure values in LFG treebanks
`[PP > #x:NP & #x > PP]`	`PP > NP > PP`	chaining of relations

4.2 Querying with INESS Search

Formulating well-targeted search expressions presupposes knowledge about the analyses in the treebank. One way of quickly gaining such knowledge is to use

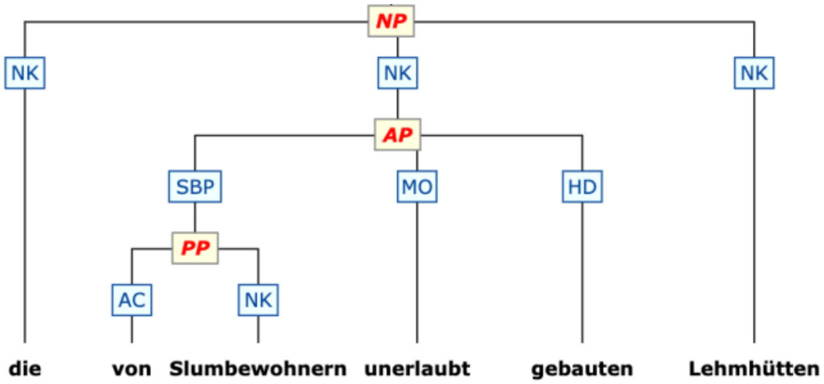

Figure 13: TIGER tree for (5) (http://hdl.handle.net/11495/D8B8-3970-851A-3@dep101299)

XLE-Web to parse sentences with the kind of grammatical phenomenon one is interested in and to study the analyses. Suppose that we want to search for passive sentences. The Norwegian passive sentence in (8) gets the analysis in Figure 14 when parsed in XLE-Web.

(8) Norwegian
Verden ble skapt av Gud.
world.DEF.SG was created by God
'The world was created by God.'

Examining the f-structure shows that the verb *skape* 'create' is the head of the XCOMP. It is a two-place predicate, with the PRED of the OBL-AG, *Gud* 'God', as its first argument, the agent. The XCOMP also has an attribute-value pair 'PASSIVE +'. A simple search expression for passives with agent phrases can thus be formulated using these f-structure characteristics, as shown in (9).

(9) `#x >PASSIVE #y:'+' & #x >OBL-AG`

This expression may be read: "There is an f-structure #*x* which has an attribute PASSIVE with the value '+' (bound to #*y*), and this same f-structure #*x* also has an attribute OBL-AG."

The negation operator in INESS Search allows users to restrict searches with respect to properties that sentences should *not* have. The search expression in (10), where the exclamation point is the negation operator, searches for passives *without* agent phrases. The sentence in (11) is one of those found by this expression; its c- and f-structures are shown in Figure 15. The f-structure nodes that are named with explicit variables in the search expression are marked in red in the

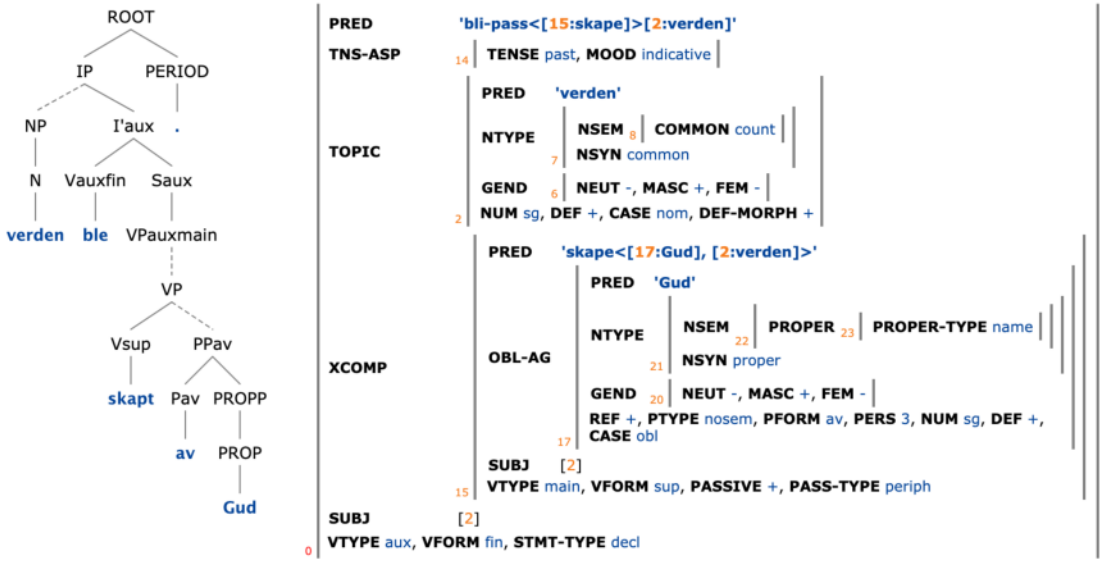

Figure 14: C- and f-structures from XLE-Web for the passive sentence in (8)

search result. In the f-structure we note that the XCOMP does not have an OBL-AG, and that the first argument of the main PRED is 'NULL'.

(10) `#x >PASSIVE #y:'+' & #x !>OBL-AG`

(11) Norwegian
Hvordan er verden skapt?
how is world.DEF.SG created
'How was the world created?'

4.3 An example-based introduction

For some researchers, INESS Search can be difficult to use, even with the simplifications that have been introduced. To assist users of NorGramBank in formulating search expressions, an example-based introduction to the search system has been written.[19] It is based on the Norwegian reference grammar *Norsk referansegrammatikk* (Faarlund et al. 1997) and the chapters and examples therein. Most researchers in Norwegian syntax will be familiar with the rather theory-neutral analyses in this book, and the goal is to provide them with LFG analyses of the

---

[19] This introduction, in Norwegian, is part of the INESS documentation: https://clarino.uib.no/iness/page?page-id=norgram-soek#innledning.

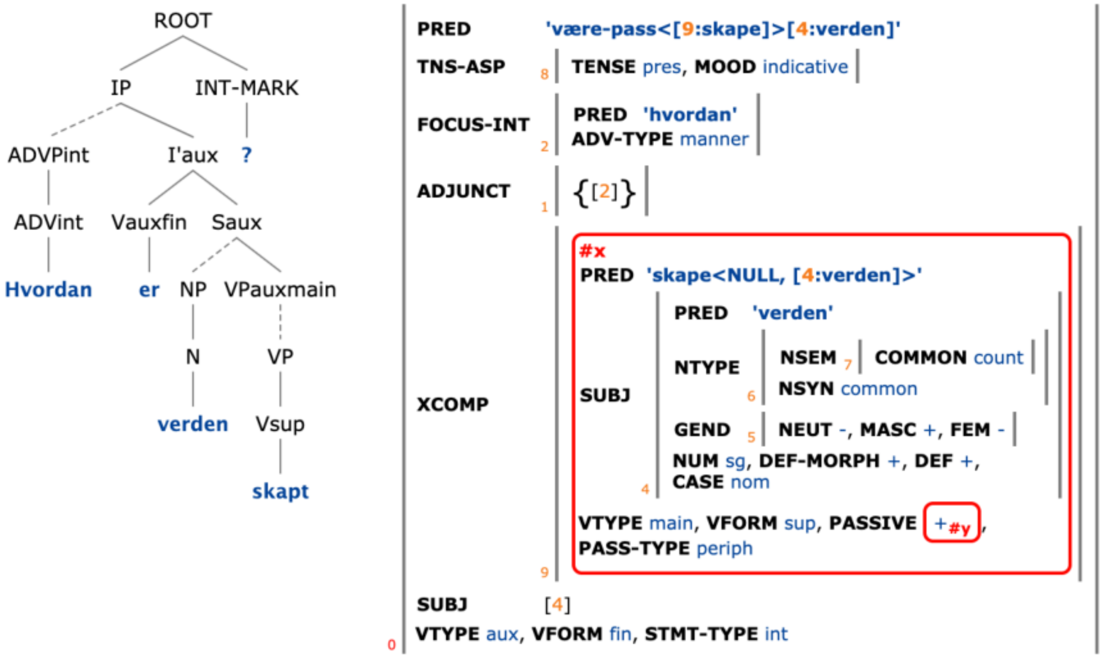

Figure 15: C- and f-structures for the passive sentence in (11) (http://hdl.handle.net/11495/D8B8-3970-851A-3@lfg6174124)

constructions that are of interest, including the page numbers in the book where the constructions are treated. For each construction, the example-based documentation provides an LFG analysis of one sentence together with a commentary explaining the analysis. A search expression that will find the construction is provided, along with both a paraphrase and a lengthier prose explanation of the expression. Finally a list of a few matching sentences is presented.

A construction type that is difficult to search for without a treebank is relative clauses without complementizers. It would not be straightforward to find these in corpora which are not syntactically annotated, so this is a good illustration of the added value of treebanks. The search expression for relatives without complementizers is given in (12).

(12)
```
#x >(ADJUNCT $) #f >TOPIC-REL #g
& #f >OBJ #g & #f >CLAUSE-TYPE 'rel'
& !(#f >COMP-FORM)
& !(#x >PRON-TYPE 'free')
```

This search expression may be read: “An f-structure #*x* has an attribute ADJUNCT with a value that includes an f-structure #*f*; furthermore, #*f* has an attribute TOPIC-REL with the value #*g*, and an attribute OBJ with the same value #*g*;

#f also has an attribute CLAUSE-TYPE with the value ‘rel’ and does not have an attribute COMP-FORM; the f-structure #x does not have an attribute PRON-TYPE with the value ‘free’ (the last specification ensures that free relatives will not be found).” An example sentence found by this expression in NorGramBank is given in (13), where the boldfaced relative clause *jeg så* lacks a complementizer.

(13) Norwegian
Alt **jeg så** var frontlykt-ene.
all I saw was headlight-DEF.PL
‘All I saw was the headlights.’

4.4 Search with templates

A further simplification in INESS Search is the implementation of search templates, which abbreviate complete parameterized search expressions. For the Norwegian treebank NorGramBank, a number of such templates have been provided, primarily for the benefit of lexicographers.[20] Templates obviate the need for understanding an often complicated search expression, since users can choose one on the basis of a description of its intention, but they can examine the whole expression if desired. Templates are parameterized in the sense that the user can fill in values for one or more parameters, such as word or lemma forms, predicates, or grammatical features.

Suppose you want to find out how common nominal complement clauses with and without complementizers are after certain verbs. The template shown in Figure 16, named *AT-verbwithandwithout(@verb)*, may be used for this purpose. The user fills in the verb, in this case *fortelle* ‘tell, relate’, and clicks on *Run query*. The results of the search are presented in a table, sorted according to whether they include the complementizer or not. We see that the vast majority of occurrences of complement clauses with this verb, 21,465 (97.5%), do have complementizers.

This can be compared with the results for the verb *tro* ‘think, be of the opinion’, shown in Figure 17. For this verb the proportion of uses with the complementizer is only 33.8%. In this screenshot the user has clicked on the first row in the table, showing the number of occurrences for the verb without the complementizer (66,258). This brings up a list over all the sentences with this pattern. Here the user has clicked twice on *Next* in order to come to page 3; there are so many hits that the list consists of 3,313 pages. When the user mouses over a sentence, a simplified f-structure is displayed to the right of the list. Clicking on a sentence

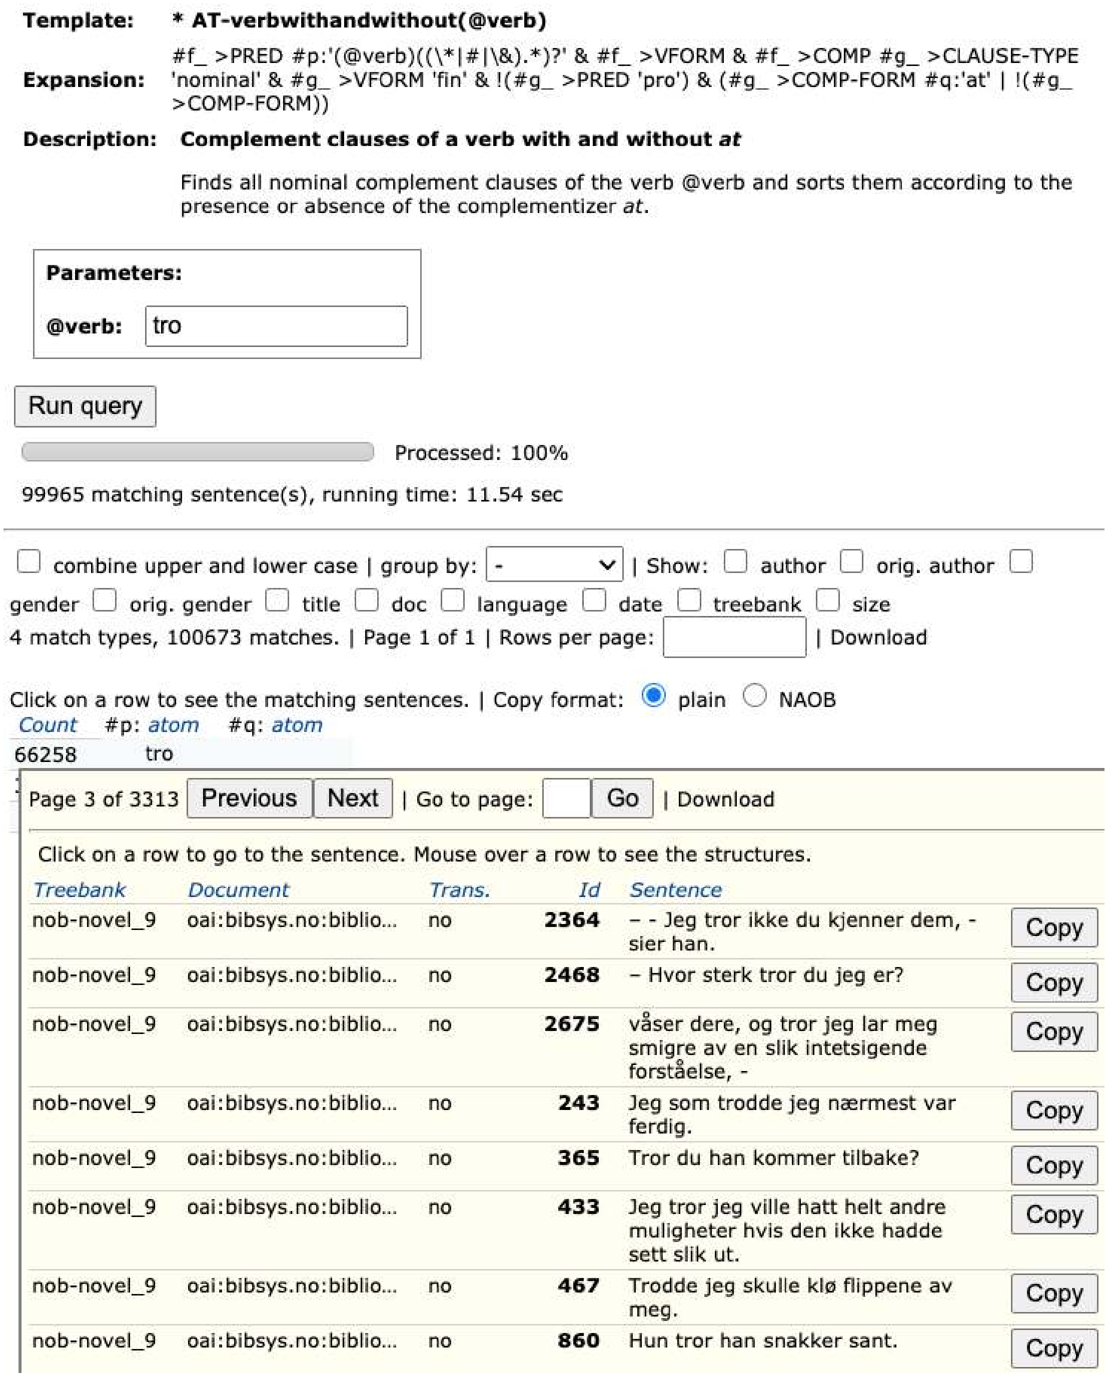
21465	fortelle	at
549	fortelle	

Figure 16: Template for nominal clause search with and without complementizer for the verb *fortelle* ‘tell, relate’

brings the user to the *Sentence* page where the c-structure and the full f-structure are displayed. By default the quite complicated search expression which is used in this template is hidden, as in Figure 16. In Figure 17, the user has clicked on the template name, bringing up the expansion with the search expression. In this figure a more detailed prose description is also displayed, obtained by clicking on the boldfaced, more compact, part of the description.

Rauset et al. (2021) provide concrete examples of the use of template search in NorGramBank for various dictionary projects in Norway. The lexicographers use templates to examine both the usage and frequency of words. The most common valency frames for verbs, as well as the most common prepositions and/or particles that they occur with, are examined by using the template *V-argframes(@V)*; this template also provides evidence about whether the verbs occur reflexively. The templates *ADJ-attrib-or-nominal(@ADJ)* and *V-attr-or-pred-ptc(@V)* provide evidence of the nominal and adjectival use of participles, which is sometimes the basis for the creation of separate entries for derived adjectives.



Template: * **AT-verbwithandwithout(@verb)**

Expansion: `#f_ >PRED #p:'(@verb)((\*|#|\&).*)?' & #f_ >VFORM & #f_ >COMP #g_ >CLAUSE-TYPE 'nominal' & #g_ >VFORM 'fin' & !(#g_ >PRED 'pro') & (#g_ >COMP-FORM #q:'at' | !(#g_ >COMP-FORM))`

Description: **Complement clauses of a verb with and without *at***

Finds all nominal complement clauses of the verb @verb and sorts them according to the presence or absence of the complementizer *at*.

Parameters:

Figure 17: Template for nominal clause search with and without complementizer for the verb *tro* 'think, be of the opinion'

Targeted queries that provide evidence for colligations are useful when treating high-frequency words with many senses. The template *N-argofverbs(@N)* provides a list sorted by frequency of the verbs that occur with a certain noun as their first or second argument. Such results help lexicographers determine whether the sense distinctions made in older versions of the dictionaries are still reasonable, or whether there should be changes made by adding or removing distinctions, or for instance by promoting a sense that is now more common than previously.

An example of a word which was missing a sense is the reflexive verb *utmerke seg* 'distinguish oneself', which was defined as having only a positive connotation. The lexicographers, however, did not believe this to be accurate. The template *V-prepobj(@V,@P)* was used to examine which words occur as objects of the prepositions *med* 'with' and *ved* 'by'. The search results showed several occurrences of the noun *mangel* 'lack' as the object of *ved*; one of these examples is given in (14). This and similar searches provided empirical support for the establishment of a new subsense of the verb with a negative connotation.

(14) Norwegian (http://hdl.handle.net/11495/D8B8-3970-851A-3@lfg14979442)
Han vil ... utmerke seg med mangel på konsistens i sine
he will distinguish REFL with lack of consistency in his
handlingsvalg ...
action.choice
'He will ... distinguish himself with lack of consistency in his choice of actions ... '

4.5 Comparison of search in LFG and dependency treebanks

Dependency treebanks are the most widely used type of treebanks, notably via the Universal Dependencies (UD) initiative.[21] The UD treebanks are grounded in dependency grammar, which assigns dependency relations between words, and does not analyze phrases and constituency relations (Tesnière 1959). An important early dependency treebank was the Prague Dependency Treebank (Hajič et al. 2001). Among the treebanks provided by INESS, dependency treebanks are the most numerous (250), with the UD treebanks accounting for most of these (200). The latest version in INESS at the time of writing is 2.8. INESS also keeps earlier versions, making it possible to track progress between versions.

The LFG and UD analyses of the sentence in (15) are shown in Figures 18 and 19. For both treebanks, information about lemma, part of speech and morphological

---

[21] https://universaldependencies.org

features may be displayed (by clicking on the word for the dependency treebank, or by clicking on the preterminal node for the LFG treebank). The c-structure in Figure 18 shows the hierarchical phrase structure of the sentence, labeled with a rich inventory of syntactic categories. The corresponding f-structure encodes syntactic functions, grammatical features, and predicate–argument relations, as represented in the semantic forms of the verbs. The dependency structure in Figure 19 is shallower and less detailed than the LFG structure. Dependencies between words are shown by labeled arrows that go from a word to its dependents.

(15) Norwegian
Han hadde aldri vært lykkeligere.
he had never been happier
'He had never been happier.'

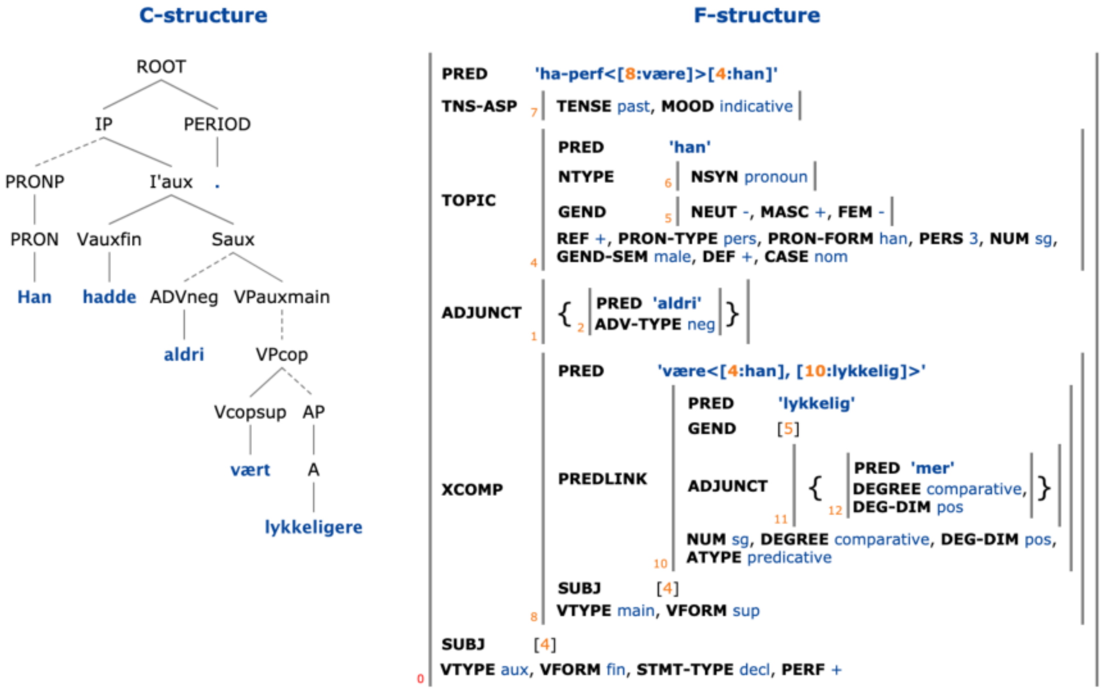

Figure 18: LFG analysis of the sentence in (15) (http://hdl.handle.net/11495/D8B8-3970-851A-3@lfg4292653)

The deeper analysis in an LFG treebank improves the search possibilities as compared with a dependency treebank. Rosén et al. (2020) compares search in the UD version of the Norwegian Dependency Treebank with the same texts in NorGramBank. The example given there is searching for the first argument of verbs. This may be done straightforwardly in an LFG treebank, but it is much

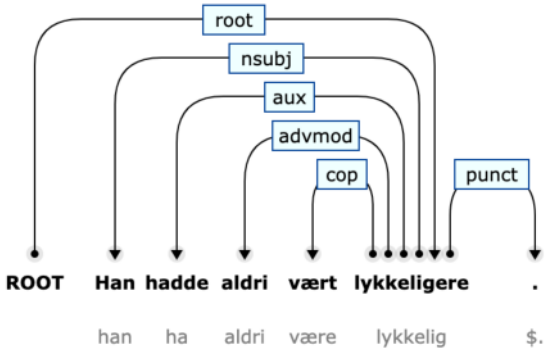

Figure 19: UD analysis of the sentence in (15) (http://hdl.handle.net/11495/D8B8-3970-851A-3@dep8965528)

more difficult in a dependency treebank since predicate–argument structure is not encoded there. The first argument of a verb can be the subject of an active verb or of a predicative present participle, the agent phrase of a passive verb, or the head of an attributive present participle. And since the UD guidelines allow for several ways of annotating some of these possibilities, creating a search expression to capture them is extremely complicated. For more detail on this comparison, see Rosén et al. (2020).

5 Conversion between LFG treebanks and other treebanks

Besides pure parsebanking with a grammar, other approaches have been used to construct treebanks by converting between formalisms or by enriching treebanks with additional information. The Universal Dependencies initiative is in some ways similar to ParGram in that both approaches aim at assigning common annotations to comparable items and structures across languages.

Since dependency relations may be labeled as grammatical functions such as subject and object, dependency structures have a resemblance to f-structures in LFG. The PARC 700 Dependency Bank is a treebank in dependency format based on the English LFG grammar developed at PARC (King et al. 2003). The corpus was created only to make a dependency bank. LFG analyses were transformed to dependency graphs, but no LFG treebank per se was created.

The TIGER corpus, mentioned in Section 3.2, utilized the large-scale German LFG grammar of the ParGram project for the semiautomatic creation of TIGER treebank annotations. The grammar was used for full parsing, followed by semiautomatic disambiguation and automatic transfer into the treebank format (Zinsmeister et al. 2002). The hybrid representation structure of TIGER, combining constituent analysis and functional dependencies, benefited from information in the c-structures and f-structures provided by the LFG grammar.

Conversely, an LFG treebank may be created by enriching phrase-structure oriented treebank resources with functional structures, as suggested by Frank et al. (2003) and Cahill (2004). For more on grammar induction, see Cahill & Way 2023 [this volume].

Forst (2003) describes a method for converting the TIGER treebank to a testsuite for the German LFG ParGram grammar. The conversion utilizes the machine translation transfer system in XLE.

Recently, detailed algorithms for the conversion from LFG analyses to dependency structures were proposed by Meurer (2017) and Przepiórkowski & Patejuk (2020). While the latter follow the more standard assumption that f-structures provide a good basis for developing dependency trees, the former takes c-structures as the starting point, but combines this with information from f-structures.

6 Conclusion

This chapter has provided an introduction to LFG treebanks, illustrated throughout with the tools and visualizations of the INESS treebanking infrastructure. The process of developing an LFG grammar in tandem with a treebank through incremental parsebanking has been described. Both large and small LFG parsebanks for a number of languages have been presented. Several different methods for searching LFG treebanks with INESS Search have been explained: users can write search expressions themselves with the aid of XLE-Web and the INESS Search documentation; they can find search expressions for the phenomena they are interested in by consulting the example-based search documentation; and they can use search templates that only require filling in one or more search items. LFG treebanks have been compared with other treebanks, and it has been shown that the more detailed and sophisticated annotation in LFG treebanks provides richer opportunities for research than simpler annotations.

While INESS has already been developed over more than a decade, the system, and especially its interface, will continue to evolve. Consequently, future interactions may be slightly different from the interactions and screen displays shown in this chapter.

Although LFG treebanks are certainly valuable resources for research and development, building an LFG treebank is a time-consuming and expensive undertaking, especially for a language for which no large-coverage LFG grammar and lexicon yet exist. However, the task is made somewhat easier with the help of the LFG Parsebanker as described above, and INESS is open to making more treebanks accessible for research and development.

Acknowledgments

I thank Koenraad De Smedt, Stefanie Dipper, Helge Dyvik, Jonas Kuhn, Paul Meurer, Agnieszka Patejuk, Heike Zinsmeister and three anonymous reviewers for helpful comments and suggestions. Thanks are also due to Mary Dalrymple for all of her help and her boundless patience.

Language families and regions

Chapter 26

LFG and African languages

Adams Bodomo
University of Vienna

Dewei Che
Harbin Engineering University

Lexical Functional Grammar (LFG) as a formal, constraint-based grammatical theory has been used to analyze various languages around the world since the 1970s. These analyses comprise grammatical descriptions, grammatical formalizations, and computational implementations of the grammars developed using LFG. Africa is home to over 2000 languages and while not even half of these have established writing systems let alone descriptive grammars in any linguistic framework, quite a substantial number of these languages, especially many Bantu languages, have been analyzed using LFG. The list includes languages such as Swahili, Chicheŵa, Chishona, Kichaga, Dagaare, Akan, Tigrinya, Wolof, Soso, Wan, Setswana, Yąg Dii, Malagasy, and Ndebele. In this chapter we first outline the major, salient linguistic features of African languages and then indicate how LFG has been used to analyze these salient features, covering topics such as the lexical integrity principle, applicative constructions, object asymmetries, agreement, reciprocal marking, locative inversion, serial verb construction, and focus marking phenomena. In the process of doing all this, the analyses in the chapter point to the major contributions of African languages to the development of LFG and, in turn, to the major contributions of LFG to the understanding of African language phenomena.

1 Introduction

Since the second half of the 20th century, African language data have been applied to the development of many descriptive and formal frameworks within modern linguistics – from phonology through morphosyntax to semantics and

Adams Bodomo & Dewei Che. 2023. LFG and African languages. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 1209–1252. Berlin: Language Science Press. DOI: 10.5281/zenodo.10185994

pragmatics. Descriptive frameworks such as Greenbergian universals, Hallidayan systemic functional grammar, Chomskyan generative grammar, and Goldsmithian autosegmental phonology, among others, have been used to analyse African languages. One of these major frameworks is the Lexical Functional Grammar (LFG) framework as developed by Bresnan & Kaplan (1982).

In this chapter we focus on the symbiotic relationship between African languages and LFG, showing how African languages have provided useful data for developing and testing LFG and how LFG has been used to analyze some intricate grammatical structures and processes in African languages like Swahili, Chichewâ, Dagaare, Akan, Tigrinya, Wolof, and Setswana.

The chapter is organized as follows. This introductory part provides a brief outline of the language situation in Africa, showing that Africa is a highly multilingual society and its people are very polyglottic. We also provide a snapshot of the major features of African languages. Section 2 is the main and longest part of the chapter. We provide concise illustrations of how LFG has been used to analyze various grammatical structures and phenomena including the lexical integrity principle, applicative constructions, object symmetries and asymmetries, agreement, reciprocal marking, locative inversion, serial verb constructions, and discourse function analyses. In Section 3, we briefly summarize the contribution of LFG to the analyses of African language phenomena, and conclude the chapter in Section 4 by tying together the various strands in all the sections of the chapter.

1.1 The language situation in Africa

Africa is not only a mineral resource rich continent, it is also a linguistic resource rich continent. Not only are there many languages on the African continent, Africans also exhibit a rich polyglottic repertoire in multilingual societies with many individual Africans, particularly in urban centres, speaking an average of four to five languages per person. Indeed, Africa has the second largest number of languages among the continents. According to Eberhard et al. (2020), there are at least 7,102 living languages in the world and 2,138 of them are in Africa.[1] African languages belong to a diverse set of language families, mainly including the Niger–Congo language family (divided into Niger–Congo A and Niger–

---

[1] We use the term *African languages* (or the *Languages of Africa*) broadly to refer to languages indigenous to the African continent. This term is to be distinguished from the term *Languages in Africa* which would comprise the indigenous languages and non-indigenous languages including former colonial languages like English, French, and Portuguese, which continue to be used as "official" languages in many African countries.

Congo B, which comprises the Bantu languages), the Afro-Asiatic language family, and the Nilo-Saharan language family, as well as members of the disputed Khoisan language family (Güldemann 2014); see Figure 1.[2]

The great amount of language diversity on the African continent and elsewhere is of interest to linguists and other scholars who believe in the need for

---

[2] As suggested by one reviewer, Austronesian languages, especially on the islands to the East of Africa, like Madagascar, ought to also be included in Figure 1; see Arka & Yeh 2023 [this volume] for more on Austronesian languages. In addition, we should also acknowledge that not many people believe in the genetic unity of "Khoisan" language family anymore.

Figure 1: Language families of Africa

Map adapted by Sebastian Nordhoff from https://commons.wikimedia.org/wiki/File:African_language_families_en.svg (c) Mark Dingemanse (original PNG version); https://fr.wikipedia.org/wiki/Utilisateur:Pmx (SVG version), CC BY-SA 3.0

linguistic and cultural diversity, and therefore the need to document and preserve these languages and their associated cultures. This diversity itself is a double-edged sword (Bodomo 2017). On the one hand, each of these 2,138 languages in Africa is the basis of a rich culture as languages are the main media through which we express and convey our cultural values. On the other hand, the fact that we have many languages within each of the 55 polities in Africa means that we face serious challenges and problems for language policy formulation and language planning. With this brief mention of the language situation, we now sketch some salient features of African languages in Section 1.2.

1.2 Salient linguistic features of African languages

African languages have contributed a lot in informing descriptive and theoretical frameworks for analyzing the world's languages:

> In brief, whether the search for universals is pursued along the lines of cross-linguistic generalizations, as recommended by Comrie, building on the work of Greenberg and others, or it is conceived of in terms of the biologically specified abstract principles that determine the form of human grammars and characterize the content of the language responsible cognitive structures, it is clear that African languages will definitely continue to make valuable contributions to progress in generative grammar. (Mchombo 1997: 202)

Thirty years ago, in her plenary address *African Languages and Syntactic Theories* on the occasion of the 20th Annual Conference on African Linguistics, Joan Bresnan recognized the impact of African languages on syntactic theories in these aspects: logophoricity, topic/subjecthood, agreement, argument asymmetries, and the syntax of verbs. But the impact was thought to be fairly mild compared to advances in phonology (Bresnan 1990). As time went by, Henderson (2011: 15) asserts that the significant development in this area "has been the exponential increase in syntax researchers who are interested in African languages, along with the sheer volume of work they have produced".

The complex morphology of many African languages has been of great interest among linguists, lending support to the study of morphosyntax largely dominated by Bantu languages (Bresnan & Mchombo 1995, Mchombo 1980, 1997, 2002, 2003, 2004, Moshi 1995, Morimoto 2002, Matambirofa & Mabugu 2014). The syntactic derivation of the verb stem in Bantu languages typifies the highly agglutinative nature of these languages, including various suffixes (sometimes called extensions) and prefixes associated with negation, tense/aspect, modality, markers of agreement with the subject and the object, as shown in (1).

(1) Swahili (Petzell 2004: 152–153)

a. si-ku-mw-on-a
NEG.SM-NEG.T-OM-see-FV
'I didn't see him/her.'

b. Erik a-li-pig-i-w-a simu na mwalimu.
Eric SM-PST-ring-APPL-PASS-FV phone by teacher
'Eric was rung by the teacher.'

Example (1a) involves the phenomenon of negation spread in which *si* is both a negative marker and a subject marker. In this case, the morpheme *si* can be called a *portmanteau morph*, i.e., a single morpheme expressing two meanings. Portmanteau morphs and feature spreading such as the negation spread are said to be frequent phenomena in Bantu and other non-Bantu languages such as Mande. In (1b), it is demonstrated that these affixes follow a strict order and certain combinatorial restrictions. For example, the applicative comes before the passive in Swahili.

In general, Creissels & Good (2018) provide a good context to the discussion of African languages with a list of generalizations regarding the state of the art of the morphosyntactic typology of the languages of the continent. These features are listed in (2) below (Creissels & Good 2018: 709–710):

(2)
a. The ergative type of core syntactic role coding is exceptional among African languages.
b. Case-marked subjects or objects are less common among African languages than at world level.
c. The so-called "marked-nominative" type of case contrast between subjects and objects is exceptional in other parts of the world but very common among African languages that have a case contrast between subjects and objects.
d. Obligatory agreement of transitive verbs with their object does not seem to be attested among African languages.
e. Second-position clitics are relatively common in the languages of the world, but exceptional among African languages.
f. In a relatively high proportion of African languages, the construction of verbs with an argument frame of the type giver–given–recipient tends to assimilate the recipient (rather than the thing given) to the patient of prototypical transitive verbs, and double object constructions are particularly frequent.

g. Focus strategies implying morphosyntactic alternations, and in particular focus marking by means of verbal inflection, are particularly common in Africa.
h. The use of special verb forms in sequential constructions is particularly widespread among African languages.
i. Applicatives are particularly common in Africa, and a relatively high proportion of African languages make a wide use of obligatory applicatives and of various types of non-canonical applicatives.
j. Classifier systems are exceptional among African languages.
k. Relatively few African languages are devoid of a morphological plural or have a morphological plural restricted to a subset of nouns occupying a high position in the animacy hierarchy.
l. African languages that do not use the same morpheme as a noun phrase coordinator and as a comitative adposition are relatively rare.
m. The proportion of languages with a syntactically flexible constituent order is much lower among African languages than at world level.
n. The constituent order SOVX, relatively rare at world level, is relatively frequent among African languages.
o. Clause-final negative particles occur among African languages much more frequently than in other parts of the world.
p. Changes in the constituent order triggered by negation are particularly common among African languages.
q. True relative pronouns are particularly rare in African languages, and the use of dependent verb forms in postnominal relatives, relatively rare in the languages of the world, is common among African languages.
r. Logophoricity is particularly widespread among African languages.
s. Systems of coding of spatial relations in which the distinction location at/movement towards/movement from manifests itself exclusively on verbs are more frequent in Africa than in most other parts of the world.

Admittedly, when it comes to the analyses of African languages in LFG, it is hard not to be “Bantu-centric”, given the pioneering work done by Sam Mchombo and Joan Bresnan. In more recent times, however, much more work is being produced in non-Bantu languages, and we have tried to include the analyses on these non-Bantu languages as much as possible. These mainly include Wolof, Tigrinya, Soso, Wan, Yąg Dii, Malagasy, Dagaare, and Akan. In Section 2, we illustrate the analyses of many of these features.

2 Major African language grammatical phenomena analysed in LFG

In this section, the longest in the chapter, we do a concise analysis of major constructions and grammatical phenomena in African languages from an LFG perspective. We begin with the lexical integrity principle, showing how data from African languages have been used to illustrate one of the best known principles in the LFG theoretical framework. We then move on to discuss argument structure and morphology, agreement, reciprocal marking, locative inversion, serial verbs, and discourse functions.

2.1 Lexical integrity principle

This subsection begins with a constraint on the architecture of grammar inspired by African language structure. When we encounter a sequence of morphemes in African languages, a natural question to ask is: what is indeed a word? In the framework of Lexical Functional Grammar, the lexical integrity principle has been of great importance with respect to c(ategorial)-structure and f(unctional)-structure in clarifyng that the morphemic structure of words differs from the c-structure of phrases both in constituents and principles of combination. In their seminal paper, Bresnan & Mchombo (1995) elicit a great deal of evidence from Bantu noun class markers in support of the lexical integrity principle. They argued that "the Bantu noun class markers are a particularly fruitful domain for investigations of lexical integrity because they straddle the borderlines between syntax and morphology and between inflection and derivation" (Bresnan & Mchombo 1995: 183).

Bantu noun class markers have a mixed inflectional and derivational nature when they mark nominals for number and gender, specifying the agreement forms of determiners, modifiers and predicates. The number classes, on one hand, trigger the syntactic agreement as an inflectional process, and on the other hand, the gender classes change the semantic class of the stem since they are associated with semantic properties such as animacy, configuration, location, size, plurality or quality and the process is seen as derivational. The standard morphological analysis was strongly advocated by Doke (1929, 1935), in which the class markers are analyzed as morphologically bound morphemes. However, this position has been challenged alternatively by the syntactic analyses (e.g. Myers 1987) or the head-movement theories of word derivation (e.g. Kinyalolo 1991, Carstens 1991). Throwing themselves into this debate, Bresnan & Mchombo (1995) draw the evidence that supports the lexical integrity principle from the morphology and syntax of Bantu noun class prefixes by applying a couple of effective tests of lexical integrity to the class markers of nouns in Chicheŵa and other Bantu languages. Four main tests go to build up the argument.

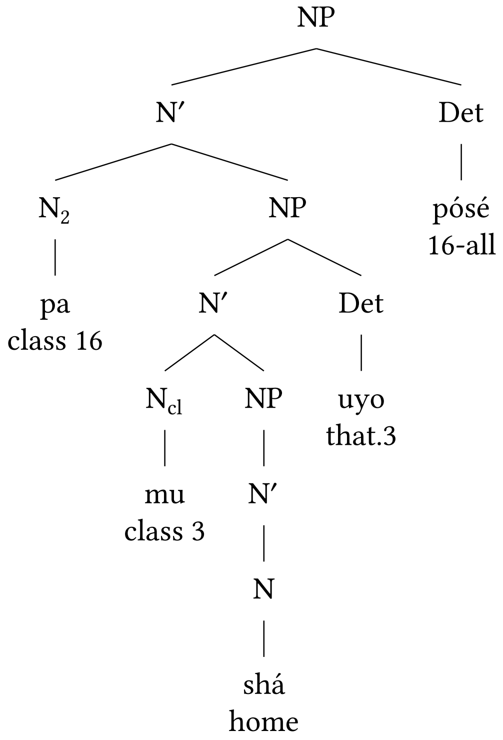
2.1.1 Test 1: phrasal recursivity

The central idea of phrasal recursivity is that the arbitrarily deep embedding of syntactic phrasal modifiers is not allowed in word-internal constituents. For Bresnan and Mchombo, there are mixed results on this front due to the so-called alternative concord when modifiers simultaneously show concord with any of several class markers on the same noun (Bresnan & Mchombo 1995: 195), as shown in example (3).

(3) Chishona (Myers 1987: 104)
pa-mu-shá uyo p-ósé pa-káchéna
16-3-home that.3 16-all 16-white
'at that whole white house'

The noun 'home' is preceded by two noun class markers from classes 16 and 3. Interestingly, the first following modifier agrees with the inner class 3 marker and the final two agree with the outer class 16 marker. Myers (1987) provides the following syntactic representation:

(4)



This representational analysis also correctly accounts for the fact that the inner concord modifiers must precede the outer ones as indicated by the ungrammaticality in (5).

(5) Chishona
*pa-mu-shá apo w-ósé pa-káchéna
16-3-home that.16 3-all 16-white

The same holds true for Chicheŵa, shown below in (6a)–(6d).

(6) Chicheŵa

a. pa mu-dzi p-áthú p-ônse
16 3-village 16-our 16-all
'at all of our village'

b. pa mu-dzi w-áthú p-ônse
16 3-village 3-our 16-all
'at all of our village'

c. pa mu-dzi w-áthú w-ônse
16 3-village 3-our 3-all
'at all of our village'

d. *pa mu-dzi p-áthú w-ônse
16 3-village 16-our 3-all

But the syntactic analysis of Myers (1987) does not necessarily apply to all class markers. As a matter of fact, it turns out that the class marker 16 in these examples belongs to the locative classes comprising of 16, 17 and 18, and an alternative concord is only possible with these locative classes. As for the nonlocative class markers, they are prefixed to the nouns and noun stems without the recursive structure of syntactic NPs, where alternative concord is impossible, as shown in (7).

(7) Chicheŵa

a. ka-mu-ndá k-ánga
12-3-field 12-my
'my small field'

b. *ka-mu-ndá w-ánga
12-3-field 3-my

2.1.2 Test 2: inbound anaphoric islands

The inbound anaphoric islands test can also tell a true syntactic phrase from a derived word. According to this test, anaphoric and deictic uses of pronouns should occur within the phrasal NP complement to a class marker. Again it is true with the locative class markers but not with the other class markers as shown in (8) and (9).

(8) Chichewâ

a. mu iyi
18 9.this
'in this (e.g. house)'

b. pa icho
16 7.that
'on that (e.g. hat)'

c. ku ǐwo
17 6.them
'to them (e.g. pumpkins)'

(9) Chichewâ

a. *chi iyi
7 9.this

b. *ka icho
12 7.it

c. *ti ǐwo
13 6.them

Since morphological words are inbound anaphoric islands, the ungrammaticality of the examples in (9) can only be explained by the morphological analysis of these prefixes instead of the syntactic analysis shown in (8).

2.1.3 Test 3: conjoinability

As expected, the locative classes pass the conjoinability test. Following the syntactic analysis, two NP complements should be conjoinable under a single class marker, shown below in (10). However, the other class markers fail the test as shown in (11).

(10) Chicheŵa

a. Mu-ku-pít-á ku [m-sika kapéná m-zinda]?
II.pl/hon.sbj-prog-go-ind 17 3-market or 3-city
'Are you going to the market or the city?'

b. A-na-gw-ér-á m [chi-tsîme kapéná chĭ-gwa]?
1sbj-rec.pst-fall-appl-ind 18 7-well or 7-valley
'Did he fall into the well or the valley?'

c. Mu-na-ík-á pa [m-pando kapéná m-tŏndo]?
II.pl/hon.sbj-rec.pst-put-ind 16 3-chair or 3-mortar
'Did you put (it) on the chair or the mortar?'

(11) Chicheŵa

a. *Mu-na-chéz-á ndí m- [phunzitsi kapéná sangalatsi]?
II.pl/hon.sbj-rec.pst-converse-ind with 1- teacher or entertainer
'Did you converse with the teacher or entertainer?'

b. *A-na-b-á ka- [m-pando kapéná m-tŏndo]?
1sbj-rec.pst-steal-ind 12 3-chair or 3-mortar
'Did he steal a little chair or a little mortar?'

2.1.4 Test 4: gapping

Under this test, it is possible to gap the noun following the locative class marker. In contrast, none of the other class markers allow this gapping, as shown in (12).

(12) Chicheŵa

a. A-nyamăta a-na-vín-á njerero pa bwaló lá mfúmú Kapanga ndí pá (bwaló) lá mfúmú Kapatuka.
2-boy 2sbj-rec.pst-dance-ind 9.name.of.dance 16 5.courtyard 5asc 9chief K. and 16 5.courtyard 5asc 9chief K.
'The boys danced the njerero dance on Chief Kapanga's courtyard and on Chief Kapatuka's (courtyard).'

b. *Kodí áná awa a-ku-fún-á m-pira w-á mphira kapéná m-*(pira) w-á nsanza?
Q 2.child 2this 2sbj-prog-want-ind 3-ball 3-asc 9.rubber or 3-(ball) 3-asc 10.rag
'Do these children want a rubber ball or a rag ball?'

All these tests show that the locative class markers are syntactically independent and all the others are morphological prefixes. Bresnan & Mchombo (1995) provided an explanation with regard to the split between the syntactic and morphological class markers. As hypothesized by Greenberg (1977, 1978), the class markers in Niger-Congo have evolved historically from syntactic elements of NPs into being morphologically bound as prefixes or suffixes. Along this line, it is possible that this process of historical change has been completed for most of the class markers of proto-Bantu that became prefixes, but a few like locatives retained their syntactic behavior as nominal constituents.

According to Bresnan & Mchombo (1995), the fact that agreement is marked both syntactically and morphologically does not violate the lexical integrity principle:

> By factoring apart the syntactic levels of f-structure and c-structure, we can distinguish naturally between structure-dependent syntactic principles (e.g., constituent order), which respect lexical integrity, and function-dependent syntactic principles (e.g., agreement), which do not. (Bresnan & Mchombo 1995: 213)

In the LFG framework, the correspondence between structural form and syntactic function is in general imperfect. Take Bantu noun class markers, for example. Here changes in form can occur partly independent of changes in function. As a result, this lends strong support to the lexical integrity principle. With this illustration of the lexical integrity principle, we now go on to discuss argument structure in Section 2.2.

2.2 Argument structure and morphosyntax

In this subsection we discuss two main constructions, applicatives and objective asymmetries mainly in Bantu languages, before outlining some recent works in mainly non-Bantu languages.

2.2.1 Applicative constructions

The discussion of grammatical functions came to the fore in the 1980s and early 1990s (Marantz 1984, Baker 1988a, Alsina 1992, Alsina & Mchombo 1990, 1993, Bresnan & Moshi 1990). Valency-changing operations like the passive, applicative, causative and similar alternations had raised the question whether grammatical functions (GF) should be seen to be primitives or derivatives. Bantu languages contributed a lot to this discussion since these languages are characterized by applicative, causative and passive morphemes (see (1b) for example).

This section centers on a critique made by Alsina & Mchombo (1990) on Baker (1988b) over applicatives in Chicheŵa. Baker (1988b) proposes an asymmetry in the assignment of the beneficiary and instrumental theta-roles. For Baker, instrumentals are assigned their theta-roles as NP sisters of the verb, while beneficiaries are theta-marked in a PP complement to the verb. In other words, beneficiaries get their theta-role indirectly from the verb through the PP but instrumentals are theta-marked directly by the verb. According to Alsina and Mchombo, Baker's theory is particularly successful in two aspects (Alsina & Mchombo 1990: 495):

(13) a. Word order: while the beneficiary NP must precede a theme/patient NP in the verb phrase, the instrumental NP may either precede or follow it.

b. Object markers: while only the applied object in a beneficiary applicative may be expressed by means of an object marker, either the applied or the patient/theme object in an instrumental applicative may be so expressed.

At the same time, they also adduced three types of evidence against Baker's theta theoretic asymmetry.

2.2.1.1 Extraction facts

As observed by Baker (1988b), a patient or a theme can be extracted both in beneficiary (14a) and in instrumental applicatives (15a), but in contrast, it is not possible to extract a beneficiary object (14b) as an instrumental (15b).

(14) Chicheŵa

a. Īyi ndi mphátso iméné chítsîru chí-ná-gúl-ír-a atsíkāna.
9.this be 9.gift 9.REL 7.fool 7SBJ-PST-buy-APPL-FV 2.girls
'This is the gift that the fool bought for the girls.'

b. *Āwa ndi atsíkána améné chítsîru chí-ná-gúl-ír-a mphâtso.
2.these be 2.girls 2.REL 7.fool 7SBJ-PST-buy-APPL-FV 9.gift
'These are the girls that the fool bought the gift for.'

(15) Chicheŵa

a. Īli ndi dengu liméné ányǎni á-kú-phwány-ír-a
5.this be 5.basket 5.REL 2.baboons 2SBJ-PROG-break-APPL-FV
mwǎla.
3.stone
'This is the basket that the baboons are breaking with a stone.'

b. Ūwu ndi mwalá úméné ányǎni á-kú-phwány-ír-a
3.this be 3.stone 3.REL 2.baboons 2SBJ-PROG-break-APPL-FV
dēngu.
5.basket
'This is the stone that the baboons are breaking the basket with.'

Baker (1988b) explains these differences on the basis of the *nonoblique-trace filter*. Unfortunately, the whole analysis collapses given the fact that there are grammatical instances of extractions of beneficiaries or goals in a Chicheŵa passive sentence (Alsina & Mchombo 1990: 498):

(16) Chicheŵa
Āwa ndi atsíkána améné á-ná-gúl-ír-ídw-á mphâtso.
2.these be 2.girls 2.REL 2SBJ-PST-buy-APPL-PASS-FV 9.gift
'These are the girls that were bought a gift.'

2.2.1.2 Transitivity effects

Baker's proposed D-structure distinction between beneficiaries and instrumentals predicates that beneficiary applicatives cannot be formed from intransitive verbs. However, Alsina & Mchombo (1990) prove it to be incorrect again, as in (17).

(17) Chicheŵa
Yêsu a-ná-wá-f-er-a (anthu).
1.Jesus 1SBJ-PST-2OBJ-die-APPL-FV 2.people
'Jesus died for them (the people).'

2.2.1.3 Locative applicatives

According to Alsina & Mchombo (1990: 503), "locative applicatives constitute a crucial source of evidence for evaluating Baker's (1988b) theory". In Baker's theory, beneficiaries and locatives are conceptually similar because they are both theta-marked by the verb via a preposition. In contrast, the facts show that locatives behave like instrumentals and not like beneficiaries considering things like word order, object marking, and relativization.

Consequently, a classical transformational approach appears to be quite problematic when dealing with applicatives in Chicheŵa given its complex morphosyntax.

2.2.2 Object symmetries/asymmetries

So far, we have briefly discussed one asymmetrical object type: applicatives. This subsection will look deeper into this construction in parallel to the symmetrical type. The distinction between the two types is associated with *primary object* syntactic properties of passivizability, object agreement, adjacency to the verb, and the like. The asymmetrical object type language means that only one of the postverbal NPs exhibits *primary object* syntactic properties, while in the symmetrical object type language there are more than one NPs that can do so.[3] Bresnan & Moshi (1990: 149–157) identify the typological differences based on their observation on Kichaga (symmetrical) and Chicheŵa (asymmetrical).[4]

(18) Kichaga

a. N-a̋-i̋-lyì-í-à m̀-kà k-élyà. $\text{V NP}_{ben}\ \text{NP}_{pt}$
FOC-1SBJ-PROG-eat-APPL-FV 1-wife 7-food
'He is eating food for/on his wife.'

b. M̀-kà n-a̋-i̋-lyì-í-ò k-élyâ. $\text{NP}_{ben}\ \text{V}_{\text{pas}}\ \text{NP}_{pt}$
1-wife 1SBJ-PROG-eat-APPL-PASS 7-food
'The wife is being benefited/adversely affected by someone eating the food.'

c. K-èlyá k-i̋-lyì-í-ò m̀-kà. $\text{NP}_{pt}\ \text{V}_{\text{pas}}\ \text{NP}_{ben}$
7-food 7SBJ-PROG-eat-APPL-PASS 1-wife
'The food is being eaten for/on the wife.'

---

[3] The asymmetrical type includes languages such as Kiswahili, Chimwi:ni, Hibena and Chicheŵa, while the symmetrical type includes languages such as Kinyarwanda, Kihaya, Kimeru, Mashi, and Luyia (or Luhya).

[4] The examples in this chapter are selected from various papers covering a wide range of African languages. We cannot guarantee their consistency in orthography. All we can do is transcribe them as originally as possible. In terms of tones, the symbol ˝ represents a superhigh tone, ´ a high tone, ˇa rising tone,^ a falling tone,` a low tone, and ¯ a superlow tone.

The Kichaga examples (18b)–(18c) show that any object in the symmetrical type can be passivized, but in Chichewâ, examples like (18c) are ungrammatical (Baker 1988b).

Another difference is related to object markers, illustrated in (19).

(19) Kichaga

‘He/She is eating it for/on the wife.’

c. N-a̋-i̋-kì-ḿ-lyì-i̋-à. $\mathrm{OM}_{pt}\text{-}\mathrm{OM}_{ben}\text{-}\mathrm{V}_{\mathrm{stem}}$
foc-1sbj-prog-7obj-1obj-eat-appl-fv
‘He/She is eating it for/on him/her.’

In Kichaga, the object marker can be put on the verb from any or all of the multiple objects. Again, cases such as (19b) and (19c) are not allowed in Chichewâ.

Bresnan & Moshi (1990) also compared the two types in terms of unspecified object deletion, reciprocalization and interactions of object properties. They went on to discuss the problems posed by the data for previous theories (Gary & Keenan 1977, Perlmutter & Postal 1983, Marantz 1984, Baker 1988b, Kiparsky 1988). Along the lines of Alsina & Mchombo (1988), Bresnan & Kanerva (1989) and Alsina (1999), Bresnan & Moshi (1990) show that the LFG treatment is capable of providing a single parameter of variation for the symmetrical and asymmetrical object types from which all the typological differences follow, instead of postulating multiple unrelated differences in the grammar of the two types of languages. In doing so, they decomposed syntactic functions by two crucial properties: $[-r]$ and $[+o]$, schematized in (20).

(20)
$$\begin{bmatrix} -r \\ -o \end{bmatrix} \ \textsc{subj} \qquad \begin{bmatrix} +r \\ -o \end{bmatrix} \ \textsc{obl}_\theta$$
$$\begin{bmatrix} -r \\ +o \end{bmatrix} \ \textsc{obj} \qquad \begin{bmatrix} +r \\ +o \end{bmatrix} \ \textsc{obj}_\theta$$

However, there is a peculiarity in applicative and dative constructions. Following Alsina & Mchombo (1988), Bresnan and Moshi acknowledged that there is a limitation concerning the applied beneficiary and recipient roles, i.e., they universally lack the [+*o*] classification and receive the [−*r*] classification. An asymmetrical object parameter was therefore proposed:

(21) Asymmetrical Object Parameter (AOP)

$$* \quad \begin{array}{ccc} \theta & \dots & \theta \\ | & & | \\ [-r] & & [-r] \end{array}$$

For ditransitive constructions in Chichewâ (Mchombo & Firmino 1999), the applied NP must be adjacent to the verb if it is a beneficiary or recipient; otherwise, either the patient NP or the applied NP may be adjacent to the verb (Bresnan & Moshi 1990: 172). Serving as the parameter of variation, it states that only one role can be intrinsically classified as unrestricted. The idea is illustrated in (22).

(22)

	‘eat-for⟨	*ag*	ben_{appl}	*pt*	⟩’
AOP:		[−*o*]	[−*r*]	[+*o*]	
defaults:		[−*r*]		[+*r*]	
		SUBJ	SUBJ/OBJ	OBJ$_\theta$	
well-formedness:		SUBJ	OBJ	OBJ$_\theta$	

Based on Alsina & Mchombo’s (1988) extended version of intrinsic classifications to account for applicative and dative constructions, the applied beneficiary or recipient role (traditionally called *indirect objects*) can only be [−*r*], whereas the patient can be either [−*r*] or [+*o*]. Similarly in Kichaga, the applied beneficiary role will always be [−*r*], however, since the AOP does not apply to the symmetrical type, the patient can be either [−*r*] or [+*o*] as shown in (23) and (24). The only problem with (23) is that two unrestricted roles will lead to a violation of the final well-formedness condition of Function-Argument Biuniqueness which states that each expressed lexical role must be associated with a unique function, and conversely. So the patient role can only take the [+*o*] option in the active as shown in (24).

(23)

	‘eat-for⟨	*ag*	ben_{appl}	*pt*	⟩’
		[−*o*]	[−*r*]	[+*o*]	
defaults:		[−*r*]			
		SUBJ	SUBJ/OBJ	SUBJ/OBJ	
well-formedness:		SUBJ	OBJ	*	

(24)		‘eat-for⟨	*ag*	*ben*$_{appl}$	*pt*	⟩’
			[−*o*]	[−*r*]	[−*o*]	
	defaults:		[−*r*]		[+*r*]	
			SUBJ	SUBJ/OBJ	OBJ$_{\theta}$	
	well-formedness:		SUBJ	OBJ	OBJ$_{\theta}$	

The analysis also explains adequately why in Chicheŵa only the object that is adjacent to the verb in the active can become the subject in the passive, as seen in (25), while in Kichaga, either object can be passivized, because when one of the two [−*r*] roles is realized as the subject in the passive construction, the other may be the unrestricted object, as shown in (26).

(25)		‘eat-for⟨	*ag*	*ben*$_{appl}$	*pt*	⟩’
	AOP:		[−*o*]	[−*r*]	[+*o*]	
	Passive :		∅			
	defaults:				[+*r*]	
				SUBJ/OBJ	OBJ$_{\theta}$	
	well-formedness:			SUBJ	OBJ$_{\theta}$	

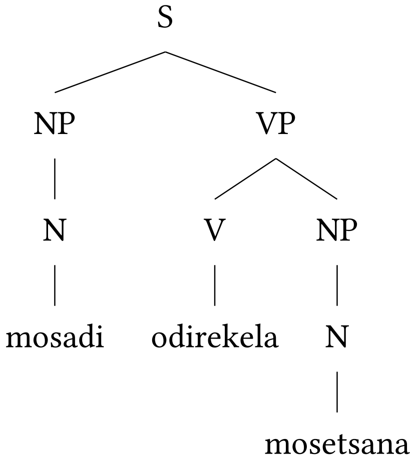
(26)		‘eat-for⟨	*ag*	*ben*$_{appl}$	*pt*	⟩’
			[−*o*]	[−*r*]	[−*r*]	
	Passive :		∅			
	defaults:					
				SUBJ/OBJ	SUBJ/OBJ	
	well-formedness:			SUBJ	OBJ	or
				OBJ	SUBJ	

The single parameter of variation under LFG provides good explanations for other typological differences equally well, namely object deletion, reciprocalization and interactions of object properties, which have been observed between the symmetrical and asymmetrical object types.

In the LFG literature, two recent works on Setswana are from Berg et al. (2013) and Pretorius & Berg (2019). The latter proposes an LFG-based analysis of the tense and aspect features of Setswana auxiliary verbs. In Setswana, auxiliary verbs indicating tense, aspect and time may appear juxtaposed inside a VP, following a specific order determined by the semantic values associated with the auxiliaries. Here we focus on Berg et al. (2013) which analyses Setswana constructions with double objects and double object agreement morphemes.

(27) Setswana
Mosadi o-**di**-rek-el-a mosetsana.
1.woman 1-8-buy-APPL-FV 1.girl
'The woman buys the girl it'.

(28) c-structure: f-structure:



$$\left[\begin{array}{ll}
\textsc{pred} & \text{`}\textsc{rek}\langle\textsc{subj},\textsc{obj}_{\theta},\textsc{obj}\rangle\text{'} \\
\textsc{subj} & \left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{sadi}\text{'} \\ \textsc{nounclass} & 1 \end{array}\right] \\
\textsc{obj}_{\theta} & \left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{setsana}\text{'} \\ \textsc{nounclass} & 1 \end{array}\right] \\
\textsc{obj} & \left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{pro}\text{'} \\ \textsc{nounclass} & 8 \end{array}\right] \\
\textsc{ap} & + \\
\textsc{class} & 1 \\
\textsc{tense} & \textsc{pres} \\
\textsc{verbtype} & \textsc{main}
\end{array}\right]$$

In the end, these works also provide a computational model of these phenomena using the XLE grammar development platform.[5] Other LFG work on argument structure and grammatical functions can be seen in Zaenen (1984), Mchombo (1980, 1999a, 2002, 2003, 2004), Harford (1993), and Kioko (1995). For recent papers on this topic within Bantu languages, one may refer to Matambirofa (2010) and Matambirofa & Mabugu (2014).

2.2.3 Recent work in argument structure on non-Bantu languages

As is well known, at least among LFG practitioners, LFG research on African languages has been pioneered and dominated by analyses of Bantu languages, as shown in the previous analyses. In this subsection, we bring to light a few recent studies involving four languages outside the Bantu group: Tigrinya, Wolof, Soso, and Wan, the latter two of which belong to the Mande language family.[6] Particularly, the discussion of object properties is found in all four languages.

---

[5] For those who are interested in XLE implementations, they can see them both in Dione (2013b) and Berg et al. (2013).

[6] Our special thanks go to one of the reviewers who summarized for us some parts of works included in this section.

2.2.3.1 Work on Tigrinya

In previous discussions, we have seen that the correlation of properties such as pronominal marking and passive typology has been used in object asymmetries as a proof for primary objecthood (Bresnan & Moshi 1990, Alsina & Mchombo 1993, Alsina 1996a). Kifle's (2007) analysis reveals that Tigrinya exhibits symmetric properties of objects in its ditransitive constructions, and asymmetric properties in its applicative constructions.

(29) Tigrinya

a. ʔɨt-omɨ tämäharo n-ät-i mäṣɨḥafɨ-ti
def-3m.pl student.pl obj-def-3m.sg book.pl
tä-wahib-om-wo.
pass-prf.give-sm.3m.pl-om$_1$.3m.sg
'The students are given books.'

b. ʔɨt-i mäṣɨḥafɨ-ti nɨ-tämäharo
def-3m.sg book.pl obl-student.pl
tä-wahib-u-womɨ.
pass-prf.give-sm.3m.sg-om$_1$.3m.pl
'The books are given to students.'

The recipient (29a) and the theme (29b) display primary object properties in the sense that both of them function as subjects in passivization. However, it is observed that only the theme role can function as a subject in passivization when it comes to applicative constructions, as shown in (30). The type of asymmetry found in Tigrinya seems to be the reverse version of the asymmetry found in Bantu languages like Chicheŵa.

(30) Tigrinya

a. ʔɨt-i mäṣɨḥafɨ n-saba tä-gäzi-u-la.
def-3m.sg book.sg obl-Saba.f pass-prf.buy-sm.3m.sg-om$_2$.3f.sg
'The book was bought (for) Saba.'

b. *saba mäṣɨḥafɨ tä-gäzi-ʔa
Saba.F book.sg pass-prf.buy-sm.3f.sg

Therefore, in Tigrinya ditransitive clauses, the symmetric objects possess the [$-r$] features classified as objs, while the applied object in an applicative construction functions as obj$_\theta$ with the [$+r$] feature and the verbal object is obj with the [$-r$] feature. Given these facts, the Tigrinya data pose a particular challenge to the claim made about the correlation between the passive typology and the restrictions on pronominal marking. When applied to Tigrinya (Kifle 2011), the grammatical tests commonly used to distinguish between symmetrical and asymmetrical objects do not converge into a single primary object property. In Tigrinya, the applied object often displays the opposite properties to what is predicted by the lexical mapping theory (LMT).

2.2.3.2 Work on Wolof

In relatively recent research, diverse phenomena in the morphosyntax of Wolof have been analyzed in LFG, including its cleft constructions and their relations to copular constructions (Dione 2012), the interaction between Wolof clitics and different grammar components (Dione 2013a), and pro-drop and control constructions (Dione 2019). In addition, there are several recent works on Wolof that take a computational approach to handle various aspects of the language within the LFG framework (Dione 2014a,b, 2017, 2020).

Among his extensive work on Wolof, Dione (2013b) proposes an LFG-based analysis to deal with applicative-causative polysemy in Wolof using a predicate composition approach of complex predicate formation. He postulated an a-structure for each derivation (applicative and causative) by analyzing polysemous suffixes as carrying their own PRED(ICATE) argument structure which they share with other suffixes of the same derivation type. The focus of his work is on Wolof applicative and causative suffixes.

(31) Wolof

a. Móodu la Faatu wax-al.
Móodu FOC.3SG Faatu talk-APPL
'Faatu talked to MÓODU.'

b.
Faatu *Móodu*
-al comitative: SUBJ OBJ
| |
'ap⟨'wax⟨ _ ⟩', ARG ⟩'
agt com

(32) Wolof

a. Faatu daw-al woto bi.
Faatu run-CAUS car the
'Faatu made the car run.'

b.

	Faatu	*woto*
-al causative:	SUBJ	OBJ
	|	|
‘caus⟨	ARG, ‘daw⟨	_ ⟩’⟩’
	causer	causee

Dione proposed a special argument ARG as the matrix argument for each derivation type. In the applicative clause (31b), he assumed that ARG bears the matrix’s second argument and is underspecified for a comitative, while in the causative clause (32b), ARG occupies the subject position and bears the matrix first argument.

2.2.3.3 Work on Mande

Nikitina (2011a, 2019) examine a highly unusual basic word order pattern in Mande languages: the rigid S-O-V-X word order, meaning subjects and objects precede the verb, while all oblique arguments and adjuncts follow the verb. For example,

(33) Soso, Central Mande

S	O	V	[PP	]
ń	nìngéé	fíí-mà	í	má
1SG	cow	give-FUT	2SG	to

‘I will give you a cow.’

Mande languages are not regarded as “real” verb-final languages in the sense that arguments of a verb are not realized within the same verb phrase: object noun phrases must be placed next to their verb, but postpositional arguments appear in the position outside the verb phrase.

(34) Wan, Southeastern Mande

a.

è	[kúnà]$_{\text{VP}}$	ságlā	[yrɛ	é	gó]$_{\text{PP}}$
3SG	climb	started	tree	DEF	in

‘She began to climb onto the tree.’

b.

*è	kúnà	[yrɛ	é	gó]$_{\text{PP}}$	ságlā
3SG	climb	tree	DEF	in	started

c.

*è	[yrɛ	é	gó]$_{\text{PP}}$	kúnà	ságlā
3SG	tree	DEF	in	climb	started

Because the oblique argument *yrɛ é gó* does not form a syntactic constituent with the verb *kúnà* that selects for it, it cannot appear next to that verb as shown in (34b) and (34c), and only (34a) is grammatical in which the verb *kúnà* is embedded in the non-finite complement of the finite verb *ságlā*. Nikitina (2019) explains this unexpected placement of postpositional arguments in terms of a surface-oriented account of high attachment of PPs.

(35) Wan, Southeastern Mande

è	á	bɛ̰̀nì	lé	sógò-mù-è	lé
3sg	prog	fear	prog	horse-pl-def	at

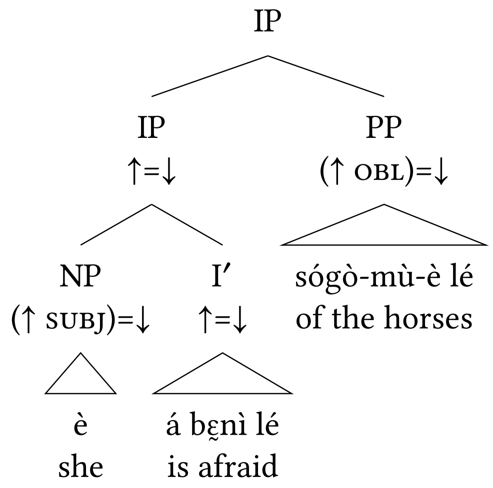
‘She fears horses.’

The phrase structure rule in (36) allows for PPs to adjoin to the clause (Nikitina 2008, 2011b):

(36)
$$\begin{array}{llcc} \text{IP} & \longrightarrow & \text{IP} & \text{PP} \\ & & \uparrow=\downarrow & (\uparrow \textsc{gf}^{*}\ \textsc{obl})=\downarrow \end{array}$$

The Kleene star indicates that the PP can contribute information regarding an oblique argument at any level of embedding, but the ambiguity at the c-structure can be solved at the f-structure where the PP is associated with the main verb to satisfy the well-formedness conditions on f-structure. The resulting structures of (35) is thus represented below:

(37) c-structure: f-structure:



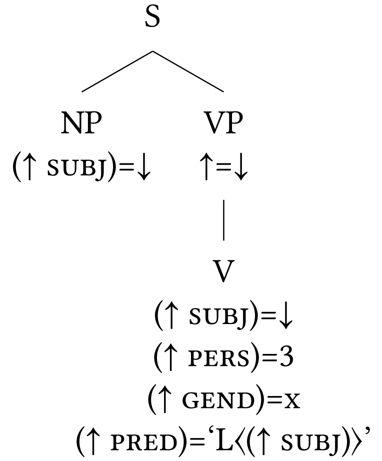
$$\left[\begin{array}{ll} \textsc{pred} & \text{‘}\textsc{fear}\langle\textsc{subj,obj}\rangle\text{’} \\ \textsc{asp} & \textsc{prog} \\ \textsc{tense} & \textsc{pres} \\ \textsc{subj} & \left[\begin{array}{ll} \textsc{pred} & \text{‘}\textsc{pro}\text{’} \\ \textsc{pers} & 3 \\ \textsc{num} & \textsc{sg} \end{array}\right] \\ \textsc{obl} & \left[\begin{array}{ll} \textsc{pred} & \text{‘}\textsc{horse}\text{’} \\ \textsc{num} & \textsc{pl} \\ \textsc{def} & + \\ \textsc{form} & \textsc{le} \end{array}\right] \end{array}\right]$$

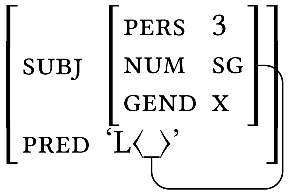
2.3 Agreement

African languages exhibit an interesting nature of agreement (Bresnan & Mchombo 1987, Culy 1996, Mchombo 2004, Nsoh 2011). This section will focus on pronouns in particular. Two particular LFG papers dealing with pronouns and agreement are Bresnan & Mchombo (1987) and Dalrymple (2015).

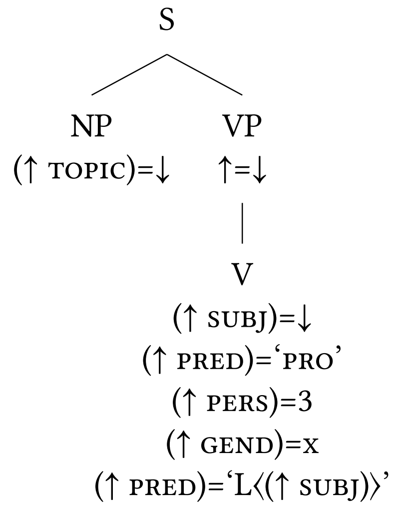
Like other Bantu languages, the subject marker (SM) and object marker (OM) in Chichewâ indicate agreement in their verbal morphology. For Bresnan and Mchombo, the OM is always an incorporated pronoun but the subject NP has two possibilities: a true subject grammatically agreeing with the verb or a topic NP anaphorically agreeing with the subject pronominal in the verb, as shown in (38).

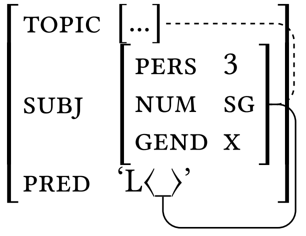
(38) c-structure: f-structure:





c-structure: f-structure:





In a recent paper, Dalrymple (2015) carries out a thorough investigation on the complicated pronominal system in Yąg Dii. According to her, Yąg Dii provides counter-evidence to the general assumption that languages do not have grammatical dependencies that are exclusively nonlocal. The following observations are made regarding the distribution of four types of Yąg Dii pronouns (Dalrymple 2015: 1113):

(39) a. MÍ: can bear any grammatical function, except for subject of ÀǸ̨ clause; antilogophoric in BI domain
  b. ÀǸ̨ : must appear as subject of ÀǸ̨ clause; antilogophoric in BI domain
  c. BI: appears only in BI domain; can bear any grammatical function (except for some subordinate subject positions within BI domain); coreferent with logophoric antecedent
  d. ÌI: appears only as subordinate subject within logophoric domain; coreferent with logophoric antecedent

Take the BI pronouns, for example (Bohnhoff 1986: 118):

(40) Yąg Dii
Nà'á Ø 'ọd bà'á [Múúsà bà Ø 'ọ [bà biǹ hį́į́
Mother$_i$ (she$_i$) tells Father Moses$_j$ that (he$_j$) says that he.BI$_{j,*i}$ wants
lààlɨ kaalɨ]].
to.go town.to
'Mother$_i$ tells Father that Moses$_j$ says that *she$_i$/he$_j$ wants to go to town.'

(41) Yąg Dii
*Nà'á Ø 'ọd bà'á [bà mí 'ọ [bà biǹ hį́į́ lààlɨ kaalɨ]].
Mother$_i$ (she$_i$) tells Father that I say that she.BI$_i$ wants to.go town.to
'Mother$_i$ tells Father that I say that she$_i$ wants to go to town.'

The analysis is built on LFG's binding theory, which is schematized in (42) (Dalrymple 2015: 1114).

(42) $$(\uparrow_\sigma \textsc{ant}) = ((\underset{\substack{\textsc{delimits}\\ \textsc{binding}\\ \textsc{domain}}}{\textsc{gf}^*} \quad \underset{\substack{\textsc{grammatical}\\ \textsc{function of}\\ \textsc{pronoun}}}{\textsc{gf}_{\textsc{pro}}} \quad \uparrow) \quad \underset{\substack{\textsc{grammatical}\\ \textsc{function of}\\ \textsc{antecedent}}}{\textsc{gf}_{\textsc{ant}}} \quad)_\sigma$$

f-structure: $$\begin{bmatrix} \textsc{gf}_{\textsc{ant}} & [\textsc{antecedent}] \\ \ldots\textsc{gf}^*\ldots\textsc{gf}_{\textsc{pro}} & [\textsc{pronoun}] \end{bmatrix}$$

The equation dictates that the antecedent must be found within the binding domain ($\mathrm{GF}^{*}\ \mathrm{GF}_{\mathrm{PRO}}\ \uparrow$). In order to constrain the distribution of the four types of pronouns, Dalrymple (2015) adds the LOG feature to the inventory of features that are universally available in the binding domain, inspired by Bresnan (2001), Adesola (2006), Asudeh (2009), and Strahan (2009, 2011).

The binding constraints for BI was proposed by Dalrymple as follows:

(43)
$$(\uparrow_{\sigma}\ \mathrm{ANTECEDENT}) = ((\begin{array}{ccc} \mathrm{GF}_{\mathrm{LOG}} & \mathrm{GF}^{*} & \uparrow) \\ (\rightarrow \mathrm{LOG}) & \neg(\rightarrow \mathrm{LOG}) & \\ 1 & 2 & \end{array}\ \begin{array}{c} \mathrm{SUBJ})_{\sigma} \\ \\ 3 \end{array}$$

The logophoric pronoun must appear within the logophoric domain which is the f-structure value of the $\mathrm{GF}_{\mathrm{LOG}}$ feature. The numbers occur under each element of binding equation where constraints are imposed. For example, the number 2 states that the BI pronoun may be embedded at an arbitrary depth within the logophoric domain, but it must be bound by the closest logophoric binder: examples (40)–(41) show the evidence that the smallest BI domain must be chosen (see Dalrymple 2015: 1116 for more details).

2.4 Reciprocal marking

African languages have also provided rich linguistic data for the analysis of reciprocity under the LFG framework (Mchombo & Ngunga 1994, Dalrymple et al. 1998, Mchombo 1999b). Hurst (2012) examined the reciprocal in Icelandic (Germanic), Malagasy (Austronesian) and Swahili (Bantu), based on Hurst (2006, 2010).

According to Hurst (2006), the Malagasy reciprocal construction is formed by way of a prefix *-if-* or *-ifamp-* to the verb, as shown in (44).

(44) Malagasy

N-ifamp-i-laza	ho	namboly	vary	Rasoa	sy	Ravelo.
PST-RECP-act-say	COMP	PST.cultivate	rice	Rasoa	and	Ravelo

‘Rasoa and Ravelo said of each other that s/he cultivated rice.’

Hurst (2006) proposes that the verb’s valency remains unchanged at the level of f-structure and the reciprocal morpheme creates a reciprocal pronoun selected by the verb as an internal argument. The lexical entries for (44) are thus given below:

(45) *n-ifamp-i-laza* V (↑ pred) = ‘say⟨(↑ subj) (↑ xcomp)⟩(↑ obj)’
(↑ xcomp subj) = (↑ obj)
(↑ obj pred) = ‘pro$_{\text{rec}}$’ (from *-ifamp-*)
(↑ voice) = active
(↑ tense) = past

namboly V (↑ pred) = ‘cultivate<(↑ subj) (↑ obj)>’
(↑ voice) = active
(↑ tense) = past

vary N (↑ pred) = ‘rice’

Furthermore, Hurst (2010) examines two reciprocal constructions in Swahili: the monadic construction that incorporates the participants into the subject NP while losing an object NP and the dyadic construction that has two participants in the subject NP and in a comitative phrase respectively. According to his LFG analyses, the syntactic and semantic (to a lesser extent) behaviour of reciprocal constructions results from more fundamental reciprocation strategies by which asymmetric predicates are made to describe symmetric situations, rather than from structural features, i.e., the formation process that may involve clitics and affixes. Khumalo (2014) also touches upon similar constructions (monadic and dyadic) in Ndebele using the Lexical Mapping Theory (LMT). Like in most Bantu languages, the Ndebele reciprocal is marked by the verbal suffix *-an-*, as shown in (46).

(46) Ndebele
Aba-ntwana ba-ya-thand-an-a.
2-children 2sm-prs-love-recp-fv
‘The children love each other.’

The monadic construction seems to violate the mapping principle in the LMT since each semantic role is assigned to a grammatical function and vice versa. According to the semantic interpretation of the reciprocal, the only participant in (46), *abantwana*, acts both as an agent and a beneficiary, as illustrated in (47).[7]

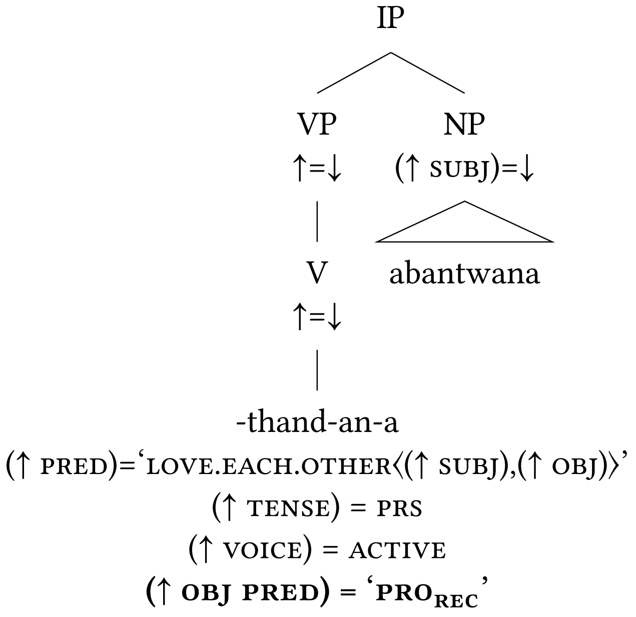
(47) A-structure: *thanda* ⟨Agent, Beneficiary⟩
F-structure: *thandana* ⟨subj⟩

---

[7] See Alsina (1996b: 260–263) for a similar analysis of the formation of reciprocal expressions in Catalan.

Following Hurst (2006, 2010), Khumalo (2014) attempts to solve the puzzle by proposing the following analysis:

(48) c-structure:



f-structure:

$$\left[\begin{array}{ll} \textsc{subj} & \left[\text{“}\textsc{abantwana}\text{”}\right] \\ \textsc{obj} & \left[\textsc{pred}\ \text{‘}\textsc{pro}_{\textsc{rec}}\text{’}\right] \\ \textsc{pred} & \text{‘-}\textsc{thandana}\langle(\uparrow \textsc{subj}),\ (\uparrow \textsc{obj})\rangle \\ \textsc{voice} & \textsc{active} \\ \textsc{tense} & \textsc{prs} \end{array}\right]$$

In this analysis, the reciprocal pronoun is licensed by the reciprocal morpheme through the definition, -**an**-: $(\uparrow \textbf{OBJ PRED}) = \text{‘}\textbf{PRO}_{\textbf{REC}}\text{’}$. As for the dyadic construction, Hurst (2010) proposes that the comitative NP should be treated as an argument-adjunct which cannot receive a theta role but is crucially licensed in the a-structure.

2.5 Locative inversion

The discussion of locatives in African languages has also attracted considerable attention (Bresnan & Kanerva 1989, Bresnan 1991, 1994, Moshi 1995, Morapedi 2010). Interestingly, unlike the PP locative in English, locatives have the structure of NP and occur freely in the subject and object positions. The locative phrase is a subject in (49a) and an object in (49b). Example (49c) is the passivized version of (49a) in which the locative is the object of the preposition "by". Obligatory subject-verb agreement can also be seen with locative subjects as shown in (49).

(49) Chichewa (Bresnan 1991: 58)

a. Ku San José kú-ma-ndi-sangalâts-a.
17 San Jose 17-sbj-prs.hab-I.sg.obj-please-ind
'It pleases me in San Jose, (Being in) San Jose pleases me.'

b. Ndí-ma-kónd-á ku San Josê.
I.sg.sbj-prs.hab-love-ind 17 San Jose
'I like it in San Jose.'

c. Ndí-ma-sangalats-ídw-á ndí ku San Josê.
I.sg.sbj-prs.hab-please-pass-ind by 17 San Jose
'I am pleased by (being in) San Jose.'

Another salient feature of locatives is exhibited by locative inversion construction.

(50) Chichewa (Bresnan 1991: 60)

a. A-lendô-wo a-na-bwér-á ku-mu-dzi.
2-visitor-2those 2sbj-rec.pst-come-ind 17-3-village
'Those visitors came to the village.'

b. Ku-mu-dzi ku-na-bwér-á a-lendô-wo.
17-3-village 17sbj-rec.pst-come-ind 2-visitor-2those
'To the village came those visitors.'

The locative *ku-mu-dzi* is the oblique complement of the intransitive verb (or passive verbs) and undergoes locative inversion as illustrated in (50b). According to Bresnan and Karneva's analysis, "the inverted subject is the thematic subject, the syntactic object, and the presentational focus in discourse" (1989: 38), which can be accounted for by generalizing the special subject default to the focus subject default:[8]

(51)
$$\begin{array}{ccc} [f] & \mathit{loc} & /\ \mathit{expl} \\ & | & \\ & [-r] & \end{array}$$

---

[8] The feature $[f]$ refers to the presentational focus attribute(s), and *expl* represents an expletive subject that may appear as an alternative to the *loc* classification.

There is a constraint regarding the distribution of the focus feature [*f*] in Chicheŵa: only the theme argument can bear an [*f*] feature, and only when it is the highest expressed role.[9]

Morapedi (2010) argues that the preverbal locative NP in Setswana is not the subject but the topic setting the scene for the focused NP in the sense that the preverbal locative NP does not pass the subjecthood test, while the post-verbal NP shows features atypical of objects.

2.6 Serial verbs and complex predicates

Complex predicates can be defined as predicates which are composed of more than one grammatical element (either morphemes or words), each of which contributes a non-trivial part of the information of the complex predicate (Alsina et al. 1997). Within the framework of LFG, the pioneer work has been done by Alsina (1993, 1994), Butt (1995, 1998), Frank (1996), Bodomo (1996, 1997), and Mohanan (1997).

Bodomo (1996) provides a series of syntactic and semantic tests on two types (causative and benefactive) of SVCs in Dagaare and Akan, arguing that the various verbs do indeed behave as a unit in the1form of a complex predicate.

(52) Dagaare

a. Báyúó dà ngmɛ-ø lá Áyúó lɔɔ-ø.
Bayuo PST beat-PRF FOC Ayuo CAUS+fall-PRF
'Bayuo knocked Ayuo down.'

b. Ò dà dé lá à bíé zѐglѐ bàrѐ.
he PST take FOC DEF child seat leave
'He seated away the child.'

(53) Akan
Kofi fa-a ntoma ma-a me.
Kofi take-PRF cloth give-PRF me
'Kofi took a cloth for me.'

Bodomo adopted and extended Alsina's (1994) idea of predicate composition to license the idea of composing the PRED features of SVCs into a single predicate-chain feature, labeled PREDCHAIN. Since in standard LFG unification is not possible with PRED values, Alsina replaces the annotation, ↑=↓, found on heads with the annotation, ↑=H↓, which will then allow the PRED values to be composed and not unified, represented below:

---

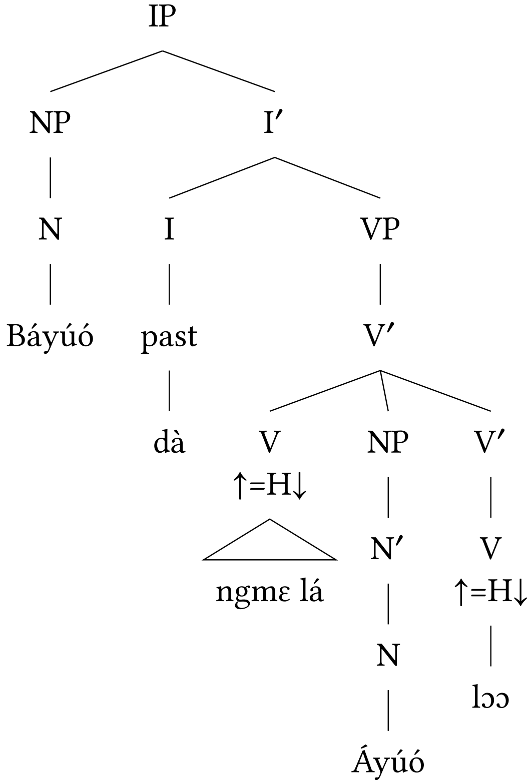
[9] Bresnan & Kanerva (1989) is another long and complex paper. For reason of conciseness, we cannot include all details here, but we encourage those who are interested in the analysis to read the whole paper.

(54) $\uparrow = \mathrm{H}\downarrow \equiv_{\mathrm{def}} \quad \uparrow\backslash_{\textsc{pred}} = \downarrow\backslash_{\textsc{pred}}$
$(\uparrow \textsc{pred}) = \mathrm{F}((\downarrow \textsc{pred}), (\rightarrow\mathrm{H}\ \textsc{pred}))$

What the definition says is that if a c-structure node has the head equation, its features are identical to the features of its mother node M except for PRED, and its PRED feature composes with that of its head sister node to yield the PRED feature of M. According to Bodomo, Alsina built his extension of the classical LFG notation on the assumption that one of the PREDs which compose must be incomplete. However, it is difficult to consider any of the verbs in the SVC data of Dagaare and Akan as any less complete than the other. A solution would be to consider, as does Baker (1989), a distinction of the notion of head into secondary and primary heads. Some of the predicates in the SVC would then be secondary to others in terms of headedness. It is these “secondary predicates” which count as the equivalents of the incomplete predicates in the sense Alsina used them. In this way predicate composition is possible with SVCs and thus licenses the existence of PREDCHAIN, as shown in (55).

(55)

c-structure:



f-structure:

$$\left[\begin{array}{ll} \textsc{predchain} & \text{‘}\textsc{ngmɛ lá}\langle\textsc{f}1, \textsc{f}2\rangle\text{’} \\ \textsc{tense} & \textsc{pst} \\ \textsc{aspect} & \textsc{prf} \\ \textsc{subj} & \left[\begin{array}{ll} \textsc{pred} & \text{‘}\textsc{Báyúó}\text{’} \\ \textsc{num} & \textsc{sg} \\ \textsc{gend} & \textsc{masc} \end{array}\right] \\ \textsc{obj} & \left[\begin{array}{ll} \textsc{pred} & \text{‘}\textsc{Áyúó}\text{’} \\ \textsc{num} & \textsc{sg} \\ \textsc{gend} & \textsc{masc} \end{array}\right] \end{array}\right]$$

More recent work on LFG analyses of serial verb constructions in African languages can be seen in Nyampong (2015) and Lovestrand (2018).

2.7 Discourse functions

Discourse functions have constituted another topical issue in African linguistics. The major LFG work includes Kanerva (1990), Bresnan (1995), Mchombo (2003), Marfo & Bodomo (2005) Mchombo & Morimoto (2009) and Abubakari (2018). Among them, Marfo & Bodomo (2005) stand out for attempting a constraint-based analysis, Optimality-Theoretic LFG (OT-LFG), when addressing *wh*-question fronting and focus constructions in Akan. It is shown that both *wh*-question fronting and focus constructions essentially share common representations in the c-structure and the f-structure but a variance is drawn between them in the information (i-) structure. Q-word fronting in Akan refers to the dislocation of the Q-word to the left-periphery of an extra-sentential position by using a clitic morpheme, *na*, referred to as a focus marker (FOCUS), at the right-edge of the fronted Q-word, as shown in (56).

(56) Akan

a. [$_{\text{IP}}$ Pàpá rè-sèré hwáí]
Father PROG-laugh who
'Father is laughing at who?'

b. Hwáí$_i$ nà [$_{\text{IP}}$ Pàpá ré-séré nó$_i$]
who FOC father PROG-laugh 3SG
'Whom is father laughing at?'

Both (56a) and (56b) are legitimate question forms in Akan. On the other hand, in a focus construction in Akan, contrastive information (of certainty) is intentionally employed for the purpose of emphasis as in (57). Both Q-word fronting and focus constructions essentially share a common marked categorial configuration, i.e., [$_{\text{FOCP}}$ XP *na* [$_{\text{IP}}$ …]].

(57) Akan
[$_{\text{FOCP}}$ ɛmóó$_i$ nà [$_{\text{IP}}$ ɔbáá nó [$_{\text{VP}}$ nóá [$_{\text{NP}}$ Ø$_i$]]]]
rice FOC lady DEF cook.HAB *e*
'It is rice (that) the lady cooks.'

Following Boadi (1990), Marfo & Bodomo (2005) argue that the Q-word fronting lacks semantic contrast given the fact that Q-words are actually inherently focus-marked. As a result, there is a difference in their i-structures regarding the focus type (F-TYPE):

(58) a. Q-word fronting:

$$\left[\begin{array}{ll} \text{FOCUS} & \left[\begin{array}{ll}\text{F-TYPE} & \text{NEUTRAL}\\ \text{I-PRED} & \text{‘HWAI’}\end{array}\right] \\ \text{BCK} & \left[\begin{array}{l}\text{PÀPÁ}\\ \text{RÉSÉRÉ NÓ}\end{array}\right]\end{array}\right]$$

b. Focus:

$$\left[\begin{array}{ll} \text{FOCUS} & \left[\begin{array}{ll}\text{F-TYPE} & \text{CONTRASTIVE}\\ \text{I-PRED} & \text{‘ƐMÓÓ’}\end{array}\right] \\ \text{BCK} & \left[\begin{array}{l}\text{ƆBÁÁ NÓ}\\ \text{NÓÁ}\end{array}\right]\end{array}\right]$$

This semantic distinction between the two constructions is further shown in the OT-LFG framework by ranking the following i-/c-structure correspondence/ alignment constraints (Choi 2001):

(59) a. NEW-L: [+NEW] aligns left in the construction of occurrence.
b. PROM-L: [+PROM] aligns left in the construction of occurrence.
c. NEUT-L: [+NEUT] aligns left in the construction of occurrence.
d. CONST-L: [+CONST] aligns left in the construction of occurrence.

(60) NEW-L » PROM-L » CONST-L » NEUT-L

	$[_{\text{FOCP}}$ NP$_i$ *na* $[_{\text{IP}}$ Pro$_i$ $[_{\text{VP}}$ V NP]]][10]	NEW-L	PROM-L	CONST-L	NEUT-L
a.	$[_{\text{FOCP}}$ ɛmóó$_{[\text{+CONST,+NEW,+PROM}]}$ nà $[_{\text{IP}}$ Pro$_i$ $[_{\text{VP}}$ V NP]]]				*
b.	$[_{\text{FOCP}}$ Hwáí$_{[\text{+NEUT,+NEW,+PROM}]}$ nà $[_{\text{IP}}$ na $[_{\text{IP}}$ Pro$_i$ $[_{\text{VP}}$ V NP]]]			*!	

The table in (60) signals a few things. First, since both Q-word and constituent in focus are noted as “[+PROM] [+NEW]” at the i-structure and each of them sits at Spec-FOCP, it is obvious the i-/c-structure correspondence constraints in ((59a)–(59b)) will be satisfied in both constructions. However, Q-word fronting and focus constructions have been set apart in the semantics as “discourse-neutral”

---

[10] This optimal candidate emerges as $[_{\text{FOCP}}$ NP$_i$ *na* $[_{\text{IP}}$ Pro$_i$ $[_{\text{VP}}$ V NP]]] via OT for both Q-word fronting and focus constructions in an earlier section of the paper. We encourage those who are interested to read the whole paper.

and "discourse-contrast" respectively through the projected i-structure (see 58). These separate semantic orientations of Q-word fronting and focus are expressed in constraint terms ((59c)–(59d)). Second, CONST-L must crucially outrank NEUT-L where there is a need to establish i-/c-structure harmonic alignment in a focus construction (i.e., a correspondence between a constituent in focus and the Spec-FOCP position, as against harmonic alignment between a fronted Q-word and the Spec-FOCP position). Third, the ranking between CONST-L and NEW-L/PROM-L is hardly crucial because both fronted Q-word and focus constituent sit at Spec-FOCP and specify for [+new]/[+prom]. Fourth, the fact that the focus construction outperforms the fronted Q-word construction does not mean that the Q-word fronting construction is ungrammatical since CONST-L and NEUT-L are only necessary constraints motivated on individual semantic content to draw attention to the semantic distinction between Q-word fronting and focus constructions. It only explains that, unlike in a focus construction, no semantic contrast is realized in a Q-word fronting construction.

This main section of the chapter has documented a diverse set of features of African languages and shown how they have been analyzed in the LFG framework. In Section 3, we summarise the important role that LFG has played in analyzing African languages.

3 Contributions of LFG to the understanding of African language phenomena

In general, many African languages are characterized by rich morphosyntactic properties, stacked inflectional morphemes and mixed derivational and inflectional uses of the same morphemes, which have posed serious challenges to syntactic movement approaches (Mchombo 1980, Mchombo & Mtenje 1983, Bresnan 1994). The appearance of LFG in the 1970s has provided an important alternative under these circumstances. Petzell (2004) makes a comparison between LFG and transformational theories when dealing with certain phenomena in Bantu languages and concludes that LFG is more suitable for a surface-oriented, lexical analysis of syntactic and morphological issues in Bantu languages. Indeed, the Africanist research done under a constraint-based theory of grammar like LFG shows that multitiered, parallel structure analyses help understand a phenomenon at different levels of the grammar by means of unification, as we have already shown in Section 2. Bresnan & Kanerva (1989) put it accurately:

> The architecture of generative grammar has been predominantly based on the representation of independent levels of grammatical organization by

> configurations of the same kind of syntactic sentence structure; yet the need to constrain derivational relations among syntactic representations conflicts with the actual divergence of what is being represented. Although it is possible to superimpose thematic, structural, and functional relations onto the same syntactic representation, only the natural factorization of grammar will enable us to discover the deeper principles of language. (Bresnan & Kanerva 1989: 38)

There is no doubt that African languages and LFG are valuable to each other. For one thing, African languages provide a particularly rich empirical domain for testing the adequacy of the LFG framework. And for another, LFG provides a resourceful theoretical tool to look into the nature of these languages (Kroeger 2007).

4 Conclusion

In this chapter, we began with a brief outline of the language situation in Africa as well as a snapshot of the major features of African languages in Section 1. In Section 2 we then indicated how LFG has been used to analyze some of these salient features, covering topics such as the lexical integrity principle, applicative constructions, object asymmetries, agreement, reciprocal marking, locative inversion, serial verbs and complex predicates, and discourse functions. In the process of doing all this, the analyses in the chapter point to the major contributions of African languages to the development of LFG and, in turn, the major contributions of LFG to the understanding of African language phenomena, as shown in Section 3.

But, of course, there are other topics that we have unfortunately not been able to fully address here so as to keep this chapter concise enough. These include causatives (Alsina 1992), dative and passive (Mchombo 1980), comparatives (Beermann et al. 2005), negation (Bond 2016), mismatches/mixed categories (Bresnan 1995, Bresnan & Mugane 2006, Morimoto 2002), among others. It seems that most of the work has been done within the Bantu languages,[11] although there is now

---

[11] As pointed out by one of our reviewers, a lot of the key LFG papers in Bantu are from the 1990s while more recently there has been comparatively less work. At the same time, there has been a bit of a Bantu boom beyond LFG, in particular in GB/MP and in comparative studies of variation, including locative inversion, applicatives, agreement, etc. However, these current trends in African linguistics have not yet been addressed fully in the LFG community. On the other hand, recent trends in LFG have not yet been linked specifically with African languages. This includes partial agreement (Sadler 2016) and information structure effects. More discussion of

an increasing availability of works in other languages in recent years. We could not agree more with Henderson (2011) that future research on African languages needs more comparative work. Such work will impact not only LFG but also syntactic theory on the whole in a more profound way.

Acknowledgments

We would like to thank a number of people for their help in writing this chapter. First, we thank the editor, Mary Dalrymple, for assigning us this important task of doing an overview of LFG works on African languages. We thank Tatiana Nikitina and four anonymous reviewers for critical and insightful comments that led to what we believe is an improved chapter. We would like to dedicate this chapter to the pioneers of LFG analyses of African languages. Professor Sam Mchombo deserves particular mention in this respect given the sheer number and quality of his contributions in collaboration with prominent LFGists such as Joan Bresnan and Alex Alsina.

Abbreviations

Besides the abbreviations from the Leipzig Glossing Conventions, this chapter uses the following abbreviations.

9-, 3-, etc.	(nominal) class 9, class 3, etc.	OM	object marker
APPL	applicative	PL	plural (also used for honorification of an individual)
ASC	associative	REC.PST	recent past
FV	final vowel	SM	subject marker
HAB	habitual	T	tense
HON	honorific

Chapter 27

LFG and Australian languages

Rachel Nordlinger
University of Melbourne

Australian languages exhibit many interesting grammatical properties and have featured in LFG-related research since the earliest days of the framework. In this chapter I survey the features of Australian languages that have featured most prominently in work within LFG, and show how they argue strongly for the parallel architecture of LFG and in particular the separation of functional relations at f-structure from phrasal constituency and linearity at c-structure. These morphosyntactic features include non-configurationality and flexible word order, the role of morphology in encoding grammatical relations, case stacking, valence-changing phenomena and complex predicates. I show how the flexibility afforded by LFG's parallel architecture, which separates c-structure from f-structure with a many-to-many mapping between them, allows for a natural and explanatory account of these properties of Australian languages. In return, the empirical questions prompted by these theoretical analyses and their predictions have led to a more detailed understanding of the intricate grammatical structures of various Australian languages, and explain the appeal of the LFG formalism for fieldworkers engaged in Australian language documentation.

1 The languages of Australia

Across the continent of Australia there are hundreds of Indigenous languages. The literature typically cites upwards of 800 named language varieties, which can be grouped into 250-300 distinct languages (Koch & Nordlinger 2014b), but it is not always straightforward to determine language differences from dialectal differences and so these numbers are approximate to a certain extent.[1] Prior to

---

[1] It is important to note that these >800 language varieties are considered different languages by Indigenous communities themselves, and thus the grouping of these into a smaller number of 'distinct languages' is a purely linguistic enterprise.

Rachel Nordlinger. 2023. LFG and Australian languages. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 1253–1287. Berlin: Language Science Press. DOI: 10.5281/zenodo.10185998

the English invasion of Australia, these languages were spoken across a population of perhaps 750,000 to one million people, which highlights the enormous linguistic diversity of Indigenous Australia. In many cases languages were maintained by very small populations (e.g. 40–50 people), and the largest populations speaking a single language variety were probably no bigger than 4000 people. Linguistic diversity is highly valued culturally for its indexical relationship to heritage, identity and group membership (Evans 2007) and is not an impediment to communication, since high degrees of multilingualism were (and often still are) the norm across Indigenous Australia, with individuals typically speaking up to 4–6 languages of the surrounding area, as well as understanding others, given widespread practices of receptive multilingualism (Singer 2018).

Australian languages are generally considered by linguists to all be related to one another, although the detailed comparative work needed to establish this is still underway. Such research is confounded by a number of factors, the most significant of which is the extraordinary time depth (perhaps as much as 65,000 years) that Indigenous people have been living on and moving around the continent, with almost no written records of any of the languages prior to the last 200 years or so, and few detailed descriptions until substantially later. Research to date has established that the Australian languages can be grouped into around 25 different language families. One of these, the *Pama-Nyungan* family, covers approximately 85 percent of the continent, stretching from the south-west of Western Australia all the way to the tip of Cape York in far north Queensland. The other families, known collectively as the *non-Pama-Nyungan* families, are concentrated in the northern parts of Western Australia and the top half of the Northern Territory, but higher order groupings amongst these non-Pama-Nyungan families have not yet been clearly established.

The sociolinguistic situation varies enormously across these hundreds of languages and their communities (DITRC et al. 2020). Some languages remain strong, and are used by their communities as the daily language of communication and learned as first languages by the children. Many others are used fluently only by older members of the community, with younger generations having passive and varying degrees of partial knowledge of the language; while many other languages, particularly those from the areas most heavily populated by non-Aboriginal populations since the nineteenth century, have no first language speakers at all and are instead in the process of being relearned and revived by community members from (often scant) historical materials.

Australian languages are relatively similar phonologically (Fletcher & Butcher 2014) but exhibit greater variation in grammatical organisation. While all Australian languages are morphologically complex, we can see them as falling into two broad grammatical types which we can loosely call dependent-marking and head-marking (Nichols 1986) (although most of the head-marking languages have some dependent-marking as well, and some of the dependent-marking languages have bound pronominal clitics cross-referencing verbal arguments). The Pama-Nyungan languages are dependent-marking languages with grammatical relations primarily encoded through case marking. These languages are generally morphologically ergative languages, and have elaborate case systems that cover a range of grammatical and semantic case functions. Examples such as the following are typical.

(1) Jiwarli
Ngatha tharla-laartu ngurru-martu-nha pirru-ngku.
1sg.erg feed-usit old.man-group-acc meat-erg
'I used to feed the old men with meat.' (Austin 2001a: 310)

(2) Jiwarli
Wuru ngunha tharrpa-rninyja ngarti-ngka kajalpu-la…
stick.acc that.acc insert-pst inside-loc emu-loc
'(He) inserted the stick inside the emu…' (Austin 2001a: 315)

However, some other Pama-Nyungan languages combine a robust case-marking system with bound pronominal clitics cross-referencing verbal arguments, as illustrated in the following examples:

(3) Bilinarra
Liward-ba=nggu=lu garra nyununy gajirri-lu.
wait-ep=2min.obj=3aug.sbj be.prs 2min.dat woman-erg
'The women are waiting for you.' (Meakins & Nordlinger 2014: 121)

(4) Bilinarra
Jamana-lu=rni=warla=rna=rla ma-ni warlagu=ma nyila=ma,
foot-erg=only=foc=1min.sbj=3obl do-pst dog(acc)=top that(acc)=top
garndi-murlung-gulu.
stick-priv-erg
'I kicked the dog of his with just my foot, not with a stick.' (Meakins & Nordlinger 2014: 121)

The head-marking languages largely belong to non-Pama-Nyungan families of northern Australia and encode core grammatical relations primarily through verbal morphology. Some of these are characterised as polysynthetic since verbs can be so morphologically complex that they can stand alone as a single complex clause, and may even allow noun incorporation as in (5). The polysynthetic, head-marking languages of Australia have minimal grammatical case marking, although many still employ case for semantic case functions. Polysynthetic Australian languages include Bininj Gun-wok (Evans 2003) and Murrinhpatha (Blythe 2009, Nordlinger 2017, Mansfield 2019), as illustrated in the following examples.

(5) Bininj Gun-wok
Nga-ban-marne-yawoih-dulk-djobge-ng.
1sg.sbj-3pl.obj-ben-again-tree-cut-pst.pfv
'I cut the tree/wood for them again' or 'I cut another tree for them.'
(Evans & Sasse 2002: 2)

(6) Murrinhpatha
Puddan-wunku-rlarl-deyida-ngime=pumpanka.
3du.sbj.shove.nfut-3du.obj-drop-in.turn-pc.f=3du.sbj.go.nfut
'They (dual sibling) are dropping them (paucal, female, non-sibling) off, one after the other, as they go along.' (Blythe 2009: 134)

Australian languages exhibit many interesting grammatical properties that have been the focus of much theoretical and typological discussion, including flexible word order, syntactic and morphological ergativity, elaborate case systems and case marking, nominal classification, complex verb structures, polysynthesis, noun incorporation, grammaticalised expression of kin relations, and many more – see the overviews and discussions in Dixon (2002), Koch & Nordlinger (2014a), and Bowern (2023) for more details. It is not possible for me to do justice to all of this work here, so in this chapter I focus on the features of Australian languages that have featured most prominently in work within the LFG framework.

2 Overview of work on Australian languages in LFG

Australian languages have featured in LFG-related research since the early days, beginning with Jane Simpson's PhD work on Warlpiri (Simpson 1983). The non-configurational clausal structure of languages like Warlpiri, first discussed by Hale (1981, 1982, 1983), argues strongly for the parallel architecture of LFG and in particular the separation of functional relations at f-structure from phrasal constituency and linearity at c-structure. Languages like Warlpiri provide clear support for the idea that the same f-structure information can be realised across different languages with wildly diverse c-structures. This is illustrated by comparing Figure 1 and Figure 2 (based on Bresnan et al. 2016: 3–4), where we see that the same f-structure can correspond to both the highly configurational c-structure of English, and the flat non-configurational c-structure of Warlpiri. Warlpiri in addition allows multiple alternative word orders in c-structure, all of which correspond to this same f-structure.[2]

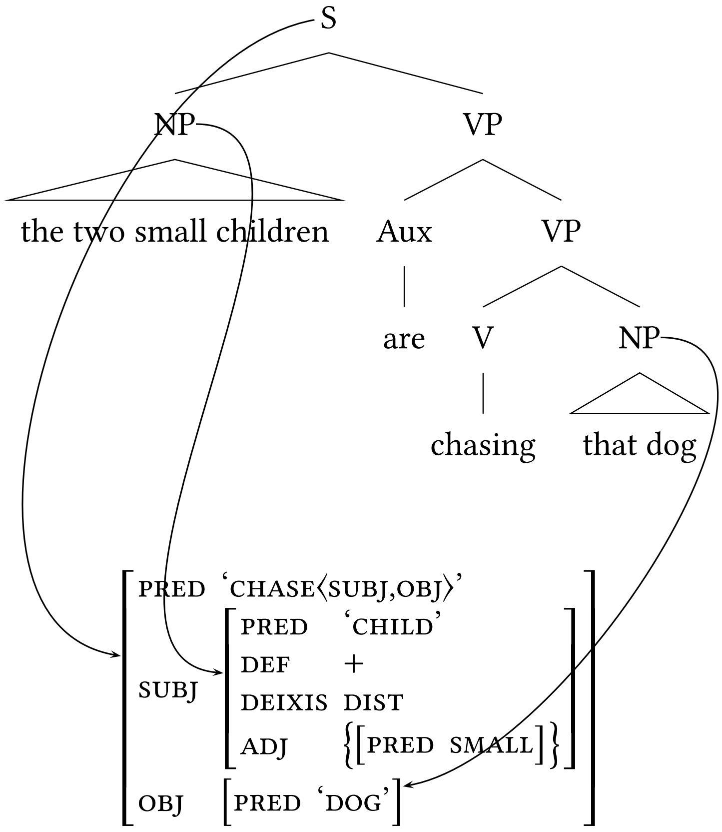

Figure 1: Simple c-structure/f-structure correspondences in English

While early work in LFG focussed on Warlpiri (Simpson 1983, Simpson & Bresnan 1983, Simpson 1991) subsequent work has brought in empirical data from a number of other Australian languages including Jiwarli (Austin & Bresnan 1996), Wambaya (Nordlinger & Bresnan 1996, Nordlinger 1998b), Dyirbal (Manning 1996), Wagiman (Wilson 1999), Kayardild (Evans & Nordlinger 2004), Wubuy

---

[2] Any order of words and categories in the c-structure given in Figure 2 is grammatical and semantically equivalent, as long as *ka=pala* remains in second position. See (8) below for further exemplification.

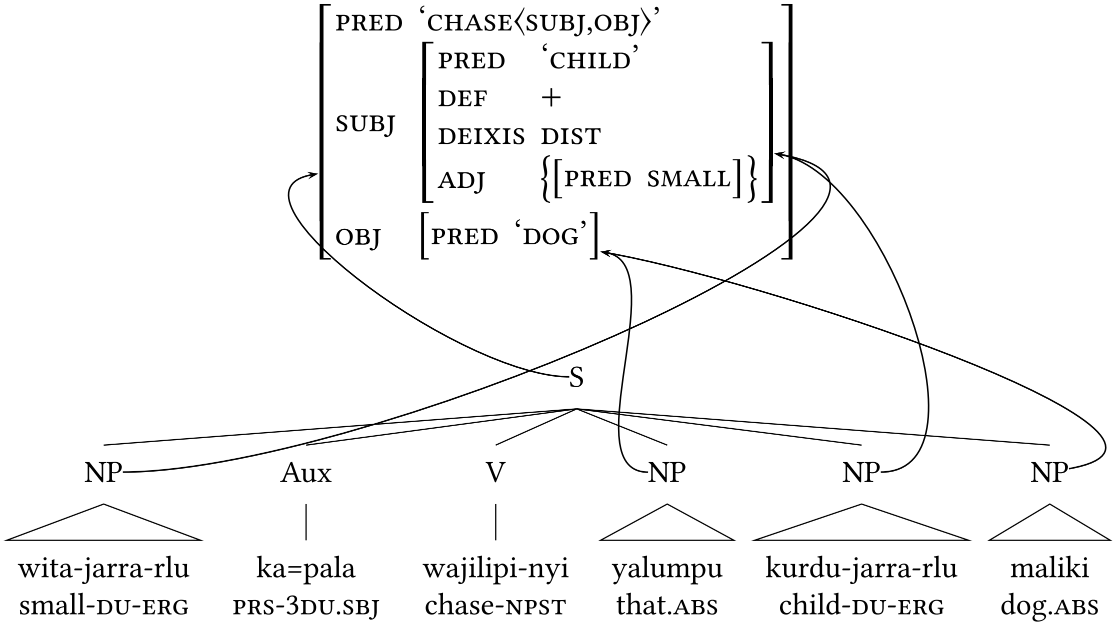

Figure 2: Simple c-structure/f-structure correspondences in Warlpiri

(Baker & Nordlinger 2008, Baker et al. 2010), Anindilyakwa (van Egmond 2008), Arrernte (Dras et al. 2012) and Murrinhpatha (Seiss & Nordlinger 2010, Seiss 2013). The morphosyntactic properties of Australian languages that have been discussed and analysed in this LFG literature range from clause structure and especially non-configurationality (Simpson 1991, Austin & Bresnan 1996, Nordlinger & Bresnan 2011, Snijders 2015; see also Andrews 2023a [this volume]); the role of morphology in encoding grammatical relations (Nordlinger & Bresnan 2011, Nordlinger 1998b) including pronominal incorporation and verbal agreement (Austin & Bresnan 1996) and case marking (Simpson 1991, Andrews 1996, Nordlinger 1998b, Andrews 2017); and flexible noun phrase structure and discontinuity (Simpson 1991, Sadler & Nordlinger 2006a, 2010, Snijders 2016) to other morphosyntactic interactions such as the marking of tense/aspect/mood on NPs (Nordlinger & Sadler 2004a), valency-changing phenomena (Austin 1997, Seiss & Nordlinger 2010) and complex predicates (Wilson 1999, Andrews & Manning 1999). These are discussed further in Section 3.

Given the morphological complexity of Australian languages – some head-marking and even polysynthetic, and others heavily dependent-marking – the LFG work on Australian languages has focussed largely on the morphology-syntax interface. It is here that the data from Australian languages contributes most to the development of LFG theory, and where the flexibility afforded by LFG's parallel architecture, which separates c-structure from f-structure with a many-to-many mapping between them, allows for a natural and explanatory account of the morphosyntax of Australian languages. Crucial to this flexibility is the fact that words (and therefore morphology) can contribute information directly to the f-structure alongside, or instead of, f-structure information coming from the c-structure. This enables the framework to capture the cross-linguistic generalisation that languages rich in morphological structure, such as the Australian languages, often make less use of phrase structure – a generalization that Bresnan (2001: 7) captures with the slogan "morphology competes with syntax" – essentially words and phrases are different means of encoding the same grammatical relations (Nordlinger & Bresnan 2011). The unification-based architecture of LFG allows for compatible information from different structural sources to integrate into a single f-structure. The independence of grammatical functions from c-structure, along with features such as economy of expression (allowing for the optionality of c-structure heads) and an exocentric S category have contributed to the analysis of Australian languages in the framework, as discussed in more detail in Section 3. In return, the empirical questions prompted by these theoretical analyses and their predictions have led to a more detailed understanding of the intricate grammatical structures of various Australian languages, and explain the appeal of the LFG formalism for fieldworkers engaged in Australian language documentation.

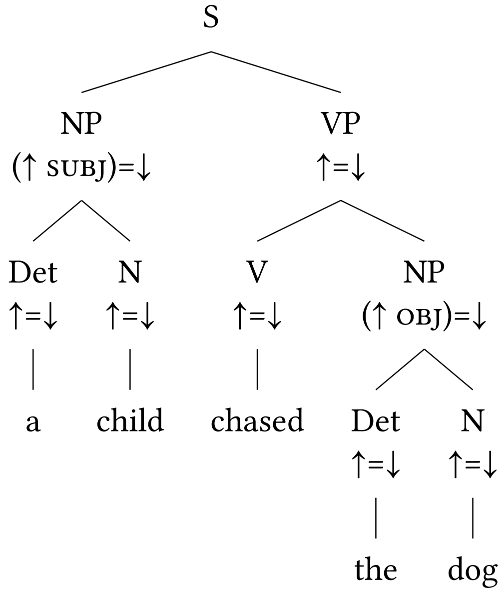
3 Phenomena analysed within LFG

3.1 Non-configurational clausal structure

Simpson (1983: 18) observes that "Warlpiri, a Pama-Nyungan language spoken in Central Australia, is a language in which the burden of representing the relations between predicates and arguments [...] is borne by the morphology rather than the syntax." Thus, many properties commonly associated with constituent structure in languages such as English are instead associated with morphological structure in Warlpiri, including the encoding of grammatical relations such as subject and object. In a configurational language like English grammatical relations can be associated with positions in a hierarchical constituent structure, as shown in (7b).

(7) a. A child chased the dog.

b.



In a language such as Warlpiri, on the other hand, constituent structure plays no role in identifying the grammatical relations of subject and object, as shown by the fact that the NPs in the Warlpiri sentence in (8) can appear in any position in the clause without affecting the meaning. Rather, it is the case marking, the morphological information carried by the nominals themselves, that plays the role of encoding grammatical relations information. In (8), the presence of the ergative case on ‘child’ and absolutive case on ‘dog’ unambiguously identifies the former as the subject NP and the latter as the object NP, irrespective of their positions in the constituent structure.

(8) Warlpiri
Kurdu-ngku maliki wajilipu-ngu.
child-ERG dog.ABS chase-PST
‘A child chased the dog.’ (Mary Laughren, pers. comm.)

Maliki wajilipu-ngu kurdu-ngku
Wajilipu-ngu kurdu-ngku maliki
Maliki kurdu-ngku wajilipu-ngu
Kurdu-ngku wajilipu-ngu maliki
Wajilipu-ngu maliki kurdu-ngku.

The disassociation of grammatical functions from hierarchical constituent structure in this way is known as ‘non-configurationality’, and discussion of Warlpiri, as well as some other dependent-marking Australian languages such as Wambaya (Nordlinger 1998b) and Jiwarli (Austin & Bresnan 1996, Austin 2001a) has been central to debates about the ways in which such languages are syntactically distinct from more configurational languages, and how best to represent these differences in formal syntactic theory. Hale (1983) identifies three key properties of Warlpiri syntax that he considers to be characteristic of its non-configurational structure: 'free word order' as illustrated in (8), 'the use of syntactically discontinuous expressions', whereby elements relating to the same grammatical relation can be discontinuous in the clause (9), and 'extensive use of null anaphora', which allows for the free omission of argument NPs (10).

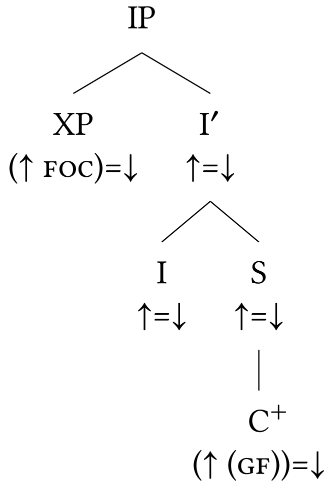
(9) Warlpiri
Wawirri kapi=rna panti-rni yalumpu
kangaroo.ABS AUX=1.SG.SBJ spear-NPST that.ABS
'I will spear that kangaroo.' (Hale 1983: 6)

(10) Warlpiri
Panti-rni ka.
spear-NPST AUX
'He/she is spearing him/her/it.' (Hale 1983: 7)

Each of these properties illustrates the fact that grammatical relations in Warlpiri (and other similarly non-configurational languages) are not uniquely determined by the phrase structure position of the relevant argument NP. The fact that argument NPs can grammatically appear in any position in the clause, and that there can be multiple, discontiguous positions associated with the same grammatical function suggest that standard endocentric principles of X′ Theory do not apply uniformly in these languages. The free omission of argument NPs indicates that information about grammatical relations can be encoded elsewhere in the clause (e.g. as part of the verb's lexical and/or morphological content), not necessarily by phrase structure position. Austin & Bresnan (1996) show that these three properties vary independently of each other and that a language may be non-configurational without allowing 'discontinuous NPs', for example; rather, what is definitional for non-configurationality is the fact that grammatical relations are not directly defined by phrase structure position.

Simpson (1983, 1991) (also Hale 1983, Austin & Bresnan 1996, Nordlinger 1998b) argue that such non-configurationality supports a theoretical model in which phrase structure constituency is separated from functional relations, as in LFG (Austin & Bresnan 1996 call this the 'dual structure' hypothesis). The principles of c-structure in LFG, in addition to the standard categories determined by X′ theory, include a non-projective category S, distinguished from these other categories by the fact that it is not headed by something of the same category as itself (exocentric) (Bresnan 2001; see also Andrews 2023a [this volume]). The availability of this category in c-structure allows for languages to have non-hierarchical, non-configurational phrase structures. Since this category is non-projective and exocentric, it can have a head of any category and, since it is not subject to the constraints of X′ Theory, it can dominate multiple constituents not bearing the typical relations of sisters in endocentric structures. Thus, S may define a totally flat phrase structure in which all constituents are sisters – all daughters of the clause – and functional annotations are assigned freely to all constituents, thereby capturing properties such as free word order and the possibility of discontinuous constituents. Following the analysis of Warlpiri c-structure provided by Austin & Bresnan (1996), the c-structure of a basic Warlpiri sentence can be given as in (11):[3]

(11)



Where C = X^0, or NP

In this structure a non-configurational category S is generated as a sister to I within IP.[4] I is the position of the auxiliary, and the (optional) specifier of IP carries the discourse function of focus. The annotation (↑ (gf)) = ↓ associated with the constituents of S indicates that the functional annotations ↑ = ↓ (the head

---

[3] Note that this is a more elaborated c-structure than the simplified version shown in Figure 2, which captures the fact that the auxiliary is required to appear in second position. See Austin & Bresnan (1996) for more detailed discussion.

[4] In some non-configurational languages such as Jiwarli (Austin & Bresnan 1996) there may be no evidence for an IP so that the top node of a clause is simply S.

relation) and (↑ GF) = ↓ (where GF stands for the disjunction of all possible grammatical functions) are assigned freely within S (Simpson 1991, Austin & Bresnan 1996). Effectively this means that no specific functions are assigned within S at all. Rather, it is the information encoded in the morphology in conjunction with the principles of Completeness and Coherence (see Belyaev 2023 [this volume]) that ensures a grammatical c-structure and f-structure.

The principle of Economy of Expression in LFG (Bresnan 2001) states that all phrase structure nodes are optional unless they are required by independent principles. This allows for the possibility of null anaphora, since argument NPs are not required if the relevant grammatical function information is also contributed by morphological information (or by something else in the structure). Grammatical relations such as SUBJECT and OBJECT are encoded at f-structure and, since words in LFG can contribute information to the f-structure in the same way as syntactic phrases (Belyaev 2023 [this volume]), words can contribute grammatical function information to f-structure directly, without the need for such information to also be reflected in the phrase structure. This provides a great deal of flexibility in terms of where and how different languages may encode grammatical function information, and even allows for languages to express it redundantly in both the phrasal syntax and the morphology, as long as the information is compatible under unification at f-structure (see Nordlinger (1998b: Chapter 3) for detailed discussion). Dependent-marking non-configurational languages such as Jiwarli (Austin 2001a) encode grammatical function information primarily in case marking morphology, while head-marking non-configurational languages such as Bininj Gun-wok do this through verbal morphology. Warlpiri, with both case marking and pronominal argument clitics, combines both of these properties. These options and their treatment in LFG are shown in the following (examples repeated from (1), (5) and (9) above):

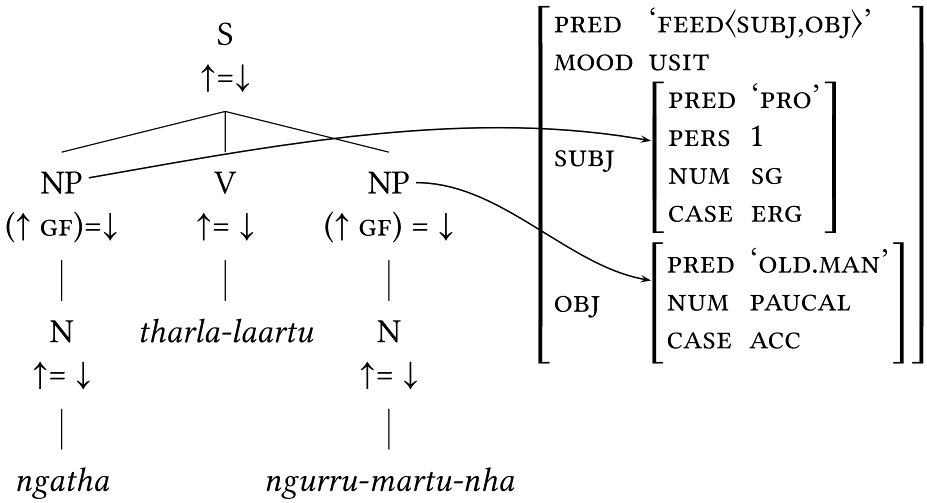
(12) Jiwarli

Ngatha	tharla-laartu	ngurru-martu-nha.
1SG.ERG	feed-USIT	old.man-GROUP-ACC

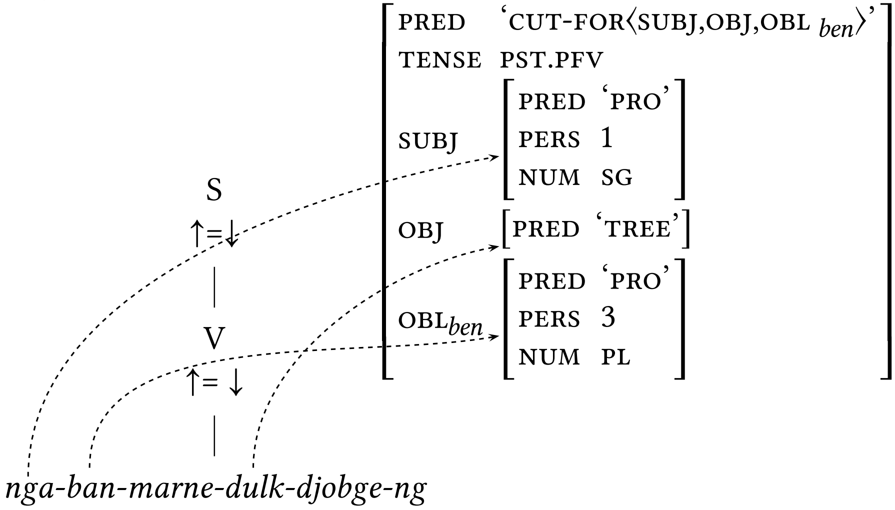
‘I used to feed the old men.’ [5]

---

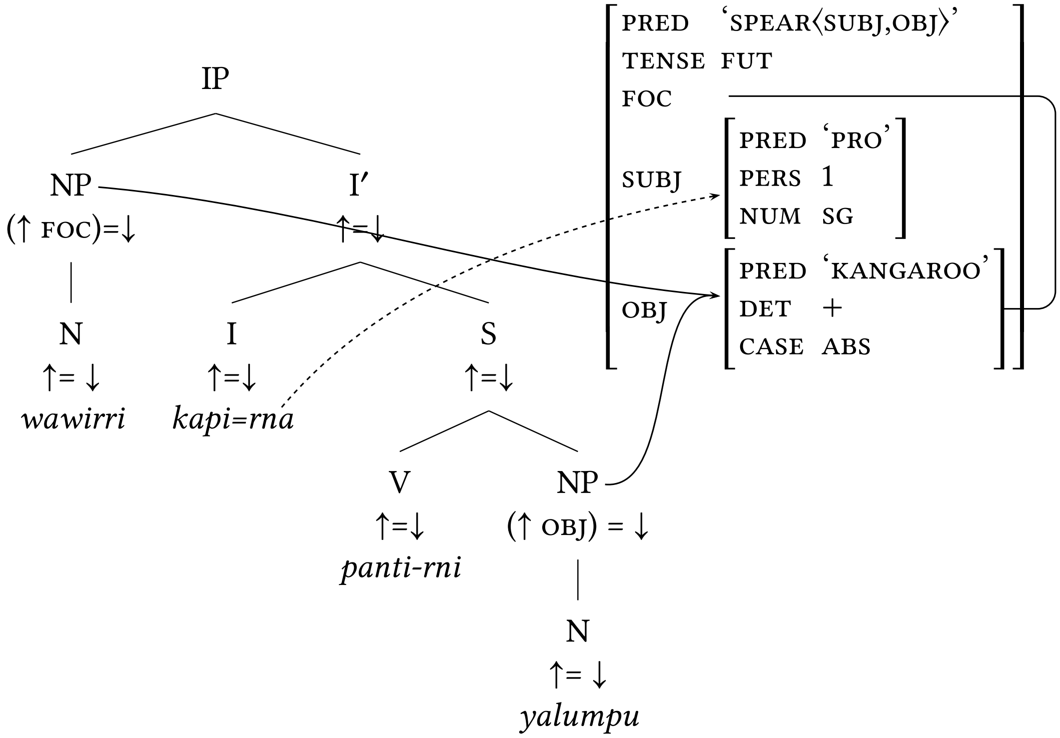
[5] This example is modified from Austin (2001a: 310). I have left the adjunct phrase *pirru-ngku* ‘with meat’ out here just to simplify the structures for presentational purposes.



(13) Bininj Gun-wok
Nga-ban-marne-dulk-djobge-ng.
1SG.SBJ-3PL.OBJ-BEN-tree-cut-PST.PFV
‘I cut the tree for them.’



(14) Warlpiri
Wawirri kapi=rna panti-rni yalumpu
kangaroo.ABS AUX=1.SG.SBJ spear-NPST that.ABS
‘I will spear that kangaroo.’



In head-marking languages, grammatical function information is encoded as part of the inflected verb's lexical entry, associated with verbal agreement morphology in the usual way (see Haug 2023 [this volume], also Börjars et al. 2019: Chapter 4 for detailed exemplification). Consider a Bininj Gun-wok verb such as that given in (15), the lexical entry for which is shown in (16). Following Bresnan & Mchombo (1987), the PRED values associated with the verbal morphology are optional to capture the fact that the verb can combine optionally with external argument NPs. When there are no co-referential NPs in the clause, the principle of Completeness will ensure that the PRED 'PRO' features are present, since otherwise the resulting f-structure will be incomplete, containing a SUBJECT and OBJECT lacking PRED features. In the presence of a co-referential NP, however, as in example (15), the OBJ PRED feature will be omitted since it will not be able to unify with the PRED value of the external object NP (see Belyaev 2023 [this volume] for discussion of the Uniqueness principle and PRED values). This flexibility captures the fact that such verbal morphology can function as pronominal arguments, and also as agreement morphology in the presence of external NPs (see Toivonen 2023 [this volume]).

(15) Bininj Gun-wok
Abanmani-na-ng bininj.
1SG.SBJ:3DU.OBJ-see-PST.PFV man
'I saw the two men.' (Evans 2003: 417)

(16) *abanmaninang* (↑ PRED) = 'SEE⟨SUBJ,OBJ⟩'
(↑ TENSE) = PST.PFV
((↑ SUBJ PRED) = 'PRO')
(↑ SUBJ PERS) = 1
(↑ SUBJ NUM) = SG
((↑ OBJ PRED) = 'PRO')
(↑ OBJ PERS) = 3
(↑ OBJ NUM) = DU

In dependent-marking languages, such as Jiwarli and Warlpiri, grammatical function information is encoded by case morphology. There have been a number of different approaches to capturing this in LFG. Simpson (1983, 1991) assumes a verb-mediated approach, where verbs select for the case values of their arguments in their lexical entries. Thus, a verb such as *panti-* 'spear' would include in its lexical entry (↑ SUBJ CASE)=ERG and (↑ OBJ CASE)=ABS, which then must unify with the case value of the NP in the f-structure, constrained by the principles of Completeness and Coherence. Nordlinger & Bresnan (2011) supplement the verb-mediated approach with case conditionals of the type in (17), thus capturing the generalisation that there is a direct relationship between case and the encoding of grammatical functions.

(17) $(\downarrow \text{CASE}) = \kappa \Rightarrow (\uparrow \text{GF}) = \downarrow$

The idea is that each case value (represented here by κ) is associated in the grammar with a set of grammatical functions. For example, the case conditional for the Warlpiri ergative case might look as in (18), which specifies that an element with ergative case is to be associated with the subject grammatical function:

(18) $(\downarrow \text{CASE}) = \text{ERG} \Rightarrow (\uparrow \text{SUBJ}) = \downarrow$

Thus, by virtue of its case value each NP is assigned a grammatical function (or set of possible functions). In addition, verbs and other lexical predicators select for the case features of their arguments.[6] The unification of the possible functions

---

[6] In the majority of cases this is predictable from the argument structure of the verb, so can be covered by a lexical rule.

of the NP and the requirements of the predicator, in conjunction with the general principles of Uniqueness, Completeness and Coherence, ensures that the NPs in the c-structure are associated with the appropriate grammatical functions in the corresponding f-structure.

For example, a transitive verb stem such as *wajilipi-* 'chase' requires that its subject have ergative case and its object have absolutive case, thus corresponding to an f-structure such as the following:

(19)

$$\begin{bmatrix} \textsc{pred} & \text{`}\textsc{chase}\langle\textsc{subj,obj}\rangle\text{'} \\ \textsc{subj} & \begin{bmatrix}\textsc{case} & \textsc{erg}\end{bmatrix} \\ \textsc{obj} & \begin{bmatrix}\textsc{case} & \textsc{abs}\end{bmatrix} \end{bmatrix}$$

The only f-structures for a sentence headed by this verb stem that satisfy Completeness and Coherence will be those in which an absolutive NP is identified with the OBJ grammatical function and an ergative NP is identified with the SUBJ grammatical function. Thus, the f-structure for the sentence in (20a) is that given in (20b).

(20) a. Warlpiri
Kurdu-ngku maliki wajilipu-ngu.
child-ERG dog.ABS chase-PST
'A child chased the dog.'

b.

$$\begin{bmatrix} \textsc{pred} & \text{`}\textsc{chase}\langle\textsc{subj,obj}\rangle\text{'} \\ \textsc{tense} & \textsc{pst} \\ \textsc{subj} & \begin{bmatrix}\textsc{pred} & \text{`}\textsc{child}\text{'} \\ \textsc{case} & \textsc{erg}\end{bmatrix} \\ \textsc{obj} & \begin{bmatrix}\textsc{pred} & \text{`}\textsc{dog}\text{'} \\ \textsc{case} & \textsc{abs}\end{bmatrix} \end{bmatrix}$$

Nordlinger (1998b) provides a third approach to the analysis of case morphology and its role in encoding grammatical relations, known as 'constructive case'. This is discussed in more detail in Section 3.3.

The discussion of non-configurationality in Australian languages and its treatment in LFG has been expanded in more recent years to integrate information structure and its interaction with different word order possibilities. Simpson (2007) focusses on Warlpiri and the pragmatic constraints on its different word orders; this is also discussed for Jiwarli in Austin (2001a). Snijders (2015) builds on and expands the earlier LFG work to provide a typology of configurationality that integrates information structure into the analysis, and extends the discussion beyond just the languages of Australia.

3.2 Flexible NP structure

Another feature common to many Australian languages that has been the subject of theoretical work in LFG is flexibility of NP structure.[7] While some researchers (including Hale 1983) consider this phenomenon to be central to the issue of non-configurationality, in fact – as Austin & Bresnan (1996), Nordlinger (1998b) and others have argued – the two phenomena are logically distinct, although they may co-exist in a single language of course, as found in Warlpiri (Hale 1983), Jiwarli (Austin 2001a), Wambaya (Nordlinger 1998b) and many other Australian languages. It is possible, however, for a language to be non-configurational at the clausal level while having strictly defined and non-flexible NPs. This is what we find in the Australian languages Kayardild (Evans 1995) and Murrinhpatha (Mujkic 2013), for example, both of which have clearly defined NP constituents with little or no discontinuity, while allowing great word order freedom at the clausal level and no clear association of grammatical relations with phrase structure. Languages such as these are thus non-configurational as discussed in Section 3.1 despite not allowing discontiguous nominal phrases.

The flexibility of NP structure in (some) Australian languages has been addressed within the LFG literature with regards to two different aspects. The first of these is NP discontinuity, the general LFG approach to which was discussed in Section 3.1 above (see also Snijders 2016 and Börjars & Lowe 2023 [this volume]). The second is nominal juxtaposition – whereby many semantically different NP structures, including coordination, are expressed through the simple juxtaposition of nominals in seemingly flat NP structures (Sadler & Nordlinger 2006a, 2010). Sadler & Nordlinger (2010) provide the following illustrative examples:

(21) Coordination (Nyangumarta)
Pala-nga ngatu jarri-nya-pinti-ngi, mima-nikinyi-yi puluku,
that-LOC stationary INCH-NMLZ-ASSOC-LOC wait.for-IPFV-3PL.SBJ 3DU.DAT
kujarra kangkuru-jirri waraja yalapara.
two kangaroo-DU one goanna
'And there, on the finishing line, the two kangaroos and one goanna waited for those two.' (Sharp 2004: 315)

---

[7] Recent work investigating this aspect of Australian languages in more detail includes Louagie & Verstraete (2016), Louagie (2020) and Reinöhl (2020). The details of these typological studies have not yet been fully addressed within LFG analyses.

(22) Generic-Specific (Yidiny)
Gana mayi jimirr jula:lin.
try vegetable(abs) yam(abs) dig.going.imp
'Go and try to dig some yams up!' (Dixon 1977: 247)[8]

(23) Apposition (Wambaya)
Garidi-ni bungmanyi-ni gin-amany yanybi.
husband-erg old.man-erg 3sg.m.sbj-pst.twd get
'(Her) old man husband came and got (her).' (Nordlinger 1998a: 133)

(24) Inclusory (Kayardild)
Nga-rr-a kajakaja warra-ja thaa-th.
1-du-nom daddy.nom go-act return-act
'Daddy and I will go.' (lit. 'We two, including daddy, will go') (Evans 1995: 249)

Sadler & Nordlinger (2010) draw on the standard LFG treatment of coordination (Dalrymple & Kaplan 2000) to account for asyndetic coordination structures such as (21). Thus, the coordination structure is licensed by the c-structure rule in (25), where X is a metavariable ranging over N and NP, and the syntactic resolution of pers and num features that is characteristic of coordination is captured by the template @np-cnjt associated with each coordinand, which is defined as in (26). The resulting f-structure of the coordinated NP in (21) is given in (27).

(25)
$$\textsc{x} \longrightarrow \begin{array}{c} \textsc{x} \\ \downarrow \in \uparrow \\ @\textsc{np-cnjt} \end{array} \quad , \quad \begin{array}{c} \textsc{x} \\ \downarrow \in \uparrow \\ @\textsc{np-cnjt} \end{array}$$

(26)
$$\textsc{np-cnjt}\textit{:} \quad \begin{array}{l} (\downarrow \textsc{ind pers}) \subseteq (\uparrow \textsc{ind pers}) \\ (\downarrow \textsc{ind num}) \subseteq (\uparrow \textsc{ind num}) \end{array}$$

(27)
$$\begin{bmatrix} \textsc{index} & \begin{bmatrix} \textsc{pers} & 3 \\ \textsc{num} & \textsc{pl} \end{bmatrix} \\ \multicolumn{2}{l}{\left\{ \begin{array}{l} \begin{bmatrix} \textsc{pred} & \text{‘}\textsc{goanna}\text{’} \\ \textsc{index} & \begin{bmatrix} \textsc{pers} & 3 \\ \textsc{num} & \textsc{sg} \end{bmatrix} \end{bmatrix} \\ \begin{bmatrix} \textsc{pred} & \text{‘}\textsc{kangaroo}\text{’} \\ \textsc{index} & \begin{bmatrix} \textsc{pers} & 3 \\ \textsc{num} & \textsc{du} \end{bmatrix} \end{bmatrix} \end{array} \right\}} \end{bmatrix}$$

---

[8] This Yidiny example has been rewritten in a standard practical orthography which uses 'ny' for a palatal nasal, 'j' for a palatal stop and 'rr' for an alveolar trill.

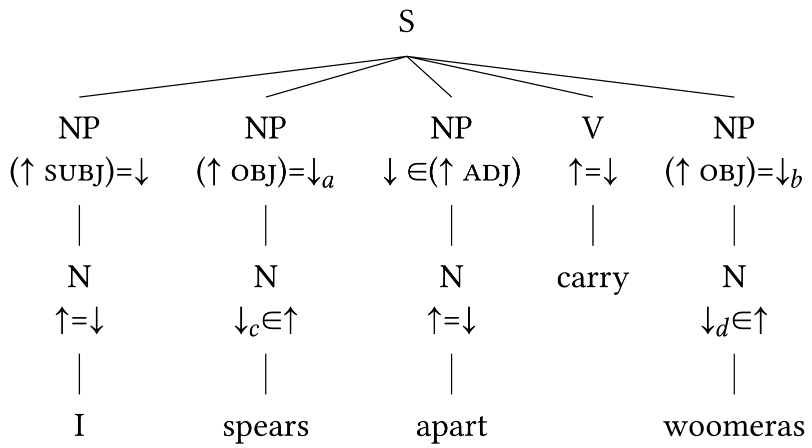
Sadler & Nordlinger (2010) show how this approach to coordination also extends naturally to discontinuous examples such as (28) by combining the standard LFG approach to discontinuity and non-configurationality discussed in Section 3.1 above. Since Economy of Expression allows all nodes to be optional unless independently required, each of the discontiguous coordinands can be represented at c-structure as a coordinate structure with just one daughter present (29), corresponding to the f-structure in (30).

(28) Kuuk Thaayorre

Ngul	ngay	kirk	kempthe	kal-m	thul=yuk.
then	1SG(ERG)	spear(ACC)	apart	carry-PST.IPFV	woomera(ACC)=STUFF

‘I used to carry spears and woomeras separately.’ (Gaby 2006: 320)

(29)



(30)

$$\left[\begin{array}{ll}
\text{PRED} & \text{‘CARRY}\langle\text{SUBJ,OBJ}\rangle\text{’} \\
\text{ADJ} & \left\{\left[\text{PRED ‘APART’}\right]\right\} \\
\text{SUBJ} & \left[\begin{array}{ll}\text{PRED} & \text{‘PRO’} \\ \text{INDEX} & \left[\begin{array}{ll}\text{PERS} & 1 \\ \text{NUM} & \text{SG}\end{array}\right]\end{array}\right] \\
\text{OBJ} & {}_{\substack{a\\b}}\left[\begin{array}{ll}
\multicolumn{2}{l}{\left\{\begin{array}{l}
{}_{c}\left[\begin{array}{ll}\text{PRED} & \text{‘SPEAR’} \\ \text{CASE} & \text{ACC} \\ \text{INDEX} & \left[\begin{array}{ll}\text{PERS} & 3 \\ \text{NUM} & \text{PL}\end{array}\right]\end{array}\right] \\
{}_{d}\left[\begin{array}{ll}\text{PRED} & \text{‘WOOMERA’} \\ \text{CASE} & \text{ACC} \\ \text{INDEX} & \left[\begin{array}{ll}\text{PERS} & 3 \\ \text{NUM} & \text{PL}\end{array}\right]\end{array}\right]
\end{array}\right\}} \\
\text{INDEX} & \left[\begin{array}{ll}\text{PERS} & 3 \\ \text{NUM} & \text{PL}\end{array}\right]
\end{array}\right]
\end{array}\right]$$

All of the other instances of nominal juxtaposition exemplified above are also assumed to have the same syntactic structure with the differences between them arising from differences in the distribution of agreement features, and semantics. An appositional phrase such as (23), for example, is generated by the c-structure rule in (31), which is the same as the c-structure rule for coordination given in (25) except for the fact that each coordinand is associated with the appositional template @NP-APPOS instead of @NP-CNJT. The appositional template governs the distribution of agreement features as shown in (32). This ensures that the coordinated structure has the same INDEX features as each coordinand, as shown in the f-structure in (33).

(31)
$$\text{X} \longrightarrow \begin{array}{c}\text{X}\\ \downarrow\in\uparrow\\ @\text{NP-APPOS}\end{array} \quad , \quad \begin{array}{c}\text{X}\\ \downarrow\in\uparrow\\ @\text{NP-APPOS}\end{array}$$

(32) NP-APPOS: $(\downarrow \text{IND}) \subseteq (\uparrow \text{IND})$

(33)
$$\left[\begin{array}{l} \begin{array}{ll}\text{INDEX} & \left[\begin{array}{ll}\text{PERS}&3\\ \text{NUM}&\text{SG}\\ \text{GEND}&\text{MASC}\end{array}\right]\end{array}\\ \left\{\begin{array}{l} \left[\begin{array}{ll}\text{PRED}&\text{`HUSBAND'}\\ \text{INDEX}&\left[\begin{array}{ll}\text{PERS}&3\\ \text{NUM}&\text{SG}\\ \text{GEND}&\text{MASC}\end{array}\right]\end{array}\right]\\ \left[\begin{array}{ll}\text{PRED}&\text{`OLD.MAN'}\\ \text{INDEX}&\left[\begin{array}{ll}\text{PERS}&3\\ \text{NUM}&\text{SG}\\ \text{GEND}&\text{MASC}\end{array}\right]\end{array}\right]\end{array}\right\}\end{array}\right]$$

Sadler & Nordlinger (2010) show how the different juxtaposed structures can be captured in LFG by assuming that they all share the same syntactic structure (modulo differences in the distribution of agreement features, as illustrated above), while mapping onto different semantics. In this way the flexible architecture of LFG provides a unified account of a range of juxtaposed nominal constructions common to many Australian languages, while still accounting for their semantic differences, through the use of hybrid structures already motivated independently for analyses of coordination (Dalrymple & Kaplan 2000) (see also Patejuk 2023 [this volume]).

3.3 Constructive case and case stacking

In Section 3.1 above we saw that case marking in non-configurational languages can encode grammatical relations, and saw that one way of capturing this in LFG is through the use of case conditionals. Nordlinger (1998b) provides an alternative approach, known as constructive case, which uses inside-out function application (see Belyaev 2023 [this volume]) to capture the fact that the grammatical function information comes directly from the case morphology itself. Returning to the Warlpiri example discussed in (20a), on the constructive case approach the functional information associated with the ERG case would be that in (34):[9]

(34) (↑ CASE) = ERG
(SUBJ ↑)

The second line in this functional description specifies that the f-structure with which the case morphology is associated (i.e. ↑) is the value of a SUBJ function in a higher f-structure. Thus, the inflected nominal *kurdu-ngku* ‘child-ERG’ does not just encode the fact that the nominal is inflected with ergative case, but also that the nominal is functioning as a subject of the higher clause, corresponding to the f-structure given in (35):

(35)
$$\left[\text{SUBJ}\ \left[\begin{array}{ll}\text{PRED} & \text{‘CHILD’}\\ \text{CASE} & \text{ERG}\end{array}\right]\right]$$

This approach has the benefit of capturing the essence of dependent-marking more accurately than the verb-mediated approaches described in Section 3.1 since the case-inflected nominal itself carries information about the grammatical function that it holds in the higher clausal f-structure. A further benefit, as discussed in detail by Nordlinger (1998b), is that it can straightforwardly capture other case behaviour found in dependent-marking Australian languages such as case stacking (Dench & Evans 1988, Andrews 1996), and the use of case morphology to mark clausal information such as tense/aspect/mood.

Case stacking arises through abundant case agreement, where a single nominal can carry multiple case markers, each one signalling a relationship to a higher level of structure. Consider the following examples:

---

[9] This is a slightly simplified representation for expository purposes. Nordlinger (1998b: 73) in fact suggests that the grammatical function information would be ((SUBJ ↑) OBJ) for ergative case, to capture the fact that it is only used with transitive subjects (i.e. subjects of f-structures that also contain an OBJ grammatical function).

(36) Warlpiri
Karnta-ngku ka=rla kurdu-ku miyi yi-nyi parraja-rla-ku.
woman-ERG PRS=3.DAT baby-DAT food.ABS give-NPST coolamon-LOC-DAT
'The woman is giving food to the baby (who is) in the coolamon.'
(Simpson 1991: 206)

(37) Martuthunira
Ngayu nhuwa-lhala tharnta-a kupuyu-marta-a thara-ngka-marta-a.
1.SG.NOM spear-PST euro-ACC little-PROP-ACC pouch-LOC-PROP-ACC
'I speared a euro with a little one in its pouch.' (Dench & Evans 1988: 7)

In (36) the locative-marked nominal *parraja-rla* 'coolamon' carries an additional case marker in agreement with the dative nominal *kurdu-ku* 'baby' which it modifies. Thus, the case marking on 'coolamon' specifies two different structural relationships: first, the locative case specifies that 'coolamon' functions as part of a locative adjunct, and then the dative case specifies that this locative adjunct is part of a higher dative-marked oblique argument. In (37), the most deeply embedded nominal *thara* 'pouch' is inflected with three case markers, each one specifying a successively higher structural relationship. Thus, the single inflected nominal *thara-ngka-marta-a* constructs the f-structure shown in (38).

(38)
$$\left[\text{OBJ}\ \left[\begin{array}{ll}\text{CASE} & \text{ACC}\\ \text{ADJ}_{\text{PROP}} & \left\{\left[\begin{array}{ll}\text{CASE} & \text{PROP}\\ \text{ADJ}_{\text{LOC}} & \left\{\left[\begin{array}{ll}\text{PRED} & \text{‘POUCH’}\\ \text{CASE} & \text{LOC}\end{array}\right]\right\}\end{array}\right]\right\}\end{array}\right]\right]$$

Nordlinger (1998b) shows that this approach can account for a range of case stacking structures in Australian languages, as well as the interaction of case stacking with number marking and possession (see Chapters 4 and 5 therein). Sadler & Nordlinger (2004, 2006b) extend and improve Nordlinger's formal account to provide an analysis that integrates better with an LFG approach to the morphology-syntax interface (Sadler & Nordlinger 2004), and also show how Nordlinger's original morpheme-based account can be recast using a realizational approach to morphology (Sadler & Nordlinger 2006b). In some Australian languages, case morphology can also be used in complex clauses to encode cross-clausal reference and clause linkage relations. For discussion of how this use of case can be accounted for within the constructive case approach see Nordlinger (2000) and Austin (2016).

The fact that case morphology provides information to the clausal f-structure (by attributing a grammatical function to it) allows for case morphology to contribute other types of clausal information as well, such as tense/aspect/mood.[10]

---

[10] A different type of interaction between case morphology and the clause arises with semantic cases that can also function as clausal predicates; see Simpson (1991) for discussion.

Nordlinger (1998b: Chapter 4) shows that this is also found in some Australian languages, and can be accounted for straightforwardly with the constructive case approach. In Pitta Pitta (Blake 1987), for example, there are two ergative case morphs, one which is used in the future tense and the other in the non-future tense. The information associated with each of these can be represented as below, where the second f-description in each case specifies that the f-structure within which the case-marked nominal has a grammatical function (namely, the clausal f-structure) has a particular value for TENSE. The tense information associated with the case marker will be unified with the clausal f-structure and any tense information associated with the verb, thereby contributing to the overall tense value of the clause.

(39) *-lu* (↑ CASE) = ERG
((SUBJ ↑) TENSE) ≠ FUT

(40) *-ngu* (↑ CASE) = ERG
((SUBJ ↑) TENSE) = FUT

While it is typologically unusual for nominal morphology such as case to contribute clause-level information such as tense/aspect/mood, it is in fact found across languages of the world as shown by Nordlinger & Sadler (2004a,b). For a more detailed discussion of case in the LFG framework, see Butt 2023 [this volume].

3.4 Complex predicates

A number of Australian languages have complex predicates that take the form of light verb and coverb structures (see Andrews 2023b [this volume] for a more detailed discussion; the construction type focussed on here corresponds to type (1b) in this chapter). Detailed discussion of these constructions across Australian languages can be found in Schultze-Berndt (2000), McGregor (2000) and Bowern (2014). An example from Schultze-Berndt's discussion of Jaminjung is provided in (41).

(41) Jaminjung
walig gani-ma-m barrig.
go.round 3SG:3SG-HIT-PRS paddock
'He walks around the fence (in a full circle).' (Schultze-Berndt 2000: 4)

In this construction the clausal predicate is formed through the combination of a finite inflected verb (e.g. *gani-ma-m*) with a coverb (e.g. *walig*). The two elements of the construction belong to distinct lexical classes, and thus are morphologically and syntactically different. Finite verbs are inflected for tense/aspect/

mood and other verbal inflectional categories such as subject and object features. They form a closed class – in many languages restricted to between 10 and 30 members – and tend to have more general semantics (at least within the complex predicate). Coverbs, on the other hand, are usually uninflected, form a large open class and contribute more specific semantic content. The two elements together jointly determine the argument structure and event semantics, and therefore jointly construct the clausal predicate. In the languages of northern Australia where these constructions are found (see Bowern 2014), the majority of predicates are complex in this way.

Wilson (1999) provides a detailed LFG analysis of such complex predicates in Wagiman. Wilson shows that both the finite verb and the coverb in Wagiman are argument-taking predicates, and therefore each have their own PRED values, yet the complex predicate heads a single syntactic clause which in LFG requires a single clausal PRED at f-structure. To account for this, Wilson develops an account of complex predicate formation which uses a type of predicate fusion, modelled using lexical-conceptual structures (Jackendoff 1990), drawing on earlier work in LFG by Alsina (1993, 1996), Butt (1995, 1997), Mohanan (1994, 1997) and Andrews & Manning (1999).

Wilson's analysis follows that of Butt (1995, 1997) in using lexical conceptual structures (LCSS) to model complex predicate formation, but follows Andrews & Manning (1999) in locating these in f-structure (rather than a-structure as Butt does), replacing the PRED attribute with the more elaborated LCS attribute instead. Wilson proposes that the LCS of the coverb fuses into any position of the LCS of the finite verb where it is able to unify (Wilson 1999: 142). As an illustrative example, consider the complex predicate in (42):

(42) Wagiman
guk-ga nge-ge-na gahan warri-buga?
sleep-ASP 2SG-put-PST that child-PL
'Did you put the kids to sleep?' (Wilson 1999: 136)

According to Wilson's analysis, the finite verb *nge-ge-na* has the LCS in (43), and the coverb *guk-* has the LCS in (44).[11]

(43) $[_{\text{Event}}\ \text{CAUSE}([_{\text{Thing}}\ ]_A, [_{\text{Event}}\ \text{BECOME}\ ([_{\text{State}}\ \text{BE}([_{\text{Thing}}\ ]_A,[_{\text{Place}}\ -])])])]$

---

[11] The abbreviations used in the LCSS and associated attribute value matrices (AVMS) are as follows: the subscripted As denote positions which have to be linked to grammatical functions – in the AVMS these correspond to the attribute A-MARK with the value 'yes'; 'Ident' stands for Identificational and is used to extend otherwise spatial functions (such as BE or AT) to the semantic field of ascription (thus, AT_{Ident} describes a property rather than a location); the value of the FUNC attribute in the AVMS is the function which expands the entity (e.g. GO, CAUSE, etc.). 'Thing' entities are not expanded by functions, but they can contain information about their referent, which is stored in the CONTENT attribute.

(44) $[_{\text{State}}\ \text{BE}_{\text{Ident}}\ ([_{\text{Thing}}\ ]_{A}, [_{\text{Place}}\ \text{AT}_{\text{Ident}}\ ([_{\text{Property}}\ \textit{asleep}])])]$

These can be presented as attribute value matrices, as shown in (45) and (46) respectively.

(45) From Wilson (1999: 145: example (36)):

$$\left[\begin{array}{ll} \text{TYPE} & \text{Event} \\ \text{FUNC} & \text{CAUSE} \\ \text{ARG1} & \left[\begin{array}{ll} \text{TYPE} & \text{Thing} \\ \text{CONTENT} & \varnothing \\ \text{A-MARK} & \text{yes} \end{array}\right] \\ \text{ARG2} & \left[\begin{array}{ll} \text{TYPE} & \text{Event} \\ \text{FUNC} & \text{BECOME} \\ \text{ARG1} & \left[\begin{array}{ll} \text{TYPE} & \text{State} \\ \text{FUNC} & \text{BE} \\ \text{ARG1} & \left[\begin{array}{ll} \text{TYPE} & \text{Thing} \\ \text{CONTENT} & \varnothing \\ \text{A-MARK} & \text{yes} \end{array}\right] \\ \text{ARG2} & \left[\begin{array}{ll} \text{TYPE} & \text{Place} \end{array}\right] \end{array}\right] \end{array}\right] \end{array}\right]$$

(46) From Wilson (1999: 147: example (39)):

$$\left[\begin{array}{ll} \text{TYPE} & \text{State} \\ \text{FUNC} & \text{BE} \\ \text{FIELD} & \text{Ident} \\ \text{ARG1} & \left[\begin{array}{ll} \text{TYPE} & \text{Thing} \\ \text{CONTENT} & \varnothing \\ \text{A-MARK} & \text{yes} \end{array}\right] \\ \text{ARG2} & \left[\begin{array}{ll} \text{TYPE} & \text{Place} \\ \text{FUNC} & \text{AT} \\ \text{FIELD} & \text{Ident} \\ \text{ARG1} & \left[\begin{array}{ll} \text{TYPE} & \text{Property} \\ \text{CONTENT} & \text{asleep} \end{array}\right] \end{array}\right] \end{array}\right]$$

The c-structure rule which creates the complex predicate in (42) includes functional annotations that license and constrain predicate fusion through the unification of these LCSs. This is shown in (47), where C is the category ‘coverb’ (Wilson 1999: 144).

(47)
$$\overline{\text{V}} \quad \longrightarrow \quad \begin{pmatrix} \text{C} \\ \uparrow\backslash_{\text{LCS}}{=}\downarrow\backslash_{\text{LCS}} \\ (\uparrow \text{LCS SF}^{*}){=}(\downarrow \text{LCS}) \end{pmatrix}, \quad \begin{array}{c} \text{V} \\ \uparrow{=}\downarrow \end{array}$$

The finite verb is annotated with ↑=↓ so that its inflectional features such as tense, aspect, and the information about the subject and object contribute to the f-structure of the complex predicate, and ultimately that of the clause. The annotations associated with the coverb ensure that (i) all information associated with the coverb apart from the lcs (e.g. any aspectual information) is contributed to the f-structure of the complex predicate, and (ii) the lcs of the coverb is fused into the lcs of the finite verb: (↑ lcs sf*) = (↓ lcs). Here sf stands for 'semantic function' and is defined as the set of attributes which can be contained in lcss such as (45) and (46) (e.g. type, func, arg1, arg2). The use of functional uncertainty allows the lcs of the coverb – (↓ lcs) – to unify with any part of the lcs of the finite verb (the path consisting of any sequence of sfs, including none). So the f-structure will only be licit if the expansion of sf* picks out a place in the lcs of the finite verb where unification with the lcs of the coverb is possible. In the case of the complex predicate given in (42), based on the lcss in (45) and (46), this path must be (↑ lcs arg2 arg1), since the coverb *guk* 'sleep' is of type State, and there is only one place in the lcs of the finite verb where this can unify. Thus, the fused lcs for the complex predicate *guk -ge-* 'put to sleep' is that given in (48):

(48) From Wilson (1999: 147: example (39)):

$$\left[\begin{array}{ll}
\text{TYPE} & \text{Event}\\
\text{FUNC} & \text{CAUSE}\\
\text{ARG1} & \left[\begin{array}{ll}\text{TYPE} & \text{Thing}\\ \text{CONTENT} & \varnothing\\ \text{A-MARK} & \text{yes}\end{array}\right]\\
\text{ARG2} & \left[\begin{array}{ll}
\text{TYPE} & \text{Event}\\
\text{FUNC} & \text{BECOME}\\
\text{ARG1} & \left[\begin{array}{ll}
\text{TYPE} & \text{State}\\
\text{FUNC} & \text{BE}\\
\text{FIELD} & \text{Ident}\\
\text{ARG1} & \left[\begin{array}{ll}\text{TYPE} & \text{Thing}\\ \text{CONTENT} & \varnothing\\ \text{A-MARK} & \text{yes}\end{array}\right]\\
\text{ARG2} & \left[\begin{array}{ll}
\text{TYPE} & \text{Place}\\
\text{FUNC} & \text{AT}\\
\text{FIELD} & \text{Ident}\\
\text{ARG1} & \left[\begin{array}{ll}\text{TYPE} & \text{Property}\\ \text{CONTENT} & \textit{asleep}\end{array}\right]
\end{array}\right]

\end{array}\right]
\end{array}\right]$$

Wilson shows that this approach to complex predicates in Wagiman can account for the range of different complex predicates found in the language, without requiring a radical extension of the LFG formalism beyond that already proposed by other complex predicate analyses (e.g. Alsina 1993, 1996; Butt 1995, 1997; Mohanan 1994, 1997; Andrews & Manning 1999). This general approach to the formal analysis of complex predicate formation in Australian languages has also been adopted by Bowern (2004) for Bardi, and Nordlinger (2010) for associated motion and motion serial verb constructions in Wambaya. An alternative approach to complex predicate formation using glue semantics as suggested in Andrews & Manning (1999) is proposed for the analysis of similar complex predicates in the central Australian language Arrernte by Dras et al. (2012).

Seiss (2013) provides a comprehensive analysis of the complex predicate system in Murrinhpatha which builds on the LCS-based approaches discussed above, but combines LCSs with a relational approach to lexical semantics, modelled with hierarchies of selectional restrictions. These hierarchies are then used to derive the argument structure of the complex predicates in the form of what Seiss calls LCS blueprints (based on the idea of templates, e.g. Dalrymple et al. 2004). The blueprint LCS for causative complex predicates such as those in (49) and (50) is defined as in (51). The LCS blueprint states that the complex predicate expresses the meaning that something or someone (α) causes something (β) to become a certain result state with the help of some specific instrument. In Murrinhpatha the complex predicate forms a single morphological word, and combines a classifier stem in first position in the verb, with a lexical stem (here *lerrkperrk*) in a subsequent position in the template. In a causative complex predicate, the result state is provided by the lexical stem while the instrument is provided by the classifier stem. For example, the lexical stem *lerrkperrk* 'crush' contributes the result state 'crushed', while the classifier stems 'do with HANDS' and 'do with FEET' contribute the instruments 'hand' and 'foot' respectively.

(49) Murrinhpatha
ku tumtum mam-lerrkperrk
CLF:ANIM egg 1SG.SBJ.HANDS.NFUT-crush
'I crushed the egg in my hand.' (Seiss 2013: 127)

(50) Murrinhpatha
ngunungam-lerrkperrk
1SG.SBJ.FEET.NFUT-crush
'I crushed the egg with my foot.' (Seiss 2013: 127)

(51)
$$\begin{bmatrix} \text{CAUSE}\left(\left[\text{Thing}\right]^{\alpha}_{A}, \left[\text{BECOME}\left(\left[\text{BE}\left(\left[\text{Thing}\right]^{\beta}_{A},\left[\text{RESULT}\right]\right)\right]\right)\right]\right) \\ \left[\text{BY}\left[\text{CAUSE}\left(\left[\text{Thing}\right]^{\alpha}_{A}, \left[\text{AFF}^{-}\left(\left[\text{INSTRUMENT}\right],\left[\text{Thing}\right]^{\alpha}_{A}\right)\right]\right)\right]\right] \end{bmatrix}$$

On this view, the classifier stem and the lexical stem do not each bring a complete LCS, but instead just a specific instrument (the classifier stem) or a specific result state (the lexical stem). The rest of the LCS is provided by the LCS blueprint. The lexical entries of the classifier stem and the lexical stem thus only consist of this information, as is illustrated in (52).

(52) do with HANDS: instrument = hand
do with FEET: instrument = foot
lerrkperrk: result = crushed

The LCS blueprint used by a particular combination is determined by the classifier and lexical stem together, whose compatibility is modelled by the hierarchies of selectional restrictions; the reader is referred to the comprehensive discussion in Seiss (2013) for further details. A notable aspect of Seiss's work on this topic is that, in addition to providing a comprehensive analysis of complex predicate combinations in Murrinhpatha, Seiss presents an implementation of Murrinhpatha's morphology using the Xerox finite-state technology tools XFST and LEXC (Beesley & Karttunen 2003), and an implementation of some parts of Murrinhpatha's syntax using the XLE grammar development platform (Crouch et al. 2011).

Valence-changing constructions such as applicatives and causatives have also been analysed as complex predicates in many languages, including by Austin (1997), who draws on Alsina's (e.g. 1997) approach to complex predicates in analysing causatives and applicatives across a number of Australian languages (see Andrews 2023b [this volume] for further discussion of Austin's analysis in the context of LFG approaches to complex predicates).

4 Conclusion

In this chapter, I have covered the primary linguistic phenomena in Australian languages that have been given detailed analysis in LFG research, focussing particularly on the morphology-syntax interface, where the morphological complexity of Australian languages has made the most significant contributions to theoretical debate and development. Other areas where there has been some work on Australian languages, but for which space was not available for discussion here, include control and obviation constructions in Warlpiri (Simpson & Bresnan 1983), zero anaphora (Austin 2001b) and noun incorporation (Nordlinger & Sadler 2008, Baker & Nordlinger 2008, van Egmond 2008, Baker et al. 2010). Work on Australian languages within the LFG framework has also contributed to the discussion and analysis of grammatical relations cross-linguistically, in such areas as syntactic and morphological ergativity (Manning 1996), information structure and its role in case marking patterns (Simpson 2012), distinctions between syntactic and semantic cases (Andrews 2017) and the role of dative-marked NPs as core arguments or adjuncts (Simpson 1991). The majority of LFG researchers working on Australian languages are also descriptive linguists engaged in fieldwork and language documentation. This crossover has ensured that theoretical questions and implications arising from LFG analyses are fed back into language description work unearthing new findings about the languages and how they are structured, and ensuring that this research both contributes to the development of the LFG framework and to our understanding and description of these fascinating languages.

Acknowledgements

First and foremost, I would like to acknowledge all of the Indigenous language knowledge holders who have graciously worked with me and many other linguists over the years to share their knowledge and teach us about their languages. Nothing discussed in this chapter would have been possible without their generosity and insight. For input and assistance with various aspects of this chapter, I would like to thank Peter Austin, Mary Laughren, Stephen Wilson, two anonymous referees, and especially Mary Dalrymple, editor extraordinaire, who is nothing short of a LaTeX wizard and without whom this chapter would have been nothing but text! My research has been funded by the Australian Research Council over many years, most recently through the ARC Centre of Excellence for the Dynamics of Language (CE140100041), and I gratefully acknowledge their support.

Abbreviations

Abbreviations in glosses in this chapter follow the Leipzig Glossing Rules wherever possible. Non-standard abbreviations used are:

ACT	actual mood	AUG	augmented number
ANIM	animate	EP	epenthetic morph
ASP	aspectual suffix	INCH	inchoative
ASSOC	associative case	PC	paucal number

PRIV	privative case	TWD	direction towards
PROP	proprietive case	USIT	usitative mood
MIN	minimal number

Chapter 28

LFG and Austronesian languages

I Wayan Arka
The Australian National University

Li-Chen Yeh
The Australian National University

Austronesian (AN) languages are known for their diverse grammatical characteristics in many typological and descriptive works. Their properties provide fertile grounds for testing assumptions in syntactic theories. In this chapter, we demonstrate that the parallel correspondence architecture of LFG can be used as a powerful tool for language-specific linguistic analysis, while also precisely capturing the cross-linguistic differences within and between Western and Eastern AN languages. LFG is flexible in incorporating analytical tests, such as adverbial insertion and clitic placement for examining constituency; reflexive binding, nominal marking and pronominal-indexing for syntactic status of an argument. Although AN languages have posed challenges to traditional syntactic notions of subject, as well as the mapping between grammatical relations and functions, we show that such multi-dimensional views of grammar, and projection design, can deal with these challenges efficiently, and also lead to a coherent comparative representation of AN languages for the purpose of tracking morphosyntactic stages according to their respective typological categories.

1 Introduction

The world of Austronesian (AN) languages comprises a huge and diverse language family, which covers a wide geographical span ranging from Formosan languages in the northwest of the Pacific, Malagasy at its westernmost point, Māori in south Oceania, Hawaiian in the northeast and Rapanui at its most eastern point. In fact, this geographical spread is a historical outcome of the prehistoric settlement by AN speaking communities (Pawley & Pawley 1998; Bellwood

I Wayan Arka & Li-Chen Yeh. 2023. LFG and Austronesian languages. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 1289–1367. Berlin: Language Science Press. DOI: 10.5281/zenodo.10186000

2007: 242). The histories of the people in the widespread Asian-Pacific region are testimony to the genealogical continuity of AN languages that form one single language family.

Initially, the AN dispersal began from the island of Taiwan in the northern part of the Pacific island chain, outside the east Asian continental mainland (Pawley 2002, Bellwood 2007, Skoglund et al. 2016, Blust 2019). The languages natively spoken on the island of Taiwan are direct descendants of the Proto-AN language (Blust 1999). These languages are collectively called Formosan languages, and are sisters to the common ancestor of the remaining AN languages, Proto-Malayo-Polynesian (PMP).

The AN expansion took place in subsequent waves, as laid out chronologically below (Adelaar 1989, Bellwood 2007: 201-254). The PMP subgroup began to split up as it spread from Taiwan to the Philippines (est. 2200 BCE), along with early migration settling in Micronesia. There were also dispersals from the Philippines into Indo-Malaysia and eastward to New Guinea and the Bismarck Archipelago. The settlement in the Bismarck has been dated to around 1350 BCE. Later on, the dispersal went further eastwards into the Pacific (e.g. Solomons, Vanuatu, New Caledonia, Fiji, Tonga and Samoa) between 1200 and 900 BCE. After 600 CE, the AN occupation of eastern Polynesia occurred, and immigrants from Borneo arrived in Madagascar around 500 CE.

The AN migration history above shows the geographical distribution of AN languages. Meanwhile, it similarly indicates a diachronic progression in the varying prototypical features of AN morphosyntax and offers a general guideline for the typology of AN languages. A major typological distinction can be made between Western AN and Eastern AN.

The Western AN group[1] includes languages of Taiwan, the Philippines, western Indonesia, Malaysia and Madagascar. These languages are typically characterised by their robust 'alternating' and 'symmetrical voice' systems, which use verbal morphology to mark a non-Agent argument as grammatical subj(ect) or pivot without demoting the Agent argument to oblique (discussed in Section 4). This non-demotion property of the Western AN voice system differs from the commonly observed active-passive voice alternation system in Indo-European languages like English.

The symmetrical voice systems in Western AN pose challenges to many grammatical frameworks, including some versions of the standard Lexical Mapping

---

[1] In this chapter, Western AN is used as a cover term for symmetrical voice languages. It differs from Himmelmann's (2005) geographic label of 'Western Austronesian' which encompasses all non-Oceanic languages.

Theory analysis in LFG. The non-demotion property of the symmetrical voice system licenses a passive-like structure with a non-actor thematic role selected as subject, called Patient (or Undergoer) voice, but unlike in the passive, the non-subject actor role has the most prominent core status. This leads to a mismatch between its semantic and syntactic prominence: the most prominent semantic (agent) argument is not the most privileged (SUBJ) argument. The diagnostic tool for identifying this mismatch involves reflexive binding (see Section 2). The surface realisation of reflexive binding allows reflexive pronouns to be bound by antecedents bearing both the least and most prominent grammatical functions. While posing challenges to many grammatical frameworks, this unusual and intricate variation of voice alternation is best explained by the multi-layered argument structure of LFG's architecture which tackles associations between grammatical functions and grammatical relations.

The Eastern AN language group[2] includes languages of Timor-Leste, New Guinea and Oceania. In contrast to symmetrical-voice languages, Eastern AN languages no longer maintain the layered distinctions at the semantics-morphology-syntax interface. We refer to these languages as the non-alternating type because the typical alternative selection of a semantic role as grammatical SUBJ, as seen in Western AN languages, is not observed. Instead, Eastern AN languages are characterised by other properties such as the emergence of systematic pronominal indexing, as well as increased complexity in other parts of its grammar as seen in their rich serial verb constructions (SVCs) and clausal complementation (see Section 5). The pronominal indexing paradigm is an exclusive feature of Eastern AN languages, and in this regard, they may be referred to as indexing-type languages.

Indexing-type languages show distinct properties in complex constructions that are intriguing for typological comparisons and important for theoretical testing. These languages show a striking consistency in the distinction of (X)COMP (i.e. clausal complementation with(out) shared missing SUBJ: see Vincent 2023 [this volume] and Section 5 of this chapter) while also revealing a significant difference with regard to the structural tightness between regular complementation and complex predicates. The latter has usually been subsumed under the general heading of SVCs. It is not always straightforward in many syntactic theories to capture the distinction among different kinds of (X)COMP (e.g. control, SVCs and multi-verb constructions in coordination and subordination). Nonetheless, a few clear cases of the distinction in argument gapping strategies can be effectively demonstrated from the LFG perspective where, crucially, no movement is

---

[2] Eastern AN languages have been commonly referred to in the literature as preposed-possessor languages, Oceanic languages or isolating languages of eastern Indonesia.

required (cf. Sells's (2023 [this volume]) comparison of LFG with the traditional analysis of control/raising complementation in transformational grammars). Instead, the LFG perspective can clearly present how a verb form with/without an overt voice marker can serve as a diagnostic tool for testing the core status of (x)COMP, and how voice morphology (as well as negation) forms a criterion for teasing apart the differences between complementation and SVCs. Even the compound-like structure of the complex event-composition in SVCs can be captured via the interrelated specifications on different linguistic dimensions (see Section 5.2).

Even though the above description has provided a general indication of the major typological differences between Western and Eastern AN languages, two important points should be made on the typological diversity of AN morphosyntax.

First, not all Western AN languages behave alike. Symmetrical-voice languages are typically further subcategorised into 'Philippine-type' and 'Indonesian-type', due to their distinct characteristics in word order (cf. Section 3), the number of semantic roles allowed as privileged arguments (cf. Section 4.2), and the use of case-marking flagging and applicative constructions (cf. Section 4.3). Although most Western AN languages may be subcategorised further, some transitional languages do not adhere to the typological profile of either type (Kroeger 2023). Certain Western AN languages in Taiwan even appear to show disputable traits of asymmetry in syntax (cf. Section 4.4).

Moreover, geography and typology do not always neatly align. For instance, certain Barrier Island languages off the south coast of Sumatra, such as Mentawai (Lenggang et al. 1978, Arka 2006), Enggano (Crowley n.d., Hemmings in preparation) and Nias (Brown 2001), do not show a symmetrical voice property of the type seen in the Western AN group, but they have developed person-marking prefixes on verbs that encode subject similar to NOM(inative) subject prefixes in outlier AN languages in southern/eastern Indonesia, such as Kambera in Sumba (Klamer 1998) and Wooi in West Papua (Sawaki 2016). Makassarese, spoken in Sulawesi, has unmarked word order like the Philippine-type, but it also exhibits systematic pronominal indexing on the verbal predicate. In Makassarese, a transitioning state of word order change is observed in the expression of contrastive focus through clefting (cf. Section 6).

Typologically, the AN language family is intensely diverse with a variety of transitioning languages comprising two heterogeneous macrogroups. This diversity has posed difficulties for descriptive and comparative analysis, particularly for long-standing and often controversial topics of typological and theoretical significance, such as ergativity or the complex interconnection between surface grammatical relations and deeper semantic-syntactic argument structures. Nonetheless, LFG's parallel correspondence architecture provides the necessary flexibility for a coherent and comparable descriptive representation of AN grammar on these topics.

In this chapter, we show how LFG can be used as a descriptive and analytical tool to capture the typological range of AN linguistic diversity on these selected topics. We begin by highlighting the LFG modular design, and its application in modelling the morphosyntactic operation of AN voice systems (Section 2), then illustrate how the LFG framework can capture word order variation (Section 3), grammatical functions and alignment (Section 4), complex argument sharing constructions (Section 5) and information structure (Section 6).

2 LFG modular design and Austronesian linguistics

LFG is modular in its design. From the LFG perspective, a language is construed as multiple dimensions of linguistic information, and each dimension constitutes an individual module, or structure, that comes with its own formal properties. Different structures are parallel but are linked by principles of correspondence, as introduced in Belyaev 2023b [this volume].

In the standard LFG framework, traditional syntactic structure is primarily represented on two structural levels: constituent structure (c-structure) and functional structure (f-structure). Ordering of constituents and syntactic categories are analysed in c-structure, whereas grammatical functions (gfs) of arguments and grammatical features are dealt with in f-structure, as detailed in Belyaev 2023a [this volume]. In subsequent developments, semantic argument structure (a-structure) was proposed in Lexical Mapping Theory (LMT) to capture cross-linguistic gf alternations (Bresnan & Kanerva 1989); see also Findlay et al. 2023 [this volume]. Bresnan & Kanerva (1989) propose that a-structure is represented as a list of semantic roles which are directly mapped onto gfs. Bresnan & Kanerva's (1989) LMT works well to account for voice and alternative argument realisations in languages like English; e.g. the agent's subj(ect)-obl(ique) alternation in passivisation.

However, the rich voice systems of western AN languages pose a problem for this version of LMT such that semantic a-structure and the traditional analysis of gfs cannot be maintained. Based on data from western AN languages, which will be discussed in detail in this chapter, we argue against Bresnan & Kanerva's (1989) version of mapping theory; see Arka (2003a: 119–124) for a comprehensive examination of the evidence and justification. Consider the following examples from Balinese (1) and Puyuma (2):

(1) Balinese (WMP, Indonesia) (Arka, own knowledge)[3]

a. [Tiang]$_{\text{SUBJ}}$ ng-ejang [nasi]$_{\text{OBJ}}$ [*(di) bodag-e]$_{\text{OBL}_{\text{LOC}}}$.
1SG AV-put rice in basket-DEF
'I put rice in the basket.'

b. [Nasi-ne]$_{\text{SUBJ}}$ ∅-ejang [tiang]$_{\text{OBJ}}$ [*(di) bodag-e]$_{\text{OBL}_{\text{LOC}}}$.
rice-DEF UV-put.rice 1SG in basket-DEF
'I put rice in the basket.'

(2) Puyuma (Formosan) (Teng 2008: 47-48)

a. Tr<em>akaw [dra paisu]$_{\text{OBL}}$ [i isaw]$_{\text{SUBJ}}$.
⟨AV⟩steal INDF.OBL money SG.NOM Isaw
'Isaw stole money.'

b. [Tu=]$_{\text{OBJ}}$ trakaw-anay [i tinataw]$_{\text{SUBJ}}$ [dra paisu]$_{\text{OBL}}$.
3GEN= steal-CV SG.NOM his.mother INDF.OBL money
'He stole money for his mother.'

The examples above represent two salient features of the AN voice system and related argument realisations. First, verbal voice morphology marks SUBJ selection (cf. Section 4). The ACTOR VOICE (AV), indicated by *ng-* in Balinese (1a) and ⟨*em*⟩ in Puyuma (2a), selects the most agent-like role, or A (*tiang* and *Isaw* respectively) as SUBJ.[4] The UNDERGOER VOICE (UV) in Balinese is indicated by a zero prefix and selects a patient-like (P) role as SUBJ as in (1b), whereas the CONVEYANCE VOICE (CV) in Puyuma selects a peripheral role, as in the beneficiary 'mother' in (2b)[5] (see Section 4.2 for the properties of SUBJ/PIVOT and the typology of AN voice

---

[3] In this chapter, a language is presented with its linguistic and geographical classification in the first instance based on information from Glottolog for the purposes of locating genealogical and typological relations between languages. WMP and CEMP stand for Western Malayo-Polynesian and Central-Eastern Malayo-Polynesian respectively.

[4] Following standard conventions in language typology (Comrie 1978, Dixon 1979, Croft 2003, Haspelmath 2007, among others), we adopt the following abbreviations to denote generalised semantic roles: A represents the argument that is most actor-like, while P represents the argument that is most patient-like in a transitive predicate. It is worth noting that P is approximately synonymous with the undergoer (U) macro-role in Role and Reference Grammar (Foley & Van Valin 1984).

[5] In AN linguistics, non-AV or UV is also often called Objective Voice (Kroeger 1993). It is the voice type that selects certain semantic roles other than the actor as SUBJ/PIVOT. In the AN languages of the Philippines and Taiwan, there are typically different types of UV named after the associated semantic role of the SUBJ and each has its own verbal morphology, e.g. *-anay* for Conveyance Voice (CV) in Puyuma in (2).

systems). The voices in these AN languages are called symmetrical voice. Evidence for their symmetricality comes from the fact that agent and non-agent roles are equally selectable by the voice morphology as the "privileged argument", which is analysed as subj/pivot in LFG (Kroeger 1993, Manning 1994, Arka 2003a, Falk 2006). In addition, symmetricality is seen in verbal marking, particularly in Puyuma, where different voice types (e.g. av and cv) are equally marked.[6]

Second, non-av alternations in (1b) and (2b) are not passivisation. That is, in both Balinese uv and Puyuma cv, the promotion or selection of a non-A role as subj is not accompanied by the demotion of A to obl, a lower ranked function. Functionally, the A argument is the obj(ect); it retains its core status in the structure. This is clearly seen in Balinese, where the A of the uv structure in (1b) appears immediately after the verb as a bare Noun Phrase (NP), like the obj of the av verb in (1a). Note that obl in Balinese is flagged by a preposition. In addition, Balinese does have a passive, in which case the agent appears as obl (see Arka 2003a). Likewise, the A of the cv verb in Puyuma is realised as a bare gen(itive) clitic. A free obl nominal in Puyuma is also prepositionally flagged, and if it is a pronominal, it has a special obl form distinct from the gen or nom(inative)[7] form (see Teng 2008: 63). Bresnan & Kanerva's (1989) classic LMT approach cannot account for the agent's alternative realisation as obj in uv, as in Balinese (1b) and cv in Puyuma (2b), since the agent is inherently classified as [−*o*] (i.e. not object-like), thus only allowing for the subj-obl alternation as seen in passives.

To capture the non-demotion of A in uv and other salient typological and morphosyntactic properties of AN voice alternation in LFG, we distinguish gfs from grs (Grammatical Relations). grs are clause-internal relations that reflect semantic-syntactic dependency between a predicate and its dependents. They form the so-called syntacticised a-structure in Manning (1994), Arka (2003a) and Arka & Manning (2008). This syntacticized a-structure, as distinct from the semantic a-structure in Bresnan & Kanerva's (1989) classic LMT, incorporates syntactic information regarding coreness/obliqueness alongside its structural prominence, which includes thematic ranking. Although grs and gfs belong to different layers of structure, the two are interrelated and are mapped together through

---

[6] Balinese and Puyuma belong to two different subcategories of Western AN languages: the Indonesian-type and Philippine-type, respectively. They differ in their number and type of voice distinctions, and the syntactic properties of their non-subj arguments (e.g. the obliqueness of P in av) (cf. Section 4). Note that the uv verb in Balinese is also analysed as being 'marked'; it is realized as a zero uv prefix on the basis of its contrasting form with the av verb.

[7] Note that Puyuma is an ergative language. In Teng (2008), nom refers to the case assigned to subj. It should not be confused with nominative case in nom-acc languages. See the discussion in Section 4.4.

linking principles. In AN languages, the mapping is marked by verbal voice marking and/or indexing, depending on the available coding resources. Although the GF-GR distinction may not be assumed and embraced in all LFG analyses, we contend that it is essential to provide a consistent explanation for voice alternations and related alternative argument realizations in languages that exhibit both accusative and ergative properties, as seen in western Austronesian languages such as Balinese and Indonesian.

We use different convention labels for GRs and GFs to avoid confusion: small caps for GFs (e.g. SUBJ, OBJ) and lower case for GRs (e.g. subject, object). We illuminate the significance of the GF-GR distinction by taking into account recent findings (e.g. reflexive binding) in descriptive and typological research in AN linguistics. The informal GR or a-structure representation is given in (3a) for the Balinese verb *jang* 'put', and its simplified representation is given in (3b). The a-structure in (3) outlines that *jang* is a three-place predicate with core arguments (i.e. agent and patient) and a third non-core oblique locative (LOC) (i.e. location). In our analysis, we adopt the convention of using a vertical line (|) to explicitly delineate argument classes, distinguishing between core and oblique or non-core arguments within the argument structure list. This convention supplements the valency information specified in the a-structure representation in the lexicon.[8]

(3) Syntacticised argument structure of *jang* (Balinese):

a. 'put⟨ ARG1:agent , ARG2:patient | ARG3:location ⟩'
(subject) (object) (oblique)

b. 'put⟨ 1:agt, 2:pt | 3:loc⟩'

The following should be noted regarding the representation of GRs in (3). First, GRs conceptually reflect event construal and participant roles, which signify 'who

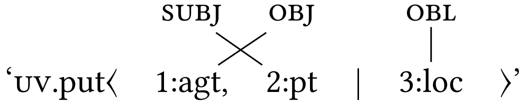
---

[8] Syntactic coreness/obliqueness and valency are distinct syntactic properties that pertain to whether an argument is core or not and the number of arguments a predicate takes, respectively. These properties are not always predictable from the semantics of the predicate, as evidenced by the variation observed across languages when expressing the same event using equivalent verbs with different syntactic argument structures. For example, the verb *give* is semantically a three-place predicate involving a giver, givee, and gift. However, languages differ in how they syntactically realize these arguments. Balinese *baang* 'give' exclusively permits ditransitive constructions without a dative alternation (Arka 2003b: 63–63), while English allows the verb 'give' to function as either ditransitive, like in Balinese, or monotransitive with an oblique as the third argument, depending on the context. Furthermore, languages such as Indonesian exhibit ditransitive/transitive alternations facilitated by applicative morphology. Consequently, this lexically specific syntactic information must be encoded in the syntacticized a-structure rather than the semantic structure within the lexicon. Arka's (2003a) work provides detailed evidence from Balinese supporting this perspective.

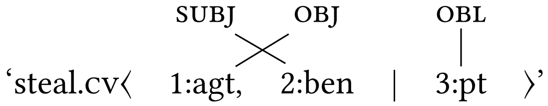
does what to whom'. This is the semantic-conceptual basis underlying valency and transitivity information in the syntacticised a-structure. The valence information specifies the number of arguments (e.g. one, two, or three arguments) and syntactic/semantic transitivity specifies types of arguments (i.e. core or oblique, and the associated semantic roles). The Balinese verb *jang* in (3) is a three-place transitive predicate with two core arguments, 1:agent and 2:patient, and one non-core argument, 3:location. For the purposes of comparative typology, 1:agent and 2:patient will be referred to as *subject* and *object*, respectively (noting lower case). They roughly correspond to the typologists' labels A and P/O respectively),which are distinguished from surface GFs, SUBJ and OBJ.

Voice morphology on the verb regulates GR-GF mapping. For example, the Balinese UV in (1b) and Puyuma CV in (2b) select 2:patient and 2:beneficiary respectively as SUBJ/PIVOT. These UV structures result in a mismatch between GF and GR prominence, informally represented by crossing lines.

(4) a. Balinese UV in (1b)



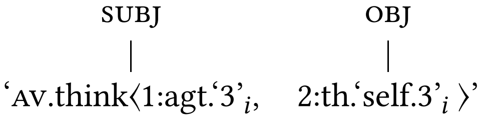
b. Puyuma CV in (2b)



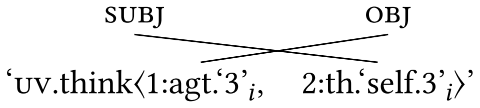
By distinguishing GRs and GFs, we can reflect a prominence mismatch in the non-AV structures in (4) above. This is evident from the interaction between reflexive binding and voice alternation in AN languages. For instance, the AV-UV voice alternation does not affect the acceptability of reflexive binding, exemplified by *awakne* in Balinese (5) and *izipna* in Kavalan (6). For simplicity, the f-structures showing reflexive binding are only given for the examples below.

(5) Balinese (Arka 2003a: 178)

a. [Ia]$_{\text{SUBJ}}$ ngenehang [awakne]$_{\text{OBJ}}$.
3 AV.think self.3
'(S)he thought of herself/himself.'

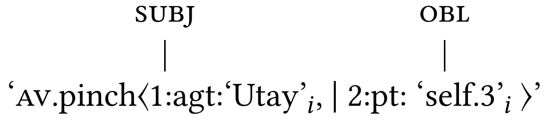


b. [Awakne]$_{\text{SUBJ}}$ kenehang[=a]$_{\text{OBJ}}$.
self.3 uv.think=3
'(S)he thought of *herself/himself*.'

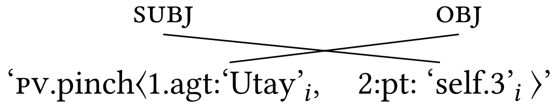


(6) Kavalan (Formosan) (Shen 2005: 57)

a. K⟨em⟩nit [ci Utay]$_{\text{SUBJ}}$ [tu izipna]OBL.
⟨av⟩pinch pn Utay obl body:3gen
'Utay pinched at himself.'



b. Kenit-an=na [ni Utay]$_{\text{OBJ}}$ [ya izipna]$_{\text{SUBJ}}$.
pinch-pv=3erg erg Utay abs body:3gen
'Utay pinched *himself*.'



c. f-structure of sentence (6a)

$$\begin{bmatrix} \text{PRED} & \text{`PINCH}\langle\text{SUBJ OBL}\rangle\text{'} \\ \text{SUBJ} & \begin{bmatrix} \text{PRED} & \text{`UTAY'} \\ \text{NTYPE} & \text{PROPER} \\ \text{INDEX} & \begin{bmatrix} \text{PERS} & \text{`3'} \\ \text{NUM} & \text{SG} \end{bmatrix}_i \end{bmatrix} \\ \text{OBL} & \begin{bmatrix} \text{PRED} & \text{`PRO'} \\ \text{PRONTYPE} & \text{REFLEXIVE} \\ \text{INDEX} & i \end{bmatrix} \\ \text{VOICE-TYPE} & \text{AV} \end{bmatrix}$$

d. f-structure of sentence (6b)

$$\begin{bmatrix} \text{PRED} & \text{`PINCH}\langle\text{SUBJ OBJ}\rangle\text{'} \\ \text{SUBJ} & \begin{bmatrix} \text{PRED} & \text{`PRO'} \\ \text{PRONTYPE} & \text{REFLEXIVE} \\ \text{INDEX} & i \end{bmatrix} \\ \text{OBJ} & \begin{bmatrix} \text{PRED} & \text{`UTAY'} \\ \text{NTYPE} & \text{PROPER} \\ \text{INDEX} & \begin{bmatrix} \text{PERS} & \text{`3'} \\ \text{NUM} & \text{SG} \end{bmatrix}_i \end{bmatrix} \\ \text{VOICE-TYPE} & \text{PV} \end{bmatrix}$$

The above data points show that reflexive binding in Balinese and Kavalan takes place at the level of a-structure, as shown in the a-structure representations on the right side. In Balinese, for example, both (5a) and (5b) share the same a-structure, but differ in their respective mapping to GFs: consider the crossing line in (5b) in the UV structure. In Kavalan, both (6a) and (6b) are similar in their a-structure representations except that the non-actor argument in (6a) is non-core, as represented by the vertical line (|). Both languages demonstrate that the reflexive is bound by the subject, as indicated by the subscript *i*. However, the voice alternations trigger a difference in the resulting GFs of the reflexive. It is realised as OBJ in the AV in (5a) and SUBJ in UV in (5b) for Balinese. In Kavalan, on the other hand, the patient is realised as OBL flagged by an OBL marker *tu* in the AV verb in (6a) (due to the ergative system of this language), and it is realised as SUBJ and flagged by the marker *ya* in Patient Voice (PV) in (6b). In both instances, the relationship between the reflexive pronoun (*izipna* 'body.3GEN') and its binder (i.e., the intended antecedent) is expressed through coindexation in the f-structure, indicated by the subscript *i*. The PERS and NUM values (i.e., 3SG) of the INDEX attribute of the bindee (*izipna*) are linked or bound to the INDEX values of the binder (*Utay*). This binding of INDEX values between the binder (*Utay*) and the reflexive pronoun (*izipna*) is permissible due to a binding requirement associated with the reflexive pronoun (cf. Rákosi 2023 [this volume]). Crucially, being the first core agent (i.e. ⟨1:agent⟩) argument, *Utay* outranks the reflexive pronoun (*izipna*) in the a-structure.

The acceptable reflexive binding of SUBJ (i.e. the most privileged argument) by OBJ in (5b) and (6b) would be unexpected if binding took place at the surface grammatical function level because the antecedent (OBJ) has lower syntactic prominence. The occurrence of reflexive binding in non-AV structures confirms the prominence outranking in the a-structure (i.e., A > P). This finding emphasizes the necessity of a separate syntacticized a-structure to provide an accurate analysis of reflexive binding phenomena in Austronesian languages, including Balinese and Kavalan.

In LFG, the important characteristics of the AN voice system can be captured using the layered a-structure, and cross-linguistic variation in the voice system is effectively illustrated by the varying transparency of the mapping. A distinction between GFs (the primitives of f-structure) and GRs (the primitives of a-structure) is maintained in western AN, but collapses in accusative languages like English, and Eastern AN languages that lack a symmetrical voice system (see Section 4).

Without this notion of layered structures, the unusual variation in the surface realisation of reflexive binding cannot be easily captured in other theories.[9]

Having shown how the basics of the AN voice system work from an LFG perspective, we now move on to an overview of some typologically interesting phenomena in AN languages in the subsequent sections.

3 Clausal word order

In Western AN languages, there are two broad patterns of clausal word order that are geographically distributed (Blust 2013: 461–461). Verb-initial order is encountered in the AN languages of Taiwan, the Philippines, northern and central Sulawesi, and Madagascar. Philippine-type languages tend to be verb-initial, whilst Indonesian-type languages, including Balinese, Madurese and Indonesian, are verb-medial. Diachronically speaking, the development of these two types of word orders appears motivated primarily by information structure—such as clefting to express contrastive FOCUS (see Section 6)—resulting in synchronic word order variation. The broad classification of Western AN will be used in the ensuing discussion with regard to the typology of word order. However, it should be noted that there is also a great deal of variation across the Philippine-type and Indonesian-type languages due to the flexibility of the order of agent and non-agent arguments relative to the head verb, giving rise to languages with or without a VP and languages with a rigid or flexible subject position (see Riesberg et al. 2019 for further details). In addition, language-internal variation exists, and it has been claimed that some AN languages do not have a fixed basic word order, or that word order choice may differ by voice construction, among other things (cf. Riesberg et al. 2019).

Unlike most Western AN languages, word order varies among Eastern AN languages. The AN languages of eastern Indonesia and many Oceanic languages have typically developed systematic pronominal indexing systems,[10] and therefore show a greater degree of freedom and variation for the ordering of cross-referencing NPs. Thus, there are Eastern AN languages that show SVO clausal

---

[9] For the sake of brevity, a detailed comparation with other theories is omitted here. We confine our illustration to the use of LFG in analysing AN languages. An in-depth comparative discussion of LFG and other frameworks is provided in Part VII.

[10] Some Formosan languages (e.g. Puyuma and Kavalan) have pronominal indexes on verbs. While they closely interact with robust voice verbal morphology, they do not usually contain a complete set of forms exhibiting the full range of case/role alternations. For this reason, we propose that the systematic pronominal indexing systems in Eastern AN languages are distinct from those in Formosan languages.

word order with indexed NPs ordered flexibly (e.g. Kambera), and there are others that are verb-initial (e.g. Fijian), and further still, there are other languages which are verb-final as a result of Papuan contact (e.g. Tobati, an AN language spoken in Jayapura Bay, west Papua, and Torau, an Oceanic language spoken in Bougainville; cf. Lynch et al. 2002).

In LFG, word order variation reflects the surface differences between 'default' (or unmarked) clausal order and pragmatically marked order. These are dealt with in terms of variation at the level of c-structure (see Andrews 2023 [this volume]).[11] Below we illustrate word order variation in Philippine-type, Indonesian-type and indexing type languages, from an LFG perspective.

Verb-initial sentences in Philippine-type languages are finite clause structures with the (inflected verbal) predicate, or the auxiliary, occupying the left-headed inflection (I) node. Hence, a sentence is head (or predicate) initial. However, the precise structures of post-verbal elements vary, with certain languages like Squliq Atayal (Formosan) showing a rigid hierarchical Verb Phrase (VP) structure, whereas others like Tagalog have a non-configurational structure. Evidence for a VP in Atayal comes from an adverbial insertion test. As shown in (7a), *hira'* 'yesterday' cannot intervene between a transitive verb and its object. The c-structure of (7a) is represented in (7b). Note that LFG adopts a version of X-bar syntax that allows nonbinary branching, as seen in the top/root node of IP in (7b).

(7) Squliq Atayal (Formosan) (Liu 2017: 41)

a.

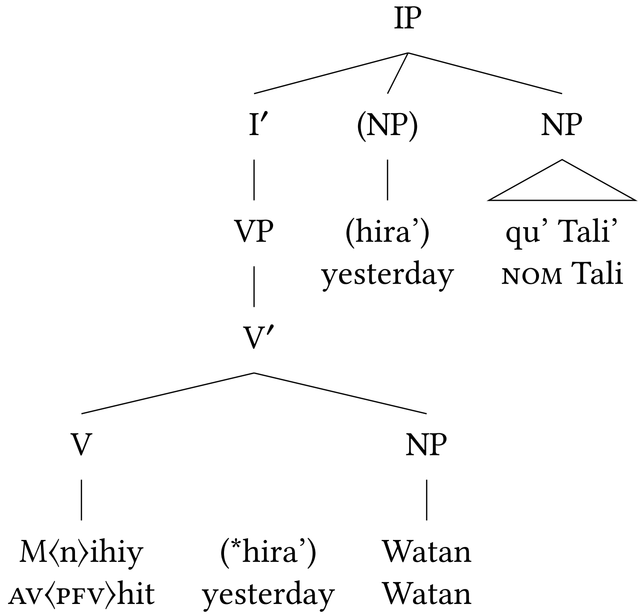
M⟨n⟩ihiy	(*hira')	Watan	(hira')	qu'	Tali'.
AV⟨PFV⟩hit	yesterday	Watan	yesterday	NOM	Tali

'Tali hit Watan yesterday.'

---

[11] While c-structure in LFG is modelled using phrase structure trees, with properties possibly following an X-bar schema, it does not represent a deeper 'universal' syntactic relation in which, for example, the object or patient argument is uniformly represented in the complement position of a VP as typically characterised by Chomskyan generative models. Further, there is no constituent movement in LFG, even though we may informally refer to 'fronting'; see Bresnan & Kaplan (1982), Bresnan et al. (2016: chapter 6), Dalrymple et al. (2019: chapter 3), Andrews 2023 [this volume].

b.

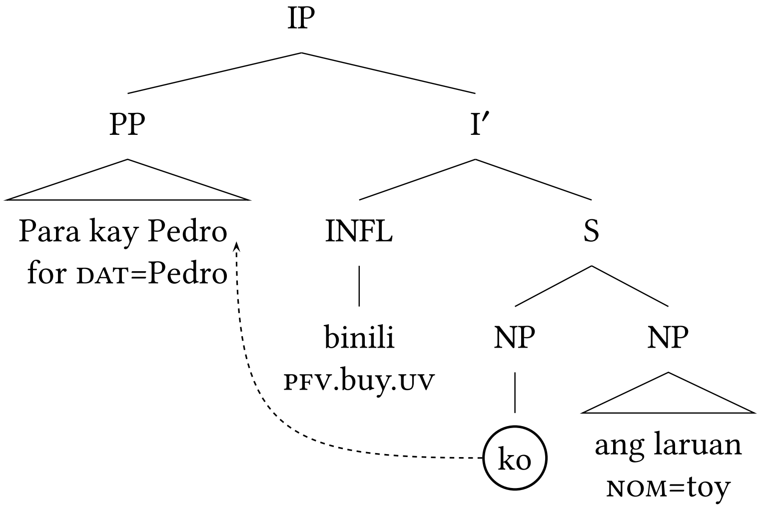


Turning to Tagalog, we can posit that the finite sentence (IP) in this language contains a non-configurational (i.e. exocentric, flat) Sentence (S), as shown in (8b) for the example in (8a); for further discussion of exocentricity and the category S, see Andrews 2023 [this volume]. Evidence for this comes from the fact that post-verbal arguments of non-verbal predicates (e.g. subj and obl) can be freely ordered (Kroeger 1993: 133). There is no surface VP in Tagalog because a second-position (2P) clitic – which must appear in the second syntactic position of a clause in order to obey syntactic-phonological constraints – is hosted by the finite verb alone and not the verb complement if the clause is verb-initial (not exemplified here), or by the first/fronted X(P) as exemplified in (8). Any attempt for a VP (i.e. V and its argument) to host a 2P clitic is ungrammatical (Kroeger 1993: 136).

(8) Tagalog (WMP, Philippines) (Kroeger 1993: 129)

a. [Para kay=Pedro]=ko binili ang=laruan.
for dat=Pedro=1sg.gen pfv-buy-pv nom=toy
‘For Pedro I bought the toy.’

b.



Variation in predicate-initial word order is pragmatically driven, and allows a unit to be 'fronted' to a sentence-initial position before the verb. This position bears a Discourse Function (DF) and is not uniquely associated with a particular grammatical function. In the Tagalog example (8a), the fronted DF, the OBL 'for Pedro', structurally occupies the Specifier position of the finite sentence, [Spec,IP], as shown in the c-structure in (8b). While generated under the S node by the phrase structure rule, because *=ko* is a 2P clitic, it is hosted by the Prepositional Phrase (PP), the first syntactic unit, following the final word of the phrase, *Pedro*.[12] Additionally, as in example (9) for Squliq Atayal, the sentence-initial position can be occupied by a grammaticalised topic that co-references SUBJ. This results in a pragmatically marked order for the pseudo-SV(O), namely, SUBJ-VERB-(OBJ/OBL). A pause, indicated by a comma in (9), is observed between the adjoined topic and the IP.

(9) Squliq Atayal (Liu 2017: 202)
Pagay qani (ga), kguh-an na' ngta'.
rice this TOPIC scatter-LV OBL chicken
'(Speaking of) the rice, (it) was scattered by the chicken.'

---

[12] Kroeger's analysis of clitic placement follows the standard approach in LFG (cf. Bresnan et al. 2016: 155), which treats a clitic as a syntactically independent unit like any other word. It occupies a terminal c-structure node, but is post-lexically hosted by another X(P) node due to a prosodic requirement in the syntax-phonology interface in the grammar. A different approach is to treat a clitic as a phrasal affix which does not occupy a terminal syntactic node on its own (cf. O'Connor 2002). See Halpern (1995), Halpern & Zwicky (1996), King (2005), and Bögel et al. (2010), among others, for further discussion of (2P) clitic placement.

The distribution of pronominal special clitics, such as 2P clitics, may also be determined by syntactic-pragmatic conditions that give rise to variations in clausal ordering. This is observed in Pazeh-Kaxabu (Formosan). Pazeh-Kaxabu has two types of bound pronominals: a full set of 2P clitics, and a 'peripheral' clause-final clitic. Crucially, the 2P pronominals are strictly used as an operational device so the speaker can direct an addressee's attention to the predicative element that is syntactically intransitive, as seen in examples (10a–b).

(10) Pazeh-Kaxabu (Formosan) (Li & Tsuchida 2001: 106, 140)

a. [[Ma-desek]$_{\text{V:FOCUS-C}}$ [=siw]$_{\text{SUBJ}}$]$_{\text{IP}}$.
STAT-belch =2SG.ABS
'You *belch*!' (emphasis added)

b. [[M⟨in⟩e-ken]$_{\text{V:FOCUS-C}}$ [=siw]$_{\text{SUBJ}}$ sumay=lia]$_{\text{IP}}$?
AV ⟨PFV⟩eat =2SG.ABS rice(meal)=MODAL
'Have you *eaten* meals?' (emphasis added)

c. [M⟨in⟩e-ken asai paj= [isiw]$_{\text{SUBJ}}$]$_{\text{IP}}$?
AV ⟨PFV⟩eat what MODAL= 2SG
'*What* have you eaten?' (emphasis added)

In (10a–b), the 2P clitic pronoun *=siw* appears as the sole argument of a simple stative intransitive verb (*madesek* 'belch' in 10a) and an intransitive clause[13] (*meken* 'eat' in actor voice in 10b). These sentences come with an emphatic focus on the predicates[14] (indicated by italicisation in the free translation; cf. 10b and 10c). The free pronoun *isiw* that encodes the SUBJ of a wh-question in sentence (10c) differs from the 2P clitic pronoun in its pragmatic function. Unlike the predicate host in (10b), there is no emphatic focus on the verb in (10c), and meanwhile, the pronominal SUBJs in the two sentences differ in their clausal positions — the free pronoun appears clause-finally, while the 2P clitic appears in an immediately post-verbal position.

Unlike 2P clitics and free pronouns, the host of the peripheral pronominal in Pazeh-Kaxabu is the last word of the clause. The peripheral pronominal clitic, while neutral in case, bears DF for contrastive meaning to encode a highly top-

---

[13] The issue of semantic versus syntactic transitivity of actor-voice clauses in some AN languages is discussed in Section 4.4.

[14] The term "focus" is used in this chapter to refer to the notion in information structure (Zaenen 2023 [this volume]), which is different from the term for the "focus system" that is primarily used by Formosan linguists. The latter will be discussed in Section 4 as "voice alternation."

ical entity.[15] The use of the peripheral pronominal entails that the post-verbal core arguments are pragmatically ordered according to their df roles, giving rise to order variation for VOS with a focused subj in (11a) and VSO with a salient referent of obj in (11b).

(11) Pazeh-Kaxabu (Li & Tsuchida 2002: 96)

a. [Ka-kan-en [nimisiw]$_{\text{obj}}$ =lia [=aku]$_{\text{subj:focus-c}}$]$_{\text{ip}}$.
dur-eat-pv 3erg =modal =1sg.neutral
'She (the leopard) would surely eat *me*.' (emphasis added)

b. [Ta-padudu-i [isiw]$_{\text{subj:focus-c}}$ =na [=aku]$_{\text{obj:topic}}$]$_{\text{ip}}$.
hortative-consult-pv 2sg =modal =1sg.neutral
'Perhaps, let *me* consult you.' (emphasis added)

Non-predicate-initial Indonesian-type languages, such as Balinese (Arka 2003a), Batak (Erlewine 2018), Madurese (Davies 2010: 249) and Sasak (Wouk 2002), have slightly different structural properties. First, the [Spec,IP] position is occupied by the grammatical subj, accounting for the verb-medial (SVO) structure in these languages. This is exemplified by Balinese in (12) and Madurese in (13).

(12) Balinese (Arka 2003b: 78)
[[Tiang]$_{\text{subj}}$ [[nunas kopi-ne niki]$_{\text{VP}}$]$_{\text{I}'}$]$_{\text{IP}}$.
1 av.take coffee-def this
'I took this coffee.'

(13) Madurese (WMP, Indonesia) (Davies 2010: 149)
Sengko' ng-enom kopi.
1 av-drink coffee
'I drink coffee.'

Unlike Tagalog, Indonesian-type languages, such as Toba Batak (Erlewine 2018), Indonesian (Arka & Manning 2008) and Balinese (Arka 2003a), appear to have a VP. Evidence for this comes from constituency tests such as material intervention

---

[15] The 1st person singular pronominal form in Pazeh-Kaxabu lends empirical support to the emergence and development of split-subjecthood in Formosan languages, where a non-subj agent that bears a high degree of topicality in the discourse is developed to possess syntactic and morphological subject properties. Readers are directed to Liu (2017) for discussion of split-subjecthood.

and joint-fronting. This is particularly evident when the patient/agent argument is indefinite. The material-intervention test is given in (14) for Toba Batak, where a clausal adjunct cannot intervene between a verb and its argument.

(14) Toba Batak (WMP, Philippines) (Erlewine 2018)
Man-jaha (*nantoari) buku (nantoari) si Poltak (nantoari).
AV-read yesterday book yesterday PN Poltak yesterday
'Poltak read a book yesterday.'

The joint-fronting test is evident when the verb receives Contrastive Focus (FOCUS-C) and is required to appear sentence-initially. The whole V+NP string should be included, otherwise the structure is ungrammatical. For example, in contrast to the default SVO order in Balinese in (12), sentence (15a) is a pragmatically marked VOS sentence (as seen from its translation).[16] A postverbal subject is unacceptable, as depicted in (15b).

(15) Balinese (Arka, own knowledge)
a. [[Nunas kopi-ne niki]$_{\text{VP}}$, [[tiang]$_{\text{SUBJ}}$]$_{\text{IP}}$]$_{\text{IP}}$.
AV.take coffee-DEF this (pause) 1
'Taking this coffee was what I did.'
b. *[[Nunas]$_{\text{V:FOCUS-C}}$, [[tiang]$_{\text{SUBJ}}$ [kopi-ne niki]$_{\text{VP}}$]$_{\text{IP}}$]$_{\text{IP}}$.

Clause structure variation in Indonesian-type languages is usually driven by pragmatic considerations, primarily to express varying levels of informational salience or attention, for example, emphatic or contrastive focus and frame setting or topic (Arka 2003a: 257–260, Arka & Sedeng 2018, Davies 2010: 175–176, Norwood 2002: 104–107). The unit that functionally bears a Contrastive Discourse Function is fronted sentence-initially. Following Arka (2021), we explicitly represent contrastive FOCUS and TOPIC as FOCUS-C and TOPIC-C, respectively, where necessary.

In order to integrate the latest advancements in the study of information structure within Austronesian languages (Riesberg et al. 2018) and beyond (Dalrymple & Nikolaeva 2011, Zaenen 2023 [this volume], among others), we deviate slightly from the LFG representation of TOPIC and FOCUS proposed by, for example, Bresnan & Mchombo (1987). Our approach introduces distinct types of Discourse

---

[16] VOS order is also possible when the subject is an afterthought TOPIC. This is a different structure, and the pragmatics and related prosody are different.

Functions, including focus-c, beyond the traditional analysis assumed in LFG during the 1980s and early 1990s. Apart from contrastive topic and focus, the fine-grained realm of topic and focus encompasses additional types such as 'new, first mentioned topic', 'default topic', 'secondary topic', and 'new/completive focus'. Arka & Sedeng (2018) provide examples of these categories in Sembiran Balinese. The suggested contrastive df is ideally situated within an independent i-structure (King 1997, Andréasson 2007, Butt 2014, among others), although it can also be, for simplicity, integrated within LFG's conventional unified f-structure representation (cf. (16c) below). The focus-c case is exemplified by (15) in Balinese above and by (16) in Indonesian below.

However, the precise structural position of contrastive dfs may vary depending on whether or not a language has a functional complementiser (C) word. For a language like Indonesian, which has a C (*bahwa* 'that'), the contrastive df is in [Spec,CP]. That is, a finite clause is CP, the maximal projection of C. The finite CP in Indonesian is evident in the relative clause (RC) with *yang* bearing focus-c, as exemplified in (16a) (cf. Arka 2011: 78-80 and Arka (2021) for details). The c-structure tree is given in (16b), showing that the pronominal relativiser *yang* is grammatically obj, and the RC is structurally OSV. The f-structure is shown in (16c).[17]

(16) Colloquial Indonesian[18] (WMP, Indonesia) (Arka, own knowledge)

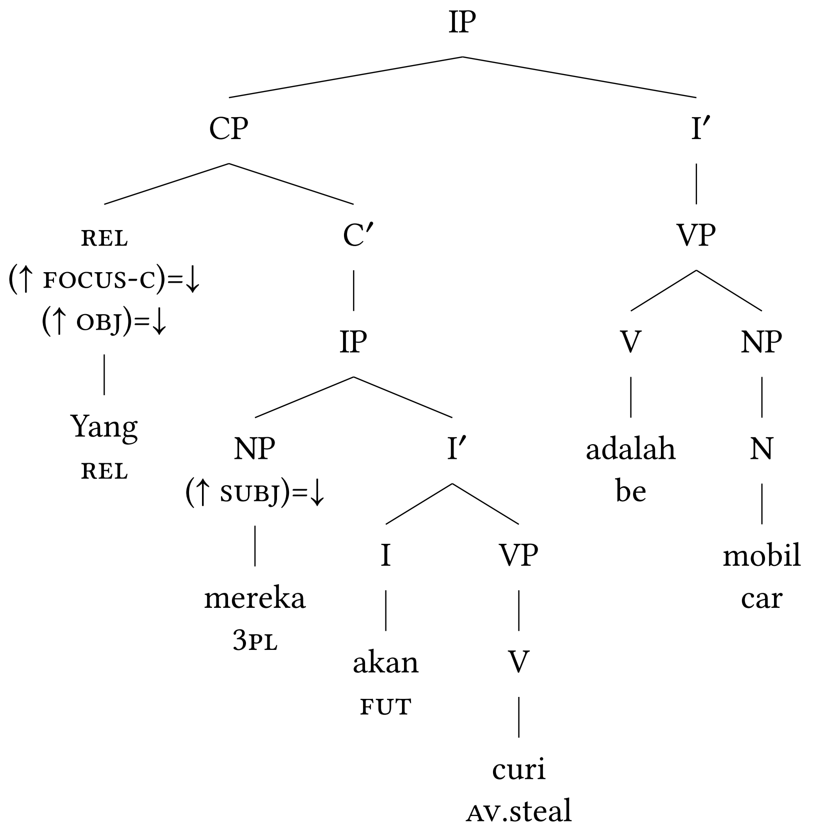
a. [Yang mereka akan curi]$_{\text{CP}}$ adalah mobil.
rel 3pl fut av.steal be car
'The thing that they were going to steal was a car.'

---

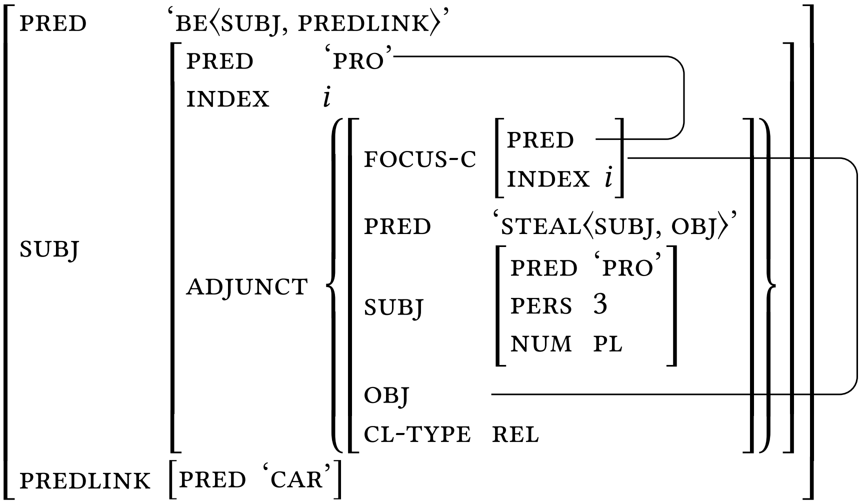
[17] Note that the Indonesian copular verb *adalah* is analyzed as requiring predlink, which is one way of analyzing a nominal predicate in LFG. For discussion of single-tier/double-tier analysis of non-verbal predicates, see Andrews (1982), Butt et al. (1999), Dalrymple et al. (2004), among others.

[18] Standard Indonesian and Colloquial Indonesian differ in their morphological properties of verbs and the formation of relativisation. See Arka (2021) for more exemplification.

b.



c.



Unlike Indonesian, Balinese has no complementiser C equivalent to English *that* (Arka 2003a).[19] A fronted element bearing a contrastive DF can be analysed as being left-adjoined to IP. This structure is shown by the IP subscripts in example

---

[19] However, certain prepositions (e.g. *unduk* ‘about’) and conjunctions (e.g. *apang* ‘so that’) may function like complementisers in particular contexts (Natarina 2018: 54).

(15a). Note that the fronted element bearing a marked focus-c is typically given stress with a clear pause after it (indicated by a comma above) resulting in a VOS structure.

Like Tagalog, the clausal linear order in Indonesian-type languages may also vary if the subj is a 2P clitic. The variation may involve contrastive dfs. For instance, Sasak has a 2P clitic subj (Austin 2004) which appears after the first constituent for independent syntactic-phonological reasons, giving rise to clausal word-order variation. Thus, while S-(Auxiliary)-V-O is the unmarked order in Sasak, the subject may also be cliticised to an auxiliary if it is the first word in the sentence; this results in an Aux-S-V order, as seen in (17a). In (17b), however, the verb is fronted sentence-initially, as it bears focus-c. Therefore, it hosts the subject clitic and results in a VSO order.

(17) Ngenó-ngené Sasak (WMP, Indonesia) (Asikin-Garmager 2017: 29, 32)
a. Kenyengken=ne tokol.
prog=3 sit
'They (the women) were sitting.'
b. M-pantòk=ne$_i$ begang inó (isiq lóq Mus$_i$).
predfoc-hit=3 rat that by art.m Mus
'Mus hit the rat. (He finally got it!)' (emphasis added)

In contrast, the clausal word order is typically fixed when an argument is generic or indefinite (see Section 4.4 for further discussion of definiteness). For example, the Balinese generic statement about a cow in (18a) must be in SVO; a VOS variant is unacceptable, as in (18b).

(18) Balinese (Arka 2019: 261)
a. Sampi ngamah padang.
cow av.eat grass
b. *Ngamah padang sampi.
av.eat grass cow
'A cow eats grass.'

Some AN languages in the peripheral regions, geographically distant from their original homeland of Taiwan, are morphologically isolating and typically exhibit rigid SVO clause order. These languages are encountered on Flores Island in Indonesia and other peripheral areas, such as in Southeast Asia and the Pacific. Structurally, their clauses are like Indonesian-type languages with good evidence for a surface VP. Consider the following intervention test in Rongga (central Flores), a highly isolating language, where the verb and object form a VP:

(19) Rongga (CEMP, Indonesia) (Arka 2016: 192)

a. Ardi [ngedho wolo]$_{\text{VP}}$ **nembumai**.
Ardi see mountain yesterday
'Ardi saw a/the mountain.'

b. *Ardi ngedho **nembumai** wolo.

Rongga has developed a relativiser (REL) from the noun meaning 'person', *ata*, exemplified in (20a). As in Indonesian, it may also be analysed structurally as appearing in [Spec,CP], bearing a contrastive DF (Arka 2016). The c-structure is given in (20b), which shows that sentence (20a) is a highly marked structure. Both TOPIC and FOC are present, with TOPIC preceding FOC in the left periphery. Note that FOCUS-C in this example is associated with two elements having the same referent (indicated by the subscript *i*). Hence, it is doubly marked: first by the relativiser, *ata*, and second by the fronted question word (Q), *sei* 'who'. The sentence is a cleft structure with the Q, *sei*, being the (fronted) predicate and the relative clause being the SUBJ (as shown by the literal translation). Considering that relativization introduces a contrasting emphasis by focusing on or restricting a specific referent under discussion or question, we analyze the relativizer as carrying FOCUS-C. In example (20a), for instance, multiple individuals were present, and the relative clause singles out one of them through the event of 'taking (my) water'.[20]

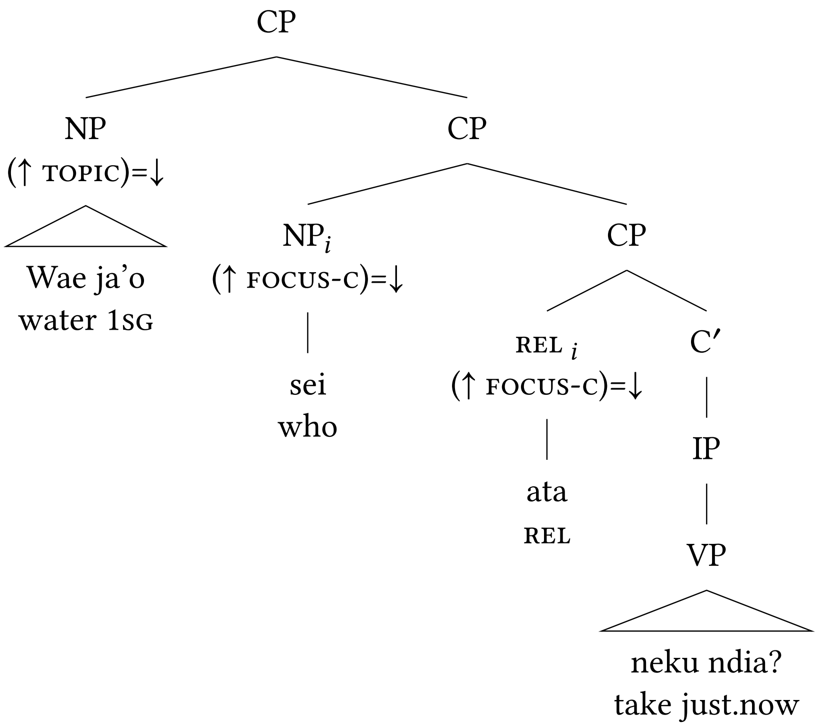
(20) Rongga (Arka 2016: 212)

a. Wae ja'o, sei ata neku ndia?
water 1SG who REL take just.now
'As for my water, who's the one taking (it) just now?'
(Lit. 'As for my water, the one taking (it) just now is who?')

---

[20] It should be noted that, from the broader viewpoint of the matrix noun phrase, the relativizer is linked to the specific referent being talked about, to which the relative clause adds its semantic restriction. Therefore the relativizer can also be analyzed as a topic (cf. Bresnan & Mchombo 1987).

b.



Unlike Philippine-type and Indonesian-type languages, the indexing-type AN languages of eastern Indonesia and Oceania have developed systematic pronominal indexing systems. The salient grammatical trait of AN (symmetrical) voice is either disappearing or already lost in these languages. As a result, these languages have relatively free word order determined largely by discourse pragmatics.

For example, Kambera in Sumba, eastern Indonesia, has developed different sets of bound pronominal indexes (nom, acc, gen and dat) that appear on the predicate with a fixed order (Klamer 1998: 79). In example (21) below, *na-* and *-nya* are subject and object arguments, respectively. They appear with free cross-referencing NPs. These free NPs are optional and freely ordered, hence allowing NP$_i$-[subj$_i$-V-obj$_j$]=NP$_j$ (or SVO: (a)) and NP$_j$-[subj$_i$-V-obj$_j$]=NP$_i$ (or OVS: (b)) orders. OSV, despite not being shown here, is also possible. The SVO structure in (21a) is the default/unmarked order for transitive clauses, and OVS is a marked order when obj is contrastive topic (Klamer 1996: 22). The basic word order for an intransitive sentence is, however, VS (Klamer 1998: 85). Kambera syntax is typologically like Chicheŵa (albeit with a difference in the 'agreement' status of the verbal subj marker),[21] and it can be analysed in LFG in the same way as outlined in Bresnan & Mchombo (1987): the bound pronominal indexes are the actual syntactic arguments whereas the free NPs bear dfs, and are pragmatically linked to the arguments, which gives rise to some kind of anaphoric agreement.

(21) Kambera (CEMP, Indonesia) (Klamer 1996: 13)

a. Ka nyuna$_j$ na$_j$-tinu-nya$_k$ na lau$_k$.
cnj she 3sg.nom-weave-3sg.dat art sarong
'So that she weaves the sarong.' (Lit. 'she she-weaves-it the sarong.')

b. Ka na lau$_k$ na$_j$-tinu-nya$_k$ nyuna$_j$.
cnj art sarong 3sg.nom-weave-3sg.dat she
'So that the sarong was woven (by her).' (Lit. 'the sarong she-weaves-it she.')

To sum up this section, LFG is well-suited for analysing word order variation across different types of AN languages based on a few parameters that are empirically motivated (e.g. VP vs non-configurational, head-initial vs head-final, a contrastive df in [Spec,CP], [Spec,IP] or left-adjoined to IP). This is made possible by the c-structure representation in LFG which follows a flexible version of X-bar Theory, and which not only captures cross-linguistic structural similarities (e.g. headedness in lexical and functional categories), but also varying language-specific properties (e.g. the distinction between the endocentric phrase and an exocentric S that is not X′-theoretic, and their multiple branching units).

---

[21] The verbal subj/obj markers in Chicheŵa differ from those in Kambera in the following ways. As in Kambera, the subj marker in Chicheŵa is obligatory in the verbal template. However, the Chicheŵa subj marker is only optionally pronominal. It serves as the actual argument when there is no free subj NP. Therefore, unlike in Kambera, it can also function as a 'syntactic' agreement marker when there is a free subj NP present. The subj/obj markers in Kambera hold a compulsory position within the verbal template and are consistently pronominals, meaning they refer to entities even in the absence of their corresponding free NPs. Consequently, these markers do not serve as syntactic agreement markers. In this regard, these affixes share similarities with verbal affixes found in Papuan languages (Arka et al. forthcoming) and certain Australian Aboriginal languages like Wambaya and Warlpiri. In these languages, the affixes exhibit ambiguity as they can function both as (anaphoric) agreement markers and incorporated pronominals (see Austin & Bresnan 1996 and references therein).

4 Grammatical functions and alternative argument realisations

4.1 Introduction

In LFG, grammatical functions are dealt with independently from the a-structure. Recall that in Section 2, we briefly introduced the basics of the voice system in Western AN and the rationale behind adopting a syntacticised a-structure in LFG (following Manning 1994, Arka 2003a, Arka & Manning 2008). Certain aspects of our architecture and related representations/mechanisms differ slightly from the assumptions generally adopted in LFG. One example is the argument linking/ mapping mechanism (cf. Findlay et al. 2023 [this volume]). The presentation used in this chapter is to account for salient symmetrical AN voice system where both accusative and ergative properties are observed within the same grammatical system, as in Balinese (Arka 2003a), which allows an underlying argument to have alternative gf realisations, like the a-subject/object to be the surface obj/subj as seen in Balinese in (5) and Kavalan in (6). These languages are classified as alternating languages for our discussion here.

On the other hand, AN languages of the indexing type, like Kambera, Wooi, and Taba, lack symmetrical voice and the associated subj/pivot distinction, and thus tend to be non-alternating languages (Klamer 1996, Bowden 2001, Sawaki 2016). Typically, their AN voice morphology and related voice system have disappeared. Consequently, core arguments (subject/object) do not have surface gf alternations like the kind witnessed in the alternating languages. The transitive subject and object are consistently surface subj and obj, respectively.

In other words, non-alternating languages tend to have fixed argument linking. In a genuinely non-alternating system, there is typically no distinction between gfs and grs. This gives rise to the salient typological property of non-alternating systems that gfs are typically semantically transparent. For a transitive predicate, subj is therefore always the most agent-like argument as seen, for example, in Kambera in the examples in (21) above. The bound (nom) proclitic *na=* is always the arg1:agent/subj argument of a transitive verb in this language, even when it is cross-referenced by a postposed free NP as in (21b). That is, sentence (21b) is not grammatically passive despite being given a passive translation in English; the agent is neither obl nor an adjunct (cf. the pronominal marking in a verbal cluster in Klamer 1996). Given the semantic transparency of gfs, intransitive predicates unsurprisingly show a split-S property in non-alternating AN languages. This is seen in, for example, Acehnese in examples (45)-(46) below.

In the ensuing sub-sections, we present, from the LFG perspective, how GFs (e.g. SUBJ, OBJ, OBL) are realised differently in the languages that have robust voice systems (i.e. alternating languages) and in those that do not (i.e. non-alternating languages). Specific diagnostics to identify SUBJ, OBJ and OBL, or their grouping as core versus non-core arguments, vary depending on the language type and morphosyntactic resources available (such as verbal morphology, pronominal marking, and phrase/case marking) in a given language. The complexity of the properties has led to a wide variety of competing analyses, for example, in the context of grammatical alignment systems to be discussed in Section 4.4. We begin by clarifying the subtle and crucial difference between SUBJ and PIVOT.

4.2 SUBJECT and PIVOT

There have been competing proposals within LFG for analysing and representing the predicate's most prominent argument, traditionally referred to as 'subject' (cf. subjecthood in Falk 2006, Belyaev 2023a [this volume]). In this book chapter, we keep the standard LFG conception of SUBJ(ECT) (i.e. in upper case): it is the surface grammatical subject, the most prominent GF on the relational GF hierarchy. It is part of f-structure, distinct from the thematic subject (or $\hat{\theta}$), the most prominent role on the thematic hierarchy, and part of the semantic argument structure (Bresnan & Kanerva 1989, 1992).[22] It is also distinct from the a-subject, the syntacticised a-structure subject (Manning 1994). Separating SUBJ from a-subject is necessary to account for symmetrical voice alternations and related properties in AN languages (cf. the separation of GF-GR in Section 2), otherwise certain unusual phenomena, such as the binding of SUBJ by OBJ (e.g. in Balinese example [5]) cannot be accounted for.

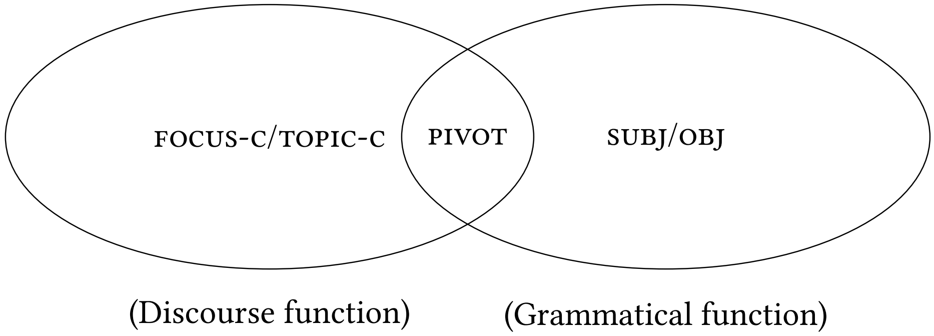
Furthermore, it is essential to distinguish SUBJ from PIVOT to account for the complex morphosyntax/pragmatics interface, which constrains voice alternation in certain constructions such as fronted questions in Balinese and Amis (to be discussed in Section 4.2.2). We also want to emphasize our conception of PIVOT as schematised in (22a): PIVOT is at the interface of syntax and pragmatics; that is, it shows grammatical properties (i.e. GF-related, typically intersecting with SUBJ, though not always) as well as discourse-pragmatic (DF) properties (e.g. FOCUS-C). In this sense, PIVOT is an 'overlay' or 'intersection' of GFs and DFs (Arka 2021). PIVOT is evident in the formation of bi-clausal structures, such as relativisation and coordination, and other grammatical mono-clausal structures involving

---

[22] The thematic subject roughly corresponds to the so-called 'logical subject', or the most prominent role-based A/S in linguistic typology (i.e. agentive argument of transitive verb, or sole argument of intransitive verb; see Jespersen (1924) and Manning (1994: 7).

marked DFs, such as FOCUS-C in Balinese fronted questions. Informally, licensing SUBJ to bear FOCUS-C as PIVOT can be represented as (22b), thus [DF-C=SUBJ] PIVOT for SUBJ PIVOT.

(22) a.



b. $[\text{FOCUS-C=SUBJ}]_{\text{PIVOT}}$

The notion of 'pivot' has been discussed and used in previous typological research. In what follows, we briefly provide some context for the conception of PIVOT adopted in this chapter. Its usage here is broadly aligned to descriptive functional and typological linguistics in place of 'Subject' and 'Topic' in the analysis of ergativity (Chao 1968, Heath 1975, Dixon 1979, Foley & Van Valin 1984, Van Valin & LaPolla 1997). The explicit incorporation of PIVOT into LFG was proposed by Manning (1994) to replace the GF attribute label SUBJ in f-structure (or Manning's GR-structure) and also to account for 'inverse' mapping in ergative languages while maintaining LFG's ability to account for 'straight-through' mapping in familiar accusative languages. In short, Manning's PIVOT is intersubstitutable with the standard LFG's SUBJ to capture the cross-linguistic variation and similarity of ergative and accusative systems. Like SUBJ, PIVOT in Manning's proposal is a subcategorised GF that is licensed by the head PRED. This is an important point that makes Manning's PIVOT different from Falk's proposal, to which we now turn.

Falk (2000, 2006) also incorporates PIVOT into LFG. While his conception of PIVOT is broadly in line with PIVOT in typological/functional linguistics (Dixon 1979, Foley & Van Valin 1984, Dixon 1994) and with PIVOT in Manning's proposal, Falk's PIVOT in LFG is different in the following respects. First, Falk's PIVOT is a slightly narrower notion than the generally understood PIVOT in language typology, and in Manning's interpretation. It is only related to what Schachter (1977) calls reference-related properties of subject, not role-related ones. That is, in Falk's conception, pivot is a syntactic function primarily for cross-clausal, combinatoric purposes (Falk 2006: 76).[23]

Second, given that it is a syntactic function, like in Manning's conception, Falk's pivot is an attribute in the f-structure. However, it should be noted that there is an element of grammaticalisation of topichood in clause combining processes. For example, the zero or unexpressed argument in control structures is strongly motivated by topicality and pragmatic efficiencies in cognitive processing (Givón 2001: 219; Hawkins 2004: 163-165). Thus, our conception of pivot as schematised in (22) is slightly different from Falk's in that it is not purely syntactic. pivot should also be understood as carrying a (grammaticalised) element of discourse-pragmatics in the interface with syntax.

Third, the crucial difference between Falk's and Manning's proposals relates to the status of pivot in relation to the deeper conception of argument structure. Falk's pivot is more like dfs or adjuncts in that it is not part of the pred's argument structure. In contrast, Manning's pivot is like subj in that it is licensed by the predicate argument structure. There is good evidence that pivot is grammatically constrained due to its tight link to the pred's argument structure. For instance, pivot selection in relativisation and fronted qs in Balinese impose a verbal voice constraint. Such a constraint is unexpected on Falk's conception of pivot as a non-subcategorised or adjunct-like gf. For this reason, our conception of pivot is in line with Manning's interpretation rather than Falk's. Our pivot is also in agreement with the widely used notion of pivot in typological linguistics.

Finally, it is worthwhile briefly commenting on Falk's conception of pivot and $\widehat{\text{gf}}$, and their related mapping. The notation of $\widehat{\text{gf}}$ (parallel to $\hat{\theta}$ in thematic structure) means the highest gf in the subcategorisation frame of the head pred. Since there is no syntacticised a-structure (distinct from f-structure) in Falk's framework, his $\widehat{\text{gf}}$ is equivalent to the conflated subj in the traditional LFG analysis of gfs (cf. Bresnan & Kanerva 1989), and Manning's syntacticised a-structure. Crucially, the gf-pivot mapping in Falk's analysis does not result in gf alternations. For example, unlike in our analysis where the av-uv alternation changes the mapping of agent and patient, which results in the patient being mapped onto subj in uv, the uv structure in Falk's analysis keeps the patient as syntactic obj and the agent as $\widehat{\text{gf}}$ (i.e. his subj). This is surprising and not empirically supported: the patient of the uv in Balinese shows up in the surface syntax as

---

[23] Falk's (2006) conception of pivot as a syntactic function has been extended in Falk (2007) to account for pragmatic-semantic information in NP syntax (i.e. construct state nominals (CSN) in Hebrew: cf. Sadler 2023 [this volume]. The function of pivot in AN languages differs from the CSN in Hebrew in its application at the clausal level, where it operates exclusively in the symmetrical voice systems, and is most evident in clause combining.

grammatical SUBJ, not OBJ. The evidence comes from the fact that the patient is structurally in the preverbal SUBJ position. In contrast, the agent (which would be SUBJ in AV) appears as OBJ in UV, appearing in the post verbal position (cf. examples 1a–b).

To conclude, our conception of PIVOT is more in line with Manning's interpretation than Falk's interpretation. However, unlike Manning's proposal, we keep the standard LFG conception of SUBJ in f-structure, as we want to keep SUBJ as the clause-internal and most prominent GF, licensed by the head PRED. This is the SUBJ in its role-related dimension in connection to the PRED, distinct from PIVOT (which encapsulates its other clause-external reference-related dimension; Schachter 1977). In addition, and unlike in Falk's and Manning's proposals, we do not represent PIVOT as a separate attribute in f-structure, given the nature of PIVOT with overlapping GF-DF properties as shown in (22a). Its presence can be captured as a construction-type (or language-specific) constraint: see Section 6.3.

In what follows, we discuss and exemplify AN SUBJ and PIVOT further. We begin by illustrating the major differences among AN in the morphosyntactic and behavioural properties of clause-internal SUBJ, and then move on to cases where PIVOT is also present. While SUBJ and PIVOT are oftentimes the same argument, they may diverge (Arka 2021).

4.2.1 SUBJECT: Voice marking and argument flagging

Voice marking encodes SUBJ selection. There are at least three types of voice marking across the AN languages: (i) a multi-way voice system without distinct passive/applicative morphology; (ii) a two-way (AV versus UV) voice system, typically with distinct passive/applicative morphology, and; (iii) a restricted and mixed voice-indexing system. Each is discussed below, including its related argument flagging, from an LFG perspective.

SUBJ selection in multi-way voice systems is encountered in Formosan/Philippine-type languages such as Puyuma (Teng 2008), Tagalog, Kelabit (Borneo), Talaud (North Sulawesi; see Utsumi 2013) and Malagasy. The systems in these languages exhibit several salient properties. First, verbal morphology selects SUBJ as having a specific semantic role rather than a generalised role. This role-specific linking of SUBJ is particularly clear in non-actor voice types. Tagalog, for example, shows Patient Voice (PV), Locative Voice (LV), Instrumental Voice (IV), and Dative Voice (DV, including dative/goal/benefactive), in addition to Actor Voice (AV: Foley & Van Valin 1984: 135; Arka 2003b). Kelabit, on the other hand, shows a simpler system with a three-way opposition between AV, UV, and IV. For simplicity, only AV-PV-LV alternations, like in Tagalog, and AV-PV alternations, like in Kelabit, are given in (23)-(24) below.

(23) Tagalog (Kroeger 1993: 14)

a. M⟨um⟩ili **ang**=lalake ng=isda sa=tindahan.
⟨PFV.AV⟩buy SUBJ=man CORE=fish NONCORE=store
'The man bought fish at the store.'

SUBJ $\text{OBJ}_{\text{PATIENT}}$
'AV.buy⟨1:agt, 2:pt ⟩'

b. B⟨in⟩ili-∅ ng=lalake **ang**=isda sa=tindahan.
⟨PFV⟩buy-PV CORE=man SUBJ=fish NONCORE=store
'The man bought the fish at the store.'

$\text{OBJ}_{\text{AGENT}}$ SUBJ
'PV.buy⟨ 1:agt, 2:pt⟩'

c. B⟨in⟩ilih-an ng=lalake ng=isda **ang**=tindahan.
⟨PFV⟩buy-LV CORE=man CORE=fish SUBJ=store
'The man bought fish at the store.'

$\text{OBJ}_{\text{AGENT}}$ $\text{OBJ}_{\text{PATIENT}}$ SUBJ
'LV.buy⟨ 1:agt, 2:pt, 3:loc⟩'

(24) Kelabit (WMP, Indonesia) (Hemmings 2021: 161)

a. **La'ih sineh** nenekul nuba' ngen seduk.
man DEM AV.PFV.spoon.up rice with spoon
'The man spooned up his rice with a spoon.'

SUBJ OBJ
'AV.spooned.up⟨1:agt,2:pt⟩'

b. **Nuba**' sikul la'ih sineh ngen seduk.
rice PV.PFV.spoon.up man DEM with spoon
'That man spooned up rice with a spoon.'

OBJ SUBJ
'PV.spooned.up⟨1:agt, 2:pt⟩'

SUBJ selection is also indicated by structural properties, such as syntactic position and flagging. In Tagalog, SUBJ is flagged by *ang*= in (23) above.[24] In Kelabit,

---

[24] The intransitive ⟨1:agt⟩ (or S) argument in Tagalog is also flagged by *ang*=, providing robust evidence for clause-internal subjecthood (i.e. the sole core intransitive argument is SUBJ):

(i) Nagsalita ang=babae.
spoke SUBJ=woman
'The woman spoke.' (De Guzman 1988: 323-324)

subj is a bare NP that occurs preverbally, and has no prepositional flagging to distinguish it from obl.

Second, the data points above exemplify the hallmarks of the AN symmetrical voice system in two respects: morphologically and syntactically (Foley 1998, Arka 2003b, Himmelmann 2005, Riesberg 2014). In terms of morphological marking, all voice types are equally marked, as clearly seen in Tagalog and Formosan languages, such as Puyuma (Teng 2008) and Pazeh-Kaxabu (Yeh 2019). None of their voice marking is morphologically 'default'. As for Kelabit, the root of the pv verb is *sikul*, and the pv marking involves *i*-ablaut and sibilation of /t/ to /s/, analysable as a variant of the infix *in-* also seen in Tagalog.[25] In LFG, semantically transitive predicates, such as 'buy' in (23) and 'spoon up' in (24), are listed in their lexical entries as verbal roots with a-structures containing ⟨1:agt, 2:pt⟩ (i.e. the most actor-like and patient-like arguments are the first two ordered core arguments). Voice morphology is a marker for subj linking, following general principles in Lexical Mapping Theory (LMT), and will be further discussed in Section 4.3.

Another syntactic hallmark of the AN symmetrical voice system is that core arguments are equally selectable as subj without obligatory demotion of any other core argument in the argument structure. This results in a non-av alternation with cross-linking as depicted in (4), where ⟨1:agt⟩ remains the most prominent argument. Evidence for the non-demotion of ⟨1:agt⟩ comes from reflexive binding as demonstrated in Balinese (5) and Kavalan (6). Other evidence comes from argument marking/flagging. This is clearly demonstrated in the av-pv alternation in Tagalog in (23a–b). The alternative linking between ⟨1:agt⟩ and ⟨2:pt⟩ to subj and obj correlates with the alternative flagging with *ang=* and *ng=*. The phrase markers *ang=* and *ng=* in Tagalog flag subj and obj respectively. Hence, in the pv in (23b), ⟨1:agt⟩ remains core as it is flagged with *ng=*. This non-demotion property is what typologically distinguishes the AN symmetrical voice system from Indo-European languages like English.

Next, subj selection in AN languages with two-way voice systems is typically encountered in the Indonesian-type. It shows similar symmetrical voice properties to those observed in Tagalog with the exception that the selection of a peripheral semantic role as subj requires a specific applicative marker. Consider the Balinese examples in (25b)-(25c) below, which is a near equivalent of the LV in Tagalog, as seen previously in (23c):

---

[25] We thank an anonymous reviewer for pointing this out.

(25) Balinese (Arka 2014b: 60, 75)

a. Ia meli baas (sig dagang-e ento).
3 AV.buy rice at trader-DEF that
'(S)he bought rice from the trader.'
SUBJ OBJ OBL
'AV.buy⟨1:agt, 2:th | 3:loc/source⟩'

b. Ia meli-**nin** **dagang-e** **ento** baas.
3 AV.buy-APPL trader-DEF that rice
'(S)he bought rice from the trader.'
SUBJ OBJ OBJ$_{\text{THEME}}$
'AV.buy⟨1:agt, 2:loc/source, 3:th ⟩'

c. **Anak-e** **nto** belin-**in** tiang potlot.
person-DEF that UV.buy-APPL 1 pencil
'I bought a pencil from the person.'
OBJ SUBJ OBJ$_{\text{THEME}}$
'UV.buy⟨1:agt, 2:loc/source, 3:th ⟩'

In Balinese, the two-place transitive verb *beli* 'buy' obligatorily requires the applicative marker -*(n)*in order to add a locative/source to the base structure as a core argument. Compare the locative/source role flagged by *sig*[26] in (25a) and the unflagged locative/source argument in (25b). The latter is licensed by the verb that contains the applicative morpheme -*in*, and receives a P(atient)-like core status, resulting in a ditransitive construction. Crucially, with an applicative verb (25b–c), the locative/source argument is promoted to the second most prominent position among the core arguments (i.e. ⟨2:loc/source⟩), essential for its selection as SUBJ; hence, it can appear sentence-initially without flagging as shown in (25c). Similar to Formosan/Philippine languages, core arguments are equally selectable as SUBJ in two-way voice systems (i.e. evidencing the symmetricality of syntax), except that the latter languages require a distinct applicative marker, while the former have more robust verbal voice morphology.

Additionally, AN languages of the Indonesian type often have a real passive voice. Sundanese, for example, has a passive marked by *di*-. In passive voice, ⟨1:agt⟩ is demoted to non-core status, resulting in the promotion of patient to the first argument and its link to SUBJ, as shown in (26b).

---

[26] The noun phrase flagged by *sig* in (25a) differs from other non-thematic locatives of OBL adjunct in terms of its thematic animacy (versus inanimate location marked by *ka*). See Arka (2014b) for other syntactic properties targeting the distinction between arguments and adjuncts.

(26) Sundanese (WMP, Indonesia) (Davies & Kurniawan 2013: 123)

a. **Asép ngirim** buku ka Enéng.
Asep AV.send book to Eneng
'Asep sent a book to Eneng.'

SUBJ OBJ OBL
'AV.send⟨1:agt, 2:pt |3:go⟩'

b. **Buku éta di**-kirim ka Enéng ku Asép.
book that PASS-send to Eneng by Asep
'The book was sent to Eneng by Asep.'

SUBJ OBL OBL
'PASSV.send⟨1:pt | 2:agt, 3:go⟩'

AN languages of the indexing type, such as Kambera, Kodi and Wooi, also show clause-internal evidence for SUBJ even in the absence of a typical voice system. In these languages, SUBJ is expressed by a pronominal index (clitic/affix) that commonly exhibits a NOM pattern. In Wooi, for example, the verbal prefix *he*- indexes the intransitive SUBJ in (27a) and transitive SUBJ in (27b). Incidentally, a free NP would optionally cross-reference the SUBJ index for pragmatic reasons (e.g. to express contrastive FOCUS) or for semantic reasons (e.g. to express an associative plural as seen in 27b). In our LFG analysis, the index *he*- fills the SUBJ slot in the verbal template. Since *he*- is referential, it contributes [PRED='PRO'], [NUM=PL], and [PERS=3] to the value of SUBJ.

(27) Wooi (CEMP, Eastern-Indonesia) (Sawaki 2016: 203, 206)

a. Henda.
he-t-ra
3PL-PL-go
'They went.'

b. Jon hendora Agus hia na ramdempe.
Jon **he**-t-rora **Agus hia** na ramdempe
John 3PL-PL-hit Agus 3PL LOC yesterday
'John and associates hit Agus and associates yesterday.'

4.2.2 Behavioural properties of SUBJECT/PIVOT

In the introduction to Section 4, we clarified the theoretical orientation for the terminology used here to denote the distinct notions of SUBJ and PIVOT. In this section, we focus specifically on how PIVOT is motivated, and exemplify cases in AN languages where PIVOT must be strictly identified with SUBJ (henceforth, SUBJ/PIVOT) and other cases where PIVOT is not necessarily SUBJ. We begin with SUBJ/PIVOT cases.

Evidence for the SUBJ/PIVOT constraint is observed in the fronted QS in Balinese and Amis. Consider the QS *apa* 'what' in Balinese (28a) and *cima* in Amis (29) below. They appear *in situ* because they are simply 'weak' FOCUS. By contrast, when the QS are placed sentence-initially (i.e. fronted) as in (28b) and (30), they must be understood as SUBJ. This discourse prominent property of FOCUS-C has turned SUBJ into the highly privileged status of SUBJ/PIVOT that is borne by the fronted Q. Now consider the contrasting status of arguments that do not involve the overlay function of PIVOT. In the Balinese example (28a), the Q is not fronted. Even for the fronted Q in example (28b), the sentence is only acceptable with reading (i) (indicated by the solid line). While the NP *ci* is closer to the subject position, it can only be understood as OBJ.

(28) Balinese (Arka 2003a: 27)

a.

[Ci	ngalih	**apa**	ditu	ibi]$_{\text{IP}}$?
2	AV.search	OBJ	there	yesterday

'What did you look for there yesterday?' (in-situ Q=OBJ$_{\text{TH}}$)

b.

Apa	ci [	__	ngalih	__	ditu	ibi]$_{\text{IP}}$?
[what]$_{\text{FOCUS-C}}$	2	SUBJ	AV.search	OBJ	there	yesterday

(PIVOT)

i) 'What looked for you there yesterday?' (fronted Q=SUBJ/PIVOT.agt)
(e.g. a ghost might have disturbed the addressee)
ii) NOT FOR 'What did you look for there yesterday?'

(29) In-situ Q (Central Amis - Formosan) (Yeh, fieldwork data)

a.

[Mi-palo'-ay	[**cima**]$_{\text{SUBJ/FOC}}$	ci	Mayaw-an]$_{\text{IP}}$?
AV-whip-REAL	who	PN	Mayaw-LOC

'Who whipped Mayaw?' (in-situ Q=SUBJ.agt)

b.

[Mi-palo'-ay	ci	Panay	[**cima**-an]$_{\text{OBL/FOC}}$]$_{\text{IP}}$?
AV-whip-REAL	PN	Panay	who-LOC

'Who did Panay whip?' (in-situ Q=OBL.pt)

(30) fronted Q (Central Amis - Formosan) (Yeh, fieldwork data)

a. [U **cima**]$_{\text{FOCUS-C}}$ [ku mi-palo'-ay __ ci Mayaw-an]$_{\text{COMP}}$?
PRT who CN.ABS AV-whip-REAL SUBJ PN Mayaw-LOC
(PIVOT)
'WHO was the one that whipped Mayaw?' (fronted Q=SUBJ/PIVOT.agt)

b. [U **cima**]$_{\text{FOCUS-C}}$ [ku ma-palo'-ay ni Panay __]$_{\text{COMP}}$?
PRT who CN.ABS PV-whip-REAL PN.GEN Panay SUBJ
(PIVOT)
'WHO was the one that Panay whipped?' (fronted Q=SUBJ/PIVOT.pt)

c. * U cima ku mi-palo'-ay ci Panay?

d. * Cima-an ku mi-palo'-ay ci Panay?

Likewise, the difference between SUBJ and PIVOT is evidenced by the distinct status of SUBJ PIVOT in (30) and SUBJ in (29). In the latter, no FOCUS-C is involved, and thus SUBJ remains in-situ. By contrast, the fronted QS in (30) specifically privilege SUBJ PIVOT as seen by the verbal voice morphology (e.g. unacceptability of 30c in contrast to 30b), and they are associated with the extra-syntactic function FOCUS-C in the discourse. Pragmatically, there is a difference between the fronted QS and in-situ QS. The in-situ Q in (29a) forms an open question without the presupposition of contrasting entities in the given context (Wei 2009: 348). In contrast, the fronted Q in (30a) is used when the SUBJ agent in question is one among a group of people present in a given situation. This indicates that the fronted Q comes with a pragmatic meaning of contrast that is not present with the in-situ Q.

Note that Amis differs from Balinese in that in-situ QS in Balinese are OBJ, whilst those in Amis can be either SUBJ or non-SUBJ. This is because the two languages differ in their word order. SUBJ is pre-verbal in Balinese, whereas Amis is verb-initial like Squliq and Tagalog (cf. Section 3) and thus, SUBJ is realised preverbally in pragmatically marked constructions.

In particular, the essence of PIVOT as the overlay function for clause-combining is evidenced by the structure of fronted QS in Amis. Structurally, the sentences with fronted QS in (30a–b) are pseudo-clefts in a bi-clausal structure. The QS are fronted nominal predicates in FOCUS, followed by a headless relative clause flagged by *ku* (i.e. the ABS case nominal marker) in which SUBJ is obligatorily relativised. The SUBJ marker supplies the pronominal value that is coreferential with the fronted Q (cf. Section 6.3 for the LFG representation of bi-clausal structures with a nominal predicate).

However, the Balinese data point in (28b) also shows that the subj/pivot constraint is not necessarily related to clause combining. This is expected as focus-c (the critical element of pivot) is pragmatically driven for communicative purposes, applicable to a mono-clausal sentence.

q fronting interacts with verbal voice morphology. In Amis, only the most prominent argument (i.e. subj) takes part in this pivot function for fronting qs. For instance, when understood as A, its selection as subj is indicated by the same av morphology for an in-situ subj, as in (29a), and a fronted subj, as in (30a) (i.e. subj/pivot). However, when the q *cima* bears the patient role, its fronting (i.e. linking Patient as the subj in focus-c) requires pv morphology as seen in (30b). Retaining av morphology on the verb renders the structure with a fronted q ungrammatical, as seen in (30c). Likewise, in contrast to (29b), the structure is ungrammatical when the fronted q *cima* is obl marked by *-an*, as in (30d).

In short, we have seen how pivot as a syntactic-pragmatic function combines the syntactic property of subj and the focus-c function in giving rise to the subj/pivot constraint associated with q fronting in Balinese and Amis. Other behavioural properties targeting subj as pivot typically encountered in Philippine-type and Indonesian-type AN languages include control/raising and relativisation (see Arka 2003a: 11-26).

Recent research in Indonesian relativisation demonstrates strong evidence that pivot is not always subj.[27] The distinction between subj and pivot in Indonesian receives further empirical support by the fact that obj can also be pivot, as seen in relativisation in (31). However, this obj relativisation through gapping (i.e. obj pivot) is highly constrained. It is only possible in a specific construction when both subj and obj are highly salient with the presence of certain contrastive adverbs, such as *hanya* 'only', where the subj-only constraint that is typically imposed in complex clause formation in Standard Indonesian is not maintained. Thus, while the agent *kamu* '2sg' is subj in (31), as evidenced from the verbal av morphology, it is not the pivot for relativisation. Readers are directed to Arka (2021) for a detailed discussion of these relativisation facts in Indonesian, and the puzzles they pose for analysis.

(31) Standard Indonesian (Arka 2021: 196)
[**Gadis** [yang [(barangkali) [**hanya kamu** bisa menaklukkan __]$_{\text{CP}}$]$_{\text{CP}}$]$_{\text{NP}}$
girl rel perhaps only 2sg can av.conquer
'the girl who perhaps only you can control'

---

[27] This is evident in relativisation in familiar languages, like English, where non-subj can be pivot (i.e. gapped in relativisation).

4.3 Non-subj functions: obj and obl

In LFG, there are three non-subj functions: obj, obj_θ, and obl. In this subsection, we explore their realisation in AN languages, and show that distinguishing these three non-subj functions is useful in the transitivity analysis of the av patient, and in the analysis of Indonesian-type applicatives. This is because LFG's modular design and conception of gfs as 'natural' classes allow us to not only distinguish obj from obl at the level of syntactic f-/a-structure, but also to capture the gradient nature of the obj-obl distinction in Prototype theory (cf. Taylor 2003) and a core index analysis (Arka 2017). We begin with a characterisation of objs.

On the basis of cross-linguistic gf classifications, and research on syntactic prominence and semantic role associations (Comrie 1989, Bresnan 2001), we define obj syntactically as a class of core complements that is prototypically and thematically unrestricted. The syntactic property of complementation distinguishes obj from subj since subj is not a complement, and the coreness property differentiates it from obl since obl is not a core argument. Defining obj as a class of gf in this way allows us to capture the varied characteristics of obj cross-linguistically, but also within the same language (cf. Dalrymple & Nikolaeva 2011). It also allows us to identify language-specific object-like patterns, which provide empirical grounds for identifying different kinds of obj: prototypical or primary obj (thematically unrestricted obj) and secondary non-prototypical obj (also thematically restricted, and otherwise known as obj_θ in LFG) (Bresnan & Kanerva 1989, Haspelmath 2007). In what follows, we show the variation in the actual morphosyntactic realisations of different types of obj in AN languages, starting with the prototypical obj.

The prototypical obj in descriptive/typological linguistics is patient-like in its semantic role. In our LFG analysis, this obj is linked to the a-object (i.e. ⟨2:pt⟩) in the a-structure representation. In AN languages with voice systems, it is the core argument of the verb in the av structure, and typically appears postverbally, like the NP *Watan* in (7) (Squliq Atayal) and *apa* 'what' in (28) (Balinese). Squliq Atayal and Balinese represent languages where free obj arguments have no specific obj flagging. obj NPs are bare, in contrast to prepositionally flagged obls.

However, there are also AN languages that specifically flag arguments with non-subj core status, like *ng=* in Tagalog in (23) above, and *te* in Tukang Besi in (32) below. In Tukang Besi, the pronominal indexing system on the main (finite) verb of an embedded clause shows diminished voice morphology (Donohue 2008: 8). The underlying ⟨2:pt⟩ 'you' surfaces as obj in (32a) and is flagged by *te*, and not indexed on the verb. It appears as subj, which is indexed by the enclitic *=ko*, and is optionally cross-referenced by the nom NP that is flagged by *na* in (32b).

(32) Tukang Besi (WMP, Indonesia) (Donohue 2002: 85)

a. No-kiki'i [te iko'o]$_{\text{OBJ}}$ [na beka]$_{\text{SUBJ}}$.
3REAL-bite CORE you NOM cat
'The cat bit you.' SUBJ OBJ
'bite⟨1:agt:'cat',2:pt:'you'⟩'

b. No-kiki'i[=ko]$_{\text{SUBJ}}$ ([na iko'o]$_{\text{SUBJ}}$) [te beka].
3REAL-bite=2SG.OBJ NOM you CORE cat
'The cat bit you.' or 'You, the cat bit.' OBJ SUBJ
'bite⟨1:agt:'cat',2:pt:'you'⟩'

Note that the GF alternation in Tukang Besi in (32) is equivalent to the AV-UV alternation in Indonesian-type languages, like the Balinese example in (5). The key differences relate to verbal voice marking and argument flagging. Unlike in Balinese, the AV structure in Tukang Besi in (32a) has no verbal AV morphology, and its OBJ is overtly flagged.

The thematically unrestricted property of OBJ is captured by the [−*r*] feature in LMT (Bresnan & Kanerva 1989; Dalrymple 2001: 21). That is, it is linkable to a range of roles other than patient. In our definition in this chapter, it is indeed a non-SUBJ core argument, as seen in Tukang Besi in (32b) where the OBJ flagged by *te* is linked to the agent. Additionally, other roles associated with OBJ include instrumental, benefactive/recipient, goal, and locative, as seen in the Indonesian-type languages that show applicative morphology (e.g. Indonesian, Balinese, Madurese, among others). Madurese has two applicative suffixes, namely *-e* (for locative/goal applicative) and *-agi* (for benefactive/instrumental), both of which are equivalent to *-i*/*-kan* in Indonesian (Arka et al. 2009) and *-in*/*-ang* in Balinese (Arka 2003a). The Madurese examples in (33) show that the post-verbal OBJ is the thematically unrestricted OBJ, which is linked to patient/theme in (33a), locative/goal in (33b) (with the verb containing the locative applicative, *-e*), and recipient/benefactive in (33c) (with the verb containing the recipient applicative, *-agi*).

(33) Madurese (Davies 2010: 283, 299)

a. Embuk ngerem [paket]$_{\text{OBJ}}$ [ka Ebu']$_{\text{OBL}}$.
elder.sister AV.send package to mother
'Big Sister sent a package to Mother.' SUBJ OBJ OBL
'AV.send⟨1:agt,2:pt |3:goal⟩'

b. Embuk ngerem-**e** [Ebu']$_{\text{OBJ}}$ [paket]$_{\text{OBJ}_\theta}$.
elder.sister AV.send-APPL mother package
'Big Sister sent Mother a package.' SUBJ OBJ $\text{OBJ}_{\text{THEME}}$
'AV.send.for⟨1:agt,2:goal. 3:th⟩'

c. Sa'diyah melle-**yagi** [na'-kana']$_{\text{OBJ}}$ [permen]$_{\text{OBJ}_\theta}$.
Sa'diyah AV.buy-APPL REDUP-child candy
'Sa'diyah bought the children candy.'
SUBJ OBJ $\text{OBJ}_{\text{THEME}}$
'AV.send.for⟨1:agt,2:goal, 3:th⟩'

While primary OBJ is thematically unrestricted, secondary non-prototypical OBJ is typically thematically restricted. This is evidenced in the important effect of applicativisation whereby the a-structure is restructured with OBJ and OBJ_θ surfacing differently. Consider, firstly, the PP in (33a), *ka Ebu'* 'mother', which is prepositionally flagged as OBL (i.e. non-core). Yet, the argument is promoted to the secondmost prominent slot in the applicative structure in (33b). Its realisation as a bare NP, and its structural position immediately following the verb, indicate that it is OBJ, while the underlying displaced theme *paket* is demoted to the third core position, and surfaces as OBJ_θ. This results in a ditransitive structure of SVOO. Likewise, the same restructuring of a-structure occurs with the benefactive applicative in (33c).

In LFG, the NP *paket* in (33b) is an instance of $\text{OBJ}_{\text{THEME}}$ in Madurese. Semantically, it is restricted to a displaced theme only. Crucially, and unlike OBJ (*Ebu'*), it is restricted in the sense that it does not surface as SUBJ in the UV voice, as seen in the ungrammaticality of (34b) in contrast to (34a). This provides clear evidence that the applied argument occupies the second argument in the restructured transitive a-structure. Hence, it is 'mappable' to OBJ in AV in (33b), or SUBJ in UV in (34a).[28]

(34) Madurese (Davies 2010: 284)

a. Ebu' e-kerem-e [paket]$_{\text{OBJ}}$ bi' Embuk.
mother UV-send-APPL package by elder.sister
'Mother was sent a package by Big Sister.'
OBJ SUBJ $\text{OBJ}_{\text{THEME}}$
'UV.send⟨1:agt,2:goal, 3:th⟩'

---

[28] The preposition *bi'* 'by' is optional in Madurese. There is no identifiable grammatical difference between the pairs with/without *bi*; the verb in this structure is therefore analysed as UV, not passive (Davies 2010: 256-258).

b. *[Paket rowa]$_{\text{subj}}$ e-kerem-e (ka) Ebu' bi' Embuk.
package that uv-send-appl to mother by elder.sister
('The package was sent (to) Mother by Big Sister.')

In AN languages with a systematic argument indexing system, obj is typically semantically transparent from its case form. That is, the obj index is part of a verbal complex structure, either as a pronominal affix or clitic, and surfaces differently according to semantic roles. In Kambera, for example, the prototypical patient-like obj is expressed by an acc enclitic immediately following the verb, whereas the benefactive obj is marked differently via dat. Hence, the first-person patient obj is *ka* '1sg.acc' in (35a), but *ngga* in (35b), since it is thematically beneficiary. Note that the displaced theme, obj$_{\text{theme}}$, in (35b) is dat. In LFG, the Kambera ditransitive sentence in (35b) has the same a-/f-structures as the Madurese examples in (33b–c), with the key differences being in the coding and feature values of the surface gfs. For the right enclitic form of obj to be selected, the lexical entry must be specified by the relevant constraints, as shown in (35c) with *=ngga*. The shorthand (↑ obj)$_\sigma$=(↑$_\sigma$ 2:ben) constraint relies on a sigma projection relating f-structure to a-structure, here establishing a correspondence between the obj in the f-structure and the second benefactive argument in the a-structure (see Belyaev 2023b [this volume] for discussion of LFG's projection architecture).

(35) Kambera (Klamer 1998: 63)

a. (Na tau wútu) na=palu=ka (nyungga).
art person be.fat 3sg.nom=hit=1sg.acc I
'The big man hit me.'
subj:nom obj:acc
'hit⟨ 1:agt, 2:pt⟩'

b. (I Ama) na=kei=ngga=nya.
art father 3sg.nom=buy=1sg.dat=3sg.dat
'Father buys it for me.' subj:nom obj:dat obj$_{\text{theme}}$:dat
'buy⟨ 1:agt, 2:pt 3:th⟩'

c. *ngga* CLITIC (↑ obj pred)='pro'
(↑ obj pers)=1
(↑ obj num)=sg
(↑ obj case)=dat
(↑ obj)$_\sigma$=(↑$_\sigma$ 2:ben)

The different coding of obj, as seen in Kambera, is not typologically unusual. It is known as Differential Object Marking (henceforth DOM) (Dalrymple & Nikolaeva 2011). For instance, Palauan has DOM that is primarily regulated by semantic features. However, unlike Kambera, Palauan demonstrates DOM that is determined by definiteness, instead of semantic roles. Definite obj receives pronominal indexing on the verb, as in (36a), whereas indefinite obj does not, as in (36b). In an LFG analysis, Palauan DOM can be captured by annotating the suffix slot in the verb formation rule with the constraining equation: (↑ obj def)$=_c$+. The suffix *-ii* also carries a definiteness feature in its lexical entry, (↑ def)=+, in addition to person and number features.

(36) Palauan (WMP, Palau) (Georgopoulos 1991: 45)

a. Te-'illebed-**ii** a bilis a rengalek.
3pl-pfv.hit-3sg dog children
'The kids hit the dog.'

b. Te-'illebed a bilis a rengalek.
3pl-pfv.hit dog children
'The kids hit a dog/the dogs/some dog(s).'

Obliques in AN languages are typically phrasally flagged. The common pattern is that obl is flagged by an adposition, like *ka* 'to' for obl locative/goal in Madurese (33a), and *teken* 'by' for obl agent in Balinese (Arka 2019: 262). However, AN languages of the Philippine type have phrasal markers that specifically mark obl status in contrast to the core status of subj. This is the case in Puyuma where the obl and subj are equally flagged. However, Puyuma shows differential obl marking on the basis of differences in nominal type (e.g. common versus proper) and definiteness (as seen in DOM) rather than differences in semantic roles. Consider example (37) below, where *kana* is used as the phrasal obl marker for a definite common noun like in (37a), and *dra* for an indefinite common noun as in (37b–d). The same phrase marker, *dra*, is used for indefinite obliques irrespective of their roles as patient, instrument, location, etc.

(37) Puyuma

a. Ku=tuLud-anay na sarekuDan **kana** temumuwan.
1sg.gen-pass-iv def.nom stick def.obl offspring
'I passed the stick to the offspring.' (Teng 2005: 23)

b. Tr⟨em⟩aka-trakaw=ku **dra** akan-an.
⟨av⟩redup-steal=1sg.nom indf.obl eat-nmlz
'I stole food repeatedly.' (Teng 2008: 146)

c. Tu=pa-ladram-aw **dra** lrangetri pa-karun.
3GEN=CAUS-know-PV INDF.OBL stick CAUS-work
'They used a stick to teach them to work.' (Teng 2008: 245) (translation adapted)

d. Ka-sa-sanan **dra** dalran.
ka-REDUP-stray INDF.OBL road
'He will get lost.' (Teng 2008: 168)

4.4 Alignment systems and related phenomena

The syntactic status of the non-SUBJ argument is relevant to the question of alignment. There is a long-standing debate in AN linguistics as to whether syntactic alignment has properties of ergativity, accusativity or split-ergativity. There are competing proposals in the literature, as well as claims that Western AN languages vary in their alignment; see Aldridge (2004), Katagiri (2005), and references therein for further discussion. In the following section, we present cases where morphosyntactic ergativity is firmly observed, like in Puyuma, then move to borderline cases.

Puyuma exhibits syntactic properties that are typical for an ergative system. However, unlike well-known ergative languages such as Dyirbal (Dixon 1972), there are no morphologically 'basic' or unmarked transitive verbs in Puyuma because they are all marked for their specific non-actor voices; e.g. *-anay* marking for CV, conveyance voice, in (37a), and *-aw* for PV, patient voice, in (37c). The AV verbs are also morphologically marked by *-em-* as in (37b).[29] The AV structure can be analysed as antipassive because the patient argument of the transitive verb is demoted to non-core status, which is flagged by the OBL marker as shown in (38). Puyuma, therefore, exhibits clear syntactic asymmetry in its voice alternations, which is the hallmark of a truly ergative system. In the transitive structure, ⟨1:agent, 2:patient/theme⟩, the two core arguments are not equally selectable as syntactic SUBJ/PIVOT. That is, SUBJ/PIVOT selection is asymmetrically aligned towards the second patient core slot. Hence, when the agent has to be linked to SUBJ/PIVOT, the patient must be removed and demoted to non-core status in order to allow for the linking of the agent to SUBJ/PIVOT. Removing the patient from the core status in the a-structure results in an intransitive ⟨1:agent | 2:patient/theme⟩ structure.

---

[29] Note that in Teng's (2005, 2008) descriptions, the AV affix *-em-* is glossed as intransitive (INTR) because the AV structure is syntactically intransitive.

(38) Puyuma (Teng 2008: 72, 187)

a. T⟨em⟩engedr=ta dra unan i, ...
⟨AV⟩kill=1PL.NOM INDF.OBL snake TOPIC, ...
'We killed a snake, ...'

b. K⟨em⟩asu=ta dra eraw, dra irupan.
⟨AV⟩bring=1PL.NOM INDF.OBL wine INDF.OBL dishes
'We brought some wine and some dishes.'

However, in many other AN languages with robust voice morphology, the antipassive analysis of AV is controversial because the evidence for the demotion of the underlying patient to OBL is often unclear and debatable. In Tagalog, for example, the patient argument of the AV sentence is flagged by the core phrase marker *ng* in (23a). Thus, the AV sentence in Tagalog is distinct from Puyuma in that it is syntactically transitive. Conversely, under an ergative analysis, the AV is analyzed as antipassive on the basis that P is understood as indefinite, which is a typical semantic property of the antipassive patient (Hopper & Thompson 1980). Yet, this semantic criterion for the core status of AV patient is disputable, as shown in the Paiwan (Formosan) examples in (39) below. While an OBL patient may be indefinite, as in (39a), the reverse does not hold since an oblique-marked patient can have a definite reading, as seen in (39b) (cf. DOM in Puyuma in Section 4.3). This suggests that in many Philippine-type languages, the coreness status of the non-SUBJ argument in AV cannot be easily and solely specified by its semantic property due to the mismatch of semantic transitivity, syntactic transitivity and voice alternation.[30]

(39) North Paiwan (Formosan) (Chang 2006: 114, 412)

a. Ki-lakarav tua sipangetjez tua zua marekaka.
obtain.AV-flower OBL.CN gift OBL.CN that both.sibling
'(He) would pluck flowers as a gift for both sisters.'

b. Na=t⟨em⟩ekeL=anga timadju tua ʔucia.
PFV=drink⟨AV⟩=COMPL 3SG.NOM OBL.CN tea
'He has drunk the tea.'

---

[30] The status of coreness must, therefore, be determined by taking into account all the relevant language-specific morphosyntactic properties. This is possible via a core index analysis (Arka 2017), for example. The core index analysis applied to the P of the AV structure in Puyuma reveals a core index of 0.44, which is classified as OBL albeit atypical. A prototypical OBL in Puyuma (e.g. LOC OBL of the AV verb) has a core index of 0.11, which is in line with the cross-linguistic tendency for prototypical OBL to have a core index of below 0.20. The degrees of coreness/obliqueness for the P of AV structures across other Philippine-type languages is a matter of future research.

Likewise, for AN languages in the regions of Sulawesi, which have been analysed as showing ergative properties, the status of the av patient is not very straightforward either. Consider the examples in (40) from Moronene (in Southeast Sulawesi). Moronene shows DOM whereby a definite obj NP receives object indexing. Conversely, an indefinite or a non-specific obj NP receives no such indexing. The av sentence with av morphology (*moN-*) has been analysed as antipassive (Andersen & Andersen 2005) based on the patient NP being indefinite or non-specific.

(40) Moronene (WMP, Indonesia) (Andersen & Andersen 2005: 246, 252)

a. Yo laku ari **kea'-o** manu.
art civet already bite-3sg.abs chicken
'The civet bit the chickens.' [laku11]

b. Da-hoo nta **mong-kea** miano.
be-3sg.abs fut av.nf-bite person
'It will bite someone.' [col85] [AuAbmV]

While it is true that the av structure shows a lower degree of transitivity in terms of parameters described by Hopper & Thompson (1980), it is not syntactically antipassive in the analysis where the a-structure consists of two core arguments; that is, the patient NP in (40) is obj, not obl. Additional evidence for this comes from its expression in bare NPs and the fact that obl is prepositionally flagged in Moronene.

In addition to semantic properties, other syntactic evidence in complex constructions such as control properties has been used to argue for an accusative and/or a split ergativity analysis (i.e. acc case for the av patient). For instance, proponents of treating av patient as a core argument (Hsin 1996, Chang 2000) would analyse the phrasal marker *tu* in Kavalan (41) as an accusative case marker, as it phrasally marks the a-object of *pumupup* that functionally controls the subject of the second verb *matiw* 'go'. The argumentation here is that only core status can allow an argument to be the controller.

(41) Kavalan (Chang 1997: 198)
P⟨um⟩upup tina-na **tu sunis 'nay** m-atiw sa Bakung.
⟨av⟩persuade mother-3sg.gen obl child that av-go prep Bakung
'That child's mother persuaded the child to go to Bakung.'

However, the status of controller in the matrix clause may not be decided purely on syntactic grounds since it also depends on the semantic properties of the matrix verb. The control construction in (41) is analysed as the 'influential' type of control, defined by lexical semantic properties (Sag & Pollard 1991), where the controller is the influenced argument (i.e. the persuadee) regardless of its GF. In other terms, the choice of controller is based on the lexical semantics of the control verb that requires an intentional agent in an open clause complement (XCOMP). However, the control verb does not specify that the syntactic properties of the influenced argument are core or oblique.

Instead, it is the status of the controllee in the embedded clause that provides the diagnosis of termhood (Kroeger 1993: 40). Only core arguments can be the controllee, as opposed to OBL arguments. In the Kavalan example (41), the controllee is the SUBJ of a non-finite AV verb *matiw*, so the agent argument in the embedded clause fulfils both syntactic and semantic properties required by the 'influential' type of control. Likewise, in Haian Amis, the core status of the AV agent is evident by its property as the controllee (i.e. AV-SUBJ) as in (42a–b), regardless of its status as the controller (i.e. PV-SUBJ or AV-OBL) in the matrix clause. By contrast, as shown in (42c), it is not acceptable for the AV patient (i.e. *ci Akian* in 42c) in the embedded clause to be the intended controllee.[31]

(42) Haian Amis (Formosan) (Wu 2006: 378–379)

a. Ma-ucur aku ci Aki mi-to'or ci Panay-an.
PV-assign 1SG.GEN PN.ABS **Aki** AV-follow PN Panay-LOC
'I assigned Aki to follow Panay.'

b. Mi-ucur kaku ci **Aki-an** mi-to'or ci Panay-an
AV-assign 1SG.ABS PN Aki-LOC AV-follow PN Panay-LOC
'I am going to assign Aki to follow Panay.'

c. *Mi-ucur kaku ci **Aki-an** mi-to'or ci Panay
AV-assign 1SG.ABS PN Aki-LOC AV-follow PN.ABS Panay
'I am going to assign Aki to be followed by Panay.'

In comparison to other grammatical tests (e.g. 2P clitic placement, pronominal bound forms and DOM), evidence of control in complex constructions for testing the status of non-SUBJ arguments should be examined carefully. That is, using control verbs as the evidence of an accusative analysis of the AV construction necessitates a meticulous evaluation and differentiation between properties of control that have semantic roots and those that are purely syntactic in nature.

At the morphological level, pronominal forms (affixes/clitics) across AN languages show nominative and ergative alignment. In AN languages with robust

---

[31] However, Haian Amis differs from Tagalog (Kroeger 1993) and Pazeh-Kaxabu (Yeh in preparation) in that the core status of a PV agent cannot be observed via properties of the controllee.

voice systems, the bound pronouns typically consist of two sets. The first set is often labelled GEN, or ERG under an ergative analysis. This pronominal form is linked to the transitive agent argument in non-AV structures, such as *ku=* and *tu=* in Puyuma in (37), *=na* in Kavalan in (6), and *no-* in Tukang Besi in (32). The second set is the SUBJ/PIVOT form and is typically labelled NOM in the AN literature. This is the thematically unrestricted form that is linkable to any semantic role of a core argument, including the patient core argument of a transitive verb and the intransitive subject. This justifies the labelling of this set as the ABS(olutive) form in an ergative analysis, as exemplified by *-(ho)o* in Moronene in example (40) above. Note that in descriptive works, such as Teng's (2008) description of Puyuma, the second set is also (confusingly) called the NOM(inative) set even though the language shows an ergative alignment property. Morphology and syntax in LFG are separate modules in grammar with case (marking) being dealt with at the morphology-syntax interface (see Bresnan & Mchombo 1987). It is captured through the CASE feature constraint, which is associated with GF linking. Thus, in a language like Puyuma and Pazeh-Kaxabu where there is empirical evidence for ergative alignment (both morphologically and syntactically), a pronominal affix/clitic can be specified as having a CASE feature in its entry: (↑ CASE)=ABS. The grammar of the language can be globally specified as having a conditional if-then constraint: (↑ SUBJ) ⇒ (↑ SUBJ CASE)=ABS. Because this constraint applies to verbs broadly, one way to handle it is by incorporating it into the rule that introduces the clausal c-structure that comes with the SUBJ annotation. This constraint means that if the argument is selected as SUBJ then it must have ABS case. Other pronominal clitics can be specified as having (↑ CASE)=ERG in their entries for languages like Puyuma, and specifically for the agent a-subject argument of a transitive predicate. However, for other languages that show a SUBJ fixed linking with NOM-ACC alignment, as in Kambera (Klamer 1998: 73), a different specification must be given for the pronominal clitic linked to the transitive agent argument, namely (↑ CASE)=NOM.

For non-pronominal forms, the semantic and syntactic information throughout the system can be specified in the entry for phrasal markers.[32] This applies to the differential OBJ and OBL marking, noting that we extend DOM to include OBL marking as well). For simplicity, only one marker of DOM is exemplified below

---

[32] The term 'phrasal markers' finds frequent usage in AN linguistics, especially when characterizing Philippine-type AN languages. These markers, like *na* and *kana*, which mark SUBJ and definite OBL relations in Puyuma (as seen in example (37a)), tend to manifest in diverse forms across various AN languages. They are often labelled differently by different authors depending on their analysis, such as clitics, case markers, non-/personal markers, or prepositions (Himmelmann 2005: 144–149).

in (43). DOM across languages commonly draws on different semantic properties. In LFG, these semantic features can be specified together with the semantic case value without affecting the syntactic status of the argument (Butt & King 1991, 2003, Dalrymple & Nikolaeva 2011).

In Pazeh-Kaxabu, DOM encodes the differential information related to the topicality and specificity/definiteness of P (Yeh in preparation). For example, in the AV structure in (43a), P is realised as OBL due to the ergative system and is flagged by *u* because the referent is definite and topical (reading [i]) or specific indefinite (reading [ii]). The non-specific indefinite P (cf. example 10b) is realised by an unmarked bare NP.

Extending from the classic, integrated i- and f-structure (cf. Bresnan & Mchombo 1987) we represent the simplified lexical entry of the phrase marker *u* in (43b). It specifies a constraint that the noun phrase flagged by *u* must be OBL whose CASE is LOC. In addition, it imposes a disjunctive specification with two options capturing the two readings in (43a). The first option in reading (i) reflects sharing of the values of OBL argument and TOPIC. This is shown in the partial f-structure in (44a) where the reference is definite and specific (cf. Enç 1991; see also von Heusinger 2002 for the distinction and interaction of definiteness and specificity). The (partial) f-structure for reading (ii) is given in (44). It captures the crucial difference in that there is no sharing as the OBL is indefinite and not TOPIC. The empirical fact about having in-/definite readings in the OBL argument (cf. also the Paiwan example in (39) above) is elegantly shown without assuming syntactic status to be determined by semantic property.

(43) Pazeh-Kaxabu (Li & Tsuchida 2002: 169)

a. … babaxa u kia'aren a arim.
AV.give LOC pretty LNK peach
(i) '… gave the pretty peach(es).' or
(ii) '… gave certain pretty peaches.'

b. *u* (OBL ↑)
(↑ CASE)=LOC
{(TOPIC ↑) (↑ DEF)=+ (↑ SPEC)=+
| (↑ DEF)=− (↑ SPEC)=+ }

(44)

a. $$\left[\begin{array}{ll} \textsc{pred} & \text{‘}\textsc{give}\langle\ldots\ \textsc{obl}\rangle\text{’} \\ \textsc{topic} & \\ \textsc{obl} & \left[\begin{array}{ll} \textsc{pred} & \text{‘}\textsc{peach}\text{’} \\ \textsc{adjunct} & \left\{\left[\textsc{pred}\ \text{‘}\textsc{pretty}\text{’}\right]\right\} \\ \textsc{def} & + \\ \textsc{spec} & + \end{array}\right] \end{array}\right]$$

b. $$\left[\begin{array}{ll} \textsc{pred} & \text{‘}\textsc{give}\langle\ldots\ \textsc{obl}\rangle\text{’} \\ \textsc{obl} & \left[\begin{array}{ll} \textsc{pred} & \text{‘}\textsc{peach}\text{’} \\ \textsc{adjunct} & \left\{\left[\textsc{pred}\ \text{‘}\textsc{pretty}\text{’}\right]\right\} \\ \textsc{def} & - \\ \textsc{spec} & + \end{array}\right] \end{array}\right]$$

There are AN languages showing properties of split intransitivity or split-S. The split can be reflected in the argument pronominal marking, as in Acehnese (Durie 1987), or the morphological marking on verbs, which correlates with the properties of semantic roles as well as lexical-aspectual properties. Acehnese, for example, is an AN language with systematic clitic sets that cross-reference A(ctor) versus U(ndergoer) roles (Durie 1987). It has a split/fluid S or active system, as seen in examples (45)-(46) below. subj in Achenese is, therefore, semantically very transparent and not a neutralised or syntactic subj/pivot as seen in Philippine/Indonesian types. It is not uniquely picked up by a set of morphosyntactic behavioural properties, such as ‘control’ (see Section 5.1). LFG is well-equipped to handle such kinds of split transitivity (cf. Zaenen 1993; Arka 2003a). For example, the A and U clitics must have a linking constraint specified in their lexical entries, as shown in (45c) and (46c), respectively. The sigma metavariable ($\uparrow_\sigma$) in the entries ensures the correct mapping or correspondence between semantic a-structure and f-structure, so the constraint represented as ($\uparrow_\sigma$ a) in (45c) states that semantically *geu* must be Actor). In addition, the specification (↑ subj) for *geu* also ensures that it is associated with subj. However, the undergoer or P clitic, *geuh*, must have a disjunctive specification to capture the fact that a sole argument (S, or subj) of an intransitive verb has the same form as the undergoer (P, or obj) in a transitive clause (i.e. S_P/P pattern of the split).

(45) Cross-reference Actor (Acehnese, WMP, Indonesia) (Durie 1987: 366)

a. Gopnyan **geu**=mat lôn.
3 3a=hold 1sg
‘S/he holds me.’

b. **Geu**=jak gopnyan.
3A=go 3
'S/he goes.'

c. *geu* CL (↑ PRED)='PRO'
(↑ PERS)=3
(↑ NUM)=SG
(↑ SUBJ)$_\sigma$= (↑$_\sigma$ A)

(46) Cross-reference Undergoer (Acehnese) (Durie 1987: 369)

a. Gopnyan ka lôn=ngieng=(**geuh**).
3 IN 1SG.A=see(=3P)
'I saw him/her.'

b. Gopnyan rhët(=**geuh**).
3 fall(=3)
'S/he falls.'

c. *geuh* CL (↑ PRED)= 'PRO'
(↑ PERS) = 3
(↑ NUM) = SG
(↑ {SUBJ|OBJ})$_\sigma$ = (↑$_\sigma$ P)

This section has demonstrated how AN languages differ in their development of the voice system, and how they also show variation in the realisation of grammatical functions and DOM patterns. The theoretical advances in LFG studies —such as the inventory of GFs, the syntacticised a-structure, the overlay function PIVOT, and the specifications of case, information status and referential semantics—have shown advantages in capturing some patterns in AN languages that have long been controversial.

5 Complex constructions

Following the discussion of word order and the basic notions of how AN morphosyntax is represented in LFG, we now move on to some complex constructions. In this section, we highlight two salient features of complex structures in AN languages which are of long-standing theoretical and typological interest: complementation that involves argument gapping or control in the embedded clause, and complex predication with a particular focus on SVCs.

5.1 Complementation and control

Complement clauses are object-like clausal arguments which, for certain matrix verbs, may be syntactically peripheral or oblique-like. Formally, and in LFG terms, they are realised as comps (finite clauses) and xcomps (non-finite clauses with syntactic subj-control). The distinction between comp and xcomp and their core status may not always be easy to identify. In what follows, we outline clear cases of (x)comps and their syntactic status.

Languages with robust voice morphology provide a diagnostic tool to determine the core status of (x)comp. For example, in Indonesian-type languages, only a core argument can be selected as subj/pivot, and a peripheral oblique/adjunct-like argument must be promoted to become a core argument in order to be realized as subj. This is the case with the Balinese verb *edot* 'want'. It is a two-place intransitive verb with the second argument being either a simple oblique argument appearing as a PP, like in (47a) below, or an xcomp (without P-flagging) as in (47b). In both cases, the applicative *-ang* cannot be used. However, when an embedded clause is fronted and given the discourse function focus-c (i.e. made the pivot/subj), as in (47c), the applicative *-ang* is obligatory; the verb *edot=a* is unacceptable. Note, however, that the matrix verb must be in uv since the av form *ng-edot-ang* 'av-want-appl' is unacceptable. That is, the clausal argument is treated as a non-Actor core argument. The obligatory applicativisation serves as evidence that the second clausal (comp) argument with *edot* is syntactically oblique-like in (47b), but a core argument in (47c).

(47) Balinese (Arka 2003b: 135)

a. Ia edot / *edot-ang [teken poh]$_{\text{OBL}}$.
   3 want want-appl to mango
   '(S)he wants a mango.'

b. Ia edot / ?*edot-ang [__ ngae umah luung]$_{\text{XCOMP}}$.
   3 want want-appl subj av.build house good
   '(S)he wants build a good house.'

c. [__ Ngae umah luung]$_{\text{PIVOT}}$ (ane)
   subj av.build house good foc
   edot-ang=a/*edot=a/*ng-edot-ang.
   uv.want-appl=3
   'Building a good house is what s/he wants.'

However, xcomp can also be a core argument. This is the case with the xcomp of the verb *coba* 'try' in Indonesian in (48a) below. In Indonesian, like in Balinese, an OBL cannot alternate with SUBJ/PIVOT without applicativisation. The XCOMP of the verb *coba* can, however, alternate to become SUBJ/PIVOT without applicativisation, as seen in (48b). Note that *coba* 'try' allows different patterns of control, including the so-called double (backward/forward) control given in (48c). This double control structure shows two gaps—left-headed and right-headed arrows indicate backward and forward control types, respectively (see Arka 2000 and Arka 2014a for details).

(48) Indonesian (Arka 2014a: 31 and own knowledge)

a. Aku sudah mencoba [__ menjual mobil itu]$_{\text{XCOMP}}$.
1SG PFV AV.try AV.sell car that
'I have tried to sell the car.'

b. [__ Menjual mobil itu]$_{\text{PIVOT}}$ yang sudah ku=coba.
AV.sell car that FOC PFV 1SG=UV.try
'Selling the car is what I have tried (to do).'

c. [Mobil itu]$_{\text{PIVOT}}$ (yang) sudah __ coba [__ ku=jual]$_{\text{XCOMP}}$.
car that FOC PFV (A) UV.try (P) 1SG=UV.sell
'That car (is the one that) I have tried to sell.'

The clausal argument of a raising verb can also have an XCOMP with the raised argument being obligatorily SUBJ. The following shows the (unusual) SUBJ raising to matrix OBL in Puyuma. In (49a) below, the clausal complement of the verb 'know' is COMP. It is syntactically non-core since it is flagged by *dra* (i.e. the indefinite OBL phrase marker; glossed as a complementiser for clarity here). The patient NP 'the fish' (indicated in bold) is selected by the PV *-aw* on the verb as SUBJ, and present in the embedded clause. In (49b), however, the SUBJ is raised and appears as OBL in the matrix clause, flagged by *kana*. Note that raising in (49b) is not possible with an embedded verb containing the voice suffix, *-anay*, since this selects an instrumental argument instead.

(49) Puyuma (Teng 2008: 153-154)

a. Ma-ladram=ku [dra tu=lriputr-**aw** **na** **kuraw**
INTR-know=1SG.NOM COMP 3GEN=wrap-PV DEF.NOM fish
dra bira']$_{\text{COMP}}$.
INDF.OBL leaf
'I know that the fish was wrapped in a leaf.'

b. Ma-ladram=ku **kana** **kuraw** [dra tu=lriputr-**aw**/
intr-know=1sg.nom def.obl fish comp 3gen=wrap-pv/
*tu=lriputr-**anay** dra bira']$_{\text{XCOMP}}$
3gen=wrap-iv indf.obl leaf
'I know that the fish was wrapped in a leaf.'

In the indexing AN languages of eastern Indonesia and Oceania, the subj (bound) pronoun is typically part of the verbal morphology and cannot be gapped. subj is not a syntactic pivot for clause combining purposes in these languages. There is, therefore, no syntactic control or raising. Clausal arguments are consistently comps with no xcomp alternative. This is the case in Taba in (50), and Mangap-Mbula in (51):

(50) Taba (CEMP, Eastern Indonesia) (Bowden 2001: 391)
Nculak wangsi de lmul akle.
n=sul-ak wang=si de l=mul ak-le
3sg=order-appl child=pl res(so.that) 3pl=return all-land
'He told the children to go home.'

(51) Mangap-Mbula (Oceanic) (Bugenhagen 1995: 272)
Ti-maŋmaŋ yo [be aŋ-kam pizin].
subj:3pl-urge obj:1sg comp subj:1sg-do dat.3pl
'They urged me to give it to them.'

Despite their rarity, some Oceanic languages with indexing systems, such as Hoava (Davis 2003), Longgu (Hill 2002), and Kokota (Palmer 1999), have syntactic subj/pivot. In Hoava, the index on the verb is only for obj. This language shows comp, as in (52a), as well as xcomp like in (52b). Complement-taking predicates in Hoava come with an invariant obj index *-a* which signals that there is an embedded complement clause in the structure.

(52) Hoava (Oceanic) (Davis 2003: 288)

a. Hiva-ni-a ria [de pule mae sa qeto]$_{\text{COMP}}$.
want-appl-obj:3sg 3pl comp return come art:sg war.party
'They wanted the war party to come back.'

b. Haku=haku-ni-a ria [de naqali-a]$_{\text{XCOMP}}$.
redup=be.tired.of-appl-obj:3sg 3pl comp carry.tr-obj:3sg
'They were tired of carrying it.'

5.2 Serial Verb Constructions

SVCs are the hallmarks of AN languages of the isolating type and are observed in the languages of eastern Indonesia, such as Rongga (Arka 2016), and also in Oceanic languages, as discussed below. Some SVCs are also encountered in the agglutinating Philippine/Indonesian-type languages, including Balinese (Indrawati 2014) and Puyuma (Teng 2008).

Unlike complementation, SVCs syntactically express complex (sub)events in monoclausal structures (Crowley 2002, Haspelmath 2016). Semantically, the relations between subevents typically convey adverbial modification with meanings such as comitative, benefactive and instrumental. However, they may also express other tightly integrated meanings often discussed under the rubric of complex predicates (see Arka & Simpson 2008). For example, the SVC expresses the desiderative 'want' (i.e. 'feel-say') in Ambae in (53), and the causative and resultative meaning in Rongga in (54) and Mwotlap in (55).

(53) Ambae (Oceanic) (Hyslop 2001: 387)
No=mo rongo vo na=ni qalo.
SUBJ:1SG=REAL feel say SUBJ:1SG=IRR fight
'I want to fight.'

(54) Rongga (Arka 2016: 227)
Selu tau mata manu ndau.
Selu make die chicken that
'Selus killed the chicken.'

(55) Mwotlap (Oceanic) (François 2006: 232)
Ne-lēn mi-yip hal-yak na-kat.
ART-wind PRF-blow fly-away ART-cards
'The wind blew the cards away.'

SVCs can be analysed in LFG in the same way as complex predicates through predicate composition (Andrews & Manning 1999). The exact c-structure varies according to the language considered, but it is typically a compound-like nested structure: $[\mathrm{V(P)}_1\ \mathrm{V(P)}_2]_{\mathrm{V(P)}}$. That is, there is a higher VP consisting of lower VPs in the c-structure. The crucial idea of the analysis is to capture the empirical fact that the SVC is monoclausal; that is, the V(P) component(s) share the same SUBJ, and possibly another argument, depending on the transitivity of V_1 and V_2 verb components.

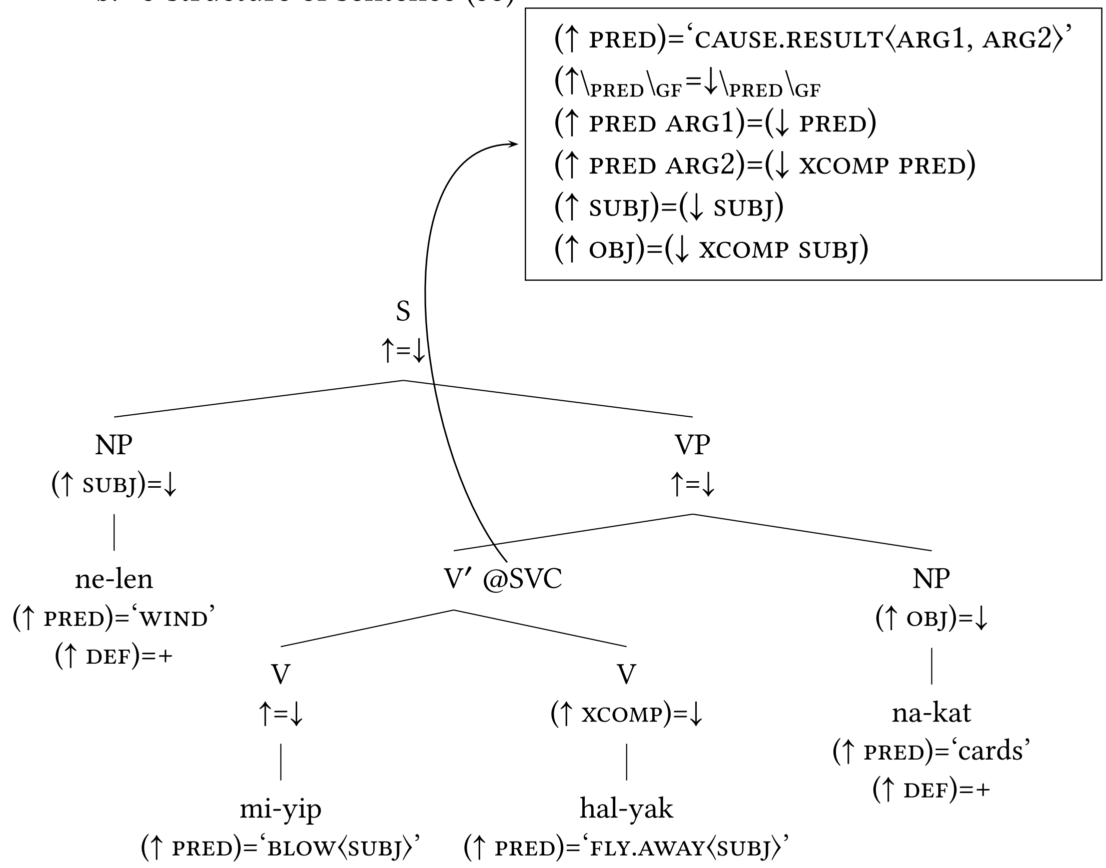
SVCs also reveal an intriguing and important property of the construction, exemplified by the Mwotlap example in (55). The causative-resultative meaning is constructed at the level of SVC because neither V_1 nor V_2 carry a causative-resultative meaning lexically. That is, the syntactic transitivity is constructional because neither V_1 nor V_2 is transitive. In LFG, such resultative constructions, as in example (55), can be captured by lexical-constructional a-structure, indicated by the SVC template, @SVC, annotated to V′ of the VP in (56b). The template consists of complex equations given in the box showing the constructional predicate of ‘cause.result⟨arg1, arg2⟩’ (where arg1 is the causing event and arg2 is the resulting event). The restriction operator expressed by $\uparrow\backslash_{\text{PRED}}\backslash_{\text{GF}}=\downarrow\backslash_{\text{PRED}}\backslash_{\text{GF}}$ (Kaplan & Wedekind 1993) regulates the predicate composition involved in the SVC; see Butt et al. (2003) for the application of the restriction operator in Urdu/Hindi and other languages. This restriction operator and the other constraints associated with @SVC result in an f-structure with the subcategorisation frame shown in (56a).

Note that, in the resultative SVC of (56b), the obj annotation is specified at the NP of the higher VP, sister of V′, of the c-structure since it is the obj argument of the constructed causative-resultative predicate; neither V1 nor V2 has obj. The @SVC template (with detailed specifications provided in the box) specifies that the SVC's obj has the same value as the lower V2's subj, and the SVC's subj has the same value as the subj of V1. This sharing of values for subj and obj is indicated through tags [1] and [2] in (56a).

(56) a. f-structure of sentence (55)

$$\left[\begin{array}{ll} \text{PRED} & \text{‘CAUSE.RESULT}\langle\text{SUBJ}[1]:\text{‘BLOW}\langle[1]\rangle\text{’},\ \text{OBJ}[2]:\text{‘FLY.AWAY}\langle[2]\rangle\text{’}\ \rangle\text{’} \\ \text{SUBJ} & \left[\begin{array}{ll} \text{PRED} & \text{‘WIND’} \\ \text{DEF} & + \end{array}\right] \\ \text{OBJ} & \left[\begin{array}{ll} \text{PRED} & \text{‘CARDS’} \\ \text{DEF} & + \end{array}\right] \end{array}\right]$$

b. c-structure of sentence (55)



However, the distinction between mono-clausal SVCs and bi-clausal subordination is not always clear. A typical diagnostic test for SVCs is negation: since SVCs are monoclausal, the criterion of single negatability applies (Durie 1997). There are also other language-specific criteria that distinguish SVCs from multi-verb constructions in coordinate and subordinate clauses. In Balinese, for example, the presence/absence of voice morphology serves as a diagnostic criterion. The second verb in an SVC may optionally contain an AV prefix, indicated by putting the AV prefix in brackets in (57a): *(ng)ajak*. The absence of the AV prefix (i.e. *ajak*) gives rise to a comitative reading only, as shown by reading (i) in (57a); this is a comitative SVC in Balinese. In contrast, the presence of the AV prefix, *ngajak*, leads to an ordinary coordination, which requires a syntactic PIVOT, as in reading (ii) in (57a). The presence of the clausal negator, *tan* ‘not’, in (57b) forces the coordination structure, which requires SUBJ PIVOT marking. Hence, the presence of an AV prefix on the verb in the second clause is obligatory, as seen in (57b).

(57) Balinese (Shiohara & Arka 2023)

a. Tiang [mlajah kelompok (ng-)ajak timpal-timpal-e]$_{\text{SVC}}$.
   1sg mid.study group (av-)invite friend.redup-def
   (i) 'I studied in a group together with friends.' (with *ajak*)
   (ii) 'I studied in a group and invited friends to join.' (with *ngajak*)

b. Tiang [mlajah kelompok], [tan ngajak/*ajak Ketut].
   1sg mid.study group neg av.invite/invite Ketut
   'I studied in a group, (but) I didn't invite Ketut (to join).'

In addition, the prosody is different: the SVC in (57a) with the bare verb, *ajak*, has one intonational contour (i.e. without a break), while the coordination in (57b) has a break indicated by a comma after the first VP (cf. prosodic properties of mono-/bi-clausality in Aikhenvald 2006: 7, Dixon 2006: 339, Haspelmath 2016: 308) Likewise, sentence (57a) in its non-SVC or bi-clausal reading (ii) is also accompanied by a prosodic break before the av verb.

6 Discourse information structure: Contrastive focus and nominalisation

In this final section, we consider the interface between information structure and morphosyntax in AN languages. Recall from Section 3 that contrastive discourse functions are a crucial factor that motivate syntactic variation for fronting. Fronting is of special interest since it involves clefting, which is closely bound with the subj-only restriction on extraction in many AN languages with robust voice systems (cf. Section 4.2.2).

In this section, we look thoroughly at the connection between contrastive dfs and the syntactic structure of clefts from a comparative perspective and demonstrate how cross-linguistic variation can be captured in LFG. We begin by introducing the basic notions of discourse features in information structure (Zaenen 2023 [this volume]) with a primary focus on focus-c because in many AN languages, focus-c is the most common discourse function associated with clefting. Then, we move on to show how focus-c expressions via clefting are structured differently across languages.

The pragmatic uses of clefting in expressing contrastive focus (focus-c) emerge as a motivating factor in the extension of bi-clausal structure across AN languages, as discussed below. In symmetrical-voice languages, bi-clausal clefting is used in combining nominal predicates and headless relative clauses, while indexing-type languages use mono-clausal clefts without relative constructions. The major difference lies in the gradual erosion of clausal nominalisation. We will see that both types of cleft-structures for expressing focus-c (with/without nominalisation) can be elegantly captured in an LFG analysis to reflect the language-specific variation.

6.1 Information structure: focus-c, fronting and cleft

Topic and focus have long been recognized as discourse functions within information structure. However, this traditional dichotomy view falls short of encompassing all the information structure nuances (Zaenen 2023 [this volume]). Decomposing i-structure features is generally adopted in LFG studies. In our analysis, marked dfs (focus-c/topic-c) are represented by three distinct decomposed features, as demonstrated by Arka & Sedeng (2018) and references therein: contrast, salience, and givenness. The [+contrast] feature is central for focus and is exemplified in (58) below. The [+salient] and [+given] features are typically topic-related, encompassing communicatively important properties, such as the particular frame/entity by which new information should be understood (i.e. the ‘aboutness’ of the topic), and the degree of importance/prominence of one piece of information relative to other bits of information in a given context. The [+salient] feature reflects the speaker’s subjective choice of highlighting one element and making it stand out for communicative purposes. While often closely linked, salience and givenness are distinct: for example, new information, [−given], can be [+salient] (see Riesberg et al. 2018 on information structure across AN languages).

focus-c is a marked focus and is typically characterised by overt marking of the conception of alternatives in the contrastive set it is associated with (cf. Krifka 2008). Clefting is a typical ‘marked’ strategy to express focus-c as seen in the English example of (58a): John is a person in the set of referents associated with the subj (i.e. John, not somebody else). The equivalent structure in Indonesian is given in (58b) below:

(58) Indonesian (Arka, own knowledge)
a. It is [John]$_{\text{focus-c}}$ [who killed the robber]$_{\text{vp:comment|given}}$.
b. [(Adalah) John]$_{\text{pred/focus-c}}$ [yang membunuh perampok itu]$_{\text{subj}}$.
be John rel av-kill robber that
‘It’s John who killed the robber.’

Note that English and Indonesian show structural parallelism in their relativisation of the second part of cleft structures, and contrastive focus fronting. Also, they both show clear evidence of biclausal structures with each part having its own predicate. However, Indonesian *adalah* 'be' is optionally present. English requires the empty SUBJ *it*, while Indonesian has no such SUBJ. The fronted NP (*John*) is the predicate, and the (headless) relative with *yang* is actually a (clausal) SUBJ.

6.2 Cross-linguistic variation in fronted FOCUS-C

Fronted content questions in other AN languages of Indonesia also typically employ the same clefting strategy that involves relativisation, including in Indonesian, Sundanese and Sasak as in examples (59)-(61) below. These sentences are biclausal. Note that these languages also allow in-situ mono-clausal content questions with no relativisation required (cf. (59) and (62a) where SUBJ is questioned).

(59) Indonesian (Arka, own knowledge)
[Siapa]$_{\text{PRED/FOCUS-C}}$ [yang membunuh perampok itu]$_{\text{SUBJ}}$?
who REL AV-kill robber that
'Who killed the robber?' (Lit. 'Who is the one who killed the robber?')

(60) Sundanese (Hanafi 1997: 3)
[Sahaʔ]$_{\text{PRED/FOCUS-C}}$ [nu meuliʔ mobil]$_{\text{SUBJ}}$?
who REL AV.buy car
'Who bought a car?'

(61) Menó-Mené Sasak (Arka, fieldwork data)
[Ape]$_{\text{PRED/FOCUS-C}}$ [*(saq) Amir paling wiq]$_{\text{SUBJ}}$?
what REL Amir steal yesterday
'What did Amir steal yesterday?'

(62) Indonesian (Arka, own knowledge)

a. [Siapa]$_{\text{SUBJ}}$ mem-bunuh perampok itu?
who AV-kill robber that
'Who killed the robber?'

b. Orang itu membunuh [siapa]$_{\text{OBJ}}$?
person that AV-kill who
'Who did the person kill?'

c. *Siapa orang itu membunuh __?

Variation in the above clefting strategies reveals the effect of the subj-only constraint on extraction of focus-c and a change in the constraint in some languages. Philippine/Indonesian type languages with robust grammatical voice cannot front the obj q NP in av (mono)clauses (Arka 2003a: 27, Kroeger 1993: 50, 208). This is exemplified by the ungrammaticality of (62c) above, in contrast to the acceptable in-situ question (62b). A voice alternation is obligatory in order for obj q NP fronting to be acceptable because it maps the patient onto the subj, and also allows possible clefting of the type seen in (59).

However, in languages where grammatical voice is in decline or has disappeared (as often observed with the erosion of AV verbal morphology), the strict adherence to the subj-only constraint might be eased. This relaxation could allow for the fronting of the obj q NP. However, this can only occur under the condition that the fronted obj q NP necessitates relativization within a bi-clausal structure. Such a phenomenon is evident in Sasak, as demonstrated in (61). Notably, when obj q is fronted, the relativizer *saq* cannot be omitted.

It should be noted that even when the AN verbal voice is completely lost, syntactic voice is not always lost as well. The languages of western and central Flores, such as highly isolating Manggarai and Rongga, exhibit a syntactic passive or undergoer voice without verbal voice morphology (see Arka & Kosmas 2005 for details). The canonical clausal word order in these languages is SVO, and the fronted q NP also makes use of clefting via relativisation, as seen in Manggarai in (63a) below. In this instance, the fronted q NP is the actor subj. Despite the absence of av verbal morphology, the syntactic structure follows the Actor Voice (av) pattern. Conversely, when the fronted q NP takes on the role of the undergoer, as depicted in (63b), the structure undergoes an alteration to become Undergoer Voice (uv). Here, the actor is expressed in genitive form, which is characteristic of actor realization in the uv voice within AN languages. Note that the verb form in (63a) is identical to that in (63b). However, they are assigned distinct voice glosses (av/uv) to signify that they are part of different voice constructions.

(63) Kempo Manggarai (CEMP, Indonesia)

a. [Cai]$_{\text{pred/focus-c}}$ [ata tengo hau]$_{\text{subj}}$?
who rel av.hit you
'Who hit you? (Lit. 'who is the one hitting you?') (Semiun 1993: 63)

b. [Cai]$_{\text{pred/focus-c}}$ [ata tengo gau]?
who rel uv.hit 2gen
'Who did you hit?' (Semiun 1993: 64)

The above discussion has shown how the different morpho-syntactic systems in AN languages are structurally connected in a bi-clausal structure with relativisation. Unlike Philippine/Indonesian type languages, a relaxed constraint on extraction is witnessed in the loss of voice morphology in languages like Manggarai, Flores. In the latter, fronting of a non-SUBJ argument is possible without the need for voice alternation.

The obligatory relativisation in fronted question NPs discussed so far brings us to the important interconnection between FOCUS-C, relativisation, voice and nominalisation. This interconnection is evident in that the AN relative clause used for fronted FOCUS-C is transparently nominal in its structure. Typically, and formally, the relativiser is a nominal phrase marker and thus, the marker is multifunctional. In Tagalog, for instance, the relativiser is the NOM marker for an ordinary NP (see (23)), but also for a verb when its SUBJ is in FOCUS-C in the content question (see (64)). Likewise, marked FOCUS-C in declarative sentences —as seen in Indonesian-type languages like Old Javanese in (65)—also use the same nominalisation strategy through relativisation. The same form *ikang* in (65) is also used as a definite determiner in Old Javanese. The NP flagged by *ang* in Tagalog also receives a definite interpretation. Based on these functional correspondences, we contend that Tagalog *ang*, Old Javanese *ikang*, and the Indonesian pronominal relativiser *yang* are clearly cognates (Kähler 1974: 266–267; Blust 2015: 465; Kaufman 2018: 228–229).

(64) Tagalog (Kaufman 2018: 219)
[Sino]$_{\text{PRED}}$ [ang d⟨um⟩ating]$_{\text{SUBJ}}$?
who NOM ⟨AV⟩arrive
'Who arrived?' (Lit. 'the coming one is who?')

(65) Old Javanese (WMP, Indonesia) (Erawati 2014: 150)
Ikang naga Taksaka [ikang s-um-ahut wwang atuha-nira].
DEF dragon Taksaka REL ⟨AV⟩bite person old-3SG.POSS
'The Taksaka dragon is the one who bit his parent.'

The same pattern of nominalisation involving a fronted FOCUS-C is observed across Philippine-type languages as shown in Table 1. These languages also use the same nominalisation strategy through relativisation. Crucially, there are two morphosyntactic properties worth noting. First, only SUBJ can be fronted as FOCUS-C. Thus, when the transitive patient is in FOCUS-C, the PV must be used, as seen in Table 1. Second, the agent argument of the PV verb is expressed in the genitive, which is the realisation of the possessor in the nominal structure.

Table 1: SUBJ FOCUS-C across the Philippine-type languages (Kaufman 2018: 220)

Tagalog	*maŋga*	*aŋ*	*kina:ʔin*	*naŋ*	*ba:taʔ*
Bikolano	*maŋga*	*aŋ*	*kinakan*	*kan*	*a:kiʔ*
Cebuano	*maŋga*	*aŋ*	*ginka:ʔun*	*han*	*bataʔ*
Hiligaynon	*pahuʔ*	*aŋ*	*kinaʔun*	*saŋ*	*ba:ta*
Tausug	*mampallam*	*in*	*kyaʔun*	*sin*	*bataʔ*
Ilokano	*maŋga*	*ti*	*kinnan*	*dyay*	*ubiŋ*
Ibanag	*maŋga*	*ik*	*kinan*	*na*	*abbiŋ*
Pangasinan	*maŋga*	*su*	*kina*	*=y*	*ugaw*
Kapampangan	*maŋga*	*iŋ*	*pe:ŋa=na*	*niŋ*	*anak*
	[mango]$_{focus\text{-}c}$	*[NOM*	*eat.PV.PFV*	*GEN*	*child]*$_{SUBJ}$

‘It was the mango that the child ate.’
(Lit. ‘the mango was the one eaten by the child.’)

The pattern showing the genitive agent in the fronted FOCUS-C with relativisation is also observed in the languages of western Flores, such as Manggarai (Semiun 1993). Recall that Manggarai is highly isolating, but it has a genitive clitic set usable in fronted FOCUS-C questions. Note that the Q *cai* in (66) below is associated with the transitive patient; questioning the agent SUBJ requires no genitive clitic (cf. Kambera example (21) above with (67a) below).

(66) Kempo Manggarai (Semiun 1993)
Cai (ata) tengo gau?
who REL hit 2SG.GEN
‘Who did you hit? (Lit. ‘who is your hitting?’)

In AN languages of the indexing type, the resources for FOCUS-C may also be parasitic to nominalisation/relativisation coding whereby the focused argument ends up being fronted sentence-initially. For example, the Kambera example in (67a) is a content question (FOCUS-C) with equational structure: the verb is affixed with the subject relativiser *ma-* and the verb appears within a nominal (headless) relative clause structure. The nominal article *na* flags the structure as an NP. The same pattern is observed in (67b), where the patient argument is FOCUS-C. Like in Manggarai and Philippine-type languages, the agent in Kambera in (67b) appears as a genitive too, which is the same case as used for the possessor of an NP.

(67) Kambera (Klamer 1998: 132, 318)

a. Ngga [na ma-palewa-kai] hi mài lai nai?
who art relS-send-2pl.acc cnj come loc dem
‘Who was the one that send you so that you’d come here?’

b. [Da kalembi-da]$_k$ [na pa-pa.marihak-na$_j$ nyuna$_j$]$_{\text{subj}k}$.
art shirt-3pl.poss art relO-caus.be.dirty-3sg he
‘Their shirts$_k$ were (the ones) made dirty by him$_j$.’

In the languages of Sulawesi, such as Makassarese, where unmarked structures are predicate-initial (like in Philippine-type languages), focus-c formation also requires fronting (Jukes 2006: 341–345). However, while relativisation uses a nominalisation strategy by means of the definite clitic *=a* as seen in (68a), the focus-c formation requires no nominalisation as seen in (68b–c). Makassarese exhibits systematic pronominal indexing, but it still shows the AN voice system. Thus, when agent subj is in focus-c, it requires the homorganic nasal substitution av prefix on the verb (*aN-* realised as *am-*) as in (68d). Crucially, the sentences with fronted focus-c NPs in (68b–d) are monoclausal.

(68) Makassarese (WMP, Indonesia) (Jukes 2006: 238, 343, 353)

a. [tau [na=buno=a sorodadu]$_{\text{RC}}$]$_{\text{NP}}$
person 3=kill=def soldier
‘the person killed by a soldier’

b. Miong=a na=buno kongkong=a.
cat=def 3=kill dog=def
‘The dog killed the cat (not something else).’/ ‘It’s the cat that the dog killed.’

c. Inai na$_i$=ba’ji [i Ali]$_i$?
who 3=hit pn Ali
‘Who did Ali hit?’

d. Inai am-ba’ji=i i Udin?
who av-hit=3 pn Udin
‘Who hit Udin?’

6.3 Representing information structure in LFG

LFG is well equipped to capture the language-specific variation in fronted focus-c discussed here. There are two kinds of analysis: the (earlier) integrated f-structure analysis (Bresnan & Mchombo 1987, King 1995, among others) and the more recent independent i-structure analysis (Butt & King 1996, Dalrymple & Nikolaeva 2011, among others). In the first analysis, dfs are part of the f-structure and share their values (fully or partially) with argument gfs in the f-structure due to the extended coherence condition (Zaenen 1980) or their anaphoric relation. This analysis is straightforward for cases involving focus-c with no requirement for nominalisation, as in the Makassar examples of (68b–d). Here, the sentences are mono-clausal, and the fronted argument is functionally not the head predicate. For the analysis to work, the sentence-initial XP is identified as focus-c and is licensed by the phrase structure rule shown in (69a) below:

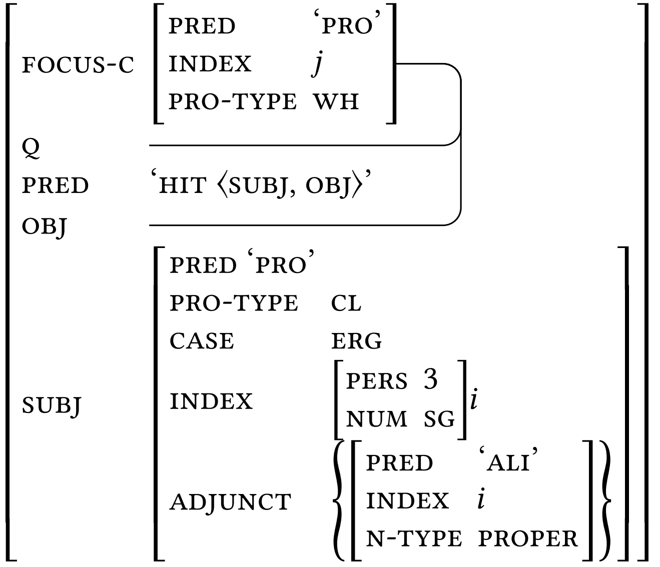
(69) a. CP ⟶ XP C′
$(\uparrow \textsc{focus-c}) = \downarrow$
$(\uparrow \textsc{focus-c}) = (\uparrow \textsc{gf})$

b. Makassarese Voice Marking:
  i) av, *aN*-: $(\uparrow \textsc{focus-c}) = (\uparrow \textsc{subj})_\sigma = (\uparrow_\sigma \text{ 1:agent})$
  ii) pv, Clitic_A=: $(\uparrow \textsc{focus-c}) = (\uparrow \textsc{obj})_\sigma = (\uparrow_\sigma \text{ 2:patient})$

The two lines of annotation in (69a) impose a sharing between focus-c and any gf, including adjunct. However, there are also other independent language-specific voice selection constraints given in (69b) to regulate how a core argument is selected as subj/obj in Makassarese, particularly when this core argument is also assigned focus-c. Therefore, in light of the rule given in (69b.ii), the example in (68c) (cf. the same example in (70) below) will have the focus-c selected as obj. The f-structure is shown in (71) below. We analyse the free NP, which cross-references the agent proclitic, as an adjunct that provides specific information about the agent.

(70) Makassarese (Jukes 2006: 353)
inai$_j$ na$_i$=ba'ji [i Ali]$_i$?
who 3=hit pn Ali
'Who did Ali hit?'

(71) f-structure of sentence (70)



The integrated f-structure analysis just outlined for Makassarese faces an issue when it is applied to fronted focus-c involving bi-clausal or relative clause nominalisation as in Indonesian, as illustrated in (58b), reproduced as (72) below. This is because the focus-c unit is the predicate (cf. the Russian examples discussed by King 1997). One way of resolving this issue is to separate f-structure from i-structure in order to focus on the pred value only and not its gfs.[33] Since space precludes a full discussion of a separate i-structure analysis in this chapter, we instead demonstrate an integrated f-structure analysis of the fronted q in Indonesian in (72) below, through the double-tier predlink analysis. This analysis is typically used for the non-verbal predicate with the copula ‘be’ (Butt et al. 1999, Dalrymple et al. 2004). The (simplified) f-structure in (73) for example (58), repeated in (72), shows that the fronted q is the focus-c predlink.

(72) Indonesian
[(Adalah) John]$_{\text{PRED/FOCUS-C}}$ [yang membunuh perampok itu]$_{\text{SUBJ}}$.
be John rel av-kill robber that
‘It’s John who killed the robber.’

---

[33] The independent i-structure with a set df value also allows more than one element in focus. This analysis requires a different df annotation in the PS rule. The independent i-structure analysis also adopts more sophisticated i-structure conceptions (e.g. with fine-grained distinctions of internal units, such as topic/focus types and background/given. See King 1997, Dalrymple & Nikolaeva 2011, Butt 2014).

(73) f-structure of sentence (72).

$$\left[\begin{array}{ll}
\text{PRED} & \text{‘BE}\langle\text{SUBJ, PREDLINK}\rangle\text{’} \\
\text{SUBJ} & \left[\begin{array}{ll}
\text{PRED} & [1]\,\text{‘PRO’}\\
\text{INDEX} & i \\
\text{ADJUNCT} & \left\{\left[\begin{array}{ll}
\text{PIVOT} & \left[\begin{array}{ll}\text{PRED} & [1]\\ \text{INDEX} & i\end{array}\right]\\
\text{PRED} & \text{‘KILL}\langle\text{SUBJ OBJ}\rangle\text{’}\\
\text{SUBJ} & \rule{6em}{0.4pt}\\
\text{OBJ} & \left[\text{PRED ‘THE ROBBER’}\right]\\
\text{CL-TYPE} & \text{REL}
\end{array}\right]\right\}
\end{array}\right]\\
\text{PREDLINK} & \left[\begin{array}{ll}\text{PRED} & \text{‘JOHN’}\\ \text{INDEX} & i\end{array}\right]\\
\text{FOCUS-C} & \rule{6em}{0.4pt}
\end{array}\right]$$

In this analysis, John in (72) is part of the (fronted) PREDLINK (Butt et al. 1999), which is introduced by the copular verb *adalah*.[34] In the absence of *adalah*, the analysis specifies the existence of an unpronounced copular verb in the c-structure. The FOCUS-C in the c-structure is occupied by the fronted PREDLINK and so PREDLINK and FOCUS-C share the same value. This connection is signified by the curved lines in (73). Note that the subject is a headless RC marked by *yang*. The headless RC contains [PRED ‘PRO’] (tag [1]) supplied by the pronominal relativiser *yang*.[35] It is coreferential with the SUBJ/FOCUS-C (i.e. PIVOT) of the RC, and the fronted complement predicate, John (indexed i).

The difference between two types of FOCUS-C fronting in indexing-type and symmetrical-voice type languages is captured in LFG by the distinct f-structures in (71) and (73). The f-structure of the indexing type (e.g. Makassarese) in (71) shows a single functional clausal PRED head (i.e. syntactically monoclausal). The Q, *inai* ‘who’, functions as the question (Q) operator, also identified as FOCUS-C and OBJ (i.e. sharing the same value). In contrast, the f-structure of the Indonesian cleft in (73), which represents the symmetrical-voice type, shows a bi-clausal structure in which the matrix PRED is the copula ‘BE’ and the embedded relative clause’s functional head is ‘KILL⟨SUBJ, OBJ⟩’. Its SUBJ is identified as FOCUS-C via anaphoric relation (represented by index i).

---

[34] In LFG, there is more than one way of analysing non-verbal predicates (e.g. nominal predicates) depending on language-specific properties: a single-tier or double-tier analysis. See Andrews (1982), Butt et al. (1999) and Dalrymple et al. (2004) for further discussion.

[35] [PRED ‘PRO’] should be optionally specified in the lexical entry of *yang*. It shows up in the headless RC, but it is not needed in the headed RC as the RC’s head noun supplies the PRED value.

To conclude, grammatical variation in FOCUS-C fronting in AN languages can be straightforwardly captured in LFG because of its modular design. In such a design, different dimensions of linguistic information are modelled in separate layers of structure. We have demonstrated how the separation of syntactic representation of linear order (c-structure), relational information about grammatical functions (GFS, or f-structure) and context-related Discourse Function (DF) information (i-structure) makes LFG well suited for explicit linguistic analysis to account for the complex constraints in the interface of morphosyntax and pragmatics.

7 Final remarks

In this chapter, we reviewed a broad range of empirically attested morphosyntactic properties in AN languages. We demonstrated how the parallel correspondence architecture of LFG is used to capture the typological diversity of AN languages at different levels of the grammar. Some of these features have posed descriptive and analytical challenges to traditional grammatical notions. Despite these challenges, LFG emerged as a robust and flexible framework for capturing the dynamics of AN languages' internal grammatical systems and the variation between them. This allows us to account for the AN voice system and related grammatical features in a holistic and coherent way. Further, the application of LFG in AN languages plays a crucial role in increasing the framework's potential to be a well-rounded descriptive and analytical tool for typological and theoretical discussions. Thus, additional documentation of AN languages is expected to uncover richer datasets and linguistic diversity, which will provide an ideal testing ground for LFG's grammar-representing architecture.

Acknowledgments

We wish to thank the anonymous reviewers for their careful and thorough reviews, and we are grateful to Malcolm Ross, Mary Dalrymple and Larry Lovell for their valuable feedback on correcting the information in the earlier draft. We are deeply indebted to Mary Dalrymple for her help on preparing the final version of this chapter in LaTeX.

The first author acknowledges support from the following grants: NSF (BCS-0617198), ARC (DP110100307), and ELDP (IPF0011). The second author acknowledges support from the Australian Government Research Training Program (RTP) and Mr. Wang, the Founder of the Fuguangtang Association, on her research.

Abbreviations

Besides the abbreviations from the Leipzig Glossing Conventions, this chapter uses the following abbreviations.

2P	Second position	mid	Middle Voice
AN	Austronesian	nf	nonfinite
av	Actor Voice	PMP	Proto-Malayo-Polynesian
CEMP	Central-Eastern Malayo-Polynesian	pn	Proper Name
cn	Common Noun	predfoc	Predicate Focus
cnj	Conjunction	prep	Preposition
cv	Conveyance Voice	prt	Particle
df	Discourse Function	pv	Patient Voice
DOM	Differential Object Marking	RC	Relative Clause
dv	Dative Voice	real	Realis
focus-c	Contrastive Focus	redup	Reduplication
gen	Genitive	relO	Object relativizer
gr	Grammatical Relation	relS	Subject relativizer
in	Inchoative	svc	Serial Verb Construction
iv	Instrumental Voice	uv	Undergoer Voice
lnk	Linker	WMP	Western Malayo-Polynesian
lv	Locative Voice

Chapter 29

LFG and Celtic languages

Jenny Graver
University of Oslo

This chapter presents an overview of LFG studies on grammatical phenomena in two of the Celtic languages, Irish and Welsh. While there is less work on the Celtic languages in LFG compared to other theories, the studies we have touch on important topics in any linguistic theory or language study, such as word order, grammatical functions, agreement and verbs of existence. The chapter is structured accordingly, and discusses issues such as the presence or absence of a VP, impersonal and passive verb forms, relative clauses and unbounded dependencies, verbal agreement, and the syntax of the Irish copula verb. The Celtic languages are minority languages, and the chapter is framed by reflections on the challenges inherent in studying languages in that situation.

1 Introduction

1.1 The Celtic languages

Historically the Celtic languages are divided into Continental Celtic and Insular Celtic. For the Continental Celtic languages such as Gaulish and Celtiberian, very little is attested. Insular Celtic is normally divided into two branches, the Gaelic or Goidelic group containing Irish, Scottish-Gaelic and Manx, and the British or Brythonic group consisting of Welsh, Breton and Cornish. The Goidelic and Brythonic languages are sometimes referred to as Q Celtic and P Celtic respectively, reflecting the development of Indo-European */k^w/ into /k/ in the Goidelic languages and /p/ in the Brythonic languages (Schmidt 2002: 68).

All the modern-day Celtic languages are minority languages influenced by the strong presence of either English or French as the majority language. While there

Jenny Graver. 2023. LFG and Celtic languages. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 1369–1406. Berlin: Language Science Press. DOI: 10.5281/zenodo.10186004

are movements to revive Cornish and Manx, these languages have no known traditional native speakers alive.

In minority languages like these, with potentially more speakers who are second language learners than there are native speakers, it is important for a researcher in any linguistic field to be aware of which variety of the language she is working with. For example, Irish is estimated to have 141,000 L1 users and 1,030,000 L2 users (Eberhard et al. 2019). This means that there are for all intents and purposes two Irish language communities, the rural communities of the official Irish-speaking areas called the *Gaeltacht* (plural *Gaeltachtaí*), and urban communities of second-language learners who go on to raise their children in what seems to be developing into new varieties of the language. McCloskey (2003) describes some of the issues involved in working with Irish in this situation. As McCloskey points out, even the question of which variety to study for the purpose of theoretical syntax is fraught with the potential to be felt painfully by the speakers in question. Kennard's (non-LFG) studies on Breton word order (Kennard 2014), and on an impersonal construction and initial mutation[1] in Breton (Kennard 2019), are other excellent examples of some of the complexities involved in studying minority languages like these.

Another issue to be aware of is the differences between the spoken and literary varieties in these languages, a distinction which is particularly prominent in Welsh, but also relevant for Irish. Areas where different varieties come into play in this chapter are among others Irish verbal agreement (dialect, register and diachronic development, Section 4.2) and Irish numerals ("school" language vs. spoken language, Section 4.3).

1.2 On the selection of topics in this chapter

Relatively little work has been done on the Celtic languages in LFG compared to in other theories, and the studies we have cover very different topics. It has been my goal to write an overview chapter that shows some of this breadth. This means that there has not been sufficient room to present all the relevant theory or all the relevant language structures in detail. References to theoretical and grammatical resources are provided, including to other chapters in this Handbook. I encourage the reader to consult the referenced works.

Often the works presented in this chapter are single studies on a single grammatical phenomenon in a single language. What do these studies contribute to our understanding of LFG and of the Celtic languages? What is the theoretical context of the study? I highlight where there remains work to be done in

---

[1] See Section 1.2.

LFG through comparisons with studies on the Celtic languages in other frameworks, and through introducing relevant grammatical phenomena in the Celtic languages that are still unaccounted for in LFG. It is my hope that this may be useful for researchers down the road who want to help fill the gaps in our LFG-theoretical understanding of the Celtic language family, or otherwise study the Celtic languages within the framework of LFG.

The system of initial mutation is a striking example of a central phenomenon in the Celtic languages that has received little attention in LFG. All the Celtic languages have a system of initial mutation in which phonological changes to the initial segment of words are triggered by lexical, morphosyntactic or syntactic conditions. Taking Irish as an example, there are two initial mutations in the language, called lenition and eclipsis. Some examples of how these mutations affect consonants are provided below. In these examples the acute accent denotes a palatalised as opposed to a velarised consonant, called "slender" and "broad" respectively in traditional grammars.

(1) Some initial mutations in Irish, spelling and pronunciation (Mac Eoin 2002: 109)

Radical		Lenited		Eclipsed	
c	/k/, /k′/	ch	/x/, /ç/	gc	/g/, /g′/
d	/d/, /d′/	dh	/ɣ/, /j/	nd	/N/, /N′/
f	/f/, /f′/	fh	(silent)	bhf	/w/, /v′/
s	/s/, /s′/	sh	/h/, /ç/	N/A	

Initial mutation is perhaps one of the most studied Celtic phenomena in general (see Harlow 1989, Ball & Müller 1992, Tallerman 2006 among many others). This might be one reason why it is hard to find LFG studies on this topic beyond computational approaches such as Mittendorf & Sadler's (2006) analysis of Welsh initial mutation using the XLE grammar development environment and the associated finite state and tokenisation tools. However, initial mutation is frequently mentioned when it interacts with the grammatical phenomenon under discussion, such as the Irish relative sentences discussed in Section 3.4.

2 Word order

2.1 Introduction

The Celtic languages show basic VSO word order. As pointed out for example by Fife (2002: 16), the Celtic languages are VSO not only in terms of basic word order

– they also show the features proposed by Joseph Greenberg to be implications of basic VSO word order: they are prepositional; they can be said to show SVO as an alternate order through fronting of non-verbal constituents, possibly more correctly described as XVO; they have initial interrogative particles, pre-verbal *wh*-words and the main verb after the auxiliary; and as a main rule, they show post-head modifications.

This section is centered on an LFG analysis of basic VSO word order at the clausal level, with the main issue being the presence of a VP in the Celtic languages. As will be seen, Sadler (1997) and Bresnan (2001) analyse the VSO word order of Welsh in order to develop and illustrate some very central concepts of LFG.

2.2 Is there a VP or not?

A central theoretical discussion concerning the Celtic languages has been the presence or absence of a VP. Early work on this question in other theories than LFG include Sproat (1985) for Welsh, McCloskey (1983) for Irish and Anderson & Chung (1977) for Breton.

As previously mentioned, the Celtic languages show various surface word orders in addition to VSO in different types of clauses. Tallerman (1998: 22–23) distinguishes between what she calls "two major word order patterns in finite clauses in Celtic". The first pattern has the finite lexical verb in initial position followed by the subject, object and any optional material – in other words, the standard VSOX order, as illustrated in (2) for Welsh and (3) for Irish.

(2) Welsh (Tallerman 1998: 23)
Rhoddais i afal i'r bachgen ddoe.
give.PST.1SG I apple to.DEF boy yesterday
'I gave an apple to the boy yesterday.'

(3) Irish (Ó Siadhail 1989: 205)
Labhrann Mícheál Gaeilge le Cáit go minic.
speak.PRS Mícheál Irish to Cáit often
'Mícheal often speaks Irish to Cáit.'

The other unmarked word order referred to by Tallerman (1998: 22–23) is a periphrastic construction with an initial finite auxiliary verb, followed by the subject and a non-finite verb and its complement, followed by any optional material. Examples are provided in (4) for Welsh and (5) for Irish, both of which illustrate the progressive construction.

(4) Welsh (Tallerman 1998: 23)
Mae o'n adeiladu tai ym Mangor.
be.PRS he.PROG build houses in Bangor
'He's building houses in Bangor.'

(5) Irish (Mac Eoin 2002: 131)
Tá mé ag baint fhéir.
be.PRS I PROG cut grass.GEN
'I am cutting grass.'

It is possible to front the non-finite verb and its complement in this construction using the cleft construction, illustrated in (6) for Welsh.

As we will see, this is taken as one indication of the presence of a VP in Welsh.

(6) Welsh (Bresnan 2001: 128)
Adeiladu tai ym Mangor a wnaeth o.
build houses in Bangor REL do.PST.3SG he
'He built houses in Bangor.' (VP focus)

(6) shows the periphrastic construction with the finite auxiliary verb 'do'; the non-finite verb 'build' and its complement is fronted. Similar fronting is found in Irish, as shown with the periphrastic construction in (7):

(7) Irish (from McCloskey 1983, quoted in Carnie 2005: 14):
Má's ag cuartughadh leanbh do dhearbhrathra a tá tú …
if.COP PROG seek child your brother REL be.PRS you …
'If it's seeking your brother's child that you are …'

Another argument frequently posited in favour of a VP in VSO languages is the presence of structure-dependent subject/object asymmetries such as anaphoric binding (Carnie & Guilfoyle 2000: 5–6 and references therein). The examples in (8) illustrate anaphoric asymmetries for Welsh:

(8) Welsh (Borsley 2006: 476)
   a. Welodd Gwyn ei hun.
      see.PRS.3SG Gwyn 3SG.M self
      'Gwyn saw himself.'
   b. *Welodd ei hun Megan.
      see.PRS.3SG 3SG.F[2] self Megan
      Intended: 'Megan saw herself.'

---

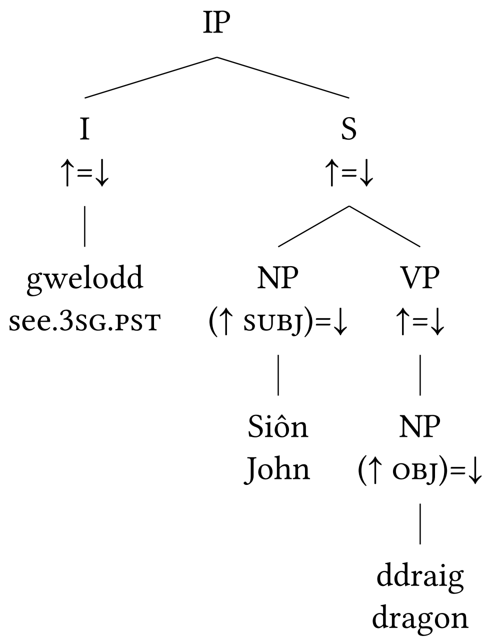
[2] This is glossed 'M' in Borsley (2006: 476).

If, as in LFG, binding constraints are taken to be a matter for f-structure (Rákosi 2023 [this volume]), examples such as the above are, however, not an argument in favour of a VP in VSO languages.

Based on examples such as (6) and (7) above, Bresnan (2001: 126–131), in line with Sadler (1997), argues in favour of a VP for Welsh as shown in the trees in (9).[3] For Bresnan (2001: 126ff), this argument is a matter of showing an example of what she calls "the noncompositionality of f-structures in c-structures", or more specifically for Welsh and the other Celtic languages that a finite VP can be discontinuous and with a head appearing external to the rest of the phrase. Crucially, this places the analysis of the word order of the Celtic languages in the context of central LFG concepts and analyses such as structure-function mapping and endocentricity and extended heads (see Belyaev 2023 [this volume]).

(9) Welsh word order

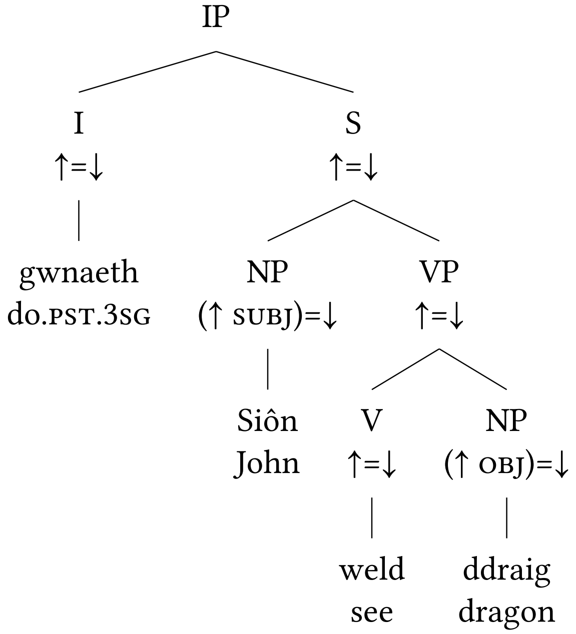
a. 'John saw a dragon.' (Broadwell 2005: 2)



---

[3] See Carnie (2005) for a discussion of Irish copula clauses as a possible counter-argument to this type of analysis of VSO languages.

b. ‘John saw a dragon.’ (Bresnan 2001: 128)



In this analysis the V in the I(nfl) position is the extended head of the VP. The tree in (9)a illustrates standard VSO order, whereas (9)b shows a Welsh periphrastic construction with the finite auxiliary verb ‘do’ in the initial position followed by the subject, a non-finite verb and its complement.

More broadly this analysis deals with several very central questions in any linguistic theory: what is the status of the VP? Is it desirable to maintain a unified analysis of different constructions in a language? Compare for example Borsley (2006), who argues against a head-raising account/discontinuous VP for finite, non-periphrastic clauses in Welsh. Borsley acknowledges the possibility of a VP in periphrastic constructions, but argues that it does not follow that there is a VP in finite, non-periphrastic clauses.

There is much more work to be done on the word order of the Celtic languages, both in general and in LFG, for example in light of Breton apparently showing verb-second effects (Schafer 1995, Tallerman 1998: 22, Stephens 2002: 400) and the development of SVO vs. V2 structure in modern Breton (Timm 1989, Kennard 2014, etc.). See also Sadler (2006: 1779–1783) for a discussion of Welsh constituent structure.

2.3 Some other patterns of word order

Within LFG there are so far relatively few studies of Celtic word order beyond clausal VSO structure. One important exception is Sadler’s (1998) article “Welsh

NPs without head movement”, on the structure of Welsh noun phrases. Her starting point is the similarity between nominal and clausal structure in Welsh, which has led to head movement type of analyses of Celtic noun phrases in which the head N raises to a functional category position, parallel to the extended head analyses described for VSO clauses. Sadler argues against this type of analysis for Welsh noun phrases for both conceptual and empirical reasons. She proposes instead an analysis in which Welsh nouns lack complements, and that what appears to be complements of the noun, are instead adjuncts. This removes the need for a head raising account for this data.

These similarities between NPs and VPs in the Celtic languages are another area that would benefit from further study. The issues raised are broader than the Celtic languages: as Sadler (1998: 2) points out, the head raising account of Celtic noun phrases is modelled on analyses of Semitic noun phrases, which show similarities with the Celtic structures.

In the introduction to this section, I mentioned some salient typological features of the Celtic languages that correspond to a VSO word order. One of these is fronting, or clefting. The Celtic pattern of fronting (see Tallerman 1998: 31–34, etc.) is illustrated below using Irish and Welsh. The basic structure of the Irish cleft construction is copula + clefted phrase + relative particle + the remainder of the sentence. This is illustrated in (10) through (a) a standard VSO sentence, (b) fronting of the subject, and (c) fronting of an adverb:

(10) Irish (Sulger 2009: 571):

a. Léigh an múinteoir leabhar inné.
read.pst def teacher book yesterday
‘The teacher read a book yesterday.’

b. Is é an múinteoir a léigh an leabhar inné.
cop agr def teacher rel read.pst def book yesterday
‘It is the teacher who read a book yesterday.’

c. Is inné a léigh an múinteoir an leabhar.
cop yesterday rel read.pst def teacher def book
‘It is yesterday that the teacher read a book.’

In Welsh, the corresponding construction does not have a copula, leaving the relative particle as the only marker of clefting (Watkins 2002: 336–337):

(11) Welsh (Watkins 2002: 337)
y bachgen a welodd y dyn
def boy rel see.pst.3sg def man
‘It was the boy who saw the man.’

The cleft construction in the Celtic languages has received relatively little attention in LFG, but see Sulger (2009) for an analysis that builds on analyses of the Irish copula.[4]

3 Arguments

3.1 Introduction

This section starts with an analysis of the Modern Irish so-called "autonomous" verb form and its diachronic development from a passive verb, which is then contrasted briefly with the Welsh impersonal verb form. These analyses deal with a crucial topic in any grammatical theory, namely mapping between verbal semantics and syntactic functions. The autonomous verb is followed by a description of a pattern in Welsh in which an adjective phrase is said to select for an object. The authors in question argue that this analysis raises wider issues about how best to understand grammatical functions in areas outside of verbal subcategorisation. Finally, there is a brief discussion of Irish relative clauses in the context of LFG analyses of unbounded dependencies.

3.2 Passives and impersonals

All the Celtic languages contain a verb form in their paradigm called "autonomous" or "impersonal" (Fife 2002: 14). There are two PhD theses dealing with this verb form within the framework of LFG, Graver (2010) for the Irish autonomous verb and Arman (2015) for the Welsh "impersonal passive" as well as another type of Welsh passive called the GET-passive. Both make use of Lexical Mapping Theory (LMT) as revised by Kibort (2007, 2014) (see Findlay et al. 2023 [this volume]).

Some classic studies of the Modern Irish autonomous verb are Stenson (1989) and McCloskey (2007). Their main conclusion is that the Modern Irish autonomous verb is an active verb with an impersonal subject comparable in semantics to French *on*, etc. In Irish, this subject is phonologically null. Drawing on this conclusion, Graver (2010, 2011) presents an LFG analysis of the Modern Irish autonomous verb and its diachronic development.

---

[4] Compare also Borsley (2020), a comparative analysis in HPSG of *wh*-interrogatives, free relatives and cleft sentences. Borsley suggests that the Welsh cleft construction involves identity predication. As mentioned, the copula does not appear in Welsh cleft sentences today. This leads Borsley to suggest that the identity predication is associated with the construction in Modern Welsh, whereas in Middle Welsh, where the copula did appear, the identity predication of the cleft sentence was associated with the copula.

Examples of the Modern Irish autonomous verb are provided in (12):

(12) Irish

a. Tugadh an corp chun na reilige agus cuireadh é.
bring.PST.AUT DEF corpse to DEF graveyard and put.PST.AUT it
'The corpse was brought to the graveyard and it was buried.' (Graver 2010: 4)

b. Deir siad go gcuirfear ar ath-chúirt é.
say.PRS they that put.FUT.AUT on re-court it
'They say that it will be appealed.' (Graver 2010: 9)

As will be shown in Section 4.2, the Modern Irish verbal paradigm contains a mixture of so-called synthetic forms, which express person and number, and analytic forms, which are used with separate pronouns. The autonomous form can thus be interpreted as a synthetic form expressing a subject with impersonal meaning, similar to a third person singular subject, etc.

The agent phrase is ungrammatical with the autonomous verb. This is an argument in favour of an active, impersonal analysis instead of a passive analysis. Assuming an analysis of the agent phrase as an oblique rather than an adjunct, this ungrammaticality is predicted by analysing the autonomous verb as an active, synthetic form, since the first argument of the verb is mapped to the impersonal subject and is thus unavailable for mapping to the agent phrase.[5] The ungrammaticality of the agent phrase with an autonomous verb is illustrated in (13).

(13) Irish (Stenson 1989: 382)
*buaileadh Ciarraí {ag, le} Gaillimh
beat.PST.AUT Kerry by, with Galway
Intended: 'Kerry was beaten by Galway.' [in a hurling match or similar]

Another argument in support of the same conclusion is object marking on the patient argument (*é* 'it' in (13)). Stenson illustrates this as follows, showing the ungrammaticality of the subject pronoun *siad* 'they' instead of the object pronoun *iad*:

---

[5] See Graver (2010: 60–61 and references therein) for arguments in favour of analysing the agent phrase as an oblique as opposed to an adjunct.

(14) Irish (Stenson (1989: 384)
buaileadh arís iad/*siad
beat.PST.AUT again them/*they
'They were beaten again.'

What is more, the autonomous verb may be used with more or less all verbs including intransitive and unaccusative verbs. I refer to the abovementioned references for additional data in favour of an active impersonal analysis.

Kibort (2007) reformulates the principles for mapping between arguments and grammatical functions compared to classic LMT, and suggests the following mapping principle.

(15) Mapping principle (Kibort 2007: 16)
The ordered arguments are mapped onto the highest (i.e. *least* marked) compatible function on the markedness hierarchy. [emphasis original]

The markedness hierarchy referred to in (15) is the classic hierarchy provided in (16), which again is based on the feature decomposition of f-structure functions shown in (17):

(16) Partial ordering of syntactic functions in terms of markedness (Bresnan (2001: 309)

$$\mathrm{SUBJ} < \mathrm{OBJ}, \mathrm{OBL}_{\theta} < \mathrm{OBJ}_{\theta}$$

(17) Feature decomposition of f-structure functions (Bresnan 2001: 308)

	[−*r*]	[+*r*]
[−*o*]	SUBJ	OBL_{θ}
[+*o*]	OBJ	OBJ_{θ}

Thus, the mapping between a- and f-structure will simply look as follows for a transitive autonomous verb, where *impers* is shorthand for "impersonal" – this mapping is similar to a regular active, transitive verb with any kind of subject.

(18) Mapping, transitive autonomous verb (Graver 2010: 62)

verb [aut.trans.]	⟨	arg1	arg2	⟩
		[−*o*]	[−*r*]	
		[−*r*]	[+*o*]	
		SUBJ *impers*	OBJ	

Three different morphosyntactic operations can be formulated to account for passivisation with and without an agent phrase, and with the second argument mapped to either the subject function (canonical passive) or the object function (impersonal passive). All of these operations result in passive verbs, the mapping of which is incompatible with the analysis of the autonomous verb as active with an impersonal subject as shown in (18).

When the agent phrase is not present in a passive sentence, arg1 undergoes mapping to zero/∅ (Bresnan 2001: 310). When the agent phrase is present, it undergoes mapping to OBL$_\theta$ (Kibort 2007: 17–19). In a canonical passive, arg2 maps to SUBJ as the least marked compatible function. In an impersonal passive, an operation called object preservation applies to map arg2 to OBJ, which entails an increase in the markedness of the mapping.

Where these mapping relations really turn out to be of use according to Graver (2010, 2011) is in the analysis of the diachronic development of the Modern Irish autonomous verb. In Old Irish, the properties of the autonomous verb appear contradictory in terms of the above mappings. Graver (2010: 179) sums this up as follows:

(19) Properties of the Old Irish autonomous verb:
   a. It is found included in the paradigm for practically any verb in every category of tense/aspect/mood, including intransitive and unaccusative verbs such as the substantive verb (Section 5.1) and verbs of inherently directed motion. (See Graver (2010: 62–63 and references therein) on passivisation and unaccusativity in LFG in the context of the Irish autonomous verb.)
   b. A third person patient is marked as subject, by nominative case on nouns, agreement in number with the verb and by the verb itself if the patient is a pronoun.
   c. There is object marking on first and second person patients, with infixed pronouns.
   d. The agent phrase is possible with transitive verbs.

The development from the above situation to the Modern Irish active impersonal can be summarised in terms of the markedness inherent in Kibort's (2007) theory: due to general changes in the morphological system of the Irish language, the patient of the Old Irish "passive" verb is reanalysed as the object rather than the subject of the verb. The resulting impersonal passive is predicted by the theory to be more marked than the original canonical passive, since an additional morphosyntactic operation/increase in markedness, object preservation, has applied.

The resulting subjectless, impersonal passive can be considered an unstable category, and for example Blevins (2003: 480–481 and references therein) suggests that subjectless impersonal passives tend to have an indefinite human agent interpretation, and that a subjectless impersonal passive thus would be practically indistinguishable from an active impersonal and consequently susceptible to reanalysis. When the autonomous verb in Irish is reanalysed as containing an impersonal active subject, there is no longer any need for the morphosyntactic increase in markedness – but see Graver (2010: 200–203) for a discussion of the difficulties of pinpointing the exact causes of such a diachronic change.

In other words, the status of the Old Irish autonomous verb could be termed contradictory or unclear in terms of the morphosyntactic operations illustrated above and the resulting impersonal and passive constructions. A comparable situation appears to apply in Modern Welsh: for example, the Welsh impersonal verb form can occur both with an agent phrase and unaccusative verbs. This phenomenon is analysed in terms of LFG by Arman (2015). Arman does not conclude whether the Welsh "impersonal" verb is in fact passive or active, but suggests that LFG, and particularly the revised mapping theory, is flexible enough to account for the Welsh data (Arman 2015: paragraph 7.3). The strength of Arman's approach is the large amount of data, the comparisons with other passives in the language and, in particular, the detailed analysis of the interaction of the impersonal verb form with different semantic verb classes (chapter 6). A similar LFG analysis of the autonomous verb in Old Irish would be highly interesting.

3.3 A Welsh adjectival construction

Mittendorf & Sadler (2008) analyse a Welsh adjective phrase construction containing a noun phrase as a constituent. They call this the *in-respect-of* construction, illustrated in (20), where the adjectives *byr* 'short' and *trwm* 'heavy', respectively, are followed by noun phrases containing a possessive clitic pronoun, here *ei* 'her':

(20) Welsh (Mittendorf & Sadler 2008: 2)

a. byr ei thymer
short her temper
'short-tempered'

b. trwm ei chlyw
heavy her hearing
‘hard of hearing’

Mittendorf & Sadler (2008: 19–20) suggest that the main theoretical contribution of their analysis of this Welsh construction is a call for more specific descriptions of the grammatical functions of LFG, particularly outside of the area of verbal subcategorisation.

Mittendorf & Sadler show that the construction occurs in similar environments to adjective phrases, as shown in (21) for attributive and predicative use respectively.

(21) Welsh (Mittendorf & Sadler 2008: 9)
a. merch fyr ei thymer
girl short her temper
‘a short-tempered girl’
b. Mae’r ferch yn fyr ei thymer.
be.PRS.DEF girl PRED short her temper
‘The girl is short-tempered.’

They go on to provide evidence, following apparently unpublished work by Jones (2002), in favour of analysing the adjective-NP sequence as one constituent, which is headed by the adjective. Phenomena in favour of this analysis include coordination – the NP in the sequence can be coordinated, which indicates that it is a subconstituent (Mittendorf & Sadler 2008: 3) – and the way that the adjective in the sequence can be modified as expected by regular adverbials and other types of intensifiers.

Initial mutation occurs in Welsh on an adjective modifying a feminine singular noun. The *in-respect-of* construction behaves as expected for an adjective when it modifies a singular feminine noun, as illustrated in (22), where the adjective *mawr* ‘big’ is lenited and becomes *fawr* following the feminine singular noun *athrawes* ‘(female) teacher’:

(22) Welsh (Mittendorf & Sadler 2008: 6)
athrawes fawr ei pharch
teacher big her respect
‘a highly-respected (female) teacher’

Having established that the adjective-noun sequence is a constituent headed by the adjective, Mittendorf & Sadler's main question is: what is the correct f-structure analysis of the noun phrase contained in the adjective phrase? What is its grammatical function? They review and reject analyses in which the noun phrase is a subj and adjunct, and tentatively conclude that the noun phrase is an obj.

They provide the f-structures in (23) for attributive and predicative use of the construction (Mittendorf & Sadler 2008: 12):

(23) F-structures, the *in-respect-of* construction (Mittendorf & Sadler 2008: 12)

a. attributive use:

$$\begin{bmatrix} \textsc{pred} & \text{`}\textsc{girl}\text{'}_i \\ \textsc{adj} & \left\{ \begin{bmatrix} \textsc{pred} & \text{`}\textsc{short}\langle\textsc{obj}\rangle\text{'} \\ \textsc{obj} & \begin{bmatrix} \textsc{pred} & \text{`}\textsc{temper}\langle\textsc{poss}\rangle\text{'} \\ \textsc{poss} & \begin{bmatrix} \textsc{pred} & \text{`}\textsc{pro}\text{'}_i \end{bmatrix} \end{bmatrix} \end{bmatrix} \right\} \end{bmatrix}$$

b. predicative use:

$$\begin{bmatrix} \textsc{pred} & \text{`}\textsc{short}\langle\textsc{subj, obj}\rangle\text{'} \\ \textsc{subj} & \begin{bmatrix} \textsc{pred} & \text{`}\textsc{girl}\text{'}_i \end{bmatrix} \\ \textsc{obj} & \begin{bmatrix} \textsc{pred} & \text{`}\textsc{temper}\langle\textsc{poss}\rangle\text{'} \\ \textsc{poss} & \begin{bmatrix} \textsc{pred} & \textsc{pro}_i \end{bmatrix} \end{bmatrix} \end{bmatrix}$$

Mittendorf & Sadler suggest that it might sound surprising that an adjective selects for an object, but propose that this is a reasonable analysis given the resources of the theoretic arsenal of LFG, as well as some cross-linguistic support from Swedish among other languages (Mittendorf & Sadler 2008: 18). However, their main argument in support of an obj analysis of the noun in this construction is a comparison with a very similar Welsh *tough* construction and the mandatory presence of the noun. See Kaplan 2023: Section 6 [this volume] on the *tough* construction in English in the context of long-distance dependencies. The *tough* construction in Welsh is illustrated below, with a verbal noun as the comp of the adjective *treulio*, verbal noun of 'to digest' in the example below, and the mandatory presence of the noun, which argues against an adjunct analysis.

(24) Welsh *tough*-construction (Mittendorf & Sadler 2008: 14)
bwyd anodd ei dreulio
food difficult its digest
'food difficult to digest'

3.4 Unbounded dependencies – the Irish relative clause

What happens when an argument of the verb is taken out of its normal position through relativisation? Irish has two relativisation strategies that conform with the Accessibility Hierarchy (Keenan & Comrie 1977). One of the earliest descriptions of these facts is McCloskey (1979). For an analysis of the more complicated Welsh data, see for example Tallerman (1990) and Borsley (2013).

In traditional grammar (such as The Christian Brothers 2002), the two Irish relativisation strategies are called the direct and the indirect relative. The direct relative is a gap strategy, whereas the indirect relative uses a resumptive pronoun.

The direct relative is used when the relative constituent is the subject or the object. It uses a relative particle that lenites.[6]

(25) Irish: the direct relative (McCloskey 1979: 5–6)

a. Relativised subject
an fear a dhíol an domhan
DEF man REL$^{\text{L}}$ sell.PST DEF world
'the man who sold the world'

b. Relativised object
an scríbhneoir a mholann na mic léinn
DEF writer REL$^{\text{L}}$ praise.PRS DEF students
'the writer whom the students praise'

The direct relative is obligatory with a relativised subject and the most common with a relativised object (McCloskey 1979: 6). However, since the VSO word order gives rise to potential ambiguity in examples like (25)b, the indirect relative with a resumptive pronoun is possible in these cases:

(26) Irish: indirect relative with a relativised object (McCloskey 1979: 6)
an scríbhneoir a molann na mic léinn é
DEF writer REL$^{\text{N}}$ praise.PRS DEF students him
'the writer whom the students praise'

Going further down the Accessibility Hierarchy, the Indirect Relative is obligatory with objects of prepositions and possessors:

---

[6] Lenition and eclipsis are the two initial mutations in Irish, as explained in Section 1.2. They are glossed L for lenition and N for nasalisation, the latter a traditional – but imprecise – term for eclipsis.

(27) Irish: the indirect relative (McCloskey 1979: 6)

a. Relativised prepositional object
an fear a dtabharann tú an t-airgead dó
DEF man REL^{N} give.PRS you DEF money to.him
'the man to whom you give the money'

b. Relativised possessor
an fear a bhfuil a mháthair san otharlann
DEF man REL^{N} be.PRS his mother in.DEF hospital
'the man whose mother is in the hospital'

These core Irish facts, as well as some more peripheral patterns described by McCloskey (2002), are analysed in detail by Asudeh in his book *The Logic of Pronominal Resumption* (Asudeh 2012: chapter 7). The chapter on long distance dependencies in this volume (Kaplan 2023 [this volume]) provides a brief description of Asudeh's analysis in the context of the development of LFG analyses of the explicit marking of f-structures in the domain of a long distance dependency – though it should be noted that Kaplan restricts himself to examples with the direct relative, in comparison with sentences with the Irish complementiser *go*^{N} 'that' – which introduces complements that are not in the domain of a long distance dependency.

4 Agreement

4.1 Introduction

There are many agreement issues in the Celtic languages that remain untouched within the LFG framework. In this section I present analyses of Irish verbal conjugation and a Welsh conjunct agreement pattern, before moving on to agreement between cardinal numbers and numerals in Welsh and Irish respectively. There are clear similarities in these areas between the two languages discussed, but also interesting differences that lack thorough analyses.

4.2 Various issues of verbal agreement

Table 1 shows parts of the standard conjugation of the Irish verb *mol* 'to praise'.[7] There is variation between analytic forms, which take a separate pronoun (or

---

[7] Welsh is quite different from Irish in this respect (see Borsley et al. 2007: 9–10). Welsh shows complete paradigms of synthetic verbal morphology. Literary Welsh permits null subjects; colloquial Welsh does not.

noun) subject, and synthetic forms (marked in bold) which are conjugated for person and number.

Table 1: Irish conjugations (The Christian Brothers 2002: 95, emphasis added)

	Present tense	Past tense	Imperfect
1sg	**molaim**	mhol mé	**mholainn**
2sg	molann tú	mhol tú	**mholtá**
3sg	molann sé/sí	mhol sé/sí	mholadh sé/sí
1pl	**molaimid**	**mholamar**	**mholaimis**
2pl	molann sibh	mhol sibh	mholadh sibh
3pl	molann siad	mhol siad	**mholaidís**

There has been a general development in Irish towards more analytic forms, but as e.g. Ó Siadhail (1989: 182–185) points out, there is a mixture of synthetic and analytic forms in all the dialects, with a tendency for the most synthetic forms in the south and the fewest in the north of the country.

There are two important descriptive generalisations associated with Irish verbal agreement. First, as a general rule, the synthetic forms are incompatible with a pronoun or noun subject, as shown in (28).

(28) *molaim mé
praise.PRS.1SG I

Second, when the paradigm contains a synthetic form, the analytic form is unavailable (though see below for a potential exception).

Irish data such as these are used by Andrews (1990) as a basis for formulating the Morphological Blocking Principle. The main intuition behind this principle is that if there is a highly specified form in the Lexicon, a less highly specified one cannot be used (Andrews 1990: 508).

Andrews (1990) shows first of all that it follows from general LFG architecture that a synthetic verb form cannot occur together with a noun phrase or pronoun. Synthetic verb forms are taken to specify the value of the PRED of the subject as ‘PRO’. A subject NP would contribute a different PRED value than that to the subject, and this is ruled out by the Uniqueness Condition (see Belyaev 2023: Section 3.4.1 [this volume]).

However, as Andrews (1990: 516) points out, the Uniqueness Condition is not sufficient to rule out the presence of a pronoun with a synthetic verb form, since the specification of the PRED value of the subject as 'PRO' from both the verb form and the pronoun would not appear to be contradictory. To solve this, Andrews refers to the principle of Predicate Indexing, which he suggests "causes each PRED-value introduced in a lexical item to receive a unique index, which distinguishes it from all other PRED-values in the structure" (Andrews 1990: 516). This principle makes a synthetic verb form and a pronoun subject mutually exclusive, since the 'PRO' values contributed by a synthetic verb form and a subject pronoun respectively would carry separate indices, which in its turn would violate the Uniqueness Condition.

Finally, to account for the ungrammaticality of an analytic verb form with a pronominal subject when there is a synthetic form available, Andrews (1990) formulates the Morphological Blocking Principle:

> Suppose the structure S has a preterminal node P occupied by a lexical item l_1, and there is another lexical item l_2 such that the f-structure determined by the lexical entry of l_1 properly subsumes that determined by the lexical entry of l_2, and that of l_2 subsumes the f-structure associated with P in S (the complete structure, after all unifications have been carried out). Then S is blocked. (Andrews 1990: 519)

Building on this, Sulger (2010) offers a computational LFG analysis of Irish verbal agreement facts. As a part of his analysis, Sulger (2010: 169–170) criticises the Morphological Blocking Principle in computational terms, suggesting that this principle has the consequence that the lexicon needs to be checked for a corresponding synthetic form every time an analytic form occurs. If there is a synthetic form, the analytic form is blocked. Sulger (2010: 170) argues, from a computational grammar viewpoint, that this approach is inefficient and that it is questionable whether it is adequate for larger-scale grammars.

McCloskey & Hale (1984: 491–492 and §6) point out that there is greater variation in the Irish paradigms than described above (see also Ó Siadhail 1989: 182–185), and that in certain cases the same person-number combination can be expressed both by a synthetic and an analytic form. Some of their examples are included in (29):

(29) Irish (McCloskey & Hale 1984: 491)

a. chuirfidís
   put.COND.3PL

b. chuirfeadh siad
   put.COND they

This matter seems to involve both dialect and register variation as well as historical developments, and is so far an understudied topic within the framework of LFG. McCloskey & Hale (1984: 531) indicate morphological blocking as potentially the most fruitful line of enquiry going forward.

Sadler (1999) discusses another agreement phenomenon in Welsh, a single conjunct agreement pattern illustrated in (30):

(30) Welsh (Sadler 1999: 2)

a. Daeth Siôn a minnau.
come.PST.3SG Siôn and 1SG
'Siôn and I came.'

b. Daethost ti a minnau/Siôn.
come.PST.2SG 2SG and 1SG/Siôn
'You and I/Siôn came.'

c. Roedd Mair a fi i briodi.
be.PST.3SG Mair and 1SG to marry
'Mair and I were to marry.'

d. Roeddwn i a Mair i briodi.
be.PST.1SG 1SG and Mair to marry
'I and Mair were to marry.'

All these examples have a plural coordinate subject.[8] When the first conjunct is a pronoun, the verb agrees with the pronoun in person and number. When the first conjunct is non-pronominal, the verb is in the unmarked third singular form. An identical asymmetrical agreement pattern shows up both in nominal structures containing possessor phrases and with objects of prepositions.

Sadler (1999: 3–4) suggests that a similar agreement pattern is found in Irish, based on data from McCloskey (1986). Some of McCloskey's examples are provided in (31):

(31) Irish (McCloskey 1986: 248)

a. Bhíos féin agus Tomás ag caint le chéile.
be.PST.1SG self and Tomás PROG talk with each.other
'Tomás and I were talking to one another.'

---

[8] See Sadler (2006) for a discussion of other coordination patterns in Welsh within the framework of LFG.

b. Bhíos -sa agus Pádraig Ó Guithín le pósadh.
be.PST.1SG -CONTR and Pádraig Ó Guithín to marry
'Pádraig Ó Guithín and I were to marry.'

Note the elements *féin* and *-sa* here; these are emphatic/contrastive elements that are mandatory in the above coordination pattern.[9]

Andrews (1990: 522–523) mentions this Irish pattern of agreement. He suggests that it presents significant difficulties for an LFG analysis and chooses to leave them aside in the context of his paper on morphological blocking. This type of pattern is also not restricted to the Celtic languages; it appears to be found in for example Czech, Latin and Palestinian Arabic (Sadler 1999: 4 and references therein).

The interesting difficulty with the Welsh data is, as Sadler (1999: 15) puts it, that "morphosyntactic and semantic agreement come apart under coordination": the only difference between the structure illustrated above and other coordinate structures is the agreement between the first, pronominal conjunct and the verb. On the other hand, data such as predicate agreement seem to indicate that semantic feature resolution appears to operate on coordinate structures in Welsh independent of whether the coordinate structure includes pronouns or not.

Sadler (1999) describes two main features of the classic LFG view of agreement: agreement features such as person, number, gender and case are an f-structure phenomenon, and agreement is a matter of constraints on the same structure rather than matching between features on different structures (see Haug 2023 [this volume] on agreement). The crucial question then is this: can this view of agreement be reconciled with the single conjunct agreement pattern illustrated above? Sadler (1999) argues that these data show that it is difficult to maintain a simple and homogenous view of what agreement is.

4.3 Noun phrase agreement: numerals

Fife (2002: 21) lists as "a common feature of Celtic nominal syntax" the use of singular forms (and/or special forms) following cardinal numerals. Mittendorf & Sadler (2005) make use of the INDEX/CONCORD distinction (referencing Wechsler & Zlatić's (2000) HPSG analysis and King & Dalrymple (2004) in LFG) to account for the resulting agreement mismatch in Welsh noun phrases.

---

[9] See McCloskey & Hale 1984: 493–496 for a thorough discussion of these and other elements and arguments why they are not pronouns.

The INDEX/CONCORD distinction describes two sets of nominal agreement features: CONCORD features relate to agreement between the noun and any determiners or adjectives, whereas INDEX features are related to the semantics of the noun and agreement between the noun phrase and a bound pronoun and often also verb agreement (see Haug 2023: Section 3 [this volume] for further details).

In Welsh, numerals require the singular form of the noun, as shown below in the examples 'five dogs' and 'three cats', where the noun in both cases is in the singular form:

(32) Welsh (Mittendorf & Sadler 2005: 6)

a. pum ci
five dog.M.SG
'five dogs'

b. tair cath
three.F cat.F.SG
'three cats'

What is more, if the noun is modified by an adjective with a distinct plural form, the singular form is used. In (33), the adjective *arall* 'other' is used in the plural form *eraill* in the phrase 'other dogs', but in the singular form *arall* when a numeral is added:

(33) Welsh (Mittendorf & Sadler 2005: 6)

a. cŵn eraill
dog.M.PL other.PL
'other dogs'

b. pum ci arall
five dog.M.SG other.SG
'five other dogs'

Demonstratives on the other hand are always plural when a noun with a plural premodifier is involved. In the below examples, the singular (feminine) form *hon* 'this' is used in the phrase 'this cat', whereas the plural form *hyn* is used in 'these three cats':

(34) Welsh (Mittendorf & Sadler 2005: 6)

a. y gath hon
DEF cat.F.SG this.F.SG
'this cat'

b. y tair cath hyn
DEF three cat.F.SG this.PL
‘these three cats’

At the same time, the noun phrase behaves overall as plural, as shown in (35), where the noun phrase ‘the five men’ controls a pronominal anaphor:

(35) Welsh (Mittendorf & Sadler 2005: 7)
Roedd y pum dyn yn gweld eu hunain yn y drych.
be.IPFV.3S DEF five man.M.SG PROG see 3PL self.PL in DEF mirror
‘The five men saw/were seeing themselves in the mirror.’

Mittendorf & Sadler (2005) suggest that these distinctions can be most usefully described as an INDEX/CONCORD mismatch: specifically, the numeral contributes the INDEX NUM feature, which will be plural. This accounts for the example in (35), where the noun phrase ‘the five men’ controls a plural anaphor. What is more, it accounts for the plural demonstrative *hyn* if Welsh demonstratives show INDEX agreement. On the other hand, the singular noun following the numeral will contribute a singular CONCORD NUM feature. This accounts for the requirement that adjectives modifying the noun be in the singular form, since adjectives are taken to show CONCORD agreement.

The f-structure for the noun phrase *tri dyn* ‘three men’ is shown in (36) to illustrate:

(36) Welsh (Mittendorf & Sadler 2005: 11)
tri dyn
three.M man.M.SG
‘three men’

$$\begin{bmatrix} \text{PRED} & \text{‘MAN’} \\ \text{INDEX} & \begin{bmatrix} \text{NUM} & \text{PL} \end{bmatrix} \\ \text{CONCORD} & \begin{bmatrix} \text{NUM} & \text{SG} \end{bmatrix} \\ \text{ADJ} & \left\{ \begin{bmatrix} \text{PRED} & \text{‘THREE’} \end{bmatrix} \right\} \end{bmatrix}$$

Irish numerals show agreement patterns of the same type as Welsh, in that numerals, as a main rule with certain exceptions described below, are followed by a noun in the singular. How this system interacts with adjective agreement lacks analysis in LFG for Irish.

Describing what he calls the “traditional” system, Ó Siadhail (1982) shows that the main rule also in Irish is that the unmarked, singular form of the noun is used after cardinal numerals:

(37) Irish

a. trí chnoc
three hill.M.SG
‘three hills’ (Ó Siadhail 1982: 99)

b. dhá chnoc d(h)éag[10]
two hill.M.SG ten
‘twelve hills’ (Ó Siadhail 1982: 100)

c. trí chnoc fhichead
three hill.M.SG twenty.GEN
‘twenty-three hills’ (Ó Siadhail 1982: 101)

The “traditional” system referred to above is a system based on multiples of twenty:

(38) Irish

a. deich lá fichead
ten day twenty.GEN
‘thirty days’ (Ó Siadhail 1982: 101)

b. naoi lá dhéag is fiche
nine day ten and twenty
‘thirty-nine days’ (Ó Siadhail 1982: 101)

c. lá is dá fhichead
day and two twenty.GEN
‘forty-one days’ (Ó Siadhail 1982: 102)

However, as Ó Siadhail (1982: 101) points out, what he calls the “school system” has introduced numerals in a decimal system, such as *tríocha* ‘thirty’, *ceathracha* ‘forty’, etc.[11] This latter system is considered standard today, and is illustrated in

---

[10] Whether the form has undergone mutation or not (*déag* vs. *dhéag*) is a matter of dialectal variation (see Ó Siadhail 1989: 100).

[11] The terms used by Ó Siadhail when he makes the distinction between “traditional” and “school” system, highlight the need for linguists to be aware of the sociolinguistic nuances of the language under study, in order to be certain of which linguistic system we are describing and analysing at a given time. Mac Eoin (2002: 118–119) suggests that the decimal system is in fact a survivor from the literary language, whereas the vigesimal system has prevailed in the spoken language. He goes on to state that “[t]he promotion of the decimal system in the schools during the last seventy years has not diminished the popularity of the vigesimal system in ordinary speech” (Mac Eoin 2002: 119).

(39) with examples from the school grammar book *New Irish Grammar* by the Christian Brothers:

(39) Irish (The Christian Brothers 2002: 76)

a. trí chapall is tríocha
three horse and thirty
'thirty-three horses'

b. seacht gcapall is caoga
seven horse and fifty
'fifty-seven horses'

The numerals three to ten are however used with certain nouns in the plural. This holds for both number systems. As illustrated in the examples above, the '-teen' part of the numeral phrase – whether the abovementioned multiples of twenty or the school system numerals – is placed after the modified noun while the numbers 1–10 are placed before the noun. Consequently, the exception to the singular rule is relevant for the number system in general and not just when counting to ten.

Nouns used in the plural with numerals can be divided into different groups, including nouns that express a unit of measure (Ó Siadhail 1982: 102–104) and "words inherent to the counting system" such as *ceann* 'head/one' vs. *trí cinn* 'three' (literally 'three heads') (Ó Siadhail 1989: 167)

There is in other words significant variation in the Irish numeral system, depending on whether you are dealing with the traditional or standard written language or the traditional spoken language with its many dialects. We may perhaps also expect to see that the use of the singular form of nouns following numerals is on the way out in the urban varieties of Irish, on the pattern of English.

5 The copula

5.1 Introduction

All the Celtic languages show or have shown a distinction between two 'be' verbs, usually labelled the substantive verb (Irish: *bí*) and the copula (Irish: *is*) (Fife 2002: 19–20, etc.). In LFG it is mainly the Irish copula that has been studied, and thus Irish will be the focus here.[12] This means that Irish copula predication has not

---

[12] Welsh has one copula verb *bod*, which appears to share properties with both the Irish copula and the Irish substantive verb (see Borsley 2019). A comparative LFG analysis of the Irish and Welsh copula systems would be interesting.

been studied in its entirety in LFG. In theoretical terms, the Irish copula and the Irish substantive verb are both copulas, but I will use the traditional labels.

For the Irish copula, it is customary in traditional grammar to distinguish between two types of copula sentences, classificatory and identificatory (e.g. Ó Siadhail 1989: 224). Some examples are provided below, as context for the following theoretical discussion:

(40) Irish (Ó Siadhail 1989: 224)

a. Is scoláire mé.
cop scholar I
'I am a scholar.'

b. Is múinteoir í Cáit.
cop teacher agr.3sg.f Cáit
'Cáit is a teacher.'

(41) Irish (Ó Siadhail 1989: 227)

a. Is mé an múinteoir.
cop I def teacher
'I am the teacher.'

b. Is é Seán an múinteoir.
cop agr.3sg.m Seán def teacher
'Seán is the teacher.'

In classificatory sentences such as those in (40), the subjects *mé* 'I' and *Cáit* are said to belong to the class of scholar/teacher. The identificatory sentences in (41) express identity between the subjects, *mé* 'I' and *Seán*, and 'the teacher'.

In this section I first discuss the syntax of the Irish copula. There are two main types of analysis proposed in the LFG literature for copula constructions, a single-tier analysis where the pred of the sentence is the non-verbal predicate, and a double-tier analysis with two varieties depending on the choice of argument function for the non-verbal predicate. It is shown that while LFG works on the Irish copula tend towards a double-tier, predlink analysis, there is philological work on older stages of the language that suggest a single-tier analysis as more appropriate to the Irish data. I go on to show how the Irish copula behaves in terms of the distinction between stage level and individual level.

5.2 Syntax of the Irish copula

In the LFG literature (Dalrymple et al. 2004 and references therein), there are three types of analyses suggested for different types of copula constructions across languages, as shown in Figure 1.

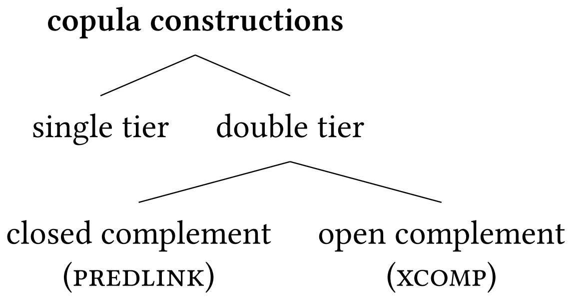


Figure 1: Types of copula constructions (adapted from Sulger 2009: 564)

Dalrymple et al. (2004) suggest that different f-structure analyses are appropriate for different copula constructions not only between languages but also within in a single language. Attia (2008) on the other hand argues in favour of a unified, general analysis of copula constructions on the f-structure level, and suggests that the variations in morphological agreement, presence or absence of the copula, etc., used as arguments in favour of different analyses by Dalrymple et al., do not warrant functional variation.

Sulger (2009) mostly follows Attia (2008) and argues that a PREDLINK analysis is universally applicable to copula constructions, thus also for Irish. In the following I show how the Irish data have been situated in the context of this discussion. I will briefly sketch the three types of copula analyses as context for Sulger's (2009) analysis, before providing his main arguments in favour of a double-tier, PREDLINK analysis for the Irish copula.

A single-tier analysis is one where the copula verb is not required or not permitted, and the copula predicate is taken to select for a subject. This is illustrated in the f-structure in (42) for the translation of a Japanese sentence meaning 'the book is red', from Dalrymple et al. (2004: 191). The copula verb, if present, may contribute tense, as seen in Japanese (Dalrymple et al. 2004).

(42) Single-tier analysis (Dalrymple et al. 2004: 191)

$$\begin{bmatrix} \textsc{pred} & \text{`}\textsc{red}\langle\textsc{subj}\rangle\text{'} \\ \textsc{subj} & \begin{bmatrix} \textsc{pred} & \text{`}\textsc{book}\text{'} \end{bmatrix} \end{bmatrix}$$

In a double-tier analysis, the copula provides the main predicate of the clause, and selects for either an open xcomp function, or the closed predlink function ("closed" meaning here that predlink does not allow functional control).[13]

(43) Double-tier analyses (Dalrymple et al. 2004: 189)

a. Open complement

$$\begin{bmatrix} \textsc{pred} & \text{`}\textsc{be}\langle\textsc{xcomp}\rangle\textsc{subj}\text{'} \\ \textsc{subj} & [\;] \\ \textsc{xcomp} & \begin{bmatrix} \textsc{pred} & \text{`}\ldots\langle\textsc{subj}\rangle\text{'} \\ \textsc{subj} & \end{bmatrix} \end{bmatrix}$$

b. Closed complement

$$\begin{bmatrix} \textsc{pred} & \text{`}\textsc{be}\langle\textsc{subj}, \textsc{predlink}\rangle\text{'} \\ \textsc{subj} & [\;] \\ \textsc{predlink} & \begin{bmatrix} \textsc{pred} & \text{`}\ldots\text{'} \end{bmatrix} \end{bmatrix}$$

Sulger's (2009) argument in favour of a double-tier, closed complement analysis of the Irish copula is twofold, and has to do with the presence or absence of the copula, and the presence or absence of agreement between the copula predicate and subject.

Sulger (2009: 570) refers to the discussion between Dalrymple et al. (2004) and Attia (2008) on what to take away from the presence or absence of the copula. Ó Siadhail (1989: 244) formulates the general rule for the Irish copula as follows: "(…) the copula may not normally be deleted when marked for mood, tense, negation, interrogation or when embedded in a sentence." This is illustrated in (44):

(44) Irish (Ó Siadhail 1989: 244)

a.

Múinteoir	é	an	fear	sin.
teacher	agr.3sg.m	def	man	that

'That man is a teacher.'

b.

Ba	mhúinteoir	é.
cop.pst	teacher	he

'He was a teacher.'

---

[13] A reviewer provided examples from Welsh where the copula occurs with an expletive subject said to be required by the complement. The examples appear to involve modal semantics. More work is needed on how this fact should be analysed in light of the above discussion on the different analyses of the syntax of the copula. Irish has periphrastic modal predicates with the copula, and for Irish my intuition would be that these would need to be treated separately from regular copula predication as discussed in this chapter. See Graver (2010: 86–94) for an overview of Irish modal verbs with references for further reading.

c. Deir siad gur duine deas é.
say.PRS they that.COP person nice he
'They say that he is a nice person.'

On the basis of these facts, Sulger (2009: 570) argues that the absence of the copula, in the contexts where it may be dropped, is a matter of stylistic variation, and that the presence or absence of the copula does not lead to semantic differences.

Sulger suggests that his argument runs counter to Dalrymple et al. (2004). Dalrymple et al. (2004: 190–191) show how the Japanese copula may be dropped with adjectival predicates but is mandatory with nominal predicates. They argue on the basis of syntactic criteria that the category of the predicate may affect whether it can license a subject and propose a single-tier analysis for Japanese copula sentences with adjectival predicates whether or not the copula is present. For Japanese copula clauses with nominal predicates, they suggest a double-tier analysis of some kind. Sulger on the other hand argues on the basis of Attia (2008) that the predication is the same independent of the presence or absence of the copula, and for this reason that a unified analysis is desirable.

For a language like Russian, where the occurrence of copula is governed by tense, Dalrymple et al. (2004: 191–193) suggest that a unified analysis is desirable, independent of the presence or absence of the copula. The point in this case is that there should not be any evidence of syntactic or semantic differences between clauses with the copula and clauses without. This is likely the case in Irish. Such a unified analysis would take two forms, either a single-tier analysis like Japanese, with the copula contributing features of tense, or a double-tier analysis with the copula as the main PRED of the clause selecting for either an XCOMP or a PREDLINK.

Sulger goes on to note that agreement between the copula predicate and the subject has been given by Dalrymple et al. (2004) as an argument in favour of an XCOMP analysis, because they view "agreement as a strong indication for a control relation between the subject and the predicate" (Sulger 2009: 566). There is no agreement between the copula predicate and the subject in Irish (see Mac Eoin 2002: 115 on the use of adjective predicates with the copula; for nouns compare (45) with (44) above).[14] Consequently, Sulger (2009: 567) argues, agreement is not an argument in favour of an XCOMP analysis in Irish.

---

[14] The pronominal element glossed AGR in some of these examples is inserted to agree with the subject, and cannot be taken to involve agreement between the subject and the predicate. See Carnie (1997: 61) and Ó Siadhail (1989: 224).

(45) Irish (Ó Siadhail 1989: 224)

Is	múinteoir	í	Cáit
COP	teacher	AGR.3SG.F	Cáit

'Cáit is a teacher.'

Not all the linguistic literature on the Celtic languages in other theories agrees with this analysis. For example, Carnie & Harley (1994) provide a Principles and Parameters analysis of certain facts of the two Irish 'be' verbs where they view the copula as a complementiser particle providing features of aspect and tense (see Doherty 1996: 9–10 for arguments in favour of such an analysis based on how the copula behaves in sentences with interrogation, negation and subordination particles, and Asudeh (2002) for a general analysis of Irish pre-verbal particles). In LFG terms, this might imply a single-tier analysis.

There are hints in the philological studies and grammars of Old Irish that a single-tier analysis might be appropriate for the older stages of Irish and Scottish-Gaelic, and perhaps also for earlier stages of Welsh. For example, Ahlqvist (1971–1972: 271) calls the copula a "verb-making particle", and Thurneysen (1998: 24–25) and McCone (1996: 211) discuss the similarities between the Old Irish copula and proclitic elements like pre-verbs and articles. Fife, in his introduction to the edited volume *The Celtic Languages*, writes as follows (Fife 2002: 20): "[f]ormerly, in both Irish and Welsh, the copula and its predicate formed a constituent, with the subject moved rightward to the end of the clause." Another point to note is the fact that Old Irish showed agreement between the subject and an adjective predicate in copula clauses. There is in other words much more Irish material to study when it comes to copula clauses.

5.3 Stage level and individual level predication

Sulger (2011) provides an analysis of copula constructions that express possession in Irish and Hindi/Urdu. For Irish he shows how the copula and the substantive verb behave in terms of the distinction between stage level and individual level predication. He argues that this contrast is expressed through lexical information. Specifically, he suggests that the substantive verb may supply a situation argument (based on Kratzer 1995) when it expresses stage level predication. The situation argument serves to embed the property expressed by the predication in some situation.

Sulger (2011: 19–20) again assumes a syntactic analysis using the PREDLINK function of the Irish copula, as mentioned in the previous section. For reasons of space he does not provide any examples of f-structures or lexical entries for his Irish data.

In the following I will use Sulger's (2011) data as a starting point for illustrating how the copula and the substantive verb behave in terms of the stage and individual level distinction.

Sulger (2011: 12) notes that the linguistic literature on Irish generally assumes that the copula expresses individual level predication and the substantive verb stage level predication (see e.g. Doherty 1996: 40). "Stage level" in this sense refers to properties that hold of an individual at some stage of their lives, whereas "individual level" refers to properties that holds of an individual at all stages. The contrast between the copula and individual level predication, and the substantive verb and stage level predication, is nicely illustrated by Mac Eoin:

(46) Irish (Mac Eoin 2002: 136)

a. Is dochtúir mise
COP doctor I.EMPH
'I am a doctor.'

b. Tá mise i mo dhocthúir
be.PRS I.EMPH in my doctor
'I am a doctor.'

(46)a is a sentence with the copula verb is. (46)b on the other hand contains the substantive verb *tá*, with a subject 'I' and a prepositional phrase with the preposition 'in' together with a possessive particle 'my'. Mac Eoin (2002: 136) describes the differences between these examples as follows: "[...] *Is dochtúir mise* [with the copula] is an absolute statement of what I am, whereas *Tá mise i mo dhochtúir* [with the substantive verb] merely states the role in which I appear."

He goes on to contrast the above examples with the following:

(47) Irish (Mac Eoin 2002: 137)

a. Is gunna é seo
COP gun this
'This is a gun.'

b. *Tá sé seo ina ghunna
be.PRS this in.its gun
Intended: 'This is a gun.'

In the latter example above, the construction with the substantive verb + 'in' + possessive particle cannot be used with 'gun' as the subject, since 'being a gun' is an absolute property of the thing referred to.

Sulger (2011) tests the claim that the Irish copula expresses individual level predication on a certain type of copula sentence in comparison with his Hindi data. Sulger terms the construction in question the possessive copula construction, where the copula is followed by a prepositional phrase with the preposition *le* 'with' expressing the possessor and a noun expressing the possessee. Sulger then applies some of the well-known tests for stage or individual level predication (Sulger 2011: 7 and references therein). For example, stage level predicates are assumed to allow temporal adverbs while individual level predicates do not. This is illustrated in (48)a, where, according to Sulger, the copula sentence is judged as questionable by native speakers with the addition of the adverb *inniu* 'today'.

Another test described by Sulger is to change the tense of a sentence, which is thought to result in a change in the perceived lifetime of the individual(s) involved in an individual level predication, but not in a stage level predication. This is illustrated for Irish in (48)b, which now implies that either Pádraig or the car does not exist anymore.

(48) Irish (Sulger 2011: 12, 14)

a. Is le Pádraig an carr nua (?inniu).
   COP.PRS with Pádraig DEF car new today
   'Pádraig has the new car today.'

b. Ba le Pádraig an carr nua.
   COP.PST with Pádraig DEF car new
   'Pádraig had the new car.'

For the substantive verb on the other hand, Sulger (2011: 15) points out, referencing Doherty (1996), that while a change in tense in examples similar to those in (48) results in the subject being perceived as dead when the copula is used, with the substantive verb the subject might have changed profession.

Sulger (2011: 12–14) goes on to show that while the copula is restricted to individual level predication, the substantive verb may in fact express both stage and individual level predication. For example, in the following example with the substantive verb, the reading is ambiguous between ownership (individual level) and temporary possession (stage level):

(49) Irish (Sulger 2011: 12)
Tá an carr nua ag Pádraig
be.PRS DEF car new at Pádraig
'Patrick has the new car' (he may or may not own it)

6 Conclusion

I hope to have shown that the work in LFG on the Celtic languages, while not very substantial, has contributed in various ways to both the theory of LFG and to our understanding of the languages themselves. For example, the question of whether there is a VP in a VSO language like Welsh has been drawn into the discussion of endocentricity and extended heads in LFG (Section 2.2), and the autonomous verb form in Irish has been analysed in the context of general, cross-linguistically applicable categories describing relationships between thematic roles and syntactic functions (Section 3.2).

At the same time, there is a lot of material in the Celtic languages remaining to be studied for the interested researcher. Does it take some extra dedication from the non-native speaker researcher especially, given the challenges of working on minority languages, the low number of native speakers and comparative lack of teaching materials? Yes. But I would still argue that it is very much worth it.

Acknowledgments

I wish to thank the three anonymous reviewers for detailed and interesting comments that greatly improved this chapter, Helge Lødrup for reading early drafts and Mary Dalrymple for her patience, sympathy and encouragement. Any remaining errors are my own.

Abbreviations

Besides the abbreviations from the Leipzig Glossing Conventions, this chapter uses the following abbreviations.

AUT	autonomous verb form	IMPERS	impersonal
CONTR	contrastive	PRED	predicative particle
EMPH	emphatic

Chapter 30

LFG and Continental West-Germanic languages

Gerlof Bouma
University of Gothenburg

This chapter presents an overview of LFG work on Continental West-Germanic languages. It starts out by giving a broad characterization of the languages that are part of this group, with a special focus on their clause layout, that is, the placement of verbs and arguments in a clause. After this, the different LFG approaches to modelling this layout are discussed, followed by a selection of clausal and verbal domain topics such as topicalization and left-dislocation, asymmetric coordination, cleft constructions, and argument ordering and realization. The chapter concludes by reviewing LFG analyses of topics from the nominal domain, namely determiner-adjective declension, preposition-determiner contraction, case indeterminacy and possessive doubling.

1 Introduction

This chapter is concerned with the Lexical-Functional Grammar treatment of the present-day West-Germanic languages *sans* English or Scots. This group is sometimes referred to as Continental West Germanic (Zwart 2008), as it is mostly comprised of Germanic languages[1] spoken in countries on the European mainland: from Belgium and the Netherlands, through Luxembourg and Germany, to Switzerland, the northernmost parts of Italy, and Austria; and in addition in smaller regions bordering these countries. In spite of the label ‘continental’, the

---

[1] Unless it is relevant to the discussion, I will use the term *language* in a broad sense that ignores matters like the language/language variety/regiolect/dialect/etcetera’s political status, whether a language label covers a homogeneous or heterogeneous group of subvarieties, or whether it is mutually intelligible with languages that do not fall under the same label.

Gerlof Bouma. 2023. LFG and Continental West-Germanic languages. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 1407–1468. Berlin: Language Science Press. DOI: 10.5281/zenodo.10186010

group of Continental West Germanic languages (henceforth: CWG) also contains languages like Yiddish (spoken in Israel, North America and elsewhere), Afrikaans (South Africa and Namibia), Dutch in the Antilles and Suriname (in terms of language politics part of the same standardization body as Belgium and the Netherlands), and German heritage variants in the Americas (Putnam 2011) and Siberia (Andersen 2016), to name but a few group members outside of continental Europe.

In terms of L1 speakers, the largest of these languages are the standard varieties of German and Dutch, with circa 75 and 25 million speakers, respectively.[2] Their status as standardized national languages in multiple countries also means they are supported by strong academic infrastructures. It is therefore not surprising that most of the work on CWG in LFG is done on these two languages. Standard German and Dutch[3] will figure prominently in this chapter. This is merely a reflection of their salience in the LFG literature, and should not be interpreted linguistically, for instance as a sign of them being more typical CWG languages than other members of the language group.

A comprehensive inventory of West-Germanic languages with demographic and linguistic information can be found in Ethnologue[4] (Eberhard et al. 2019). Bibliographic data on West-Germanic can be found in Glottolog[5] (Hammarström et al. 2019). Note that neither of these resources distinguishes a CWG branch in their taxonomies. For an overview of the syntactic traits of Continental West Germanic, I refer the reader to Zwart (2008). An accessible description of how German is syntactically different from English and from the North-Germanic languages can be found in the introductory chapters of Haider (2010), with arguments that in many cases carry over to the other CWG languages.

1.1 A general picture of Continental West Germanic, with a focus on the clause

In this subsection we will discuss some of the syntactic traits of CWG. Our focus will be on the clause/verbal domain, since this has been the main interest of the LFG literature on CWG. We will discuss the nominal domain more briefly. The purpose of this subsection is twofold. First, it gives a very general impression of CWG syntax and indicates how it differs from its North- and West-Germanic

---

[2] Counts based on Eberhard et al. (2019).

[3] Unless the context requires otherwise, I will use *German* and *Dutch* without further modification to refer to the standardized, national language varieties of these two CWG languages.

[4] https://www.ethnologue.com/subgroups/west-0, consulted July 2022

[5] https://glottolog.org/resource/languoid/id/west2793, consulted July 2022

neighbours. Secondly, it introduces some of the language-particular background needed to understand the individual LFG analyses discussed in the rest of the chapter.

1.1.1 Clause layout

A prominent syntactic feature of CWG languages is the combination of *asymmetric verb second* together with *verb final* (Zwart 2008, Haider 2010). The former label characterizes a clause structure in which the finite verb in main clauses, but *not* in subordinate clauses, is preceded by exactly one constituent, which can have a wide range of grammatical functions. The latter label covers the generalization that any verbal material that is not in second position – finite verbs in subordinate clauses and non-finite verbs in general – clusters together towards the end of the clause, potentially following arguments and adjuncts. As such, CWG contrasts with Modern English, which lacks both pervasive verb second in main clauses and verb finality, and follows a more rigid subject-verb-complement order. CWG also differs from the present-day North-Germanic languages, which can be characterized as combining verb second with subject-verb-complement order.[6]

For the discussion of the layout of a CWG clause, it is helpful to make use of the so-called *topological field model* of the clause, which can be found in traditional descriptions of German and Dutch and in reference grammars like Zifonun et al. (1997) and Haeseryn (1997). In this model, the layout of a clause is described in terms of linearly ordered fields, and different word order variants associated with different clause types are obtained by assigning constituents to different fields. The field schema we use in this chapter is given in (1).

(1) lead ‖ Vorfeld | left bracket | Mittelfeld | right bracket | Nachfeld ‖ tail

In a main clause, the *left bracket* (lb) and *right bracket* (rb) are reserved for verbal material: a single, second-position finite verb is in the left bracket, and any other verbs are in the verb cluster in the right bracket. Between the brackets there is the *Mittelfeld* 'middle field' (Mf), which may contain any number of constituents.

---

[6] Two remarks are in order with respect to this characterization of CWG clause layout. First, as it can be used to demarcate CWG from English as well as from North-Germanic, it gives some linguistic substance to the pooling of CWG languages into one group, as we do in this chapter. Secondly, and somewhat weakening the first point, once we start to look closer at individual CWG languages, we find deviations from the general pattern. Modern Yiddish in particular fits the description poorly, both in terms of the verb-second pattern and the verb-final pattern. It is beyond the scope of this chapter to go into all the exceptions, but some of them will be discussed towards the end of this section and in the context of LFG analyses of these exceptions.

The *Vorfeld* ‘prefield’ (Vf) is the designated place for the single constituent preceding the finite verb, whereas the *Nachfeld* ‘postfield’ (Nf) may contain several items, and is typically reserved for heavier constituents like clausal arguments, extraposed relative clauses and adverbial prepositional phrases. The *lead* and *tail* fields[7] host material that is more loosely connected to the clause, such as vocatives and hanging topics. Note that not every field needs to contain material. Examples of different declarative main clause types are given in (2).

(2) Dutch

a. Subject-initial declarative:

Vf———		lb—	Mf———		rb———
De	draken	doen	Doris	dadelijk	duizelen.
the	dragons	make.PRS.PL	Doris	immediately	feel.dizzy.INF

‘The dragons immediately make Doris feel dizzy.’

b. Object-initial declarative:

Vf—	lb—	Mf———			rb———
Doris	doen	de	draken	dadelijk	duizelen.
Doris	make.PRS.PL	the	dragons	immediately	feel.dizzy.INF

c. Sentence adverb-initial declarative:

Vf——	lb—	Mf———			rb———
Dadelijk	doen	de	draken	Doris	duizelen.
immediately	make.PRS.PL	the	dragons	Doris	feel.dizzy.INF

The verb-second constraint is clear here: the finite verb is always in the left bracket and precedes its subject if a non-subject is in the Vorfeld (2b,c). The subject and object can appear in identical positions – contrast the OVS order in (2b) with SVO in (2a). Linear order is therefore not fully determined by grammatical function, or vice versa. The Vorfeld is also the target of long-distance dependencies, like fronting of wh-constituents out of embedded clauses (not shown here). The Mittelfeld may contain a collection of (nominal) arguments and (simple) adverbials, which are typically local to the clause. The extent to which the order of material within the Mittelfeld is fixed differs between languages (see Section 2.4.1). Grammatical-function assignment under word order variation, long-distance dependencies, and the order of elements in the Mittelfeld are all basic CWG phenomena that the LFG models discussed below must address.

---

[7] The terminology around these last two fields is not as established as for the fields that are part of the clause proper. The lead is for instance also known as *Vorvorfeld* ‘pre-prefield’ or *linkes Außenfeld* ‘left outfield’, and the tail as *Nachnachfeld* ‘post-postfield’ or *rechtes Außenfeld* ‘right outfield’.

Other clause types have empty Vorfeld regions, such as the polar interrogative (3a), which is a verb-first construction, and the subordinate clause (3b), in which the left bracket is filled by the complementizer.

(3) Dutch

a. Polar interrogative:
lb—— Mf—————————— rb———
Doen de draken Doris dadelijk duizelen?
make.PRS.PL the dragons Doris immediately feel.dizzy.INF

b. Subordinate:
lb– Mf—————————— rb——————
…dat de draken Doris dadelijk doen duizelen.
COMP the dragons Doris immediately make.PRS.PL feel.dizzy.INF

Example (3b) has the finite verb in the right bracket, in the verb cluster. This shows the asymmetry of the verb-second phenomenon: unlike in a main clause, the finite verb in a subordinate clause can be preceded by any number of constituents in the Mittelfeld. The topological model accommodates the complementary distribution of the finite verb of a main clause and the complementizer of a subordinate clause by locating both in the left bracket.

The right bracket in (3b) contains two verbs: first the finite verb, then the non-finite verb. This is considered to be the default order in Standard Dutch, but there is considerable variation in this ordering, both between and within CWG languages. An extensive overview of ordering possibilities in CWG verb clusters is given in Wurmbrand (2004).

The topological schema based on the combination of verb second and verb final is widely applicable to the CWG languages, but, as with any generalization, there are cases where it does not apply. To start, we must keep separate the notion of main clause vs. subordinate clause *word order* from the notion of unembedded and embedded clause *uses*. This is because German, amongst others, allows embedded clauses to have verb second under bridge verbs in the absence of a complementizer (see Section 2.2.1); that is, it allows main clause word order for certain embedded clauses. Furthermore, the separation of non-verbal material in the Mittelfeld and verbal material in the right bracket is not always as clean as the topological model suggests, as languages may allow for material from the two fields to be mixed, blurring the border between them (see Section 2.1.2). Finally, Afrikaans and Yiddish have clause structures that deviate further. Spoken Afrikaans optionally allows the combination of a complementizer and verb second in subordinate clauses (Biberauer 2009). Modern Yiddish has verb second in main as well as in subordinate clauses, and in addition its status as a verb-final language is debated (Diesing 1997). Historical stages of Yiddish did however follow CWG's characteristic pattern more closely (Santorini 1992).

1.1.2 Clause union

The examples in (2) and (3) each contain two verbs. We have discussed the topological model as a schema of the clause, without questioning whether we are dealing with mono-clausal structures here. Since Bech (1955/1957), it is common to distinguish between *coherent* and *incoherent* verb combinations. The former describes a combination of two verbs into a single clause, *clause union*, whereas the latter results in a biclausal structure. The contrast is illustrated below. In (4a), the coherently combining *durfde* 'dared' shares the verb cluster with its embedded verb *te kopen* 'to buy', and the embedded object sits in the Mittelfeld of the clause headed by *durfde*. Example (4b) contains the incoherently combining *beloofd* 'promised', and here we see that both the embedded verb and its object appear after the matrix verb, in the Nachfeld of the matrix clause. As shown in (4c), this word order is not available for the coherently combining *durfde* 'dared'.

(4) Dutch

a.

	lb——	Mf——		rb——	
	…omdat	hij	geen auto	durfde	te kopen.
	because	he	no car	dared	buy.TEINF[8]

'…because he didn't dare to buy a car.'

b.

	lb——	Mf	rb——	Nf——	
	…omdat	hij	beloofde	geen auto	te kopen.
	because	he	promised	no car	buy.TEINF

'…because he promised not to buy a car.'

c.

*	…omdat	hij	durfde	geen auto	te kopen.
	because	he	dared	no car	buy

The second sign that we are dealing with one clause in (4a) and two in (4b) is the scope of the negation, as evident from the translations. In both examples, negation is marked on the embedded object through the negative determiner but it nevertheless scopes over the finite verb in (4a). The same negation marking in the biclausal (4b) yields a narrow scope negation.

---

[8] The abbreviations TEINF and ZUINF in the glosses are used for the verb forms in Dutch and German that combine the infinitive marker (*te* in Dutch, *zu* in German) with an infinitive. Unlike corresponding forms in for instance English, these combinations are generally not separable.

A third phenomenon associated with clause union is the potential to trigger *infinitivus pro participio* (IPP; German: *Ersatzinfinitiv* ‘replacement infinitive’). IPP refers to the realization of a verb in the infinitive when a participle is expected on the basis of the selecting auxiliary. For this to occur, the clause itself must also contain a further, lower verb in the infinitive.[9] The occurrence of IPP is therefore evidence of the middle and lower verb combining coherently. Below, IPP is triggered in (5a), affecting the coherently combining *durven* ‘dare’, but not in (5b) for the incoherently combining *beloofd* ‘promised’.

(5) Dutch[10]

a. Hij heeft geen auto {durven / *gedurfd} te kopen.
he has no car dare.INF dare.PTCP buy.TEINF
‘He didn’t dare to buy a car.’

b. Hij had {beloofd / *beloven} geen auto te kopen.
he had promise.PTCP promise.INF no car buy.TEINF
‘He promised not to buy a car.’

Example (5a) additionally shows that a clause can contain more than two verbs. In principle, there is no limit to the number of verbs involved in clause union, since the same couple of coherently combining verbs can appear at multiple levels of embedding.[11]

A wide range of verbs allow for coherent combination. For instance, for Dutch, the reference grammar Haeseryn (1997) lists over 100 verbs that always combine coherently, and an additional 20 that do so optionally. In this list we find auxiliaries; evidential, modal and aspectual verbs; but also verbs with a clearer lexical contribution such as causal and perceptual verbs, and for instance verbs corresponding to *help*, *learn*, *try* or *forget*. In theoretical syntactic work, combining behaviour is commonly taken to be an underived, lexical property of the embedding verb, but see Cook (2001) for an explanation of coherence in German in terms of information structure.

---

[9] Further conditions may apply, for instance on the order of the auxiliary and the middle verb.

[10] A note on the use of brackets and parentheses in examples in this chapter: I will use curly brackets to indicate choice. The choice is either between several forms in one position, such as in the current example (5), or between several positions for one form, such as in the example in (28). Square brackets delimit constituents when this is relevant, such as in (6). Parentheses indicate optionality as usual.

[11] In practice, it seems that three-verb combinations are common, but more complex clauses are rare. For instance, Coussé & Bouma (2022) report numbers for a mixed corpus of written and spoken Dutch: about 3% of coherence domains contain three verbs, but only 0.1% contain four verbs.

1.1.3 Crossing dependencies

When we have coherently combining verbs that also introduce their own object, we can end up with a clause in which a sequence of objects in the Mittelfeld is followed by a corresponding sequence of verbs in the cluster. In languages like German or West Frisian, the unmarked order of the objects is by increasing order of embedding $O_1O_2...O_n$, whereas the order of verbs is by decreasing order of embedding $V_n...V_2V_1$. This gives rise to a pattern of nested dependencies between the objects and their verbs (6).

(6) Standard German

		O_1		O_2		V_2	V_1
…dass	wir	[dem	Hans]	[das	Haus]	streichen	halfen
COMP	we	the.DAT	Hans	the.ACC	house	paint	helped

'…that we helped (V_1) Hans (O_1) paint (V_2) the house (O_2).'

In Dutch and Swiss German, however, objects and verbs can *both* be ordered by increasing level of embedding $O_1O_2...O_n$ and $V_1V_2...V_n$. This creates cross-serial dependencies between objects and verbs, as in (7).

(7) Swiss German (Shieber 1985: §2, example 1)

		O_1		O_2		V_1	V_2
…das	mer	[em	Hans]	[es	huus]	hälfed	aastriiche.
COMP	we	the.DAT	Hans	the.ACC	house	helped	paint

The phenomenon of cross-serial dependencies has received ample interest in the literature, because it requires more than context-free power to model (Bresnan et al. 1982, Pullum & Gazdar 1982, Shieber 1985).

1.1.4 In and around the nominal domain

We end the overview of CWG syntax by briefly discussing the main characteristics of the nominal domain and, even more briefly, adpositions. This is to give a general sense of what these domains look like in CWG languages. Most of what is discussed below resembles what we find in the North-Germanic languages and English.

The nominal domain in CWG generally follows a determiner–adjective–noun pattern, with further adnominal material (relative clauses, PPs, etc.) realized postnominally. This is exemplified in (8).

(8) Dutch
de mooiste plek van Europa
the beautiful.SUPERLATIVE place of Europe
'the most beautiful place in Europe'

Present-day CWG languages have at most four cases (NOM, GEN, DAT and ACC; for example Standard German), but many make fewer case distinctions (see Kasper 2014 for a compact description of the situation in German varieties and references), and several have only a subject-object form distinction remaining in the pronominal paradigm (for example, Afrikaans, Dutch, and West Frisian).[12] There are two numbers (SG, PL). Any of three genders (M, F and N; Alemannic[13], Low Saxon,[14], Standard German, West Flemish), two genders (COMMON gender and N; Dutch, West Frisian) or no distinction (Afrikaans) may occur. Gender agreement distinctions only show up in the singular. The different paradigm sizes with respect to gender are illustrated in (9). Note the form contrasts in the definite determiners.

(9) a. Alemannic
d Frau dr Maa s Chind
the.F.NOM woman the.M.NOM man the.N.NOM child
b. West Frisian
de frou de man it bern
the.COMMON woman the.COMMON man the.N child
c. Afrikaans
die vrou die man die kind
the woman the man the child

Adjectives can be associated with multiple inflectional paradigms – see Section 3.2.2 for a discussion of these *declension classes* in Standard German. Even in languages with more elaborate paradigms, there is typically a great level of syncretism between forms across inflectional dimensions for determiners, pronouns, adjectives and nouns. The consequences of syncretism for grammatical modelling are discussed in Section 3.2.4.

---

[12] See taalportaal.org for linguistic descriptions of Afrikaans, Dutch, and West Frisian. Consulted September 2022.

[13] The term Alemannic (German) covers amongst others Alsace German, Swabian and Swiss German.

[14] Low Saxon is used interchangeably with Low German by some authors. Our use of the term here comprises regional languages of the north of Germany and the east/north-east of the Netherlands. Our choice for the term Low Saxon is partly driven by the fact that LFG work on this language uses this term: see Section 3.2.1.

Adpositions are overwhelmingly prepositional (10a), but the sporadic postposition (10b) and circumposition (10c) occur as well.

(10) Gronings (Low Saxon)

a. **op** de grìns
on the border
'on the border'

b. t haile joar **deur**
the whole year through
'the whole year through'

c. **om** de provìnzie **tou**
around the province around
'around the province'

1.2 Overview of the rest of the chapter

Thus far, I have talked about the geographic distribution and the syntactic characteristics of the Contintental West-Germanic languages, to define the scope of the chapter, and to give a background for what is to come below.

The remainder of this chapter is devoted to LFG analyses of different aspects of CWG syntax. In Section 2, I discuss LFG accounts of the clause and the verbal domain, and in Section 3, I discuss LFG studies of the nominal domain. These sections are structured in a parallel fashion: they start with analyses of the overall structure of their respective domains, and then continue with a discussion of more specific LFG accounts organized by topic. In the LFG literature on CWG, the clausal and verbal domains have received by far the most attention, which means that the corresponding section dominates this chapter in terms of size.

The chapter ends with concluding remarks in Section 4, in which I briefly touch upon some LFG and LFG-related work that was not included in detail here, and give pointers for further reading.

2 LFG analyses in the clausal and verbal domains

This section deals with phenomena at the level of the clause. I will start in Section 2.1 with a discussion of the variety of ways in which the overall shape of the clause has been modelled, mostly in terms of c-structure. I then look at specific topics that have been prominent in the LFG literature on CWG languages. The topics are divided into thematic sections. Phenomena at the left and right periphery are discussed in Section 2.2 and Section 2.3, respectively. Studies dealing with the ordering of dependents are discussed in Section 2.4. Finally, mapping-based analyses of areas of CWG clause syntax are presented in Section 2.5.

2.1 The overall shape of the clause

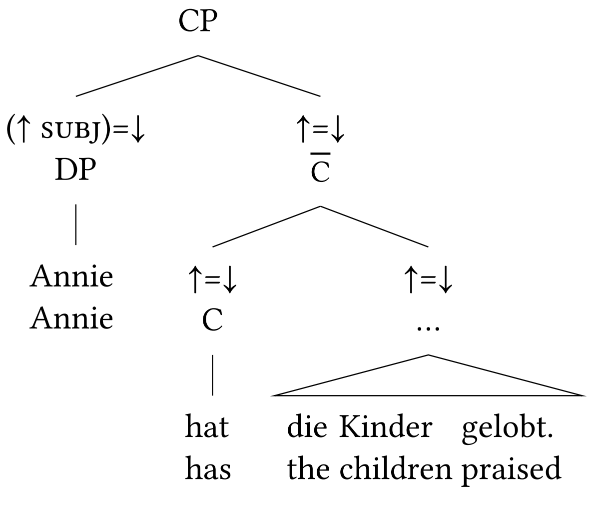
The discussion of the different LFG conceptions of the overall shape of the clause is organized according to the topological field model. I first consider the top level of the clause (directly containing the Vorfeld and left bracket) in Section 2.1.1, and then the lower level of the clause (the Mittelfeld and right bracket) in Section 2.1.2. The Nachfeld is discussed in Section 2.1.3.

2.1.1 Vorfeld and left bracket

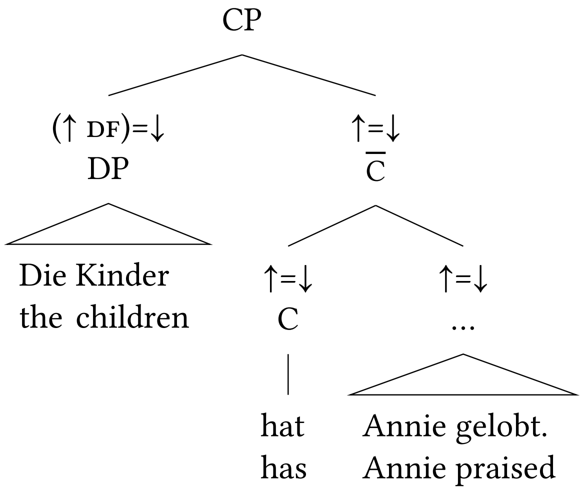
Berman & Frank (1996), Choi (1999), Berman (2003), and Frank (2006) model the German verb-second clause as a CP. The finite verb sits in C irrespective of whether the initial position is occupied by the subject of a declarative clause (11a) or by some other element, like the object in (11b). The complementary distribution between the finite verb and the complementizer in the left bracket follows as well: the complementizer can only appear in C, and when it is realized, the finite verb must occur in another, lower position (11c).

(11) German

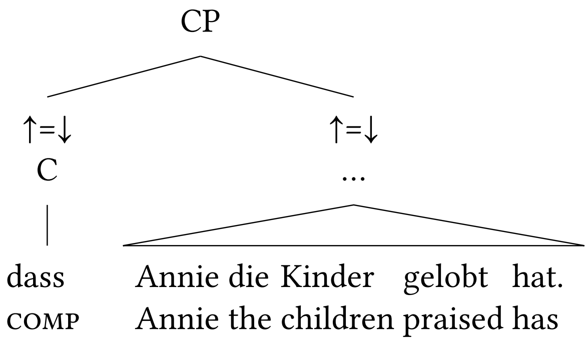
a.



b.



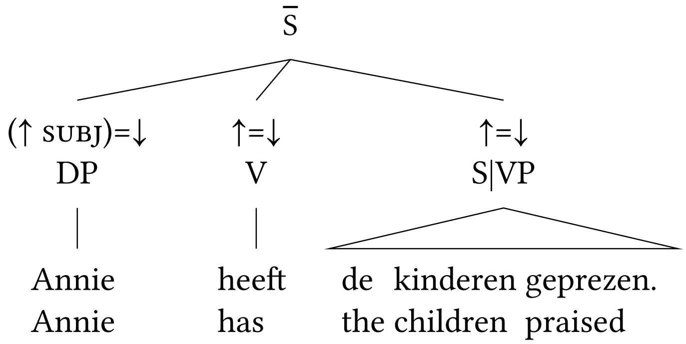
c.



The nature of Comp-CP, the node dominating the combined Mittelfeld and right bracket, differs between these authors, however, and will be discussed below. Van der Beek (2005) and Jones (2020), on Dutch, consider only main clauses, which they posit to be IPs.

Zaenen & Kaplan (1995, on Dutch; 2002 on German) prefer a slightly flatter structure, exemplified in (12). The label 'S|VP', a convention from the cited papers, is used to show that the authors do not wish to choose between these categories.

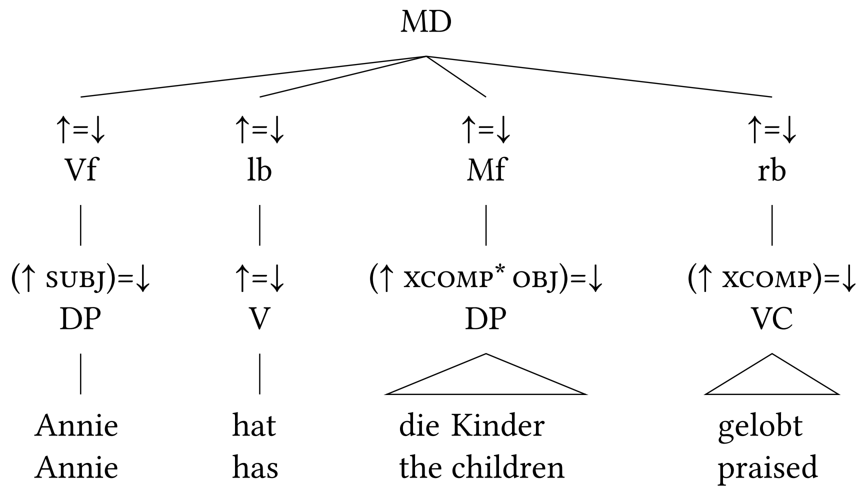
(12) Dutch



Zaenen & Kaplan's subordinate clauses are isomorphic to those in (11c), but are labelled $\overline{\text{S}}$ instead of CP.

An even flatter structure appears in the computational grammar fragment discussed in Clément et al. (2002), who model the topological field schema directly in LFG. All topological fields are c-structure nodes and direct descendants of the MD node ('main domain') that represents the whole sentence. Example (13) gives a somewhat simplified tree, using the abbreviations for the topological fields which I introduced in Section 1.1.1.

(13)



A very similar flat structure can be found in Rohrer (1996).[15]

2.1.2 Mittelfeld and right bracket

The Mittelfeld and right bracket form the lower c-structure level in the clause. This is the unlabelled Comp-CP in (11) and the S|VP node in (12). All authors agree that this part of the tree does *not* involve an IP.[16] This choice against an

---

[15] Rohrer (1996), however, also writes "Diese flache Struktur läßt sich problemlos in eine binäre rechtsverzweigende Struktur umwandeln. [...] Wir behalten das flache Mittelfeld hier primär aus expositorischen Gründen bei" (p96, fn 3). [This flat structure can be converted to a binary right-branching structure without problems. We maintain the flat Mittelfeld here primarily for reasons of exposition.]

[16] In fact, in LFG, the assumption of an IP anywhere in CWG c-structure is rare. We mentioned Van der Beek (2005) and Jones (2020), on Dutch, who use it as the category at the top level, for the whole V2 declarative clause. The choice is not further motivated in these works, and moreover it is peripheral to the respective discussions. Bresnan et al. (2016) posit that Comp-CP contains an IP in one of the book's exercises on German. However, since this is a textbook, it is unclear whether the authors are theoretically committed to this choice, or whether it was made for other reasons, for instance pedagogical ones.

intermediate IP can also be found in analyses of German in the Chomskyan tradition, for instance in the line of work summarized in Haider (2010: see §2.2 therein for an overview of the arguments).

A salient question in the analysis of this part of the clause is the order of the verbs and the arguments, and the concomitant contrast between nested versus cross-serial dependencies. We will focus first on the two polar opposites: verbs ordered after increasing level of embedding (cross-serial dependencies) and verbs ordered after decreasing level of embedding (nested dependencies). The following pair, a variation on (6–7) above, illustrates the difference with three verbs in the verb cluster:

(14) a. Standard German
…dass wir [die Kinder] [dem Hans] [das Haus] streichen helfen lassen
COMP we the.ACC children the.DAT Hans the.ACC house paint help let
'…that we let the children help Hans paint the house.'

b. Swiss German (Shieber 1985: §2, example 5)
…das mer [d' Chind] [em Hans] [es huus] lönd hälfe aastriiche.
COMP we the.ACC children the.DAT Hans the.ACC house let help paint.

As mentioned in the introduction, there is considerable variation in the order of the verbal elements beyond these two opposites, and there is even variation in the extent to which the nominal material in the Mittelfeld and verbal material in the right bracket is kept separated, both between and within CWG languages. This variation will be briefly discussed at the end of this subsection.

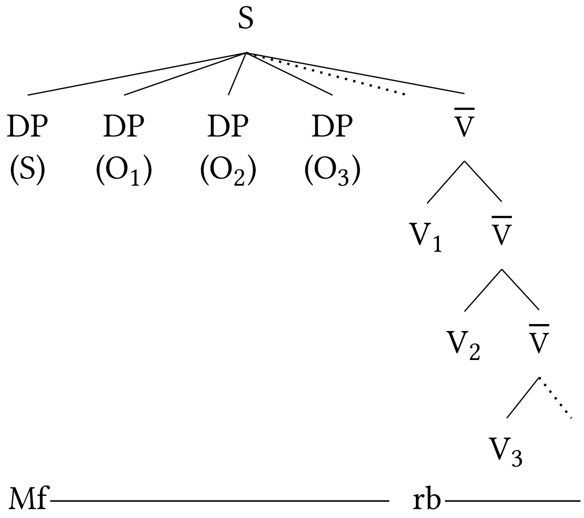
2.1.2.1 Cross-serial dependencies

An early LFG analysis of Dutch cross-serial dependencies is found in Bresnan et al. (1982), which was a prominent demonstration of how LFG's formalism has the power needed for linguistically valid analyses of such dependencies.[17] Starting from a proposal by Evers (1975), schematically in (15a), with a flat Mittelfeld and a right-branching verb-cluster, Bresnan et al. argue that a structured Mittelfeld is to be preferred, as in (15b).

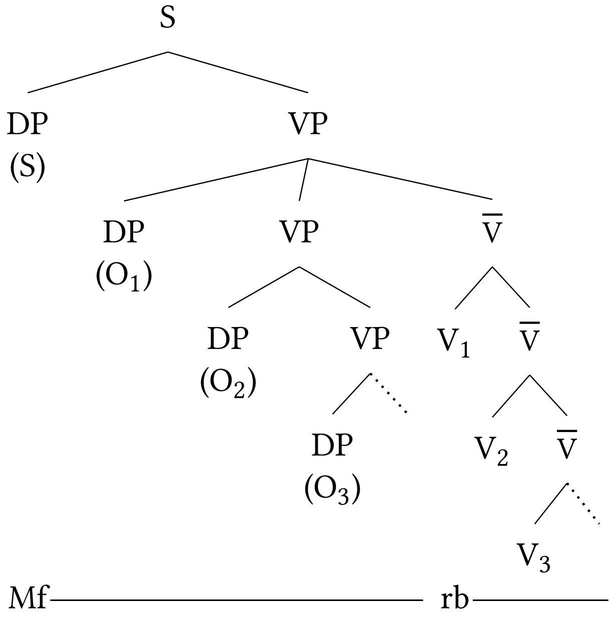
---

[17] The paper played a central role in the discussion of the context-freeness of natural language syntax. See e.g. Pullum & Gazdar (1982) and Shieber (1985) for more discussion of the issues involved and the kind of evidence considered.

(15) a.



b.



The tree in (15b) contains two parallel embedding structures: one for the objects in the Mittelfeld and one for the verbs in the right bracket. This is captured in the c-structure definitions in (16).

(16) a. $$\text{S} \longrightarrow \underset{(\uparrow \textsc{subj})=\downarrow}{\text{DP}} \quad \underset{\uparrow=\downarrow}{\text{VP}}$$

b. $$\text{VP} \longrightarrow \begin{pmatrix} \text{DP} \\ (\uparrow \textsc{obj})=\downarrow \end{pmatrix} \begin{pmatrix} \text{VP} \\ (\uparrow \textsc{xcomp})=\downarrow \end{pmatrix} \begin{pmatrix} \overline{\text{V}} \\ \uparrow=\downarrow \end{pmatrix}$$

c. $$\overline{\text{V}} \longrightarrow \underset{\uparrow=\downarrow}{\text{V}} \quad \begin{pmatrix} \overline{\text{V}} \\ (\uparrow \textsc{xcomp})=\downarrow \end{pmatrix}$$

For the objects, each level of VP embedding adds a level of xcomp embedding at f-structure. For the verbs, each level of $\overline{\text{V}}$ embedding does the same. A compatible stacking of xcomps is thus built up in both parts of the tree. The optionality of the object DP in (16b) allows for verbs that do not introduce their own object. It is essential that an xcomp level is introduced for these in both parts of the tree, too, to maintain the parallel structure.

The accusative with infinitive verbs involved in the cross-serial construction are analyzed as raising-to-object verbs. The inflected verb form *zag* ‘saw’, for instance, receives a lexical entry along the lines of (17).

(17) *zag* V (↑ pred)=‘see⟨subj,xcomp⟩obj’
(↑ xcomp subj)=(↑ obj)
(↑ xcomp form)=inf
(↑ subj num)=sg
(↑ tense)=pst

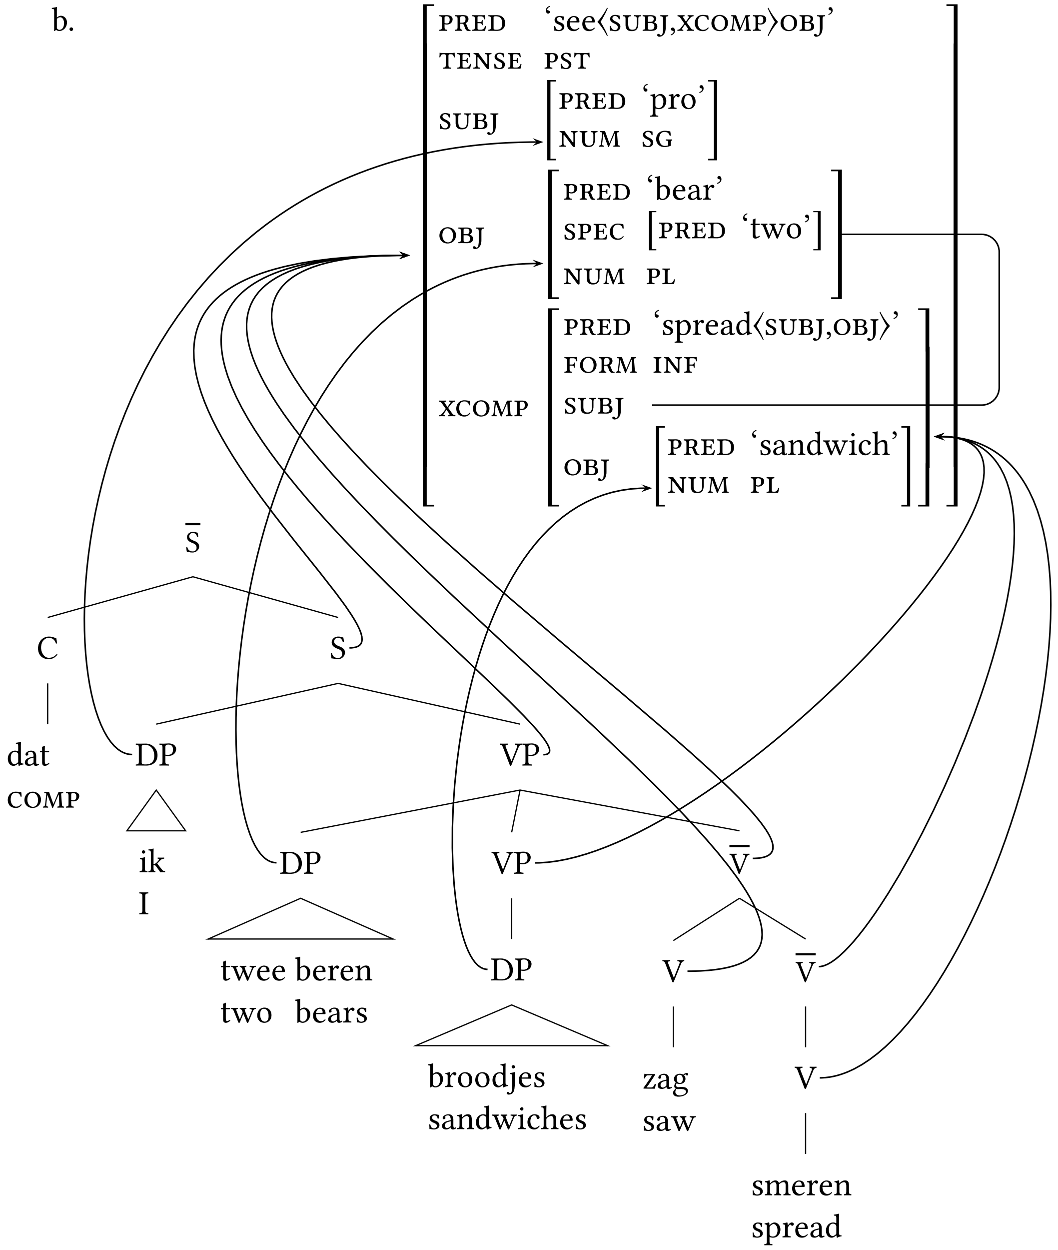
Complemented with rules for DPs and additional lexical entries, this grammar fragment gives us analyses like the one in (18).

(18) a. Dutch

	S	O_1		O_2	V_1	V_2
…dat	ik	[twee	beren]	broodjes	zag	smeren.
comp	I	two	bears	sandwiches	saw	spread

‘…that I saw (V_1) two bears (O_1) prepare (V_2) sandwiches (O_2).’

b.



However successful in capturing cross-serial dependencies, this analysis runs into descriptive problems if taken more generally as a model of the Dutch sentence. Zaenen & Kaplan (1995) give the example in (19), which involves the coordination of two V̄s that each require a different level of XCOMP embedding for the object supplied in the Mittelfeld.

(19) Dutch (Zaenen & Kaplan 1995: §2.3, example 9)

…dat	Jan	een	liedje	[[$_{\overline{\text{V}}}$ schreef]	en	[$_{\overline{\text{V}}}$ trachtte	[$_{\overline{\text{V}}}$ te verkopen]]].
comp	Jan	a	song	wrote	and	tried	sell.teinf

'…that Jan wrote and tried to sell a song.'

Since different levels of xcomp embedding of the object correspond to different c-structures in the model of Bresnan et al. (1982), example (19) cannot receive an analysis if we use the standard treatment of constituent coordination in LFG. It would require the shared material to receive two different c-structures at the same time. Zaenen & Kaplan's (1995) alternative relies on functional uncertainty to connect the objects to predicates at the required level of xcomp embedding, and on functional precedence rules to make sure that the linear order of objects reflects their level of embedding. They replace the VP and $\overline{\text{V}}$ rules of (16) with those in (20).

(20)

a. $\text{VP} \longrightarrow \underset{(\uparrow \text{XCOMP}^{*}\ \text{OBJ})=\downarrow}{\text{DP}^{*}} \quad \underset{\uparrow=\downarrow}{\overline{\text{V}}}$

b. $\overline{\text{V}} \longrightarrow \underset{\uparrow=\downarrow}{\text{V}} \left(\begin{array}{c} \overline{\text{V}} \\ (\uparrow \text{XCOMP})=\downarrow \\ \neg\big((\uparrow \text{XCOMP}^{+}\ \text{OBJ}) <_f (\uparrow \text{OBJ})\big) \end{array} \right)$

This analysis abandons the nested c-structure of the VP in favour of a flat one, which moves us back in the direction of (15a). The functional uncertainty equation on the object DP in (20a) allows connecting the object to a predicate at any depth of xcomp embedding, and the general principles of f-structure coherence and completeness make sure each object is matched to exactly one predicate. The functional precedence constraint on the $\overline{\text{V}}$ node in (20b) prevents more embedded objects from preceding less embedded ones. Together, these f-structure constraints force the same relation between Mittelfeld objects and right bracket verbs as the c-structures subtrees in Bresnan et al.'s analysis. Moreover, the interaction between functional uncertainty and the standard LFG approach to constituent coordination lets us handle sentences like (19) correctly.

Zaenen & Kaplan (1995) also apply the combined use of functional uncertainty and functional precedence to Zürich German, where cross-serial dependencies are observed as well.

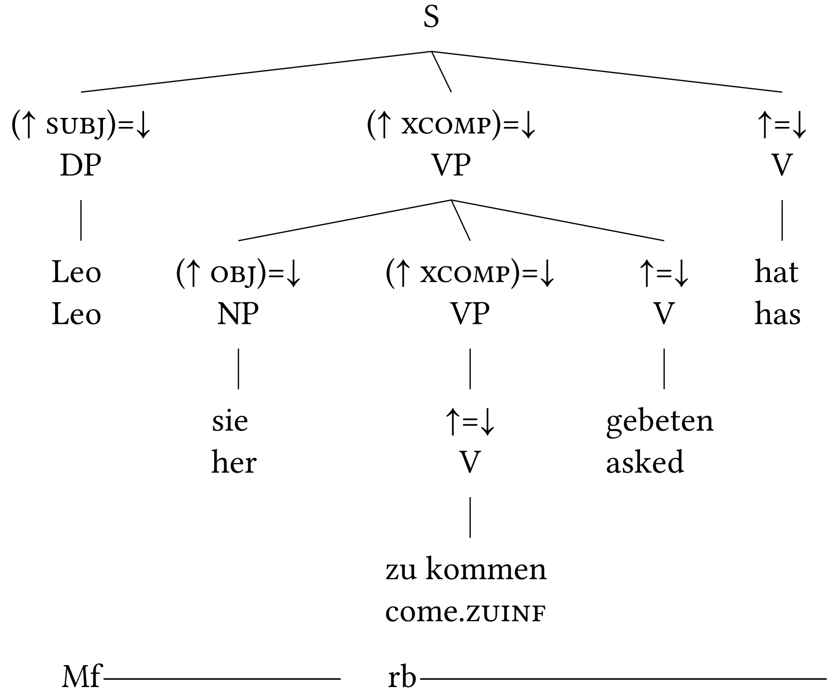
2.1.2.2 Nested dependencies

The analyses of the structures that would give rise to consistently nested dependencies all come from LFG work on Standard German. However, explicit discussion of constructions with multiple objects at different levels of embedding is rare in this part of the literature – perhaps because the modelling of these dependencies is not seen as particularly problematic. We therefore do not always fully know how the relevant nested dependencies are to be derived in these LFG models.

Some authors assume nested VPs, which rather naturally correspond to nested dependencies between objects and verbs, even when this consequence is not a central concern. One example is the grammar fragment of Netter (1988), who gives annotated c-structures like the one in (21).

(21) a. German (Netter 1988: §1, example C4)
…dass Leo sie zu kommen gebeten hat.
COMP Leo her come.ZUINF asked has
'…that Leo asked her to come.'

b.



We also find nested VPs in Choi (1999), where the combined Mittelfeld and verb cluster of the subordinate clause in (22a) would get the structure given in (22b).[18]

---

[18] Choi (1999) does not provide a tree for this exact sentence, but does show a more complex example with a comparable structure. In addition, Choi (1999) never explicitly motivates the specific c-structure associated with embedded verbs in the VP. Nevertheless, we can infer the structure given here from the examples and discussion there.

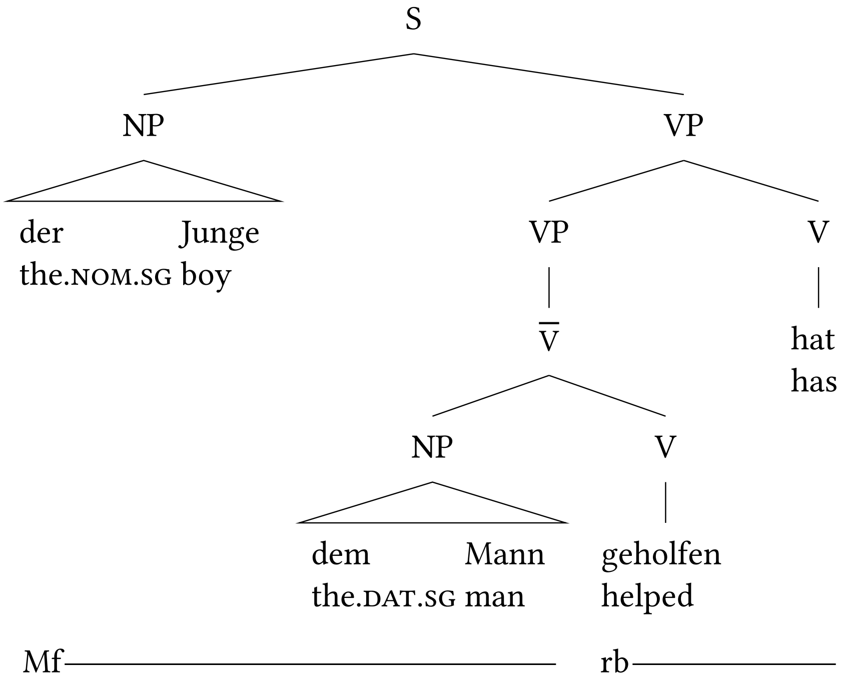
(22) German

a.

…dass	der	Junge	dem	Mann	geholfen	hat.
COMP	the.NOM.SG	boy	the.DAT.SG	man	helped	has

'…that the boy has helped the man.'

b.



In addition to a nested VP structure, the tree in (22b) shows the subject appearing in S and the object inside the VP. Any deviations from the canonical word order implied by this structure are modelled using optional adjunction of objects to higher positions. Choi (1999) motivates this partially configurational structure for German by appealing to contrasts like the following: a verb and its object can be realized together in the Vorfeld (23a), whereas – it would appear – a verb and its subject cannot (23b).

(23) German(Choi 1999: §2.1, example 12)

a.

[Dem	Mann	geholfen]	hat	der	Junge.
the.DAT.SG	man	helped	has	the.NOM.SG	boy

'Help the man, the boy did.'

b. *

[Der	Junge	geholfen]	hat	dem	Mann.
the.NOM.SG	boy	helped	has	the.DAT.SG	man

Under Choi's analysis, this contrast follows straightforwardly by assuming that a VP, unlike an S, can be put in the Vorfeld.

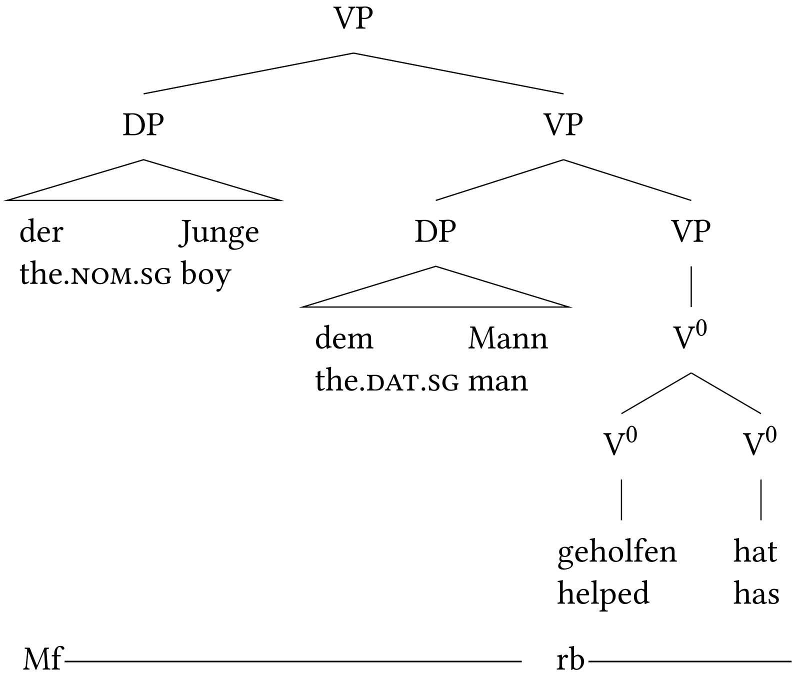
These analyses with nested VPs, which in principle could directly yield the pattern of nested dependencies we find in German, do *not* have a single node containing the whole right bracket and nothing else. Put differently, they do not include the verb cluster as such. This contrasts with the analyses we saw for the cross-serial dependency languages (Dutch, Zürich German) above, where the verb cluster exactly matched a $\overline{\mathrm{V}}$ node.

Proposals for Standard German that have a c-structure node corresponding to the verb cluster do exist in the LFG literature. One prominent such proposal is made by Berman (2003), who rejects Choi's claim that the German VP includes the object but excludes the subject, on the basis of data like (24), which, in contrast to (23b), is a successful example of Vorfeld realization of a verb with its subject.

(24) German (Berman 2003: §3.2.3.2, example 28a)
[Kinder gespielt] haben hier noch nie.
children played have here yet never
'Children have never played here.'

Instead of assuming that there are canonical positions for subjects and objects in S and VP respectively, and that only scrambled objects are adjoined, Berman does away with S completely, and always adjoins Mittelfeld arguments to VP. Furthermore, Berman posits that verbs in the verb cluster are combined by head adjunction. The structure of (23a) under this model is then (25).

(25)



Since the association of arguments with their predicates can no longer rely on positional grammatical function annotations, Berman (2003) argues that case is responsible for this association in German. This is modelled using the standard approach of conditional expressions that relate specific cases to specific functions, for instance, $(\downarrow \textsc{case})=\textsc{acc} \Rightarrow (\uparrow \textsc{obj})=\downarrow$. However, Berman does not discuss how this standard approach should be extended to allow embedded objects of coherently combined verbs in general, and it is not clear how one would correctly constrain the projection of multiple Mittelfeld objects onto f-structures that are embedded under one or more layers of xcomp without resorting to nested VPs or functional uncertainty.[19]

We have seen that the (idealized) Dutch and German patterns are mirror images in terms of the order of the verbs in the verb cluster. The approach of Zaenen & Kaplan (2002) capitalizes on this by taking the mirror image of the $\overline{\mathrm{V}}$ rule for Dutch in (20b) as the basis for their analysis of the German verb cluster (26).

(26)
$$\overline{\mathrm{V}} \quad \longrightarrow \quad \begin{pmatrix} \overline{\mathrm{V}} \\ (\uparrow \textsc{xcomp})=\downarrow \\ \neg((\uparrow \textsc{xcomp}^{+}\ \textsc{obj}) <_f (\uparrow \textsc{obj})) \end{pmatrix} \begin{matrix} \mathrm{V} \\ \uparrow=\downarrow \\ \end{matrix}$$

As before, in the proposal for Dutch, the highest $\overline{\mathrm{V}}$ node corresponds directly to the right bracket and functional uncertainty solves the relation of Mittelfeld material to embedded verbs without having to assume nested VPs.

2.1.2.3 Variation

I already mentioned at the beginning of this subsection that characterizing languages as having either cross-serial or nested dependencies is an oversimplification. For instance, both German and Dutch allow further variation in the ordering of elements in the verbal cluster. Moreover, in Zürich German – amongst other CWG languages – Mittelfeld and right bracket material can mix to some extent.

In German, *Oberfeldumstellung* (Bech 1955/1957: Vol I, §62–§66; an alternative term is auxiliary flip) can occur with three-verb combinations where V_1 is a perfect or passive auxiliary, and V_2 is itself a coherently combining verb that selects

---

[19] Berman (2003) partially sidesteps the issue by (tacitly) assuming that auxiliaries add features and do not create xcomp embeddings. This means that, for instance, *lobte* 'praised' and *hat gelobt* 'has praised' both have their objects directly in the containing f-structure as objs. However, since not all coherently combining verbs can be analysed as auxiliaries and some clearly have enough lexical content to warrant their own pred values, this does not completely address the problem.

an infinitive. In this construction, the verb cluster has the order $V_1V_3V_2$, and IPP is triggered for V_2. Contrast the "regularly ordered" (27a) with the Oberfeldumstellung in (27b).[20]

(27) German (Cook 2001: §1.4, example 1.31)

a. …dass ich dich kommen gesehen habe.
COMP I you.ACC.SG come.INF seen have.PRS
'…that I have seen you come.'

b. …dass ich dich habe kommen sehen.
COMP I you.ACC.SG have.PRS come.INF see.INF

This word order variant is problematic for the nested VP models mentioned above (namely, Netter 1988, Choi 1999), since the verb cluster-initial finite verb "interrupts" the embedded VP. Models in which a c-structure node corresponds to the verb cluster (namely, Zaenen & Kaplan 2002, Berman 2003, Clément et al. 2002) have an easier time capturing such variation. An analysis of this variation can be found in Clément et al. (2002: in terms of c-structure) and in Cook (2001: in terms of the interaction between syntax and information structure). An OT-LFG analysis of verb order in Swiss German dialects is outlined in Seiler (2007).

Dutch verb clusters have so-called *participle climbing* and *particle climbing*, which refer to the realization of participles and particles to the left of the position expected from the principle of ordering by increasing embedding. Example (28) shows the different positions a particle can occupy in a three-verb cluster.

(28) Dutch
…dat Jan het liedje {mee} zal {mee} hebben {mee-}gezongen.
COMP Jan the song along will along have along-sung
'…that Jan will have sung along to the song.'

Kaplan & Zaenen (2003) adapt their earlier model of the Dutch Mittelfeld and verb-cluster to allow these and further variants, and to capture the IPP effect. Poortvliet (2015) is a further development of this model.

Zürich German has cross-serial dependencies, like Dutch, but in addition allows the nominal and verbal material to mix, as in (29).

---

[20] *Oberfeldumstellung* also occurs with longer verb clusters. Furthermore, there is a (possibly regional) construction called *Zwischenstellung* that has $V_3V_1V_2$. See Cook (2001) for empirical discussion and an analysis.

(29) Zürich German
…das er sini chind wil mediziin la schtudiere.
COMP he his children wants medicine let study
‘that he wants to let his children study medicine.’

Zaenen & Kaplan (1995) use the combination of functional precedence and functional uncertainty developed for Dutch to capture these data. Another case of mixing verbal and non-verbal material can be found in Standard German, which allows a variant of Oberfeldumstellung where V_1 precedes a collocational nominal complement of V_3. An analysis of this construction can be found in Cook (2001).

2.1.3 Nachfeld

The two options for adding Nachfeld material to the different c-structures of the clause given above are 1) adjunction to any of the nodes at the right periphery and 2) inclusion of one or more optional daughters on the right-hand side of the relevant c-structure rules. Adjunction is used by Berman (2003), who assumes Nachfeld occupants (typically PPs, VPs or CPs) are right-adjoined at the VP level. Rohrer (1996), Clément et al. (2002) and Van der Beek (2005) model the Nachfeld as an optional daughter in the node covering the whole clause. Zaenen & Kaplan (1995, 2002), and Kaplan & Zaenen (2003) insert the optional daughter in the node covering the Mittelfeld/right bracket.

In Dutch and German, the non-finite complement of an incoherently combining verb appears in the Nachfeld. In Dutch, Mittelfeld placement of such a complement is ruled out (30), but in German it is allowed (see for instance Rohrer 1996 for examples).

(30) Dutch
Vf- lb– Mf———————— rb—— Nf————————
Hij had {*geen auto te kopen} beloofd {geen auto te kopen}.
he had no car buy.TEINF promised no car buy.TEINF
‘He had promised not to buy a car.’

To facilitate lexical specification of whether a verb combines coherently or not, and the formulation of placement restrictions on the non-finite verbal complement, Rohrer (1996), Zaenen & Kaplan (1995, 2002), and Kaplan & Zaenen (2003) associate coherence with selecting an XCOMP and incoherence with selecting a COMP. The relevant c-structure rule from Kaplan & Zaenen (2003) is an extension of (20a) and is given here in slightly simplified form as (31).

(31)
$$\text{VP} \longrightarrow \underset{(\uparrow\ \textsc{xcomp}^*\ (\textsc{comp})\ \textsc{obj})=\downarrow}{\text{DP}^*} \quad \underset{\uparrow=\downarrow}{\overline{\text{V}}} \quad \left(\underset{(\uparrow\ \textsc{xcomp}^*\ \textsc{comp})=\downarrow}{\text{VP}}\right)$$

The optional rightmost daughter contains a non-finite complement in the Nachfeld, assigned comp.[21]

The rule in (31) also allows for the so-called *third construction*, a marked construction in Dutch and German in which a dependent of an incoherently combined non-finite complement in the Nachfeld is realized in the Mittelfeld of the containing clause. In terms of word order, this construction therefore mixes properties of coherent and incoherent combination. An example of the third construction is presented in (32). Note that the lack of an IPP effect on *geprobeerd* 'tried' shows that we are dealing with incoherent combination.

(32) Dutch
Hij had een auto geprobeerd te kopen.
he had a car tried buy.teinf
'He had tried to buy a car.'

The c-structure rule in (31) captures the third construction by the functional uncertainty-based grammatical function assignment of DPs in the Mittelfeld: the optional comp in the path allows it to reach into an incoherently combined complement.[22] LFG analyses of the the German third construction are discussed in Rohrer (1996) and Kaplan & Zaenen (2003).

2.2 Topics related to the left periphery

2.2.1 Topicalization

In the context of the verb-second CWG languages, topicalization refers to Vorfeld placement of material, in particular material that is *not* put there by default. Roughly, then, topicalization is Vorfeld placement of anything but the local subject. The term topicalization is used irrespective of whether the Vorfeld occupant

---

[21] The distinction between comp and xcomp is that of complements that supply their own subject (closed complements) and complements that do not supply their own subject (open complements). Since non-finite comps do not have an overt subject, they therefore must have an f-structure subject pred 'pro', whose interpretation is equated to one of the arguments of the selecting verbs using anaphoric control. See Dalrymple (2001: Chapter 12, §3) for a discussion of anaphoric control.

[22] Kaplan & Zaenen (2003) are not concerned with CP complements – that is, finite complement clauses – but if these are assigned comp as well, the analysis of the third construction sketched here will need to be further constrained to prevent lifting dependents from finite subordinate clauses into the Mittelfeld.

is a topic or not. In both German and Dutch, the Vorfeld may be occupied by a categorially and functionally wide range of constituents. It is also a target position for material extracted from embedded clauses and phrases.

Berman (2003: Chapter 6) formally distinguishes two different types of topicalization for German, depending on whether the Vorfeld constituent is local to the matrix clause or whether a long-distance dependency is involved. Berman introduces this distinction on the basis of observations from weak cross-over, which will be discussed in Section 2.4.2, below. In either case, the Vorfeld is Spec-CP, and its definition is part of the straightforward c-structure rule in (33).

(33)
$$\begin{array}{llcc} \text{CP} & \longrightarrow & \text{XP} & \overline{\text{C}} \\ & & (\uparrow \text{DF})=\downarrow & \uparrow=\downarrow \end{array}$$

When material local to the f-structure projected from CP is put in the Vorfeld, Berman assumes information like case and agreement drives the association with grammatical function, just as it does in the Mittelfeld – see the earlier discussion of Berman's model in Section 2.1.2, around example (25). For long-distance dependencies, Berman posits the presence of a trace at the extraction site, annotated with an inside-out functional uncertainty equation to incorporate the f-structure of the Vorfeld constituents – which by (33) is the DF of the f-structure of the whole clause – into the extraction site's f-structure.[23]

German has embedded verb-second clauses with bridge verbs, provided the complementizer is absent, as in (34a). Extraction out of such embedded clauses is also allowed, on the condition that none of the clauses involved in the long-distance dependency has material in Spec-CP (that is, no intermediate clause has a Vorfeld occupant). This is shown in the contrast (34b,c).

(34) German (b,c from Berman 2003: §6.2.4, examples 23, 24)

a. Ich glaube, (*dass) der Hans sagte gestern, (*dass) die
I believe COMP the.NOM Hans said yesterday, COMP the.NOM
Maria hat den Peter eingeladen.
Maria has the.ACC Peter invited
'I think Hans said yesterday that Maria invited Peter.'

b. Den Peter glaube ich, sagte der Hans gestern, hat
the.ACC Peter think I said the.NOM Hans yesterday has
die Maria eingeladen.
the.NOM Maria invited

---

[23] See Kaplan 2023 [this volume] for more information on modelling long-distance dependencies using inside-out functional uncertainty.

c. * Den Peter glaube ich, gestern sagte der Hans, hat
the.ACC Peter think I yesterday said the.NOM Hans has
die Maria eingeladen.
the.NOM Maria invited

Berman captures this restriction with an off-path constraint ¬(→ DF) on the functional uncertainty equation for extractions. Since only Spec-CP introduces DF in Berman's model,[24] this effectively rules out examples like (34c).[25]

In non-LFG work, Reis (1996) argues that sentences like (34b) are only apparent cases of extraction, and that they involve parenthetical constructions, instead. An LFG analysis of German parentheticals with bridge verbs is given in Fortmann (2006), although he does not consider the exact type of sentence discussed here.

German allows topicalization of VPs (as discussed above in Section 2.1.2.2, example 23) and, in the case of coherent combination, topicalization of partial VPs. For instance, in (35), the main verb and its accusative object are realized in the Vorfeld, whereas the dative object is in the Mittelfeld.

(35) German (similar to Nerbonne 1994: 3a)
Ein Märchen erzählen wird er ihr.
a fairy tale tell.INF will he her.DAT
'He will tell her a story.'

---

[24] For this to hold, we need to understand DF as not including SUBJ, since subjects can be introduced in other positions in the clause, too. Indeed, as the example shows, there is no ban on subjects occurring anywhere in the path of a long-distance dependency, as long as they do not occur in the Vorfeld. An unfortunate side effect of taking DF as not including SUBJ would be that the special Vorfeld privileges of subjects, see Section 2.2.2, remain unmodelled.

[25] However, consider the following data:

(i) a. Ich denke hier, Sie sollten etwas präziser sein.
I think here you should somewhat precise.COMPARATIVE be
'I think here(:) you should be a bit more precise.'
b. Hier denke ich, Sie sollten etwas präziser sein.

(ii) a. Ich denke, Sie sollten hier etwas präziser sein.
'I think(:) you should be a bit more precise here.'
b. Hier denke ich, sollten Sie etwas präziser sein.

Although the off-path constraint against DFs gets rid of the form (i b) as a realization of the meaning of (ii), it does not block (ii b) as a realization of the meaning of (i). In other words, the off-path constraint itself leaves unexplained why the embedded V1 of (ii b) signals that it is involved in an extraction. A possible line of defence against this criticism is to appeal to a form of Economy of Expression: the embedded V1 is a slightly more complex structure than embedded V2, a complexity that is not needed for the relational information expressed in (i).

VP topicalization can in principle be modelled using the standard mechanisms. For instance, under the assumption that coherently combined verbal complements are xcomps and if we use outside-in functional uncertainty, a c-structure rule like in (36) implements topicalization of coherently combined VPs.

(36)
$$\text{CP} \longrightarrow \begin{array}{cc} \text{VP} & \overline{\text{C}} \\ (\uparrow \textsc{topic})=\downarrow & \uparrow=\downarrow \\ (\uparrow \textsc{xcomp}^{+})=\downarrow & \end{array}$$

If the rule for VPs allows partial VPs, rule (36) says very little about which material is required to be present in the fronted VP and which material can be left to be realized in-situ. Potentially, then, this also captures partial VP topicalization. Zaenen & Kaplan (2002) problematize two aspects of such a straightforward implementation: First, in the case of partial VP topicalization, the resulting f-structure for the whole VP contains the combined topicalized and in-situ material, and therefore there is no way to see at f-structure which part of the VP was topicalized. This is problematic for approaches to information structure that associate information status with f-structures. Secondly, the approach would erroneously allow examples like (37).

(37)

* [Ihr	ein	Märchen]	wird	er	erzählen.
her.DAT	a	fairy tale	will	he	tell.INF

‘He will tell her a fairy tale.’

The preverbal material is here analysed as a headless VP, which is generally only allowed postverbally.[26]

Zaenen & Kaplan (2002) solve these problems by replacing unification with *subsumption* in the functional uncertainty annotation of Spec-CP, along the lines of (38).

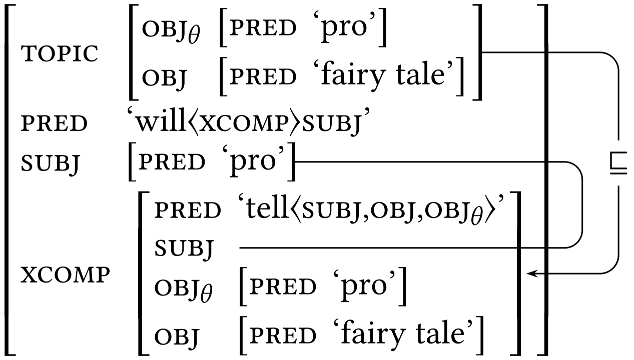
(38)
$$\text{CP} \longrightarrow \begin{array}{cc} \text{VP} & \overline{\text{C}} \\ (\uparrow \textsc{topic})=\downarrow & \uparrow=\downarrow \\ \downarrow \sqsubseteq (\uparrow \textsc{xcomp}^{+}) & \end{array}$$

This directly solves the first problem, since the information in topic now no longer contains the f-structure for the whole VP, but only information projected from the material in the Vorfeld. It also solves the second problem, since, as shown in (39), the f-structure for the example in (37) under topic now no longer meets LFG’s *coherence* condition – it contains arguments but no predicate to select them.

---

[26] I am aware that this claim is too broad. See for instance Müller et al. (2012), who use headless Vorfeld VPs in their analysis of apparent multiple fronting in German. However, a discussion of exceptions to this rule would take us too far away from the main topic here.

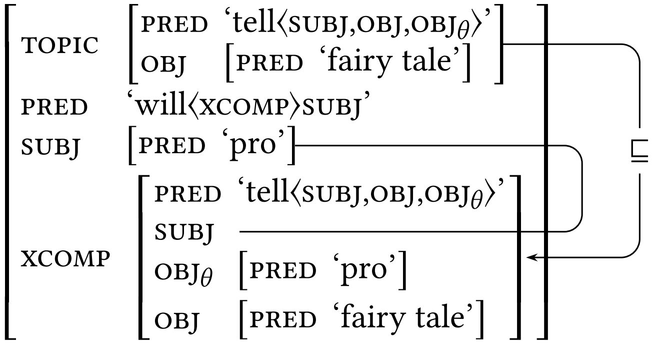
(39) F-structure for (37), which violates the coherence condition:



Finally, a reformulation of the *completeness* condition to take subsumption relations into account[27] allows the f-structures resulting from topicalizing a partial VP, as illustrated in (40).

(40) a. Ein Märchen erzählen wird er ihr.
a fairy tale tell.INF will he her.DAT
'He will tell her a story.'

b.



Berman (2003: §3.3) solves the ungrammaticality of examples structurally similar to (37) by appealing to the endocentricity principles as formulated for LFG, which include the constraint that every lexical category must have an extended head (Bresnan et al. 2016: §7.2). In (37), neither the main verb *erzählen* nor the auxiliary *wird* c-command the material in the Vorfeld VP, which leaves the fronted VP without an extended head. Note that this solution would not be compatible with Zaenen & Kaplan's conception of the German clause, as they do not assume the German VP is necessarily endocentric.[28]

---

[27] "An f-structure *g* is complete if and only if each of its subsidiary f-structures is either locally complete or subsumes a subsidiary f-structure of *g* that is locally complete" (Zaenen & Kaplan 2002: [24]).

[28] As mentioned in Section 2.1, above, Zaenen & Kaplan use the label S|VP for this category.

2.2.2 The Vorfeld subject-object asymmetry

In both German and Dutch, the main clause subject is privileged when it comes to realization in the Vorfeld. In LFG work, this can be modelled directly by annotating the Vorfeld position at c-structure explicitly with (↑ subj)=↓ (Theiler & Bouma 2012), or by annotating it with (↑ df)=↓, under the assumption that the grammaticalized discourse functions include the subject (Berman 2003: §3.2.1).[29] In an OT-LFG setting, Choi (2001) posits a high-ranking constraint Subject-Left that prefers early realization of the subject, which includes realization in the Vorfeld.

One of the reflexes of this special relation between the Vorfeld and the main clause subject is a contrast like the following:

(41) German (Meinunger 2007)
Wo ist das Geld?
'Where is the money?'
a. Es liegt auf dem Tisch.
it lies on the table
'It is on the table.'
b. * Es hat Bernd auf den Tisch gelegt.
it has Bernd on the table put
'Bernd (has) put it on the table.'

Although the referent of the weak pronoun *es* has the same information status in both cases, it appears it can only occur in the Vorfeld as a subject, and not as an object. This would fit in with any of the approaches sketched above: being a subject alone is enough reason to be allowed in the Vorfeld, but – apparently – the weak pronoun *es* is incompatible with any of the other information structural functions of Vorfeld constituents.

The ban on object *es* in the Vorfeld is not categorical, however. Meinunger (2007, and references therein) gives many examples, and shows that the conditions under which object *es* can appear in the Vorfeld coincide with the conditions for the use of the homonymic Vorfeld expletive used in the presentational construction. In particular, the subject of the clause should not be topic (42).

(42) a. Es hat {jemand / *er} geklaut
it has someone he stolen
'Someone / *he has stolen it'

---

[29] I refer, however, to the comment in footnote 24, where I point out that the analysis of German embedded verb-second clauses discussed there relies on the contradicting assumption that subj is *not* part of df.

b. Es hat {jemand / *er} das Geld geklaut
expl has someone he the money stolen
'Someone / *he has stolen the money.'

Theiler & Bouma (2012) capture this behaviour by assuming that the common source of sentences with a Vorfeld object and of those with Vorfeld expletive *es* is the latter, the presentational construction. The presence of *es* in the Vorfeld signals exactly that the main clause subject is not topic. This construction is modelled using a c-structure rule that explicitly mentions the form of its first daughter.

(43)
$$\text{CP} \longrightarrow \begin{array}{cc} \text{NP} & \overline{\text{C}} \\ (\downarrow \text{FORM}) =_c \text{ES} & \uparrow=\downarrow \\ ((\uparrow \text{SUBJ})_\sigma \text{ DF}) \neq \text{TOPIC} & \\ \big((\uparrow \text{XCOMP}^{*}\text{OBJ})=\downarrow\big) & \end{array}$$

The optional assignment to object anywhere in the coherence domain of the clause is what allows object *es* to appear in the Vorfeld, under the same circumstances as the presentational construction's expletive. Expletive *es* also shows up in other situations; see Section 2.5.1 below.

2.2.3 Left dislocation

Thus far, we have not considered the *lead* field, which is positioned before the Vorfeld in the topological model given in (1) and which we characterized as reserved for material more loosely connected to the clause proper. We can distinguish several *left dislocation* phenomena that target the lead.[30] Two questions raised by this broadened view of the clause are 1) how tightly left-dislocated material is coupled to the clause, and 2) whether there are phenomena that we have treated as Vorfeld occupation that are better analysed as left dislocation with an empty Vorfeld?

The first question is central in Zaenen (1996), who studies contrastive left dislocation (44b) in Dutch and Icelandic, and asks whether this should be treated as topicalization (44a) or as a hanging topic (44c). The former counts as a well-integrated part of the clause, the latter has a looser relation to the clause.

---

[30] We can likewise talk of right-dislocated material, positioned in the tail, but since we are not aware of any LFG discussions of right dislocation, we will ignore this phenomenon in this chapter.

(44) Dutch

a. Jan wil ik hier nooit meer zien.
Jan want I here never again see

b. Jan die wil ik hier nooit meer zien.
Jan DEM want I here never again see

c. Jan, ik wil hem hier nooit meer zien.
Jan I want him here never again see
'Jan, I never want to see (him) here again'

On the basis of categorial constraints on different kinds of left-dislocated material and on the basis of binding data, Zaenen concludes that contrastive left-dislocation patterns with topicalization in both languages. She proposes an analysis in which the contrastively left-dislocated material is connected to the clause using the same functional uncertainty equations we normally assume for topicalized material in the Vorfeld. The pronominal element in the Vorfeld in a contrastive left-dislocation is taken to be an (f-structure) adjunct to the left-dislocated material, and does not itself engage in the long-distance dependencies directly.

The second question underlies the discussion in Berman (2003: §7.4), which revolves around the contrast illustrated in (45).

(45) German (Berman 2003: §7.4, examples 58–61)

a. Dass die Erde rund ist, (das) hat ihn gewundert.
COMP the earth round is DEM.NOM has him.ACC surprised
'That the earth is round(, that) surprised him.'

b. Dass die Erde rund ist, (das) hat er nicht gewusst.
DEM.ACC has he not known
'That the earth is round, (that) he didn't know.'

c. Dass die Erde rund ist, *(dessen) war sie sich nicht bewusst.
DEM.GEN was she REFL not aware
'That the earth is round, of that she wasn't aware.'

d. Dass die Erde rund ist, *(darüber) hat sie sich gewundert.
about.DEM has she REFL surprised
'That the earth is round, that she was surprised about.'

In (45a,b), the fronted CP appears to alternate between being left-dislocated (with resumption) and appearing in the Vorfeld (without), whereas in (45c,d), the fronted CP must be left-dislocated. Berman gives an LFG interpretation of an existing approach in which this alternation is only apparent, and the CP is *always* left-dislocated. The difference in (45a,b) is that in German, nominative and accusative topics may be dropped from the Vorfeld. Whether the resumptive demonstrative pronoun is realized at c-structure or not, its f-structure presence is constant, and it is this which is assigned a grammatical function. The left-dislocated CP is connected anaphorically to the resumptive pronoun.

2.2.4 Split NPs

The split NP construction in German involves multiple NPs at different positions in the clause which together describe one argument. The first NP occurs in the Vorfeld of the top level clause, and a further NP occurs somewhere further down in the Mittelfeld of a possibly embedded clause. An example is (46a).

(46) German (Kuhn 2001: §1)

a. [Ein Schwimmbad] hat er sich noch [keins] gebaut.
a swimming pool has he REFL yet none built.

b. Er hat sich noch [kein Schwimmbad] gebaut.
he has REFL yet no swimming pool built
'He hasn't built a swimming pool yet.'

A striking property of the two NPs *ein Schwimmbad* and *keins* is that they both have the form of complete NPs: the first NP includes a determiner for the head count noun, the second NP involves the independent form *keins* 'none', rather than the form *kein* 'no', which is used when a nominal head is realized in the NP itself (46b).

Kuhn (2001) proposes a solution in terms of an LFG variant with linear logic-based semantics. Semantically, the clause-internal NP is a regular elliptical NP; the job of the Vorfeld NP is to supply a property as antecedent. By assuming that the form of the NP can be syntactically determined completely in terms of c-structure, treating the two NPs as c-structurally independent, but projecting to the same f-structure, the form-related characteristics of the NPs can be made to follow.

2.2.5 Asymmetric coordination

Frank (2006) gives an analysis of asymmetric coordination puzzles in German, like the *subject gap with fronted finite verb* (SGF) coordination in (47a).

(47) German (Frank 2006: §3.2)

a.

In	den	Wald	[ging	der	Jäger]	und	[fing	einen	Hasen]
in	the.ACC	forest	went	the.NOM	hunter	and	caught	a.ACC	hare

‘The hunter went into the woods and caught a hare.’

b.

* In	den	Wald	ging	der	Jäger	und	einen	Hasen	fing.
in	the.ACC	forest	went	the.NOM	hunter	and	a.ACC	hare	caught

At first sight, this looks like a run-of-the-mill symmetric $\overline{\mathrm{C}}$ coordination. However, this is not the case, since the PP in the Vorfeld is unambiguously a directional PP, which is incompatible with the verb in the second conjunct. Furthermore, what *is* shared between the two conjuncts is the subject in the Mittelfeld of the first conjunct, which is not in a c-structural position that would lead us to expect this possibility.

Frank models SGF coordination using an optional annotation on the rule for symmetric CP coordinations, which shares the (grammaticalized) discourse function of the first conjunct with the coordination as a whole, and therefore, with the second conjunct.[31]

(48)
$$\mathrm{CP} \longrightarrow \begin{array}{ccc} \mathrm{CP} & \mathrm{Coord} & \mathrm{CP} \\ \uparrow\in\downarrow & \uparrow=\downarrow & \uparrow\in\downarrow \\ \big((\uparrow \textsc{gdf}) = (\downarrow \textsc{gdf})\big) & & \end{array}$$

This extra annotation makes sure the completeness requirements in the second conjunct can be met. Frank also shows that this approach makes correct predictions with respect to the interpretation of the scope of quantified subjects in an SGF coordination. However, the formal account leaves unexplained why the second conjunct cannot have a fronted object, like the ungrammatical (47b). For this, Frank appeals to the discourse structure of SGF coordination: the second conjunct is conceptualized as part of the discourse-functional domain of the first. If the second conjunct were to have a Vorfeld TOPIC or FOCUS, this would indicate that it sets up its own discourse-functional domain.

2.3 Topics related to the right periphery

2.3.1 Clefts

The it-cleft construction in Dutch involves a neuter weak pronoun (typically *het* ‘it’), a copula, focused material, and a backgrounded finite clause in the Nachfeld.

---

[31] Here, too, the grammaticalized discourse functions include the subject. In fact, in this construction, the shared material will always turn out to be the subject.

Van der Beek (2005: Chapter 2) shows that, with these ingredients, there are in fact two distinct cleft constructions: the intransitive cleft (an existential copula with extraposed complement clause, 49a) and the transitive cleft (an identificational copula with extraposed relative clause, 49b).

(49) Dutch (Van der Beek 2005: Figures 2.4 and 2.1)

a. Het is aan hem dat ze denkt.
EXPL is on him COMPL she thinks.
'It is of him that she is thinking.'

b. Het zijn jouw kinderen die huilen.
it are your children REL cry
'It is your children who are crying.'

Van der Beek shows that the two cleft types differ further in whether they involve an expletive or referential neuter pronoun, whether they tolerate pseudo-copulas like *bleken* 'seem', or only forms of the verb *zijn* 'be', and whether the neuter pronoun is obligatorily the cleft subject or not.

Van der Beek models both cleft types with dedicated c-structure rules to capture the fixed position of the backgrounded clause, and to introduce the construction-specific annotations. This ensures, for instance, that the clause must be in the Nachfeld, and cannot be realized as one constituent with the pronoun or the focused material. In the intransitive cleft, both the expletive and the complement clause project to the SUBJ's f-structure, and the focused material is linked to an adjunct or oblique position in f-structure (*aan hem* 'on him' in 49a). In the transitive cleft, the relative clause is an adjunct of the referential weak neuter pronoun, which is the construction's TOPIC, and which is subject or object depending on properties of the focused material. The top level c-structure rules for the two constructions are given in (50).

(50) a. intransitive cleft:

IP	⟶	NP (↑ SUBJ)=↓		CP (↑ SUBJ)=↓ (↓ TYPE) $=_c$ THAT (↑ FOCUS)=(↑ XCOMP* { ADJ ∈ | OBL$_\theta$})

b. transitive cleft:

IP	⟶	NP (↑ SUBJ)=↓	$\bar{\mathrm{I}}$ ↑=↓	CP ↓ ∈ (↑ TOPIC ADJ) (↑ TOPIC PRONTYPE)=COP (↓ TYPE) $=_c$ REL (↑ FOCUS)=(↑ {SUBJ|OBJ})

The TYPE feature of the CP-projected f-structures distinguishes relative clauses from complement clauses headed by *dat* 'that'. The PRONTYPE=COP restriction singles out a class of special copular pronouns which are N.3SG in form, but which show a wider range of agreement, whose existence can be argued for on independent grounds.

2.3.2 Correlative *es* and extraposed CPs

The constructions discussed in Berman et al. (1998) and Berman (2003: Chapter 8) also contain a neuter pronoun and a finite clause in the Nachfeld. In this case, the pronoun and the finite clause realize a propositional argument of the clause's main verb, and they can either appear on their own (51a,b) or together (51c), in which case the pronoun is referred to as a *correlative pronoun*.

(51) German (Berman et al. 1998: §1, examples 1 and 2)

a. Hans hat bedauert, daß er gelogen hat.
Hans has regretted that he lied has
Hans regretted that he lied.

b. Hans hat es bedauert.
Hans has it regretted
Hans regretted it.

c. Hans hat es bedauert, daß er gelogen hat.
Hans has it regretted that he lied has

The central modelling assumptions made in both analyses are that the pronoun is referential – whether it occurs on its own or as a correlative together with the finite clause – and that the pronoun and the finite clause when they appear alone (51a,b), are OBJs. In the correlative pronoun construction (51c), however, it is the pronoun that has this grammatical function. The finite clause is then either seen as supplying further semantic restrictions to the interpretation of this pronoun (Berman et al. 1998: see also Section 2.2.4 above) or as an apposition to the pronoun (Berman 2003).

Berman (2003) also goes on to show that there is a range of correlative *es* data, and that despite superficial resemblances, different syntactic analyses are called for. For instance, Berman argues that in contrast to the data above, the psych verb *stören* 'disturb' in (52) has a different argument structure for the cases with correlative *es*: it either takes the finite clause as subject when the correlative is absent, or it takes *es* as subject and the finite clause as object when the correlative is present.

(52) German (Berman 2003: §8.1, example 2d)
…weil (es) mich stört, dass sie den Hans liebt.
because EXPL me bothers COMP she the.ACC Hans loves.
'…because it bothers me that she loves Hans.'

2.4 Topics related to the ordering of dependents

2.4.1 Scrambling

Material in the Mittelfeld can be reordered to a certain extent. For instance, Dutch allows different orders of object and adverb (53).

(53) Dutch
Anna heeft {de was} gisteren {de was} gedaan.
Anna has the laundry yesterday the laundry done
'Anna did the laundry yesterday.'

In German, the order of arguments themselves is free, as well. Example (54) shows one order for the arguments of a ditransitive, but the other five possible argument orders are grammatical, too.

(54) German (Haider & Rosengren 2003: §1, example 1)
…dass [das Objekt] [dem Subjekt] [den ersten Platz]
COMP the.NOM object the.DAT subject the.ACC first place
streitig macht.
competes.for
'…that the object competes for first position with the subject.'

In general, both scrambling over adjuncts and scrambling of arguments is sensitive to information structural effects, and – related to this – things like the referential form of the material involved. Choi (1999, 2001) explains German scrambling and clause-local fronting facts using an OT-LFG model in which constraints on canonical ordering of grammatical functions conflict with constraints on information structurally induced ordering. An information structural account of clause-local word order variation and quantifier scope in German is given in Cook & Payne (2006). The explanation given by Cook (2006) for a deviating unmarked word order in a small group of ditransitives is discussed below, in Section 2.5.2.

As far as the order of arguments in the Mittelfeld is concerned, Dutch is much more restricted than German. Nevertheless there is some variation. An OT account of the Dutch dative alternation, which also covers variation in the ordering of direct object and indirect object, is presented in Van der Beek (2005). Zaenen (1989) discusses scrambling of objects over subjects with Dutch experiencer verbs and passives of ditransitives, and argues for an effect of thematic role.

The cross-serial dependency pattern comes about when objects and verbs are in separate groups and both are ordered in the same fashion according to level of embedding. The verb cluster rule given in (20) above (Zaenen & Kaplan 1995), sorts embedding verbs before embedded ones, and explicitly forces the same order on the objects with the help of an f-precedence constraint. In her work on the order of objects in Dutch, Van der Beek (2005: §3.8) argues that this constraint should be treated as a violable OT constraint. An optionally higher ranking constraint prefers early realization in the Mittelfeld of a third person, inanimate pronoun. This constraint explains examples like (55), in which the object pronoun belonging to the embedded verb precedes the object belonging to the finite verb.

(55) Ik zag$_{\text{OBJ:1}}$ 't$_2$ Jo$_1$ doen$_{\text{OBJ:2}}$.
I saw it Jo do
'I saw Jo do it.'

As with all scrambling, this type of scrambling is less constrained in German, and may also apply to full NPs, and even involve scrambling of an embedded object over the main clause subject. I am however not aware of any LFG-related work on this.[32]

2.4.2 Weak cross-over

In German, scrambling and topicalization interact with binding between arguments, which results in data like (56). Note that the grammaticality judgements are relative to the co-indexations given in the examples.

(56) German (Berman 2003, §5.2, examples 10a, 11b, 10d, 11d, 27, 31; examples a–d below originally from Choi 1995)

a. …dass jeden$_i$ seine$_i$ Mutter mag.
COMP everyone.ACC his mother likes
'…that their$_i$ mother likes everyone$_i$.'[33]

---

[32] The term *embedded object shift* is van der Beek's term for this type of word order variation. In the literature on German, the phenomenon is sometimes discussed as a kind of *long(-distance) scrambling*, that is, scrambling across clause boundaries, although the view that the embedded object leaves its clause goes against the conception of coherent combining as clause union. In fact, in Lee-Schoenfeld (2007), this type of scrambling is taken as one of the hallmarks of coherence and thus of monoclausality.

[33] English seems to require the passive to achieve the intended bindings. The intended reading in (56a–d) is therefore more naturally given as *(that) everyone is liked by their own mother.*

b. Jeden$_i$ mag seine$_i$ Mutter.
everyone.ACC likes his mother
'Their$_i$ mother likes everyone$_i$.'

c. * …dass seine$_i$ Mutter jeden$_i$ mag.
COMP his mother everyone.ACC likes

d. * Seine$_i$ Mutter mag jeden$_i$.
his mother likes everyone.ACC

e. Jeden$_i$ sagte sie, habe seine$_i$ Mutter getröstet.
everyone.ACC said she has.SBJV his mother consoled
'Everyone$_i$, she said their$_i$ mother had consoled.'

f. * Jeden$_i$ sagte seine$_i$ Mutter, habe sie getröstet.
everyone.ACC said his mother has.SBJV she consoled
'Everyone$_i$, their$_i$ mother said she had consoled.'

Between dependents of the same predicate, an object may bind into the subject, provided it precedes it. It does not matter whether it precedes it in the Mittelfeld (56a) or by being moved into the Vorfeld (56b), even from an embedded clause (56e). However, as (56f) shows, an object cannot bind into an upstairs subject, even when it precedes it.

Berman (2003), using the framework of Bresnan (1998) and observations from Choi (1995), shows that the data in (56a–d) is straightforwardly explained by assuming that to bind a pronoun, an operator must either outrank it in terms of grammatical function – this isn't the case in any of these examples – or linearly precede it. The linear precedence constraint is satisfied in (56a,b), but not in (56c,d). However, example (56f) is problematic under this simple account, since the operator precedes the pronoun, but cannot bind it.

Berman therefore proposes to analyse long-distance dependencies using a trace, and to interpret the linear precedence requirement as if it includes this trace. The sentences in (56e,f) are then as in (57).[34]

(57) a. Jeden$_i$ sagte sie, habe ϵ_i seine$_i$ Mutter getröstet.
everyone.ACC said she has.SBJV his.NOM mother consoled

b. * Jeden$_i$ sagte seine$_i$ Mutter, habe ϵ_i sie getröstet.
everyone.ACC said his.NOM mother has.SBJV she consoled

---

[34] Berman (2003) assumes that local arguments are adjoined to VP, in any order. This also applies to traces – the object trace may therefore appear before its clause-mate subject. In the examples in (57) we have inserted the trace as early as c-structurally possible.

In (57a), the operator's trace precedes the bound pronoun, so that the linear order requirement is met. In (57b), however, the trace follows the pronoun, which – under Berman's definition – means the operator as a whole does not precede it This results in the unavailability of the indexed reading.

Bresnan et al. (2016: §9.5) discuss the same data using a near-identical framework. Although the difference in linear order of the bound pronoun and the operator trace between (57a) and (57b) is noted, the ungrammaticality of (57b) is ultimately explained by taking the binding domain of the operator to be the f-structure for the predicate *getröstet* 'consoled', irrespective of the operator's DF role in the matrix f-structure.[35] There is therefore no need to refer to the position of the trace to explain the long-distance dependency data. Under that analysis, it would appear that weak cross-over in German alone is not a reason to assume long-distance dependencies involve traces.

Dalrymple et al. (2001)[36] give a trace-less account of the German cross-over data. Rather than considering the linear order of the binding operator and the bound pronoun, they consider f-precedence between two f-structures that are dependents of the same predicate, such that one contains the operator and the other the pronoun. In (56f), these f-structure siblings are the SUBJ (containing the pronoun) and the COMP (containing the operator) of *sagte*. Since the latter does not f-precede the former, the linear precedence requirement on binding is not met.

2.5 Topics related to mapping

2.5.1 Sentences "without a subject" in German

A recurring debate in German clausal syntax concerns the existence of true subjectless sentences. Berman (2003: Chapter 4) points out that it would appear that German has such sentences, given that 1) under her analysis, German does not have a dedicated subject position, 2) there are no oblique subjects in German (a common view, following for instance Zaenen et al. 1985, but contra the later Eythórsson & Barðdal 2005) and 3) there are sentences without nominatives, such as (58).

---

[35] In contrast, Berman (2003: §5.2.6) explicitly considers the binding domain of the operator to be "extended to the matrix clause" because "it functions as a discourse function in the matrix clause" (p. 86).

[36] This paper is a response to the trace-based proposals of Bresnan (1998) and Berman (2003). The latter was also published/circulated on earlier occasions, which explains the apparent anachronism.

(58) German (Berman 2003: §4.2, examples 10a, 16b, 10d; indication of optionality of expletive mine)

a. …weil (*es) getanzt wurde.
   because EXPL danced was
   '…because people were dancing.'

b. …weil (*es) dem Mädchen geholfen wurde.
   because EXPL the.DAT girl helped was
   '…because the girl was being helped.'

c. …weil (es) mich friert.
   because EXPL me.ACC freezes
   '…because I'm cold.'

Note that each of these *can* occur without the expletive pronoun *es*, and the first two *must* occur without it.

Berman models clauses without a subject using argument structures without a SUBJ, and shows that these cases can be given an analysis in terms of Lexical Mapping Theory (LMT).[37] For the predicates involved in the examples above, we have the following LMT derivations:

(59) a. getanzt ⟨*agent*⟩ (lit. 'danced', impersonal passive)
   $[-o]$
   $\emptyset$

b. geholfen ⟨*agent*, *beneficiary*⟩ ('helped', passive, lexical case)
   $[-o]$ $[+o]$/DAT
   $\emptyset$ OBJ$_\theta$

c. frieren ⟨*experiencer*⟩ ('be cold', active intransitive, lexical case)
   $[+o]$/ACC
   OBJ$_\theta$

The question remains, then, why the expletive is not allowed in (58a,b), whereas it is in (58c). Berman adopts the analysis that German verbal agreement morphology is distinct enough to contribute subject features. Thus, the f-structures for the sentences in (58) all contain subjects. This way, German can be analysed as meeting the *Subject Condition*, which says that every f-structure with a predicate must contain a SUBJ.[38] Inserting a subject expletive would then be ruled out as a

---

[37] See Findlay et al. 2023 [this volume] for more information on Lexical Mapping Theory.

[38] This Subject Condition formulation pertains to f-structure. In other contexts, for instance in Bresnan et al. (2016: §14.4), the Subject Condition is taken to be a constraint on argument structures. It is clear that under Berman's view such a constraint does not hold for German.

violation of Economy of Expression. It follows that the optional *es* in cases like (58c) is selected for: verbs like *frieren* have an alternative specification like the one in (60).

(60) *frieren* (↑ PRED) = 'be-cold⟨OBJ$_\theta$⟩SUBJ'
(↑ SUBJ FORM) $=_c$ ES_

2.5.2 Mapping explanations of variation

Zaenen (1993) is concerned with (the nature of) the unaccusative/unergative distinction in Dutch. One of the challenges in the characterization of unaccusativity in Dutch is that it not only applies to intransitives, but also to a subset of transitive experiencer verbs. Consider the examples in (61), which shows two intransitives, two transitives with the experiencer as the object, and a transitive with the experiencer as the subject. The selection of a form of *zijn* 'be' instead of *hebben* 'have' as the perfect auxiliary is given here as the reflex of unaccusativity.

(61) Dutch

a. Zij *is / heeft gewerkt.
she is has worked

b. Zij is / *heeft gestorven.
she is has died

c. Zij *zijn / hebben haar geirriteerd.
they are have her irritated

d. Zij zijn / *hebben haar bevallen.
they are have her pleased

e. Zij *is / heeft hen gevreesd.
She is has them feared.

Zaenen shows that it is possible to give semantic correlates of unaccusativity, and discusses which phenomena can be related directly to unaccusativity in Dutch (namely, auxiliary selection, prenominal attributive use of perfect participle) and which only relate indirectly (impossibility of impersonal passive). Her analysis is formalized in terms of a variant of LMT that does not rely on thematic roles to determine the intrinsic classifications of a predicate's arguments. Instead, Zaenen incorporates Dowty's (1991) proto-roles into LMT using the following simple rule: a participant that has more proto-agent than proto-patient properties is marked [−*o*], otherwise the participant is marked [−*r*]. The LMT alternative is further spelled out to allow derivation of grammatical function assignments for the data in (61): the subjects in examples (61a,c,e), with *hebben* 'have', come from intrinsic [−*o*] markings, whereas the subjects in (61b,d), with *zijn* 'be', come from intrinsic [−*r*]. The choice of auxiliary can be correctly modelled by referring to the intrinsic markings of the subject. Kordoni (2003) discusses analysing the German locative alternation in terms of Zaenen's mapping account.[39]

Another variation which is shown to be driven by lexical semantic differences that affect mapping are the so-called "high" versus "low" datives in German. Although arguments in the German Mittelfeld are readily scrambled, there is an unmarked order, which can be detected by studying information structural and quantifier scoping properties. Between objects, the unmarked order is generally DAT before ACC (62; "high dative"). However, a smaller number of verbs show ACC before DAT (63; "low dative"), and for a couple of verbs both orders appear to be unmarked. In the examples, superscript M marks the marked variant.

(62) German (Cook 2006: §1, examples 1–2)

a. Es hat ein Mann [einem Kind] [ein Buch] geschenkt.
EXPL has a.NOM man a.DAT child a.ACC book given
'A man gave a book to a child (as a present).'

b. ^{M} Es hat ein Mann [ein Buch] [einem Kind] geschenkt.

(63) a. ^{M} Es hat ein Polizist [einer Gefahr] [einen Zeugen] ausgesetzt.
EXPL has a.NOM policeman a.DAT danger a.ACC witness exposed
'A policeman has exposed a witness to a danger.'

b. Es hat ein Polizist [einen Zeugen] [einer Gefahr] ausgesetzt.

Cook (2006) demonstrates that the different unmarked orders can be related to differences in lexical semantics, which in turn give rise to thematic alternations. For the alternating verbs, it is shown that the different word orders prefer different readings in line with the general lexical semantic observations. All meanings/word orders involve an agent and a patient/theme, which under standard LMT assumptions are mapped to SUBJ and (accusative) OBJ, respectively. In addition, the DAT-ACC order is associated with a bene-/maleficiary role, which is mapped to a (dative) OBJ_θ. The ACC-DAT order, however, involves a third participant which is a goal or a location and which gets mapped to a (dative) OBL_θ. Cook argues that the unmarked order of complements in the German Mittelfeld is OBJ_θ-OBJ-OBL_θ.

---

[39] It should be noted that Dowty (1991) talks about the *English* locative alternation in terms of proto-roles in depth.

The apparent word order variation is thus a fixed word order seen in the light of the unmarked order of grammatical functions. Cook extends her account to explain the compatibility of the different datives with the *kriegen*-passive, which can be used with a selection of verbs to promote the dative argument to subject.

2.5.3 Transitivity of reflexives

Lexically conditioned reflexives in German and Dutch show up in a range of situations. The simplex reflexives *sich* in German and *zich* in Dutch appear for instance in clauses with transitive verbs with co-referring arguments (64a)/(65a),[40] in anticausatives (64b)/(65b), and in inherent reflexives (64c)/(65c).

(64) a. Max rasiert sich.
Max shaves refl
'Max shaves himself.'

b. Die Tür öffnet sich.
the door opens refl
'The door opens.'

c. Max schämt sich.
Max is.ashamed refl
'Max is ashamed.'

(65) a. Max scheert zich.
Max shaves refl

b. De deur opent zich.
the door opens refl

c. Max schaamt zich.
Max is.ashamed refl

In a contrastive study of reflexivization, Sells et al. (1987) distinguish three kinds of transitivity: 1) c-structure transitivity – the reflexive is an independent constituent, 2) f-structure transitivity – the syntactic predicate selects an obj, 3) semantic transititivity – the referential identity of the arguments is accidental. Interestingly, German and Dutch simplex reflexives receive different analyses: they are both considered to be transitive in terms of c-structure, and intransitive in terms of semantics, but Sells et al. analyse the German reflexives as f-structurally

---

[40] The class of grooming verbs is part of a larger class of transitive verbs that, exceptionally, allows the simplex reflexive. In general, the complex reflexive, *zichzelf* / *sich selbst* is available to realize reflexive objects with transitive verbs. This exception is what justifies treating these reflexives as being lexically specified.

intransitive, and the Dutch reflexives as f-structurally transitive. This is based upon the contrast in (66): the German reflexive can appear in an impersonal passive, whereas the non-reflexive counterpart is ruled out. The reflexive thus patterns with intransitives. The Dutch counterpart is not well-formed, which would suggest Dutch reflexives pattern with transitives.

(66) a. German (Sells et al. 1987: §2.4, example 74)
Jetzt wird {sich / *ihn} aber gewaschen!
now is REFL him however washed
'But now it is time to wash yourself!'
Not: '…to wash him!'

b. Dutch
* Nu wordt (er) {zich / hem} gewassen!
now is EXPL REFL him washed

Sells et al. (1987) model reflexives like (64a), (65a) with a lexical rule which maps a transitive verb (in all the three senses above) to a reflexive verb. For German, this involves leaving out the object slots, and marking the predicates with '[a] feature F, forcing them to combine with the reflexive element.'[41] The resulting intransitive can then serve as input for the lexical rule for the impersonal passive. For Dutch, the reflexivization rule involves moving the thematic object to a non-thematic object slot, marked to be filled by a simplex reflexive.

The analysis of Sells et al. crucially relies on the use of lexical rules to take care of mapping. Modern LFG work would rely on a variant of LMT. Data like those in (66) then also receive a different status, as LMT does not model the (impersonal) passive as a rule to be applied on the output of another rule. Alencar & Kelling (2005) propose an analysis of the whole range of data in (64a–c) in terms of LMT, and explicitly reject the importance of the contrast in (66). Instead, they offer additional data to support the conclusion that the German reflexive *is* transitive at f-structure. Their LMT analysis of the data in (64), above, is summarized in (67).

(67) a. rasieren/öffnen ⟨*agent*, *theme*⟩ ('shave'/'open', transitive)
[−*o*] [−*r*]
SUBJ OBJ

---

[41] The reflexive itself carries a constraining equation checking this feature F to make sure it is only combined with predicates that have undergone reflexivization. It is not spelled out in the article how the presence of the reflexive would be enforced technically, however. One solution is to let the verb and the reflexive be co-heads that check for the presence of each other using constraining equations.

b. (sich) rasieren ⟨*agent*$_i$, *theme*$_i$⟩ (‘shave’, reflexive of transitive)
[−*o*] [−*r*]
SUBJ$_i$ OBJ$_i$[REFL]

c. (sich) öffnen ⟨*theme*$_i$⟩ _$_i$ (‘open’, anticausative)
[−*r*] [−*r*]
SUBJ$_i$ OBJ$_i$[REFL]

d. (sich) schämen ⟨*theme*$_i$⟩ _$_i$ (‘be ashamed’, inherent reflexive)
[−*r*] [−*r*]
SUBJ$_i$ OBJ$_i$[REFL]

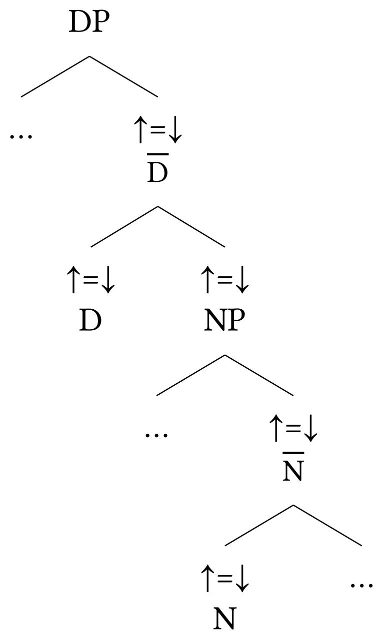
In the last two cases, the reflexive is an expletive.[42]

3 LFG analyses in the nominal domain

3.1 Overall shape of nominal constituents

The CWG nominal domain has received a lot less attention than the clausal domain in LFG. The authors that have concerned themselves with the nominal domain in more detail all assume a DP analysis (Berman & Frank 1996, Part I, Chapter 3; Dipper 2003, Chapter 7; Strunk, 2004, 2005). The general shape of the nominal constituent is characterized by the familiar representation in (68).

(68)



---

[42] The notation with indices to indicate reflexivity is taken from the paper. Note that, as they are also on expletives, these indices should not be interpreted as semantic co-reference.

In Spec-DP, elements like pre-determiners (Dutch: ***al*** *die mensen* 'all those people'), prenominal genitives (that is, non-pronominal possessives; German: ***Karls*** *Auto* 'Karl's car'), and non-genitive prenominal possessors (Low Saxon: ***de'n Jung*** *sien Vadder*, lit. 'the boy his father') can occur. We refer to the discussion of possessives in Section 3.2.1 below for more elaborate examples. D holds determiners and pronouns, although Dipper (2003) assigns pronouns proper (in contrast to determiner-like pronouns) to a category Pron, which is the single daughter of $\overline{\text{D}}$.

The NP contains mostly lexical material. In Dipper (2003: Chapter 7, the theoretical discussion), the class of adjectival quantifiers (see Section 3.2.2, below) appears in Spec-NP, whereas other attributive adjectives appear as sisters to N. Berman & Frank (1996), however, assume that attributive adjectives are left-adjoined to NP (not shown in the schematic tree), whereas oblique and clausal complements are in Comp-NP, on the right.

This overall picture is slightly different in Dipper (2003: Chapter 8, the computational implementation) and Dipper (2005), which describe a flat DP/$\overline{\text{D}}$, under which predeterminers, determiners, prenominal genitives and adjectival quantifiers (that is, the material in Spec-DP, D, and Spec-NP in 68 above) all appear as sisters of NP.[43]

3.2 Topics in noun phrase syntax

3.2.1 Possessives in Low Saxon

Low Saxon has, amongst others, the range of possessive constructions illustrated in (69–71).

(69) Low Saxon (Strunk 2004: §2.2, examples 2.52 and 2.84)

a. sienen Weg
his.M.SG.ACC way
'his way'

b. jeedeen Oort kreeg [sienen], […].
every kind got his.M.SG.ACC
'Every kind got its own, […].'

---

[43] This analysis has the explicit goal of "serv[ing] as the base of a robust and efficient implementation" (Dipper 2005: 101), but its status as a theoretical claim remains a bit unclear. The question of whether a deeper/different analysis would have been preferred in a more theoretically oriented analysis and whether this flat structure should mostly be seen as an operationalization of a deeper structure, is unfortunately not discussed.

(70) Low Saxon (Strunk 2004: §2.3, examples 2.112 and 2.177)

a. de'n Jung sien Vadder
the.M.SG.ACC boy his.M.SG.NOM father
'the boy's father'

b. Korl sien
Korl his.N.SG.NOM
'Korl's'

(71) Low Saxon (Strunk 2005: §6, example 61)
[Hinnerk=s Huss] iss groote den [Antje=s].
Hinnerk=POSS house is bigger than Antje=POSS
'Hinnerk's house is bigger than Antje's.'

Example (69a) contains a possessive pronoun in combination with a noun expressing the possessum. The possessor is anaphorically given as the referent of the possessive pronoun. Example (70a) is a case of *possessive doubling*: as before, we have a possessive pronoun and a noun, but now the possessive pronoun is directly preceded by a nominal in the accusative, which explicitly supplies the possessor. Finally, the first possessive expression in (71) is an instance of an *-s* marked nominal realizing the possessor, followed by the unmarked possessum. Examples (69b), (70b), and the second possessive in (71) show that the possessum can be elided in each of these constructions.

Strunk (2005)[44] models the three constructions in a unified way, crucially relying on optionally specified PRED 'pro' values to capture the differing amounts of explicitly realized referential information. He assumes entries for possessive pronouns along the lines of (72a) and the possessive clitic in (72b), as well as the top level rule for the DP in (72c).

(72) a. *sien* D ((↑ PRED) = 'pro-of⟨POSS⟩')
(↑ AGR) = M.SG
(↑ CASE) = NOM
((↑ POSS PRED) = 'pro')
(↑ POSS MARKING) = +
(↑ POSS AGR) = M.3SG
(↑ POSS CASE) = ACC

b. *=s* D ((↑ PRED)= 'pro-of⟨POSS⟩')
(↑ POSS MARKING) = +

---

[44] Strunk (2004) is an earlier version of this work, which contains a wealth of material on Low Saxon possessives.

$$\begin{array}{llcc} \text{c.}\ \ \text{DP} & \longrightarrow & \text{DP} & \overline{\text{D}} \\ & & (\uparrow \textsc{poss}){=}\downarrow & \uparrow{=}\downarrow \\ & & (\uparrow \textsc{poss marking}) =_c + & \end{array}$$

The entry for a possessive pronoun constrains two "regions", the first constraining the f-structure ↑ for the DP it heads – the possessum – and the second constraining the f-structure (↑ POSS) for the possessor. Both regions have agreement constraints, ↑ from inflectional morphology, (↑ POSS) from the choice of the pronominal root. The two regions also each have an optional equation defining PRED to be a pro-form. The four ways to satisfy these constraints correspond to the four cases in (69) and (70). Finally, Strunk (2005) analyses possessive *-s* as a clitic which also sits in D. Like the possessive pronoun this clitic can be realized with or without a possessum in NP. Unlike the pronoun it must be preceded by a DP that supplies a possessor, which explains the absence of an optional (↑ POSS PRED)='pro' in this entry.

Berman & Frank (1996) and Dipper (2003) discuss the standard German prenominal genitive possessive construction, exemplified in (73a). In contrast to the clitic-in-D analysis given above for the (perhaps only superficially) similar Low Saxon possessive *-s*, these authors put the prenominal material completely in Spec-DP. Berman & Frank (1996) also treat the colloquial German possessive doubling construction, which involves a prenominal dative,[45] found in (73b). As in the analysis proposed for the Lower Saxon counterpart above, the (now dative-marked) possessor is located in Spec-DP, and the possessive pronoun in D.

(73) German (Berman & Frank 1996: §3.1.2, example 136, 141)

a. Peters (*das) Haus
Peter's the house
'Peter's house'

b. der Frau *(ihr) Haus
the.F.SG.ACC woman her house
'the woman's house'

In the analysis put forward by Berman & Frank, the main *structural* difference between the the German prenominal genitive and prenominal dative is that the former requires D to be empty (73a), whereas the latter requires D to be filled (73b). A binary feature on head realization is used to control this.

---

[45] Kasper (2014: 58–59) calls the prenominal dative possessive a "non-standard German [construction] that is completely absent from the standard but can be found in almost all regional varieties/ dialects". Berman & Frank (1996) discuss the prenominal dative together with the prenominal genitive, and note that the former "allerdings eher in der gesprochenen Sprache auftritt" [is however more likely to occur in spoken language] (p. 59).

3.2.2 Declension and the status of quantifiers

Inside the German DP, determiners, adjectives and nouns show agreement with respect to gender, number and case. *Declension* is another agreement dimension, found between determiners and adjectives. Determiners have inherent declension: they can be categorized as inflected (strong declension), uninflected or mixed. In the latter case some cells are inflected/strong and others are not. Inflected adjectives, on the other hand, have strong (more distinctive morphology) and weak (less distinctive morphology) declension paradigms. Adjective declension agrees with the inherent declension of the determiner in the following way:

(74) inflected (strong) determiner: weak adjective
uninflected or no determiner: strong adjective

This phenomenon is illustrated in (75–76). For reasons of exposition, the inflection is made explicit and we use a zero morpheme to mark the lack of inflection. Note that *ein* is a member of the mixed declension class and appears both inflected (75b) and uninflected (76b).

(75) German (data from Dipper 2005: §3.2, presentation/glosses changed)

a.

d-er	süß-e	rot-e	Wein
the-M.SG.NOM	sweet-WEAK.SG.NOM	red-WEAK.SG.NOM	wine(M)

b.

ein-em	süß-en	Wein
a-M.SG.DAT	sweet-WEAK.SG.DAT	wine(M)

(76) a.

süß-er	rot-er	Wein
sweet-STRONG.M.SG.NOM	red-STRONG.M.SG.NOM	wine(M)

b.

ein-∅	süß-er	Wein
a-M.SG.NOM	sweet-STRONG.M.SG.NOM	wine(M)

Determiners that do not inflect at all (for instance, *allerlei* 'every kind', *solcherlei* 'such') are not of the strong declension, and adjectives that do not inflect at all (*lila* 'purple', *rosa* 'pink') are ambiguous between strong/weak declension.

Dipper (2005) models the facts about declension in the following way: The f-structure projected from the DP has a feature DECL, whose value is equated with ST-DET in strong determiners and with ST-ADJ in strong adjectives. This captures the fact that these two are never seen together. Weak adjectives constrain their containing DP's f-structure by DECL $=_c$ ST-DET, and therefore only co-occur with strong determiners. Uninflected adjectives and determiners do not constrain the DECL feature at all.

As seen in (75a) and (76a), when the DP/NP contains multiple adjectives, they show identical declension. Dipper (2005) uses this fact to address the issue of the categorial status of quantifiers like *alle* 'all' and *mehrere* 'multiple', for which it is difficult to decide whether they are determiners or adjectives. By inspecting the declension of adjectival material in the presence of a quantifier, Dipper is able to clearly distinguish determiner-like and adjective-like quantifiers.

3.2.3 Preposition-determiner contractions

German has a number of lexical preposition-determiner (P-D) contractions, such as *zum* 'to the', and *vom* 'of the', shown in (77).

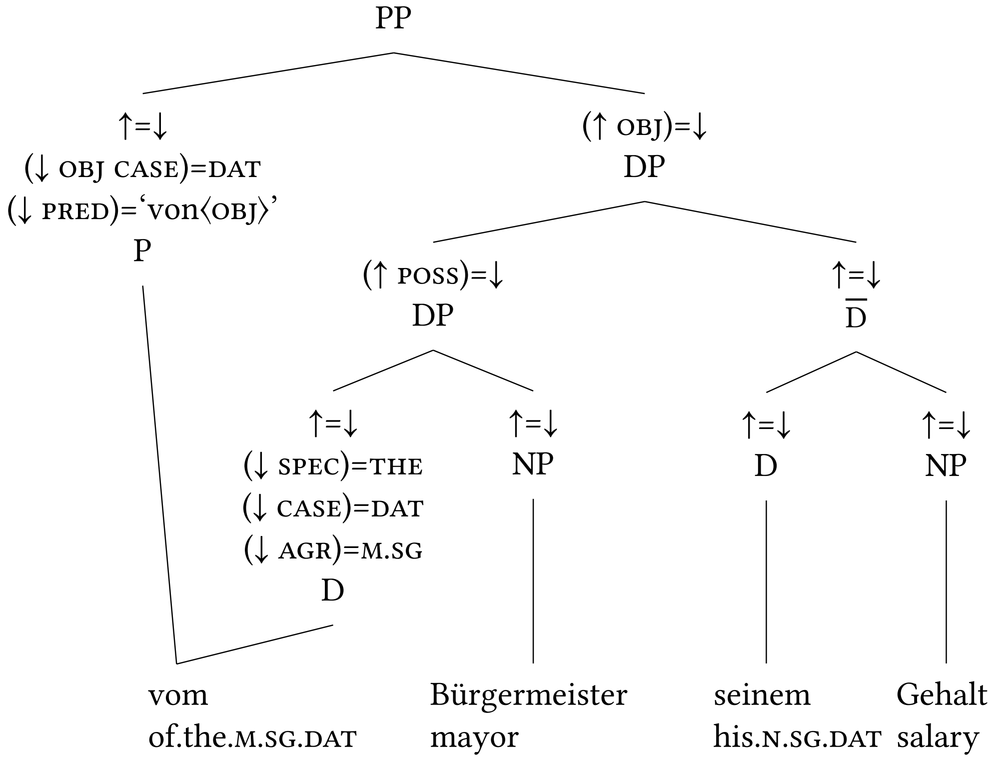
(77) a. zum König
to.the.M.SG.DAT king
'to the king'

b. vom Bürgermeister seinem Gehalt
of.the.M.SG.DAT mayor his.N.SG.DAT salary
'of the mayor's salary'

In Berman & Frank (1996), P-D contractions are treated as prepositions that not only constrain their object DP in a P-like manner – it must have a given case – but also in a D-like manner – it is marked definite and has certain agreement features. Most importantly, the object DP may not itself realize its own D. This is enforced using the binary head realization feature also used in the analysis of possessives, sketched in Section 3.2.1 above.

The example in (77b) shows that this picture is too simplistic: here, the D-like properties do not constrain the object DP, but the prenominal dative of this DP. It is inside this prenominal dative that D is left unrealized, and not in the object DP itself, which has *seinem* in D. The correct generalization about P-D contractions must therefore include that the D inherent in the contraction corresponds to a D leftmost in the object DP, and need not be the object DP's head. Wescoat (2007) gives an analysis in terms of lexical sharing that addresses exactly these points. In Wescoat's lexical sharing model, one lexical terminal can correspond to multiple adjacent preterminals. A slightly simplified analysis of (77b) is given in (78).

(78)



The fact that the preterminals projected from *vom* need to be adjacent solves the problem noted above that the generalization about P-D contractions needs to include reference to the left edge of the object DP. In the paper, Wescoat describes further constraints on the function of the projected D inside the object DP.

3.2.4 Indeterminacy of case

The German nominal inflection paradigms show pervasive syncretism. These syncretic forms can either be ambiguous or indeterminate. Ambiguous forms can be used in different contexts, but they can only be in one paradigmatic cell at a time. So *sie* in (79), which in isolation is ambiguous between plural 'they' and feminine singular 'she', can be used in either way (79a,b), but not as both at once (79c). Indeterminate forms *can* function as if they are in different cells simultaneously. For instance, *Papageien* 'parrots', which is indeterminate for case, can at the same time be selected as an accusative object and a dative object (80).

(79) a. Sie hilft Papageien.
she helps parrots

b. Sie helfen Papageien.
they help parrots

c. * Sie hilft und helfen Papageien.

(80) a. Sie hilft Papageien.
she helps parrots.DAT

b. Sie findet Papageien.
she finds parrots.ACC

c. Sie findet und hilft Papageien.

Although a simple disjunctive defining equation for a feature suffices for the ambiguous cases, this is not enough to achieve indeterminacy, since a disjunction does not change the fact that a feature can only have one value at a time. Dalrymple et al. (2009) represent indeterminate features as bundles of binary features, one for each of the values in the paradigmatic dimension. Compatibility with values is given as a disjunction of *positive* specifications, incompatibility as *negative* specifications. Two example lexical specifications are given in (81).

(81) a. *Papageien* (↑ CASE {NOM|GEN|DAT|ACC}) = +
b. *Männer* (↑ CASE {NOM|GEN|ACC}) = +
(↑ CASE DAT) = −

These specifications state that *Papageien* is completely indeterminate with respect to case (81a), whereas *Männer* is non-dative, but otherwise indeterminate with respect to case (81b).

A selecting element then expresses its case requirements in positive terms only. The entries in (82) illustrate this.

(82) a. *hilft*[46] (↑ OBJ CASE DAT) = +
b. *findet* (↑ OBJ CASE ACC) = +

Since the case feature bundles for *Papageien* defined in (81a) can satisfy both these requirements at the same time, we can capture the coordination of (80c). Dalrymple et al. show that this approach can also deal with additional material in the DP like adjectives, which further constrain the case value, and with verbs which themselves are indeterminate about their case requirements on selected arguments.

4 Concluding remarks

This chapter has presented an overview of Lexical-Functional Grammar studies of Continental West Germanic languages. The majority of the work discussed here has dealt with German clausal syntax, followed by discussions of Dutch

---

[46] We follow here the presentation in the paper and gloss over the fact that *helfen* ‘help’ might be better analysed as taking an OBJ_θ rather than an OBJ, which would complicate modelling the coordination.

clausal syntax. This reflects the status of the LFG field as a whole – the nominal domain has received less attention than the clausal/verbal domain, an overview of LFG work on the former is given in Börjars & Lowe 2023 [this volume] – but it also reflects the fact that the other CWG languages – possibly, but not only, minority, regional, and/or non-standardized languages – do not feature prominently in the LFG literature. I hope that the discussion of existing work on the syntax of the two "big" CWG languages in the current chapter may inspire further application of LFG to the other members of the family.

Obviously, not every LFG study that touches upon CWG has been mentioned in this chapter. There are some larger blind-spots that I wish to mention here.

- Bögel (2015) develops an LFG model of the prosody-syntax interface. Recent papers contain applications to Swabian (Bögel & Raach 2020, Bögel 2021) and Standard German (Bögel 2020). See also Bögel 2023 [this volume] for a discussion of the syntax-prosody interface in LFG.

- A number of authors have used OT in combination with LFG, especially in the domain of word order variation and information structure. Examples are Choi (1999, 2001), Cook (2001), Cook & Payne (2006),Van der Beek (2005), and Seiler (2007). These have been mentioned in the text, but were not discussed in any detail. OT-LFG is dealt with in Kuhn 2023 [this volume], and information structure is treated in Zaenen 2023 [this volume].

- German is blessed with a wide-coverage LFG grammar, implemented in the context of the ParGram project. This grammar can be queried in the interactive XLE-WEB interface.[47] The project page for the ParGram project in Germany,[48] contains older references. The research activities in and around this project have resulted in a long list of publications. Some of that work has already been discussed above. I will here list a small selection of further papers that also have direct relevance for theoretical debates: Forst & Rohrer (2009) and Kuhn et al. (2010) discuss problems in the analysis of German VP coordination; Rehbein & van Genabith (2006) and Forst et al. (2010) deal with the implementation of particle verbs; Forst (2006) is a "grammar writer's" contribution to the COMP-debate. The desire for parallel structures in the context of ParGram is one of the forces behind the auxiliaries-as-features style of syntactic analysis in LFG. An early contribution and implementation can be found in Butt et al. (1996).

> Computational work on LFG is the topic of several chapters in Part V of this volume.

Omitting these studies from the main text was a conscious choice, intended to keep the chapter accessible by not introducing too much conceptual machinery and too many problem domains. I made this choice with the knowledge that their topics would be touched upon in other chapters. At the same time, I wish to underline their importance, because exactly the fact that they span multiple domains and methods means that they are excellent demonstrations of the flexibility and precision that LFG offers.

Acknowledgements

I thank Bozhil Hristov and two anonymous reviewers for the detailed and valuable comments that greatly helped to improve this chapter. Moreover, I am grateful to Mary Dalrymple for editing this volume, inviting me to contribute, and her extraordinary patience during the writing process.

Abbreviations

Besides the abbreviations from the Leipzig Glossing Conventions, this chapter uses the following abbreviations.

Chapter 31

LFG and Finno-Ugric languages

Tibor Laczkó
Károli Gáspár University of the Reformed Church in Hungary

The chapter discusses some salient, sometimes competing, LFG analyses of a variety of (morpho-)syntactic phenomena in Finno-Ugric languages, with occasional glimpses at alternative generative approaches and at some related phenomena in languages belonging to Samoyedic, the other major branch of Uralic languages. We concentrate on clausal c-structure representational issues, verbal modifiers, focused constituents, negation, copula constructions, argument realization, subject-verb agreement, differential object marking, evidentiality and a set of noun phrase phenomena related to event nominalization. It argues that LFG provides an appropriate and suitably flexible formal apparatus for a principled analysis of all the phenomena in all the Finno-Ugric languages discussed here. In addition, it shows that the analysis of some of these phenomena can also contribute to LFG-internal theorizing.

1 Introduction

1.1 General remarks on Finno-Ugric languages

Finno-Ugric is one of the two branches of Uralic, the other branch being Samoyedic. In Figure 1 we show the major branches of the Uralic family tree and those leaves (languages) that are discussed, or at least mentioned, in this chapter. This figure is in accordance with the general remarks in the introductory chapter of Miestamo et al. (2015) on the representation of the Finno-Ugric branch.[1] We use

---

[1] We are thankful to Anne Tamm for helpful discussions of certain family tree issues.

Tibor Laczkó. 2023. LFG and Finno-Ugric languages. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 1469–1532. Berlin: Language Science Press. DOI: 10.5281/zenodo.10186012

the names of the individual languages as they appear in that volume.[2] The authors point out that, although there are several alternative approaches to this branch, most of them share the view that the following language groups are valid genealogical units: Samoyedic, Ugric, Permic, Mari, Mordvin, Saamic and Finnic. However, the details of the relationships among certain languages are subject to variation across these competing approaches.[3]

For the sake of a complete picture, we have included the Samoyedic branch as well. In the Northern branch there are two major sub-branches: Enets-Nenets and Nganasan. From the Enets-Nenets sub-branch Tundra Nenets will be discussed and compared with some Finno-Ugric languages in Section 7.1.2 with respect to differential object marking. The only living representative of the Southern branch is Selkup, also mentioned in Section 7.1.2. Saamic languages also have a variety of sub-branches. From these languages Inari Saami will be discussed in Section 5.2 on copula constructions and in Section 7.1.1 on subject-verb agreement.

As regards the geographical distribution of the languages indicated in Figure 1, Estonian is primarily spoken in Estonia, Hungarian is spoken in Hungary, Finnish and Inari Saami are spoken in Finland, and all the other languages are spoken in Russia.

Several languages belonging to the Finno-Ugric branch of Uralic languages have a considerable number of properties that have contributed to linguistic research in LFG. On the one hand, these phenomena provide empirical or typological evidence for theoretical generalizations. On the other hand, they exhibit cases in which LFG is well-suited for the development of principled analyses. Such phenomena include, but are not limited to, discourse-functionality, negation, *wh*-questions, copular clauses, particle-verb constructions, event nominalization, possessive constructions, the nature and inventory of grammatical functions, evidentiality, rich inflectional morphology, partitives, duals and complex agreement patterns.

In this chapter we can only concentrate on those phenomena in Finno-Ugric languages that have been analyzed in an LFG framework in such a way that the summary of the given analysis within the limitations of space serves the purposes

---

[2] Several languages in this figure are also referred to by alternative names in some other works, e.g. Khanty = Ostyak, Mansi = Vogul, Udmurt = Votyak, Mari = Cheremis; see the discussion of Dalrymple & Nikolaeva (2011) in Section 7.1.2, for instance. When we cite authors, we keep the version of the name of a language that they use.

[3] For a recent, fundamentally similar Uralic family tree representation indicating all the languages (including those that are extinct by now), see Maticsák (2020).

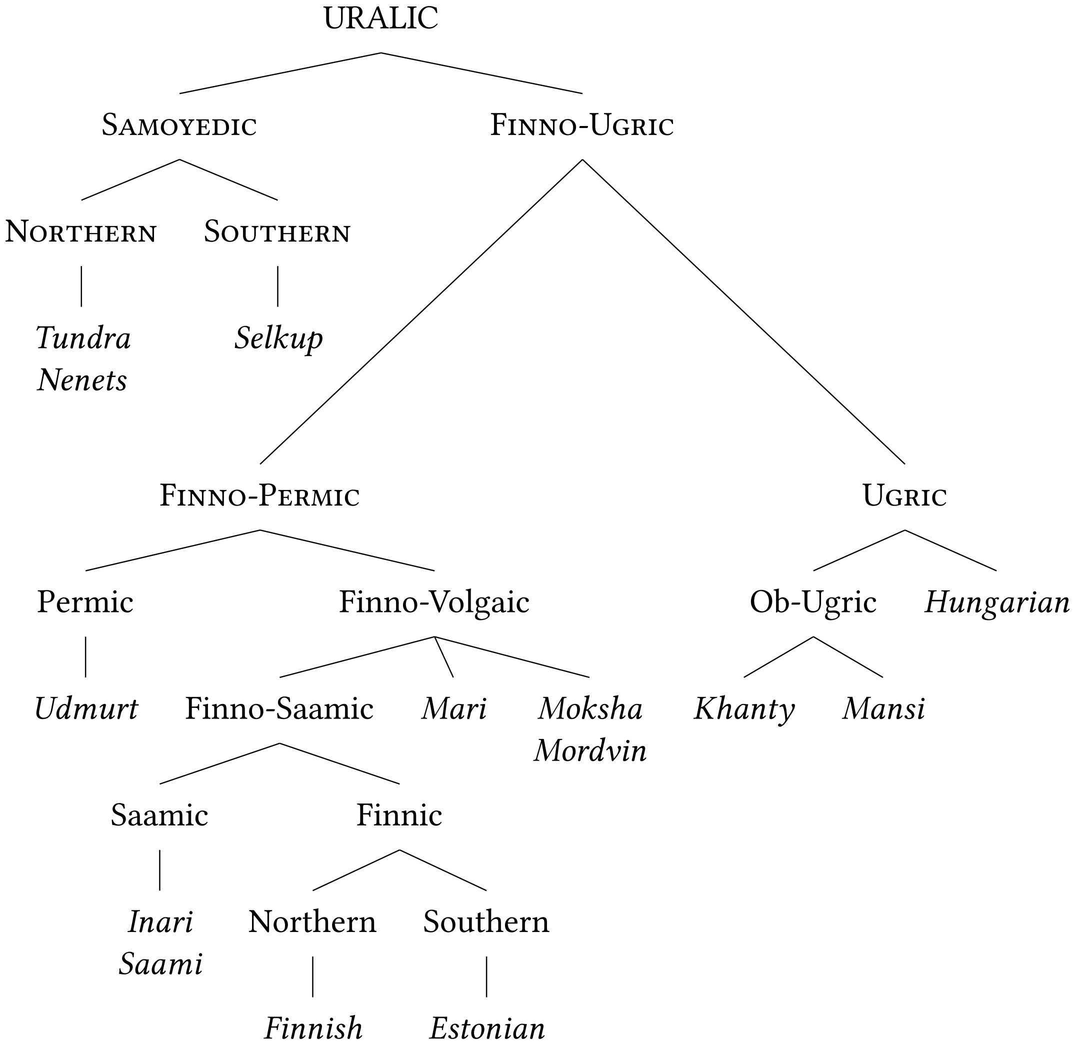

Figure 1: The (simplified) family tree of Uralic languages

of the chapter, as outlined in the foregoing paragraph. Consequently, this determines which languages appear in the chapter. Given that Hungarian is the most intensively and extensively researched Finno-Ugric language in LFG,[4] the discussions of LFG analyses of Hungarian phenomena outnumber the discussions of phenomena in other Finno-Ugric languages. For further information on related and additional phenomena and other Uralic or Finno-Ugric languages, the interested reader is referred to the following comprehensive sources: Abondolo (1998),

---

[4] For introductions to LFG in Hungarian, see Laczkó (1989) and Komlósy (2001). The following works also have introductory sections to LFG: Szabó (2017) in Hungarian and Tamm (2004a) in Estonian.

Dryer & Haspelmath (2013), Miestamo et al. (2015) and de Groot (2017).[5] The online journal *Finno-Ugric Languages and Linguistics* (http://full.btk.ppke.hu) regularly contains generative papers on Finno-Ugric languages.[6] In addition, Tamm & Vainikka (2018) present an overview of generative works on Finnish and Estonian syntax.[7]

As regards comprehensive analyses of several phenomena in Hungarian, Laczkó 2021 offers a synthesis of his earlier LFG(-XLE)[8] accounts of the following phenomena in Hungarian finite clauses: sentence structure, verbal modifiers, operators, negation and copula constructions. He posits all this in the context of a critical overview of alternative Chomskyan and lexicalist approaches to these phenomena. Tamm (2004c) develops a comprehensive LFG approach to the relations between Estonian aspect, verbs and case.

The following databases on Uralic languages are useful resources about their syntactic properties: the Uralic language typological data set at bedlan.net/data/uralic-language-typological-data-set the Selkup and Kamas corpora at www.slm.uni-hamburg.de/inel, and the typological database of Ugric languages at en.utdb.nullpoint.info.

1.2 The structure of the chapter

In accordance with the scopes of LFG works on Finno-Ugric languages, the significantly larger part of this chapter (Section 2-Section 7) concentrates on the investigation of clausal phenomena, and this is followed by the discussion of salient LFG analyses of some noun phrase phenomena (Section 8). In Section 2 we discuss clausal c-structure representational issues by focusing on a variety of

---

[5] In Section 9 we make brief references to additional works on Uralic languages in general and Finno-Ugric languages in particular that we cannot discuss here for limitations of space.

[6] See, for instance, Brattico (2019) on Finnish word order, É. Kiss (2020) on pronominal objects in Ob-Ugric, and Asztalos (2020) on focus in Udmurt.

[7] In her review, Anne Tamm has kindly provided the following information about the history of syntactic research on Estonian. "For a long while since the mid-20th century, there was more work on Estonian syntax than on Finnish syntax. Keeping abreast with western mainstream linguistics in the 60s, 70s and early 80s resulted in numerous formal syntactic works and a tradition of understanding syntax that is, in spirit, rather similar to LFG approaches. Rätsep (1978), for instance, is a lexicalist analysis of patterns of argument structures and their alternations; this work has certainly been influential in the context Uralic syntax. Tamm (2012c) provides an overview of the treatment of verb classes in this and related works, these early generative-style lexicalist works are available in Estonian only [...]. Almost all LFG work on Estonian expands that work in some way."

[8] In his XLE work he further develops Laczkó & Rákosi's (2008–2019) implemented Hungarian grammar.

LFG approaches to Hungarian. In Section 3 we concentrate on verbal modifiers in Hungarian and Estonian in general and on their radically different relations to focus in these languages in particular. In Section 4 we offer a brief overview of an LFG-XLE analysis of negation in Hungarian by also pointing out its potential contribution to the treatment of negation phenomena cross-linguistically. In Section 5 we discuss LFG accounts of copula constructions in Hungarian, Inari Saami and Finnish. In Section 6 we deal with LFG treatments of some aspects of argument realization in Finnish and Estonian. In Section 7 we concentrate on a selection of morphosemantic phenomena: (i) subject-verb agreement in Inari-Saami and Finnish; (ii) differential object marking in Uralic with particular attention to Finno-Ugric languages; (iii) the grammaticalized expression of evidentiality in Udmurt and Estonian. In Section 8 we present a summary of a variety of LFG approaches to noun phrase phenomena in Hungarian: (i) c-structure issues; (ii) event nominalization, and we add a short section on the morpho-syntax of possessive noun phrases in Finnish and Hungarian. In Section 9 we make brief references to additional relevant LFG(-related) works on Finno-Ugric languages that space limitations have prevented us from discussing. In Section 10 we conclude.

2 C-structure representation in clauses

de Groot (2017) presents a very useful tabular comparison of the major word order properties of 21 Uralic languages. In Table 1 we present the parts of his table that are relevant for our current purposes.

As the table shows, in these languages word order is predominantly free (except for Enets and Nenets). The two major patterns are SVO and SOV with roughly the same frequency. In seven languages there is a designated preverbal focus position (and in one of them, Komi, there is an additional postverbal Foc position). In three languages the Foc position is clause final. This is the general word order picture. Below we fundamentally concentrate on Hungarian because several alternative LFG c-structure analyses have been proposed for this language. In addition, we make some comparative remarks on Finnish and Estonian.

Table 1: Word order properties of 21 Uralic languages (part of Table 11, de Groot 2017: 548)

Language	word order	major pattern	focus position
Finnish	free	SVO	
Estonian	free	SVO	clause final
Votic	free	SVO	
Ingrian	free	SVO	clause final
Veps	free	SVO	clause final
Karelian	free	SVO	
South Saami	free	SOV/SVO	
North Saami	free	SVO	
Skolt Saami	free	SVO	
Erzya	free	SVO	
Mari	free	SOV	Foc V
Komi	free	SOV/SVO	Foc V / V Foc
Udmurt	free	SOV	Foc V
Hungarian	free	SOV/SVO	Foc V
Khanty	free	SOV	Foc V
Mansi	free	SOV	
Nenets	not free	strict SOV	Foc V
Enets	not free	strict SOV	Foc V
Nganasan	free	SOV	
Selkup	free	SOV	
Kamas	free		

Hungarian is a classic example of a discourse configurational language: see É. Kiss (1995), for instance.[9] The crucial empirical generalizations about Hungarian sentence structure are as follows. The fundamental sentence articulation

---

[9] On sentence structure and discourse-functionality in Finnish in non-LFG frameworks, see Vilkuna (1995) and Brattico (2019), for instance. According to Vilkuna (1995), there is a preverbal K (contrast) and also a T (topic) position in Finnish. While fundamentally these two positions are also available in Estonian, on the basis of their experimental and corpus investigation, Sahkai & Tamm (2018b, 2019) claim that other types of constituents can also occur in the preverbal domain. While Hungarian exhibits strong discourse-configurationality, Estonian is only weakly discourse-configurational: see Sahkai & Tamm (2018b: 416–417). Hiietam (2003) argues that topic is to be defined semantically and not configurationally in this language. In addition, Estonian is the only Uralic language with V2, and its V2 is prosodic: see Sahkai & Tamm (2018a). Tael (1988) claims that the focus position is at the end of the clause in Estonian.

is topic-predicate (also called topic-comment in a variety of approaches). In the topic field, the order of topics and sentence adverbs is free. In the preverbal domain, quantifiers follow the topic field. In neutral sentences[10] there is a designated immediately preverbal position for a special constituent type: 'verbal modifier' (VM). This is a conventionally used cover term for a range of radically different categories sharing the syntactic property of occupying this designated preverbal position. Preverbs (also known as verbal particles or coverbs),[11] bare nouns, designated XP arguments, etc. are all assumed to be VMs. Basically, the word order of postverbal elements is also free. In a non-neutral sentence the (heavily stressed) focused constituent occupies the immediately preverbal position, and, as a consequence, the VM has to occur postverbally, i.e. the VM and the focus are in complementary distribution. How to capture this complementarity is a crucial cross-theoretical issue. The two salient solutions are as follows. (i) There is only a single designated preverbal position for which focused constituents and VMs compete. (ii) There are two distinct positions for the two elements: focus and VM. In this approach it needs to be explained why these two elements cannot co-occur.

Börjars et al. (1999) offer some general considerations against functional projections like TopP and FocP (*à la* Government and Binding Theory and the Minimalist Program) for languages like Hungarian and some hints at a possible LFG alternative with an extended verbal projection in which word order regularities are capturable by dint of Optimality Theoretic (OT) style constraints. They claim that the assumption that discourse functions are not necessarily associated with the specifier positions of functional projections allows an analysis of Hungarian in which quantifier phrases and topics are positioned within an extended verbal projection, avoiding the postulation of functional projections without heads. They propose that Hungarian sentences are VP projections, as in (1),[12] and they suggest that the immediately preverbal occurrence of the focused constituent should be captured in terms of OT constraints. In this work, there is no discussion of VMs and their complementarity with focused phrases.

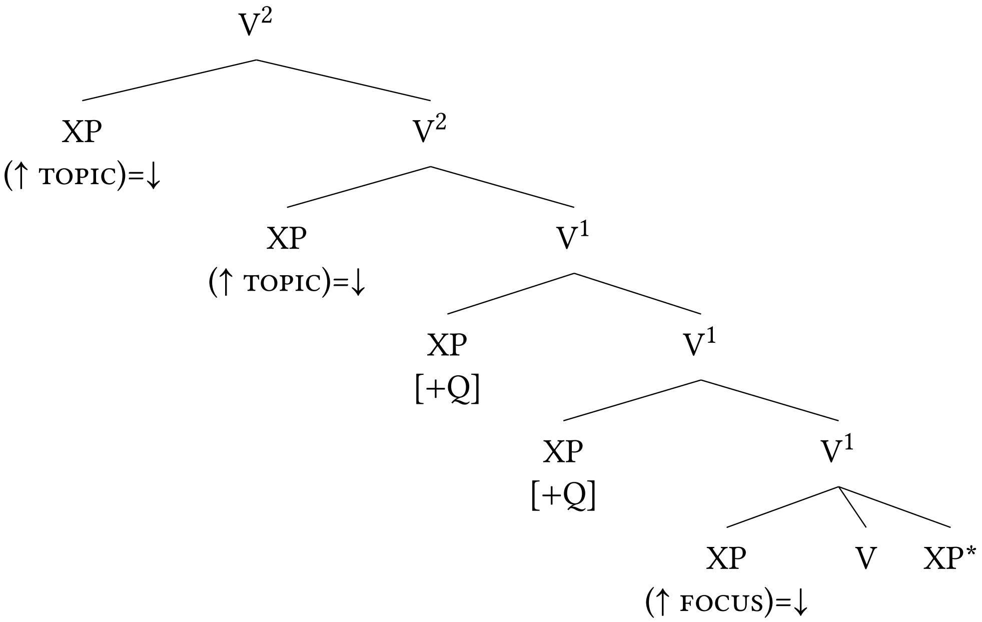
---

[10] The standard description of a neutral sentence is that it does not contain negation or focus, it is not a *wh*-question, and it has level prosody.

[11] Other Ob-Ugric languages have developed verbal particles to a lesser extent, see Zsirai (1933). For more information on Uralic (aspectual) verbal prefixation and verbal particles, see Kiefer & Honti (2003). For an analysis of Estonian sentence-final particles with focus, see Tamm (2004c: 224–242), discussed in Section 3.2.

[12] The superscripts in V^1 and V^2 indicate bar-levels.

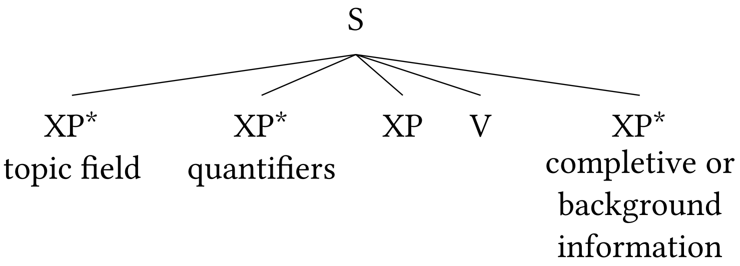
(1)



Adopting the basic representational assumptions and ideas of Börjars et al. (1999), in their OT-LFG framework, Payne & Chisarik (2000) develop an analysis of Hungarian preverbal syntactic phenomena: the complementarity of constituent question expressions, focused constituents, the negative marker and verbal modifiers.

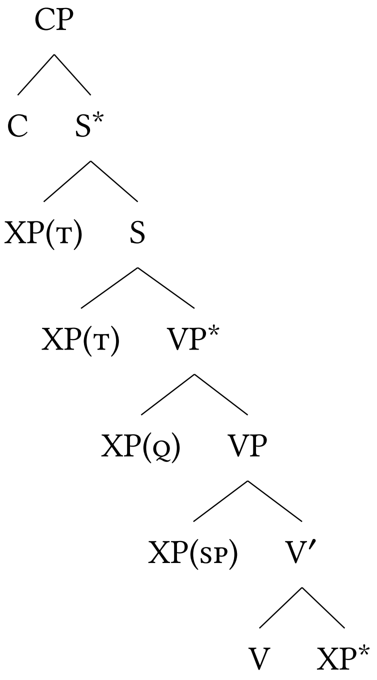
Gazdik (2012), capitalizing on Gazdik & Komlósy (2011), outlines an LFG analysis of Hungarian finite sentence structure, predominantly driven by discourse functional assumptions and considerations. She postulates two sentence structure types, and she assumes that both structures are available to both neutral (N) and non-neutral (NN) sentences, which are distinguished by their different prosodic behaviours. (2) shows one of the two structures. Here the immediately preverbal XP has a presentational-focus-like function in N sentences and the standard identificational focus function in NN sentences. The other structure differs in one important respect: the preverbal element is a VM, and the VM and the verb are dominated by V′. The VM receives the usual phonological-word-initial stress in N sentences and the focus stress in NN sentences.

(2)



Laczkó (2014b), after a detailed critical overview of previous LFG approaches, postulates the skeletal sentence structure in (3).[13] He argues against assuming an IP for the structural-categorial representation of Hungarian sentences and he argues for S as the core category.[14] He proposes a CP/S alternative that is closest in spirit to É. Kiss' (1992) special GB approach.[15]

(3)



Adopting one of the most crucial aspects of É. Kiss's (1992) analysis, he assumes that vms and focused constituents target the Spec,VP position. He employs disjunctive functional annotations to capture this preverbal complementarity.[16]

Consider the following generalization. 'The daughters of S may be subject and predicate' (Bresnan 2001: 112). In his analysis, Laczkó proposes that this generalization should be modified in the following way.

(4) The daughters of S may be subject/topic and predicate.

He points out that this modification receives independent support from the following rule from Bresnan & Mchombo (1987).[17]

---

[13] In (3) t stands for topic (position), q stands for quantifier (position), sp stands for the specifier position. S* and VP* encode the possibly iterative left-adjunction of XP(t) and XP(q) to S and VP, respectively.

[14] In LFG IP and S are taken to be parametric options in Universal Grammar.

[15] For a comparison of these GB and LFG approaches, see Laczkó (2020).

[16] For details and the discussion of what other elements are assumed to compete for the Spec,VP position, see Section 3.1 and Section 4.

[17] On the basis of (5), *subject and/or topic* is even more appropriate than *subject/topic* in (4).

(5) $$\mathrm{S} \longrightarrow \begin{pmatrix}\mathrm{NP}\\ (\uparrow \textsc{subj})=\downarrow\end{pmatrix}, \begin{pmatrix}\mathrm{NP}\\ (\uparrow \textsc{topic})=\downarrow\end{pmatrix}, \begin{pmatrix}\mathrm{VP}\\ \uparrow=\downarrow\end{pmatrix}$$

Laczkó argues that a VP can contain a subject if the XP in [$_S$ XP VP] is a topic. This requires all other occurrences of VP to be subjectless. In this scenario, the following three parametric options seem to emerge across languages: (i) strictly VP-external subject, as in English; (ii) VP-internal subject in a designated position, as in Russian[18]; (iii) VP-internal subject without a designated position, see Hungarian.

This section has demonstrated that LFG provides a suitably flexible formal apparatus by the help of which the sentence structures of typologically different languages can be described in a principled manner with respect to discourse functional configurationality.

3 Verbal modifiers and focus

In this section we discuss analyses of verbal modifiers in Hungarian (Section 3.1) and Estonian (Section 3.2).

3.1 Hungarian

As has been pointed out in Section 2, the crucial (cross-)theoretical question to address in the case of Hungarian is how to account for the preverbal complementarity of focused constituents and verbal modifiers. Compare the examples in (6). (6a) is a neutral sentence and the VM *oda* 'to.there', which is categorially a preverb, immediately precedes the verb. By contrast, (6b) is a non-neutral sentence, and in it the VM can neither precede nor follow the focused constituent (in SMALLCAPS) in the preverbal domain.

(6) Hungarian:

a. János minden-t oda adott Mari-nak.
John.NOM everything-ACC VM gave Mary-DAT
'John gave everything to Mary.'

b. János minden-t (*oda) MARI-NAK (*oda) adott oda.
John.NOM everything-ACC VM Mary-DAT VM gave VM
'John gave everything TO MARY.'

---

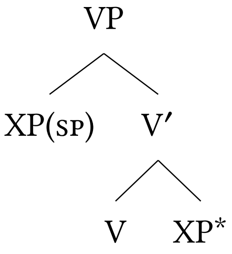
[18] See King (1995), for instance.

The cross-theoretic question is whether we should assume that the two constituents fight for one and the same syntactic position or that they occupy two distinct positions. With the salient exception of É. Kiss (1992, 1994), the GB/MP mainstream assumes two distinct positions, and employs a variety of principles that block the simultaneous occurrence of constituents in these positions: see Brody (1990) and É. Kiss (2004), for instance, and also see Laczkó (2021) for a comparative overview of different analyses of the complementarity of focused constituents and verbal modifiers in Hungarian.

Several LFG approaches have a similar view, see Ackerman (1987, 1990), Payne & Chisarik (2000), Mycock (2006, 2010), the basic idea being that vms get semantically and morphologically incorporated into the verb.[19] In Section 2 we also pointed out that Gazdik (2012) has a special proposal. She employs two distinct sentence structures, both having neutral and non-neutral versions. The main point here is that the basic vm vs. focus contrast is treated in two different structural dimensions. Thus, this can be regarded as an extreme instance of assuming that the two elements do not fight for the same syntactic position.

By contrast, Laczkó (2014b) argues that focus constituents (ordinary foci, the immediately preverbal *wh*-phrases and negated constituents)[20] and vms (of various types) target the same Spec,VP position, hence their complementarity. In (7) we repeat the relevant part of his overall sentence structure shown in (3) in Section 2.

(7)



Laczkó (2014b) employs disjunctive functional annotations to capture the complementarity of the elements he assumes to compete for this position.

As we pointed out in Section 2, vms come in several varieties: preverbs, idiom chunks, secondary predicates, designated reduced or full arguments. Preverbs are the central and theoretically by far the most challenging members of this

---

[19] At first sight, it can be taken to be a supporting fact that the vms of the preverb type and the verb make up one phonological word, i.e. it is only (the first syllable of) the preverb that receives word-initial stress. However, even XP vms follow the same pattern (in which the following verb loses its word-initial stress).

[20] On the details of negation in Hungarian, see Section 4.

heterogeneous group, because their combination with the finite verb, often called particle-verb construction (pvc), exhibits both lexical and syntactic properties (and the former motivate the incorporation analysis). Their most salient lexical characteristics are as follows. The preverb can affect the argument structure of the main verb, pvcs are often non-compositional, and both non-compositional and compositional pvcs can undergo productive derivational processes like event nominalization. However, the preverb and the main verb are strictly separable syntactically under clearly definable circumstances. For instance, as exemplified in (6) above, a focused constituent, as a rule, immediately precedes the main verb, and in such cases the preverb must occur postverbally.

In several recent LFG approaches, for instance Forst et al. (2010), Laczkó & Rákosi (2011), Rákosi & Laczkó (2011), Laczkó (2013a) and Laczkó (2014b), it is assumed that preverbs and other types of vms uniformly occupy a distinct preverbal syntactic position (typically Spec,VP), as opposed to the vm-incorporation analysis, which is primarily motivated by the preverbal complementarity of vms, focused and *wh*-constituents.

Forst et al. (2010) propose an LFG-XLE treatment of a variety of particle-verb constructions in English, German and Hungarian. Their main claim is that non-compositional and non-productive pvcs should be treated radically differently from compositional and productive pvcs. The former are best analyzed along lexical lines with the help of XLE's concatenation device. By contrast, the authors argue that the productive pvc types call for a syntactic treatment. One of the most important motivations for this sharp distinction is that productive pvcs can be analyzed 'on the fly', i.e. automatically and straightforwardly, in the syntax, without previously and lexically encoding them. Their solution is complex predicate formation in the syntax by applying XLE's restriction operator.[21]

Laczkó & Rákosi (2011) and Rákosi & Laczkó (2011) explore the tenability and implementational applicability of the approach proposed by Forst et al. (2010) by each developing an LFG-XLE analysis of two different pvc types. Laczkó & Rákosi (2013) posit this approach in a cross-linguistic and cross-theoretical context. As opposed to previous LFG accounts, Laczkó (2013a) argues that compositional pvcs should also be treated lexically in a manner similar to the treatment of non-compositional pvcs. He points out that one of the advantages of this uniform lexical treatment is that classical LFG's view of the distribution of labour between the lexical and the syntactic components of grammar can be maintained, at least

---

[21] For formal details, see Forst et al. (2010).

in this domain. He also shows how various morphological processes (often consecutively) involving pvcs can be handled (e.g. causativization, nominalization, and preverb reduplication), which may cause potential problems for a syntactic analysis of compositional pvcs.

Laczkó (2014b) captures the preverbal complementarity of focused constituents and vms by assuming that they fight for the same Spec,VP position. He encodes this by associating the disjunctive sets of annotations in (8) with this position. The first disjunct of the main disjunction says that a constituent bearing any grammatical function can have the focus discourse function. The second disjunct handles vms. Laczkó employs XLE's check feature device here.[22]

(8)

$$\begin{array}{l} \{\ (\uparrow \text{gf}) = \downarrow \\ \ \ (\uparrow \text{focus}) = \downarrow \\ \mid (\downarrow \text{check\_vm}) =_c + \\ \ \ \{\ \uparrow = \downarrow \\ \ \ \mid (\uparrow \text{gf}) = \downarrow \}\} \end{array}$$

The check feature in (8) is used for all types of vms. It requires the presence, in Spec,VP, of an element lexically marked with the defining counterpart of this feature. Preverbs are intrinsically associated with this feature, i.e. in their lexical forms they are associated with the defining member of the check_vm feature pair, and they receive the functional (co-)head annotation, see the first disjunct in the second major disjunct. All the other types of vms are specified for this status by individual verbs. It depends on the verb whether it selects a vm, and, if so, which argument (bearing any subcategorized grammatical function) will be singled out, see the second disjunct in the second major disjunct.[23]

---

[22] The essence of this device is that check features come in pairs: there is a defining equation and it has a constraining equation counterpart. These check feature pairs, which can be used both in c-structure representations and lexical forms, can ensure that two elements will occur together in a particular configuration or a particular element occurs in a particular position. The check feature in (8) is of the latter type.

[23] Laczkó also assumes that a *wh*-phrase (or, in multiple *wh*-questions the immediately preverbal *wh*-phrase) also fights for the Spec,VP position, so he adds another disjunction to (8) to capture this, by using additional (interrogative) check features: for details, see Laczkó (2014b). In addition, he assumes that negated constituents also occupy this position. Furthermore, he postulates that in the type of predicate negation in which there is no focused constituent, the negative marker also targets this position. Therefore, he adds two more disjuncts, see Section 4.

Laczkó (2014a) outlines an LFG analysis of a variety of VMs other than preverbs: bare nouns,[24] OBL XP arguments, XCOMP arguments and idiom chunks. The crucial aspect of this analysis is that in the lexical form of the verb taking any one of these VM types it is specified that either the verb occurs in a sentence containing a focused constituent or else its designated complement must occupy the Spec,VP position.[25]

3.2 Estonian

Tamm (2004c) presents a detailed description of PVCs in Estonian, and she outlines an LFG analysis. She points out that Estonian separable particles are basically comparable to their Hungarian counterparts, the most important difference being that aspectual particles typically occupy the clause final focus position. Tamm distinguishes three basic uses of Estonian particles, and she discusses the particle *ära,* which can perform all the three functions. Consider her examples.

(9) Directional (deictic) use of *ära*, Estonian:
ära veerema
away roll
'roll away'

Tamm points out that verbs combining with *ära* in this use have an implicit path argument that is only optionally realized overtly. The closest Hungarian counterpart is *el* 'away' (as in *el-gurul* 'roll away').

---

[24] Viszket (2004) offers a detailed empirical description of a whole range of bare noun phrases in Hungarian. In neutral sentences these constituents can only occur immediately preverbally, in the VM position. In her LFG account of the syntax of bare noun phrases, Viszket adopts Laczkó's (1995, 2000b) [+VM] feature and she also introduces a special [•VM] feature. Her new feature, when associated with a predicate in its lexical form, bans the occurrence of a bare NP in the VM position; practically, it prevents such a constituent from occurring in neutral sentences. Viszket identifies seven major types of predicates that need to be provided with this feature in their lexical forms. For instance, the verbs of PVCs, the predicates of certain idioms and certain predicates with resultative XCOMPs belong here. These types also have the [+VM] feature. In addition, there are predicates without the [+VM] feature that also need [•VM]. For example, nominal and adjectival predicates, and verbs that always need word-initial stress belong here. On partitive mass and plural NPs in Estonian, corresponding to bare nominal VMs in Hungarian, see Tamm (2007a,c).

[25] In her review, Anne Tamm points out that there are similarities between Laczkó's analysis of Hungarian particle verbs and the analysis of Estonian particle verbs and aspect in Rätsep (1969) written in Estonian, which Tamm (2012c: 62–63, 72–75) has summarized, or Rätsep's (1978) account of government structures of complex verbs in Estonian.

(10) Completive use of *ära*, Estonian:
Naaber suri ära.
neighbour die.PST.3SG ÄRA
'The neighbour died.'

Verbs that combine with *ära* in this use have a theme or patient argument, obligatorily realized as a subject or an object. The closest Hungarian equivalents are *meg* 'PFV' (as in *meg-hal* 'PFV-die') and *el* 'away' (as in *el-olvad* 'away-become.melted').

(11) Bounding use of *ära*, Estonian:
Ta suudles tüdruku ära.
s/he kiss.PST.3SG girl.GEN ÄRA
'S/he did the kissing of a girl.'

This sentence is appropriate in the following situation, for instance. Someone makes a bet to kiss a girl, and when this goal is achieved, the result can be reported by using this PVC. The closest Hungarian counterparts are *meg* 'PFV' (*meg-ebédel* 'have/eat up one's lunch') and *ki* 'out' (as in *ki-alussza magát* out-sleep oneself.ACC 'sleep one's share, as much as needed').

Tamm assumes that *ära* in its directional use has a PRED feature, and she gives the following lexical representation (Tamm 2004c: 231).

(12) *ära* P (↑ PRED) = 'AWAY⟨(↑ SUBJ)⟩'
{ ((XCOMP ↑) B1) ∨ ((XCOMP ↑) B2) }

This encodes that the particle functions as the PRED of the lexical verb, and it has a subject argument. In addition, it has disjunctive existential constraints on the boundedness (B) attributes.

Tamm assumes that *ära* in its completive use also has a PRED feature, see her lexical form in (13) (Tamm 2004c: 232).

(13) *ära* P (↑ PRED) = 'UP, COMPLETELY⟨(↑ SUBJ)⟩'
{ ((XCOMP ↑) B1) = MAX ∨ ((XCOMP ↑) B2) }

As opposed to its previous two uses, Tamm assumes that *ära* in its bounding use has no PRED feature, and it only encodes B and focus specifications, see (14) (Tamm 2004c: 229).

(14) *ära* Prt (↑ B1) = MAX
(↑ B2) = MIN
(↑ FOCUS B1) = MAX
(↑ FOCUS B2) = MIN

The particle in this use contributes f-structure information about the aspectual features of the clause, see the first two annotations, and it also encodes that this boundedness is the focused information, see the last two annotations.

In addition, verbal predicates can also carry aspectual information in their lexical forms. For instance, Tamm assumes that *suudlema* 'kiss', see (11) for instance, has the following lexical representation.

(15) *suudlema* V (↑ PRED) = 'KISS⟨(↑ SUBJ)(↑ OBJ)⟩'
(↑ B2)

This verb has an existential constraint on B2, which can be unified with the MIN value of the B2 of the particle in (14). Finally, the partitive and total case-markers on object arguments also encode aspectual information, so the entire aspectual feature value set of an Estonian sentence comes from three main sources via unification: verbs, aspectual particles and partitive/total case markers.[26]

3.3 Concluding remarks

At the end of Section 3 we can make the following concluding remarks.

Hungarian VM phenomena are relevant from both cross-theoretical and LFG-specific perspectives in two important respects.

First, the focus-VM complementarity is a general generative theoretical issue. As the foregoing discussion shows, LFG provides a flexible formal platform even for alternative analyses significantly different in nature, which may be due to partially different views of the relevant components of the architecture of LFG.

Second, the behaviour of Hungarian PVCs, representing the major class of VMs, is of great importance in the realm of complex predicates across typologically different languages, see Alsina et al. (1997) in general and Ackerman & Lesourd (1997) in that volume, in particular. The mixed lexical-morphological and syntactic properties of compositional and productive as well as non-compositional and unproductive PVCs pose a substantial challenge for both syntactically and lexically oriented generative theories, including LFG. From their entirely lexicalist perspective, Ackerman et al. (2011) give a taxonomic overview of a variety of approaches to complex predicates in LFG and HPSG. They point out that the classical models of the two theories rejected argument-structure-changing operations in the syntax, including complex predicate formation: see Bresnan (1982) and Pollard & Sag (1987). However, some more recent views in both theories admit syntactic complex predicate formation: see Alsina (1992, 1997), Butt (2003)

---

[26] On the aspectual interaction of various verb types and partitive/total case in Estonian, see the discussion of Tamm's (2006) analyses in Section 6.2.

and Müller (2006). By contrast, Ackerman et al. (2011), in their Realization-Based Lexicalism (RBL) model, reject complex predicate formation in the syntax, and, as a trade-off, they admit analytic, i.e. multiple-word, forms of predicates in their lexicon as a marked option. As regards the treatment of Hungarian PVCs, Ackerman (2003) develops an RBL analysis. Forst et al. (2010), Laczkó & Rákosi (2011), Rákosi & Laczkó (2011) and Laczkó & Rákosi (2013), in their LFG-XLE framework, handle the productive types in the syntax by means of the RESTRICTION operator. By contrast, Laczkó (2013a), in the same framework, argues that both productive and unproductive PVCs need a lexical treatment.

As regards Estonian, Tamm's (2004c) analysis has demonstrated that LFG also provides an appropriate formal apparatus for capturing the interplay of discourse functionality and the complex, multidimensional aspectuality system of this language.

4 Negation in Hungarian

Miestamo et al. (2015) discuss negation in Uralic in a comprehensive and systematically comparative fashion.[27] They show that 17 Uralic languages employ negative auxiliaries. Hungarian, Khanty, Mansi and Estonian are exceptions in that they have no such auxiliaries. Of all these languages, we are only aware of a few LFG analyses of negation in Hungarian (most of them being rather sketchy and covering only some aspects of negation phenomena).

Laczkó (2014c) develops the first comprehensive LFG-XLE approach to the following six major types of clausal (aka predicate) and constituent negation in Hungarian: (i) ordinary constituent negation (the negated constituent is focused); (ii) universal quantifier negation without (another) focused element (= ordinary constituent negation, i.e. the negated universal quantifier is focused); (iii) universal quantifier negation with focus (= there is a preverbal focused constituent following the negated universal quantifier); (iv) predicate negation, without focus, the negative particle precedes the verb; (v) predicate negation, with focus, the negative particle precedes the verb; (vi) predicate negation, with focus, the negative particle precedes the focus.[28] He proposes the following structural analysis.[29]

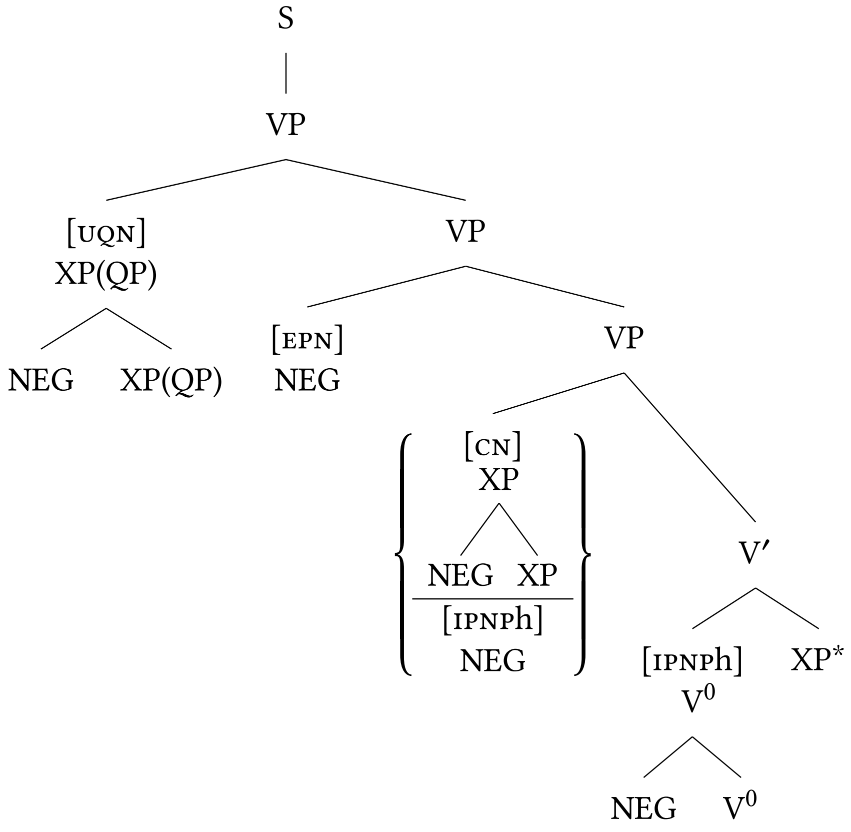
---

[27] There is a publicly accessible database on negation in Ob-Ugric and Samoyedic languages at https://www.univie.ac.at/negation/index-en.html.

[28] Payne & Chisarik (2000), in their OT-LFG framework, also sketch an analysis of some of these types. For a critical overview, see Laczkó (2014c).

[29] In (16) NEG stands fo the (category of the) negative particle and the abbreviations in square brackets indicate the types of negation: [UQN] = universal quantifier negation, [EPN] = (VP-)external predicate negation, [CN] = constituent negation, [IPNPh] = (VP-)internal predicate negation, phrasal adjunction, [IPNH] = (VP-)internal predicate negation, head-adjunction. The curly brackets signal the complementarity of [CN] and [IPNPh].

(16)



In XLE grammars three devices are used for the encoding of negation: (i) the negative morpheme (whether bound or free) can be represented as a member of the ADJUNCT set; (ii) it can encode the [NEG +] feature value; (iii) it can encode the [POL NEG] feature value. Laczkó (2015) points out that these devices are not used uniformly or consistently across the XLE grammars of various languages. He makes the following proposal. Type (i) is most appropriate when a language uses a free morpheme for the expression of negation, a negative particle. Type (ii) is best for bound negative morphemes. Type (iii) is most natural for encoding the scope of negation. In this proposed system, he develops an LFG-XLE analysis of Hungarian negative concord items.

In Laczkó's (2014c) approach negated constituents also occupy the Spec,VP position, see [CN] in (16). In addition, in the case of clause negation, the negative particle is also assumed to be in Spec,VP when there is no focused constituent there, see [IPNPh]. In his rules, Laczkó assumes that the negative particle has the category NEG, and he uses a special XLE-style phrasal categorial label for negated constituents: XPneg. His XPneg rule is given in (17).

(17) $$\text{XPneg} \longrightarrow \underset{\downarrow \in (\uparrow \text{ADJ})}{\text{NEG}} \quad \text{XP}$$

On the basis of these assumptions and rules, he adds the following two disjuncts to the disjunction in Spec,VP established so far, handling focused constituents and vms, shown in (8) in Section 3.1.[30]

(18) $$\left\{ \ldots \;\middle|\; \begin{array}{c} \text{XPneg} \\ (\uparrow \text{gf})=\downarrow \\ (\uparrow \text{focus})=\downarrow \end{array} \;\middle|\; \begin{array}{c} \text{NEG} \\ \downarrow \in (\uparrow \text{adj}) \\ (\uparrow \text{focus})=\downarrow \end{array} \right\}$$

As this section has shown, LFG provides an inventory of appropriate formal devices for analyzing complex negation phenomena in languages like Hungarian. At the same time, the treatment of these negation phenomena motivates examining the nature of the relevant formal devices carefully.

5 Copula constructions

5.1 Hungarian

The two major general LFG strategies for the treatment of copula constructions (ccs) across languages are represented by Butt et al. (1999) and Dalrymple et al. (2004). In the former approach, ccs are treated in a uniform manner functionally. The copula is always assumed to be a two-place predicate. It subcategorizes for a subject (subj) argument, which is uncontroversial in any analysis of these constructions, and the other constituent is invariably assigned a special, designated function designed for the second, 'postcopular' argument of the predicate: predlink. As opposed to this approach, in Dalrymple et al.'s (2004) view, the subj & predlink version is just one of the theoretically available options. In addition, they postulate that the copula can be devoid of a pred feature (and, consequently, argument structure) and in this use it only serves as a pure carrier of formal verbal features: tense and agreement. Finally, it can also be used as a one-place 'raising' predicate, associating the xcomp function with its propositional argument and also assigning a non-thematic subj function. When the postcopular constituent has the predlink function, it is closed in the sense that its subject argument is never realized outside this constituent. The xcomp and the predlink types involve two semantic and functional levels (tiers): the copula selects the relevant constituent as an argument. By contrast, when the copula is a mere formative, the two elements are at the same level (tier): the postcopular constituent is the real predicate and the copula only contributes morpho-syntactic features.

---

[30] Based on their prosodic and semantic behaviour, he assumes that both types of negative elements are focused constituents.

In LFG's formal system, they are functional coheads. All this is summarized in Table 2.

Table 2: Three types of copular constructions, Dalrymple et al. (2004)

role of the postcopular constituent		
open		closed
(A) main PRED, the copula is a formative: functional coheads (single-tier)	(B) XCOMP of the copula main PRED: 'be⟨(↑ XCOMP)⟩(↑ SUBJ)' (double-tier)	(C) PREDLINK of the copula main PRED: 'be⟨(↑ SUBJ)(↑ PREDLINK)⟩' (double-tier)

As regards the treatment of copula constructions, Laczkó (2012) develops the first comprehensive LFG analysis of the following five most important types of CCS in Hungarian: (i) attribution or classification; (ii) identity; (iii) location; (iv) existence; (v) possession. He subscribes to the view, advocated by Dalrymple et al. (2004) and also by Nordlinger & Sadler (2007), among others, that the best LFG strategy is to examine all CCS individually, and to allow for diversity and systematic variation both in c-structure and in f-structure representations across and even within languages. This means that he rejects Butt et al.'s (1999) and Attia's (2008) uniform PREDLINK approach at the f-structure level. Table 3 summarizes the most important aspects of his analysis.[31]

Here we can only highlight the most crucial ingredients of this approach, concentrating on the 'copula's function' and 'argument structure' columns in the table. In the attribution/classification type the copula has no PRED feature and, thus, no argument structure, cf. column (A) in Table 2. The versions of the copula in all the other four CC types are two-place predicates. In the identity and possession types the second argument is assumed to have the PREDLINK function, cf. column (C) in Table 2, while in the location and existence CCS it bears the OBL_{LOC} function, which is a variant of the closed type of postcopular constituents in column (C) in Table 2. Thus, in Laczkó's (2012) analysis the copula has five dis-

---

[31] The following abbreviations are used in Table 3: COP = copula, ATTR/CLASS = attribution/classification, PR3: COP = is the copula present in the present tense and 3rd person paradigmatic slots? PR3: NEG = how is negation expressed in PR3? VM = which element (if any) occupies the VM position in neutral sentences? S = SUBJ, PL = PREDLINK, interch = the two arguments' grammatical functions are interchangeable in the 3rd person, spec = specific, def = definite, FOC = FOCUS, agr = agreement.

Table 3: Laczkó's (2012) analysis of Hungarian copula constructions

CC TYPE	PR3		COPULA'S	ARGUMENT		OTHER
	COP	NEG	FUNCTION	STRUCTURE	VM	TRAITS
ATTR/CLASS	-	*nem*	formative	-	AP/NP	NP: -spec
IDENTITY	-	*nem*	predicate	<S, PL>	SUBJ	S: +spec, interch.
LOCATION	+	*nincs*	predicate	<S, OBL>	OBL	S: +spec
EXISTENCE	+	*nincs*	predicate	<S, (OBL)>	-	S: -spec COP: FOC
POSSESSION	+	*nincs*	predicate	<S, PL>	-	S: -def S&PL agr. COP: FOC

tinct lexical forms, which encode their respective sets of properties indicated in Table 3.

5.2 Inari Saami and Finnish

Toivonen (2007) analyzes subject-verb agreement phenomena in Inari Saami with a brief comparison with the corresponding Finnish phenomena, see Section 7.1.1. In her general approach, she also proposes an LMT (Lexical Mapping Theory: Findlay et al. 2023 [this volume]) analysis of Inari Saami possessive constructions, again with a brief comparison with the Finnish counterparts. The empirical generalizations that she starts with, and which are relevant here, are as follows. (i) The possessed item is the subject. (ii) The possessed item bears nominative case. (iii) The possessor bears locative case. Consider one of her examples in (19), illustrating these facts.

(19) Inari Saami:
Muste lah tun.
I.LOC are.2SG you.NOM.SG
'I have you.'

Toivonen assumes that the Inari Saami copula in this function is a two-place predicate with a theme (possessum) argument and a location (possessor) argument that receive the [$-r$] and the [$-o$] intrinsic specifications, respectively, and they are mapped onto SUBJ and OBL, respectively: see (20).

(20)

$$\begin{array}{llccl} & & \text{theme} & \text{location} & \\ \textit{le}\delta\textit{e} & \langle & \text{x} & \text{y} & \rangle \\ & & [-r] & [-o] & \\ & & | & | & \\ & & \textsc{subj} & \textsc{obl} & \end{array}$$

Toivonen compares Inari Saami and Finnish possessive constructions. For her comparison from the perspective of agreement, see Section 7.1.1. Here we concentrate on the GFs of the arguments of the possessive copulas of the two languages. Compare Toivonen's Inari Saami example in (19) above with her corresponding Finnish example in (21).

(21) Finnish:

Minulla	on	sinut.
I.ADE	is.3SG	you.ACC.SG

'I have you.'

She makes the following generalizations about Finnish possession CCs. The possessum is either in nominative case (ordinary noun phrases) or in accusative case, see (21), and it has the OBJ function. The possessor is an oblique case-marked noun phrase, and it has the SUBJ function.

These two sections have shown that the behaviour of copula constructions in Hungarian, Inari Saami and Finnish exhibits remarkable variation, especially in the case of possession CCs. We can make the following concluding observations. On the one hand, the LFG framework, in this case, too, provides appropriate formal tools for feasible analyses of these construction types. On the other hand, the complexity of these phenomena can be used to argue for particular approaches in the inventory of LFG's alternative formal devices in this particular domain.

6 Aspects of argument realization

6.1 Finnish

Pylkkänen (1997) develops an event-structure-based linking approach to Finnish causatives. She claims that her theory is minimalistic in two respects. On the one hand, in formalizing the relationship between event participants it minimizes reference to the thematic role properties of these participants (e.g. agent, theme and cause) by referring to events themselves. The basic assumption is that if one eventuality causes another then the participants of the former always rank higher than those of the latter. On the other hand, an adequately developed system of inferring prominence relations obviates the need for argument structure, the level of representation mediating between event structure and grammatical functions. Pylkkänen's system of inferring prominence from lexical semantic representations capitalizes on the following two assumptions proposed by Parsons (1990): (i) thematic roles are relations between events and individuals; (ii) causation is a relation between events. As a consequence, the thematic hierarchy is treated as applying at the level of individual events and not at the level of predicates. From this it follows that a predicate can have more than one thematic hierarchy: as many thematic hierarchies as events. All participants can be organized into a prominence hierarchy by ranking the individual thematic hierarchies with respect to each other. This ranking is regulated by Parsons' second assumption: the causal relations between events. In essence, if E1 CAUSES E2, then $\text{E1}_{\Theta\text{H}}$ (the thematic hierarchy of E1) is ranked higher than $\text{E2}_{\Theta\text{H}}$ (the thematic hierarchy of E2). Consider Pylkkänen's two hierarchies in (22) and (23).

(22) Thematic Hierarchy: agent/experiencer > other > theme

(23) Event Hierarchy: cause(e1,e2) → $\text{E1}_{\Theta\text{H}} > \text{E2}_{\Theta\text{H}}$

Then linking constraints provide the mapping between the prominence hierarchy resulting from (22) and (23) and the following grammatical function hierarchy.

(24) $\text{SUBJ} > \text{OBJ} > \text{OBJ}_{\theta} > \text{OBL}$

In order for the linking constraints to be unifiable, Pylkkänen converts Parsons' logical forms into attribute-value matrices. Consider her f-structure and event structure representation of (25), one of her examples, in (26).

(25) Finnish:
Matti kävel-yttä-ä koiraa.
Matti.NOM walk-CAUS-3SG dog.PAR
'Matti walks the dog.'

In the event structure there are ranked participants. IND means 'index', which is a 'pointer' to an event participant, and RANK indicates the prominence of the participant concerned. In the case of (25), the RANK1 participant is realized as the subject, while the RANK2 and RANK3 participants are realized as the object.

(26)
$$\left[\begin{array}{ll}
\textsc{f-str} & \left[\begin{array}{ll} \textsc{subj} & \left[\begin{array}{ll}\textsc{pred} & \textsc{matti}\\ \textsc{case} & \textsc{nom}\end{array}\right] \\ \textsc{obj} & \left[\begin{array}{ll}\textsc{pred} & \textsc{dog}\\ \textsc{case} & \textsc{par}\end{array}\right]\end{array}\right]\\
\textsc{eventstr} & \left[\begin{array}{ll} \textsc{e1} & \left[\begin{array}{ll} \theta\textsc{\_rels} & \left[\begin{array}{ll}\textsc{agent} & \left[\begin{array}{ll}\textsc{ind} & \textsc{matti}\\ \textsc{rank} & 1\end{array}\right]\\ \textsc{theme} & \left[\begin{array}{ll}\textsc{ind} & \textsc{dog}\\ \textsc{rank} & 3\end{array}\right]\end{array}\right]\end{array}\right]\\

\textsc{rel} & \textsc{cause}(\textsc{e1},\textsc{e2})\end{array}\right]
\end{array}\right]$$

6.2 Estonian

Tamm (2006) develops an LFG analysis of the interaction of transitive telic verbs and aspectual case in Estonian. In this language the objects of telic verbs can bear either partitive (PAR) case or total (TOT) case. The choice between partitive and total is regulated by the aspectual features of the sentence, compare Tamm's examples in (27) and (28).[32]

(27) Estonian:
Mari kirjutas raamatu ühe aastaga.
Mari.NOM write.PST.3SG book.TOT one.GEN year.COM
'Mari wrote a/the book in a year.'

(28) Estonian:
Mari kirjutas raamatut terve aasta.
Mari.NOM write.PST.3SG book.PAR whole.TOT year.TOT
'Mari was writing a/the book for a whole year.'

Tamm shows that the sentence in (27), with its object in total case, has a perfective interpretation, and the sentence in (28), with its object in partitive case, is imperfective, as is supported by the types of the adjuncts in them: 'in a year' vs. 'for a year'. In addition, Tamm shows that Vendlerian achievement verbs like

---

[32] The lexical entries for the Estonian case-markers encoding aspectual features are modeled as semantic (Butt & King 2004) and constructive cases (Nordlinger & Sadler 2004), and they provide the formal tools for Tamm's analysis. On the terminology of Finnic core cases, see Tamm (2011a, 2012c). On partitives in Finnish, see Vainikka & Maling (1996).

võitma ‘defeat’ are compatible with objects in partitive case in Estonian, although the sentences they occur in are perfective by default, see her example in (29).

(29) Estonian:
Mari võitis Jürit.
Mari.NOM defeat.PST.3SG George.PAR
‘Mary defeated George.’

In her analysis, Tamm introduces the boundedness aspectual feature: B with two values: MIN and MAX. She associates this feature both with the lexical forms of the two transitive verb types seen above and with the lexical representations of case markers in the following way. Her basic generalization is that ‘write’-type verbs are boundable, and ‘defeat’-type verbs are bounded. In the lexical form of the former boundedness is encoded as an existential constraint, while in the lexical form of the latter it is encoded as a defining equation: the B feature has the MIN value, see (30) and (31), respectively.

(30) kirjutama ‘WRITE’… (↑ B)

(31) võitma ‘DEFEAT’… (↑ B) = MIN

As regards case, the total case-marker, attached to an object noun phrase, introduces the MAX value for B, while the partitive case-marker specifies B as ≠MAX. These values are encoded with inside-out function application, see (32) and (33).

(32) *tot* (↑ CASE) = TOT
((OBJ ↑) B) = MAX

(33) *par* (↑ CASE) = PAR
((OBJ ↑) B) ≠ MAX

In this system, a ‘write’-type verb requires that the sentence should be marked for boundedness, and its underspecified B feature admits either of the two object cases. For instance, Tamm gives the following lexical representations for the verb and the object in (27).

(34) *kirjutas* V (↑ PRED) = ‘WRITE⟨(↑ SUBJ)(↑ OBJ)⟩’
(↑ TENSE) = PST
(↑ PERS) = 3
(↑ NUM) = SG
(↑ B)

(35) *raamatu* N (↑ PRED) = ‘BOOK’
(↑ CASE) = TOT
((OBJ ↑) B) = MAX

On the basis of this, her f-structure representation of (27) is as follows.

(36)
$$\left[\begin{array}{ll} \text{PRED} & \text{‘WRITE}\langle\text{SUBJ, OBJ}\rangle\text{’} \\ \text{B} & \text{MAX} \\ \text{TNS} & \text{PST} \\ \text{NUM} & \text{SG} \\ \text{PERS} & 3 \\ \text{SUBJ} & \left[\begin{array}{ll} \text{PRED} & \text{‘Mari’} \\ \text{CASE} & \text{NOM} \\ \ldots & \end{array}\right] \\ \text{OBJ} & \left[\begin{array}{ll} \text{PRED} & \text{‘BOOK’} \\ \text{CASE} & \text{TOT} \\ \text{NUM} & \text{SG} \\ \ldots & \end{array}\right] \end{array}\right]$$

Obviously, the f-structure representation of (28) would be different from (36) in one important respect: the value of B would be ≠MAX on the basis of (33).

By contrast, the value of the B feature of a ‘defeat’-type verb is MIN, which only allows compatibility with an object in partitive case, given that total case encodes the opposite value: MAX. Tamm offers the following lexical representations for the verb and the object in (29), and she points out that there is no value clash with respect to the B feature.

(37) *võitis* V (↑ PRED) = ‘DEFEAT⟨(↑ SUBJ) (↑ OBJ)⟩’
(↑ TNS) = PST
(↑ PERS) = 3
(↑ NUM) = SG
(↑ B) = MIN

(38) *Jürit* N (↑ PRED) = ‘George’
(↑ CASE) = PAR
((OBJ ↑) B) ≠ MAX

As another argument-realization topic, Torn (2006) discusses the status of certain non-core arguments and adjuncts of verbal predicates in Estonian. She points out that fundamentally there are two approaches to these constituents. One of them regards non-core arguments as oblique case-marked indirect objects, separating them from adjuncts, while the other lumps the two groups together as adverbials. Torn subscribes to the first approach.

By way of illustration, Torn shows that in this language participants of an event that are indirectly affected are realized by noun phrases bearing the same 'local' case suffixes as are used to express spatial adverbial dependents: see her examples in (39) and (40).

(39) Adverbial allative, Estonian:
Mees istus diivanile.
man.NOM sat sofa.ALL
'A man sat onto the sofa.'

(40) Oblique allative, Estonian:
Ema andis lapsele raha.
mother.NOM gave child.ALL money.PAR
'The mother gave money to the child.'

Torn says that *diivanile* 'onto the sofa', a noun phrase in allative case, is an ungoverned adverbial constituent in (39), while *lapsele* 'to the child', a noun phrase in allative case here, too, expresses the indirectly affected argument of the ditransitive verb *andma* 'give' in (40). In her terminology, *diivanile* in (39) is an adverbial modifier, and *lapsele* in (40) is an object adverbial.

Torn offers the following three arguments for distinguishing object adverbials from adverbial modifiers. (i) A verbal predicate selects a particular governed case for its object adverbial and not a semantically compatible set of cases. (ii) An object adverbial constituent can serve as an antecedent in an obligatory control construction. (iii) It is a functional similarity between object adverbials on the one hand, and subjects and objects on the other, that they can be involved in systematic case alternations. Such alternations can never involve adverbial modifiers.

Torn adopts LFG's LMT classification of governable grammatical functions. In this setting, she assumes that locative case-marked noun phrases can have either the OBL or the ADJUNCT function.

7 Morpho-syntactic phenomena

7.1 Agreement

7.1.1 Subject-verb agreement in Inari Saami and Finnish

Toivonen (2007) examines verbal inflectional morphology in Inari Saami. She develops her analysis by concentrating on the Saami copula *leδe* 'to be'. In this language, as in various Northern Uralic languages, the number feature has three possible values: singular, dual and plural. It is another special property of this language that there can be either full agreement or partial agreement between the subject and the verb. Animate and specific subjects trigger the former, see (41), inanimate subjects trigger the latter, see (42).

(41) Inari Saami:
Meecist lava uábbi já viljá.
forest.LOC are.3DU sister.NOM and brother.NOM
'In the forest are my sister and brother.'

(42) Inari Saami:
Riddoost láá kyehti keeδgi.
beach.LOC are.3PL two rock
'On the beach are two rocks.'

Subject noun phrases headed by unspecific human nouns and animal nouns can trigger either full or partial agreement. (43) illustrates the unspecific human case.

(43) Inari Saami:
Táálust lava/láá kyehti ulmuu.
house.LOC are.3DU/are.3PL two person
'There are two people in the house.'

Toivonen presents the paradigms of the copula in this three-way number and dual agreement system as in Table 4. She develops an LFG analysis with fully specified and underspecified lexical forms of verbal predicates. Consider her representations of four morphological forms of the copula in (44–47).

(44) *lava* V (↑ PRED) = 'BE'
(↑ TENSE) = PRS
(↑ MOOD) = INDICATIVE
(↑ SUBJ NUM) = DU
(↑ SUBJ PERS) = 3
(↑ SUBJ HUM) = +

Table 4: Agreement paradigms for 'to be'

		full	**partial**
SG	1	lam	lii
	2	lah	lii
	3	lii	lii
DU	1	láán	láá
	2	leppee	láá
	3	lava	láá
PL	1	lep	láá
	2	leppeδ	láá
	3	láá	láá

(45) *lam* V (↑ PRED) = 'BE'
(↑ TENSE) = PRS
(↑ MOOD) = INDICATIVE
(↑ SUBJ NUM) = SG
(↑ SUBJ PERS) = 1
(↑ SUBJ HUM) = +

(46) *lii* V (↑ PRED) = 'BE'
(↑ TENSE) = PRS
(↑ MOOD) = INDICATIVE
(↑ SUBJ NUM) = SG

(47) *láá* V (↑ PRED) = 'BE'
(↑ TENSE) = PRS
(↑ MOOD) = INDICATIVE

Toivonen makes crucial use of the principle of morphological blocking as developed by Andrews (1990). The basic idea is that if a subject noun phrase is compatible with more than one verb form, it will select the variant that exhibits the largest number of its own feature values. This explains, for instance, why human subjects do not freely co-occur with *láá* or why singular subjects cannot co-occur with *láá*. The answer to the first question is that *láá* has no [+human] feature, see (47). The answer to the second question is that there are more specific forms of the copula in that they also encode the [+singular] feature, compare (47) with (45) and (46).

Toivonen also briefly compares the Inari Saami agreement system with the corresponding Finnish system. She points out that Finnish has no grammatical dual. In addition, Finnish does not exhibit partial agreement. Furthermore, animacy has not been grammaticalized in standard Finnish. It is another significant difference that in Inari Saami, verb agreement is always triggered by grammatical subjects, while in Finnish several independent conditions need to be simultaneously satisfied for agreement to take place. First, in Finnish, as well as in Estonian,[33] only nominative NPs trigger agreement, compare Toivonen's examples in (48) and (49).

(48) Finnish:
Autot ajavat yleensä kovaa moottoriteillä.
cars.NOM drive.3PL generally hard motorways.ADE
'Cars generally drive fast on the motorways.'

(49) Finnish:
Linja-autoja kulkee nykyisin joka sunnuntai.
buses.PAR run.3SG nowadays every Sunday
'Nowadays, buses run every Sunday.'

In (48) the nominative subject triggers agreement, while in (49) the subject is in partitive case and the verb takes 3SG default agreement.

A Finnish verb also has default agreement in existential and possessive constructions. (50) illustrates the latter type.

(50) Finnish:
Koulussa on uudet opettajat.
school.INE is.3SG new.NOM.PL teachers.NOM
'The school has new teachers.'

In this example, although the (post-verbal) subject is nominative, it is not in its preverbal canonical position; therefore, here, too, the verb displays 3SG default agreement.

As regards their possessive constructions, Inari Saami and Finnish differ in two significant respects. On the one hand, in Inari Saami possessive constructions pronouns are in nominative case, while in Finnish the corresponding pronouns take accusative case, compare (51) and (52). On the other hand, the possessum is always in nominative case in Inari Saami, it has the subject function, and it always triggers agreement, while in Finnish the possessum is either in nominative

---

[33] See Hiietam (2003), for instance.

case (ordinary noun phrases) or in accusative case, and the verb always carries 3sg default agreement, compare (53) and (54).

(51) Inari Saami:
Muste lah tun.
I.loc are.2sg you.nom.sg
'I have you.'

(52) Finnish:
Minulla on / *olen sinut.
I.ade is.3sg / is.1sg you.acc.sg
'I have you.'

(53) Inari Saami:
Muste lava puásui já peenuv.
I.loc are.3du reindeer.nom and dog.nom
'I have a reindeer and a dog.'

(54) Finnish:
Minulla on / *olen poro ja koira.
I.ade is.3sg / is.1sg reindeer.nom and dog.nom
'I have a reindeer and a dog.'

Toivonen makes the following concluding generalization about Finnish possessive constructions. There is no normal agreement in them, because the possessum is not the subject, and because the subject possessor is not in nominative case. This is why 3sg default agreement is employed.

Toivonen offers a comparative overview of the agreement systems of Inari Saami and Finnish shown in Table 5.

7.1.2 Aspects of differential object marking in Uralic

Coppock & Wechsler (2010) point out that there is object agreement in Nenets, Enets, Nganasan and Selkup in the Samoyedic family and in Mordvinian (Finno-Volgaic), Hungarian (Ugric), Ostyak and Vogul (both Ob-Ugric) in the Finno-Ugric family. These languages exhibit remarkable variation with respect to the feature specifications of their object agreement. In Hungarian and Samoyedic there are two conjugation paradigms: subjective and objective, and the latter is used in the case of definite and third person objects. In Ob-Ugric languages there is a subjective conjugation and three objective conjugation paradigms, one

Table 5: Agreement in Inari Saami and Finnish

	Inari Saami	Finnish
Partial agreement	✓	
Default agreement		✓
Animacy effects	✓	
Agreement in possessive construction	✓	
Agreement in existential construction	✓	
Possessed nouns in nominative case	✓	✓
Possessed pronouns in nominative case	✓	

for each possible number value of the object (singular, dual and plural). In Mordvinian there is genuine agreement for both person and number between the verb and the object. Coppock & Wechsler (2010) concentrate on Northern and Eastern Ostyak, Hungarian and Samoyedic.[34]

In Northern Ostyak the verb agrees with its object in number but not in person: see (55) and (56). An additional factor is that the object has to be topical, otherwise the subjective conjugation is used.

(55) Northern Ostyak:
Ma täm kälang wel-sə-l-am.
I this reindeer kill-pst-plObj-1sgSubj
‘I killed these reindeer.’

(56) Northern Ostyak:
Xŭńśi näng mŭng-iluw xäĺśa want-lə-l-an?
when you we-acc where see-prs-plObj-2sgSubj
‘When did you see us where?’

Coppock & Wechsler (2010) postulate the following diachronic analysis of these facts.

At the first stage third person pronouns were incorporated (↓ pred)=‘pro’ and (↓ index pers)=3 with the three number values (↓ index num)=*n*. This was combined with the topicality condition: ($\downarrow_\sigma$ df)=topic.

---

[34] Also see Coppock & Wechsler (2012) on Hungarian.

(57) V_{aff}
(↑ OBJ) = ↓
(↓ PRED) = ‘PRO’
($\downarrow_{\sigma}$ DF) = TOPIC
(↓ INDEX PERS) = 3
(↓ INDEX NUM) = *N* where *N* ∈ {SG, DU, PL}

At the second stage the PRED ‘pro’ was dropped.

(58) V_{aff}
(↑ OBJ) = ↓
~~(↓ PRED) = ‘PRO’~~
($\downarrow_{\sigma}$ DF) = TOPIC
(↓ INDEX PERS) = 3
(↓ INDEX NUM) = *N* where *N* ∈ {SG, DU, PL}

The authors claim that it is reasonable to assume that at this stage person specification was present because Eastern Ostyak still manifests this stage.

At the third stage the person specification was lost in Northern Ostyak, see (59), but this did not happen in Eastern Ostyak.

(59) V_{aff}
(↑ OBJ) = ↓
~~(↓ PRED) = ‘PRO’~~
($\downarrow_{\sigma}$ DF) = TOPIC
~~(↓ INDEX PERS) = 3~~
(↓ INDEX NUM) = *N* where *N* ∈ {SG, DU, PL}

As a result, these objective conjugation suffixes became usable with first and second person objects, too.

Coppock & Wechsler (2010) also show that Hungarian has two conjugations that are conditioned by the definiteness of the object by using the following examples. The general pattern is that definite objects trigger the objective agreement type, see (60), and indefinite objects require the subjective type, see (61).

(60) Hungarian:
Lát-om a madar-at.
see-PRS.1SG.DEF the bird-ACC
‘I see the bird.’

(61) Hungarian:
Lát-ok egy madar-at.
see-PRS.1SG.INDF a bird-ACC
‘I see a bird.’

In addition, the objective agreement type is sensitive to the person feature of the object: in the pronominal domain only third person pronouns trigger it, see (62), while first and second person pronouns require the subjective conjugation, see (63). Coppock & Wechsler (2010) refer to this as the third person restriction in this language.

(62) Hungarian:
Lát-ják őt/őket.
see-prs.3pl.def it/them
'They see it/them.'

(63) Hungarian:
Lát-nak engem/téged/minket.
see-prs.3pl.indf me/you/us
'They see me/you/us.'

It is another property of the Hungarian object agreement system that it is not sensitive to the number value of the object.

Coppock & Wechsler (2010) propose the following diachronic analysis. At the first stage, just like in the case of Northern and Eastern Ostyak, third person pronoun incorporation took place, see (57) above. The second stage was also the same: the pred 'pro' was dropped and the topicality condition retained, see (58). This is the present-day Eastern Ostyak system. At the third stage the number constraint was dropped, but the person restriction was retained, see (64) and compare it with (59) characterizing Northern Ostyak.

(64) V_{aff} (↑ obj) = ↓
~~(↓ pred) = 'pro'~~
($\downarrow_\sigma$ df) = topic
(↓ index pers) = 3
~~(↓ index num) = *n* where *n* ∈ {sg, du, pl}~~

Finally, at the fourth stage the topicality constraint was reanalyzed as a definiteness constraint, see (65).

(65) V_{aff} (↑ obj) = ↓
~~(↓ pred) = 'pro'~~
~~($\downarrow_\sigma$ df) = topic~~ (↑ obj def) $=_c$ +
(↓ index pers) = 3
~~(↓ index num) = *n* where *n* ∈ {sg, du, pl}~~

Dalrymple & Nikolaeva (2011) investigate differential object marking (DOM) by exploring syntactic, semantic and informational structural differences between marked and unmarked objects in a wide range of genetically and typologically different languages. As regards Uralic, they concentrate on Tundra Nenets in the Samoyedic subfamily and on Ostyak (Khanty), Vogul (Mansi) and Hungarian in the Finno-Ugric subfamily.[35]

Dalrymple & Nikolaeva (2011) develop a formal theory of information structure and its place in the architecture of LFG. In this theory information structure is closely related to semantic structure. It is a favourable aspect of this approach that it makes possible a simple specification of the informational structural status of an argument by providing a DF feature value in its semantic structure.

In Tundra Nenets there is only a single object function: OBJ. First and second person (pronominal) objects do not agree with the verb, just like in Hungarian, see (63) above. Third person objects optionally agree with the verb. If there is agreement, the object has the TOPIC DF, while no such function is associated with it in the absence of agreement. Dalrymple & Nikolaeva (2011) model this in the following way.

(66) Agreement with third person topical objects:

$(\uparrow \textsc{obj pers}) = 3$
$((\uparrow \textsc{obj})_\sigma\ \textsc{df}) = \textsc{topic}$

This specification encodes that the semantic structure contributed by the third person object is associated with the topic role in information structure.

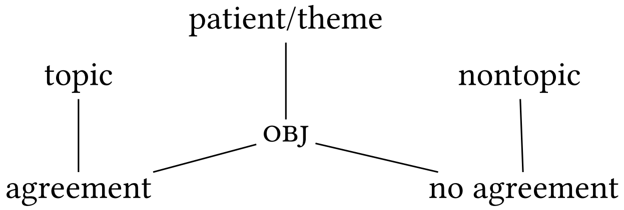
Dalrymple & Nikolaeva (2011) also distinguish a language type in which there are two object functions: OBJ and $\textsc{obj}_\theta$. They claim that Ostyak belongs to this type, in addition to Mongolian, Chatino and Hindi, among others. The $\textsc{obj}_\theta$ function in these languages is only available to patient/theme arguments. Dalrymple & Nikolaeva (2011) make the following empirical generalizations. Although Ostyak has two object functions, they cannot co-occur in a sentence, because this language does not have a double object construction. In the case of verbs such as ‘give’ there are the following two possibilities: either the goal or the theme must have an OBL function. When the goal has a dative oblique function, the theme has two object choices. If it is topical, it has the agreeing OBJ function, and if it is not topical, it has the non-agreeing $\textsc{obj}_{\textsc{theme}}$ function.

Dalrymple & Nikolaeva (2011) compare the Nenets type and the Ostyak type of DOM in the following way.

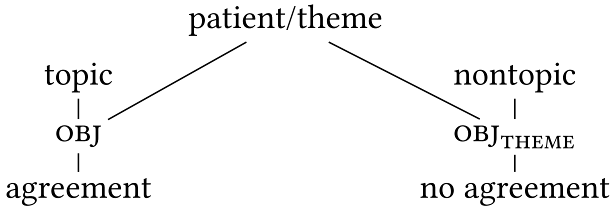
---

[35] On aspectual DOM in Estonian, see the discussion of Tamm (2006) in Section 6.2.

(67) Nenets monotransitives with third person objects:



(68) Ostyak monotransitives with patient/theme objects:



Dalrymple & Nikolaeva (2011) also point out that in the Ob-Ugric branch of Finno-Ugric languages Vogul follows the same DOM pattern as Ostyak: object marking is information structure driven: topicalization by means of object agreement. The authors hypothesize that this also held for Proto-Ob-Ugric. There are no attested semantic restrictions on agreeing objects in Ob-Ugric. As shown above, object agreement works differently in Hungarian. First and second person pronouns never trigger agreement, just like in Tundra Nenets, see above. Third person object agreement is not regulated by information structure: it is triggered by definiteness. It is only definite third person objects that trigger agreement irrespective of their discourse function status.

The authors suggest that earlier Hungarian was closer to Ostyak and Vogul, and in modern Hungarian definiteness marking is an innovation, after the development of the grammatical category of definiteness and the appearance of grammatical articles. Their reconstruction of the relevant linguistic historical processes is as follows. They assume that the Ob-Ugric system of DOM, which is exclusively based on information structure, is the most archaic type, and probably it can be hypothesized for Proto-Eastern-Uralic, i.e. the Proto-Uralic dialects from which the Samoyedic and Ugric languages developed. At a later stage, agreement became reduced to third person topical objects in Samoyedic and Proto-Hungarian as a consequence of the fact that third person was frequently associated with secondary topicality. By contrast, first and second person pronouns occupy the highest position on a scale of topic-worthiness. Dalrymple & Nikolaeva (2011) suggest that the Samoyedic languages (Nenets, Selkup and Nganasan) and Old Hungarian grammaticalized the tendency that first and second person pronouns are likely primary topics and unlikely secondary topics. Thus, they cannot correspond to the primary object, given that in these languages it tends to be strongly associated with secondary topic. No such restrictions hold for third person objects. Hungarian and (possibly) Selkup represent the next historical stage, at which the grammatical marking of third person topical objects is extended to non-topical definite objects. According to Dalrymple & Nikolaeva (2011) this change manifests the spreading of grammatical marking to non-topical objects that exhibit topic-worthy features with the concomitant loss of relatedness to information structure.[36]

This section on DOM has shown how complex these phenomena are in Uralic languages in general and in Finno-Ugric languages in particular. It has also demonstrated that LFG's well-developed modular architecture provides the necessary and appropriate formal devices to capture both the synchronic differences between languages and the diachronic processes in a principled manner.

7.2 Evidentiality

Asudeh & Toivonen (2017) propose a modular LFG approach to evidentiality, which is a well-established morpho-syntactic category in a considerable number of languages, for instance, Tariana, Cherokee, Cheyenne, Quechua and Tuyuca. These languages employ fully grammaticalized evidentiality morphology, which encodes the source and reliability of speakers' knowledge. Other languages, e.g. English, do not have such evidentiality marking, and they use alternative means to express sources of evidence or degrees of certainty about evidence (*apparently, I saw that…*, etc.). For the description of grammaticalized evidentiality they use the following f-structure features: [DIRECT ±], [VISUAL ±], [REPORTED ±], which also express semantic content to be captured as modifiers on events in Glue Semantics. In languages like English (with non-grammaticalized evidentiality) predicates like *sound* and *seem* optionally encode evidentiality information for the semantic component of the theory. The authors argue that LFG's modular architecture is especially well-suited to capturing the systematic similarities and

---

[36] Dalrymple & Nikolaeva make the following footnote comment. 'An alternative explanation was recently suggested by Coppock & Wechsler (2010), who claim that object agreement in proto-Uralic was initially restricted to third person topical objects. It later spread to all topical objects in Northern Ostyak and Vogul, whereas Samoyedic languages preserve the original situation. This suggestion provides an elegant analysis of feature loss as a mechanism of historical change: Northern Ostyak lost the specification that restricted topical agreement to third person objects (the (↑ OBJ PERS)=3 specification for agreeing verbs). However, the causal mechanism of this development remains unclear: it presupposes the spread of marking to unlikely contexts' (Dalrymple & Nikolaeva 2011: 201).

differences between grammaticalized and non-grammaticalized ways of expressing evidentiality across languages.

Szabó (2021) points out that in the family of Uralic languages both evidentiality systems can be found. For instance, the Finnic, the Saamic and the Mordvinian languages and Hungarian do not have grammaticalized evidentiality. By contrast, Estonian, Livonian, Mari, Komi, Udmurt as well as the entire Ob-Ugric and Samoyedic branches employ grammaticalized evidentiality.

Szabó (2021) sketches an LFG approach to grammaticalized evidentiality in Udmurt. She shows that there are two past tense paradigms in this language, and the 2^{nd} past is used to express the source of information, among other aspects of morpho-syntax. Therefore, this verb form is multiply ambiguous. Szabó (2021: 82) captures this by proposing that the 2^{nd} past contributes the following attribute-value pair to the f-structure of a sentence.[37]

(69) $\left[\textsc{source}\ \ \textsc{res} \vee \textsc{pfv} \vee \textsc{hear} \vee \textsc{folk} \vee \textsc{mir} \vee \textsc{infer} \vee \textsc{non-v}\right]$

As (69) shows, in this domain the f-structure is multiply ambiguous with all these disjunctive values for SOURCE, and the assumption is that it is basically the context that disambiguates.

Tamm (2008) shows that in Estonian partitive case-marking has either epistemic modality or aspectual use. In the former, it encodes incomplete evidence (cf. grammaticalized evidentiality marking), and in the latter, it presents an event as incomplete. The lack of partitive-marking indicates complete evidence and complete event, respectively. In this language both verbs and object arguments can be marked for partitive. Tamm proposes the lexical form in (70) for the aspectual partitive case marker on the object, and the lexical forms in (71) and (72) for the impersonal and personal evidentiality markers on verbs, respectively.

(70) (↑ CASE) = PARTITIVE
((OBJ ↑) EVENT) ≠ COMPLETE

(71) *[-ta-vat]* (↑ FORM) = PARTITIVE EVIDENTIAL
(↑ MODE OF COMMUNICATION) = INDIRECT
(↑ EVIDENCE) ≠ COMPLETE
(↑ VOICE) = IMPERSONAL

8 Noun phrase phenomena in Hungarian

8.1 C-structure issues

As we show below, Hungarian noun phrases have been analyzed as either NPs or DPs in LFG approaches. Both views are fully legitimate in this framework, given that the standard LFG inventory of functional categories contains D (in addition to I and C).[38] It is a crucial property of possessive noun phrases in this language that the possessor can be expressed in either nominative or dative case, and the two variants occupy distinct syntactic positions. Despite this fact, only one of them can occur in any single possessive noun phrase, that is they are in complementary distribution, as opposed to the possible co-occurrence of *'s* and *of* possessors in English.

Chisarik & Payne (2003: 189) use an NP approach to the representation of Hungarian and English noun phrases, see the structures they assume for (73) and (75)[39] in (74) and (76), respectively.

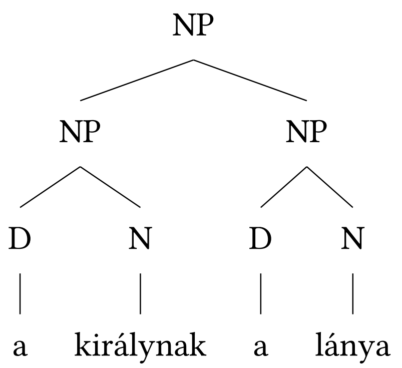
(73) Hungarian:
a király-nak a lány-a
the king-DAT the daughter-POSS.3SG
'the king's daughter'

---

[38] It is not unusual to find alternative categorial analyses of the same construction types in LFG. For instance Bresnan (2001) treats finite English sentences that contain no auxiliaries (e.g. *Mary opened the door*) as having the category S, while Dalrymple (2001) employs an IP approach.

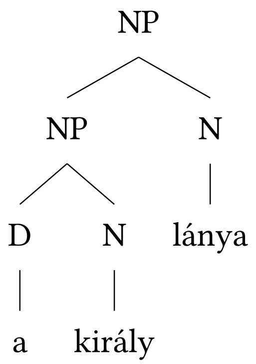
[39] Notice that Hungarian possessive noun phrases belong to the head-marking type.

(74)



(75) Hungarian:
a king lány-a
the king.NOM daughter-POSS.3SG
'the king's daughter'

(76)



They provide the following justifications for these representations. On the one hand, the dative possessor, see (74), can function as a predeterminer to coordinated NPs as in their example in (77).

(77) Hungarian:
a király-nak [$_{\text{NP}}$ [a fi-a] és [a lány-a]]
the king-DAT the son-POSS.3SG and the daughter-POSS.3SG
'the king's son and daughter'

On the other hand, the nominative possessor stands in complementary distribution with the definite article, just like the *'s* possessor in English.

The following remarks can be made on this approach. First, the coordination facts can also be captured in a DP analysis in which the dative possessor is in Spec,DP and Chisarik and Payne's NP is a D′, where the definite article is the

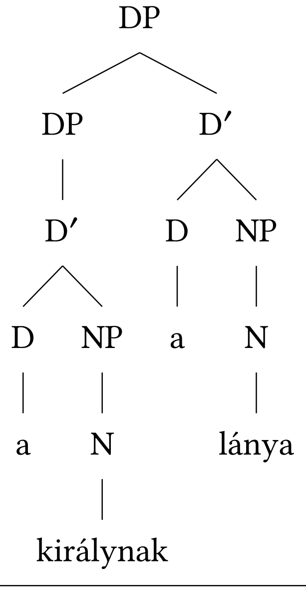
D head and the other constituent is (the head of) an NP.[40] Second, it would need some justification to assume that a word-level functional category (D) is in complementary distribution with a phrasal category (NP).[41] Third, in the case of pronominal nominative possessors there is no complementary distribution with the definite article; moreover, they must co-occur, compare (78) and (79).[42]

(78) Hungarian:
(*a) János lány-a
the John.NOM daughter-POSS.3SG
'John's daughter'

(79) Hungarian:
*(az) ő lány-a
the he.NOM daughter-POSS.3SG
'his daughter'

Motivated by Szabolcsi's (1994) seminal GB analysis, Laczkó in Laczkó (1995) and all subsequent work adapts a DP approach.[43] The essential aspects of his structural representation of (73) and (75) would be as in (80) and (81), respectively.

(80)



---

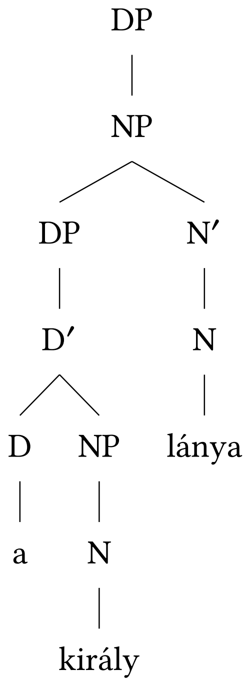
[40] See Laczkó's (1995) DP structure in (80) below.

[41] It seems to be a further minor complication that the functional category D is used in an unusual way: it does not head and project a DP.

[42] (78) shows the grammaticality properties of this construction type in standard Hungarian. However, Szabolcsi (1994) documents a dialectal version in which even such non-pronominal nominative possessor constructions follow the pattern exemplified in (79).

[43] Without adopting theory-specific details like moving the nominative possessor from Spec,NP to Spec,DP, where it acquires dative case, as in Szabolcsi's (1994) GB analysis.

(81)



This approach avoids the complications mentioned in connection with Chisarik & Payne's (2003) NP analysis.

8.2 Event nominalization

8.2.1 Argument structure inheritance

Following Grimshaw (1990) and Szabolcsi (1994), among others, Laczkó in Laczkó (1995) and in all relevant subsequent work assumes that complex event nominals (cens) derived by the *-ás/-és* suffix (henceforth: ás suffix) inherit the argument structure of the input verb, as opposed to simple event nouns (sens) and result nouns (reses). The most important properties of Hungarian cens are as follows; see also Laczkó (2000b, 2003, 2009a).

When an ás noun has both a simplex form and a complex form containing a perfectivizing preverb, the latter is always a cen and the former is very often ambiguous: cen vs. sen and/or res. Compare the examples in (82).

(82) Hungarian:

a. Anna vizsgáztat-ás-a
Anne.nom examine-ás-poss.3sg
'Anne's examination'
cen: Anne = patient
sen: Anne = examiner or examinee

b. Anna le-vizsgáztat-ás-a (a professzor által)
Anne.NOM PFV-examine-ÁS-POSS.3SG the professor by
'the examination of Anne (by the professor)'
CEN: Anne = patient

c. Anna vizsgá-ja
Anne.NOM exam-POSS.3SG
'Anne's exam'
SEN: Anne = examiner or examinee

(82a) contains a derived nominal without a perfectivizing preverb, and it can be used as either a CEN with an argument structure or as a SEN without an argument structure (with only a lexical conceptual structure). In the former use *Anna* is interpreted as the patient argument of the nominal predicate, in the latter use it is interpreted as a participant in an examination situation, whether the examiner or the examinee. By contrast, in (82b) the derived nominal contains a perfectivizing preverb, and it can only be analysed as a CEN with obligatory argument structure and *Anna* must be interpreted as the patient argument. In (82c) the head is an underived noun and it can only be a SEN.

The expression of the arguments of the derived nominal predicate is as obligatory as in the case of the input verb.

(83) Hungarian:
A vizsgáztat-ás két órá-ig tart-ott.
the examine-ÁS-POSS.3SG two hour-for last-PST.3SG
'The examination lasted for two hours.' (SEN)

(84) Hungarian:
*A le-vizsgáztat-ás két órá-ig tart-ott.
the PFV-examine-ÁS-POSS.3SG two hour-for last-PST.3SG
'The examination lasted for two hours.' (CEN)

As (83) shows, when no complement is present, an otherwise ambiguous (CEN/SEN) nominal must be interpreted as a SEN. (84) demonstrates that an 'only CEN' nominal cannot occur without its obligatory internal argument(s). The external argument can be suppressed optionally, see (82b) above.

CENs cannot be pluralized, see (85).

(85) Hungarian:
*Anna le-vizsgáztat-ás-a-i
Anne.NOM PFV-examine-ÁS-POSS.3SG-PL
'*the examinations of Anne' (CEN)

When an adjunct in the DP with a derived nominal head is expressed by a postpositional phrase, this PP has to be 'adjectivalized' either by combining it with a formative element, one of the present participial forms of the copula: *való* 'being', glossed as VALÓ, or by attaching the adjectivizing suffix *-i* (glossed as AFF) to the postposition. In such cases, the VALÓ version is only compatible with the CEN reading of an otherwise ambiguous nominal predicate, while the *-i* variant retains the ambiguity, cf. (86a) and (86b). This is Szabolcsi's (1994) famous *való*-test for unambiguously identifying CENS in Hungarian.[44]

(86) Hungarian:

a. az ebéd után való beszélget-és
the lunch after VALÓ converse-ÁS
'conversing after lunch' (CEN)

b. az ebéd után-i beszélget-és
the lunch after-AFF converse-ÁS
'conversing after lunch' (CEN)
'the conversation after lunch' (SEN)

The core arguments of CENS can receive a variety of [−*r*] GFS in several LFG approaches to Hungarian, see Section 8.2.2. Non-core arguments are typically expressed by case-marked DPs and postpositional phrases, and they are mapped onto OBL functions. Adjuncts can also be expressed by case-marked DPs and PPs. In addition, they can be realized by APs, especially when the input verb would take an AdvP for the same kind of modification, e.g. *váratlan-ul* 'unexpectedly' (Adv) vs. *váratlan* 'unexpected' (A). For empirical generalizations about the major (structural and categorial) ways of realizing OBL and ADJUNCT functions in CEN constructions and LFG analyses, see Laczkó (1995, 2003).

The Hungarian event nominalization phenomena presented above are relevant for theorizing in generative grammar in general and in LFG in particular for the following reasons. Grimshaw's (1990) influential proposal substantially distinguishing CENS from SENS and RESES is based on English data, primarily on *-tion* nominalization. In this language, however, these derived nouns are genuinely ambiguous and, therefore, it is often difficult to employ Grimshaw's diagnostics, e.g. (non-)pluralizability, to definitely tell the CEN and SEN uses apart. Due to this fact, Grimshaw's theory has been criticized from a variety theoretical perspectives, see Laczkó (2000b) and the references therein. By contrast, in Hungarian there are clear morphological and syntactic indicators, and the diagnostics can

---

[44] Also see Laczkó & Rákosi (2007).

be applied reliably and unambiguously. This situation has motivated some LFG practitioners to investigate event nominalization thoroughly and, among other things, to develop various LMT analyses of argument realization in this domain, see Section 8.2.2.

8.2.2 Functional issues

A variety of inventories of GFS in Hungarian DPs with CEN heads and a consequential variety of LMT analyses have been proposed, see Table 6.[45]

Table 6: GFS in Hungarian DPs

	Laczkó (1995)	Chisarik & Payne (2003)	Laczkó (2004)
DP_{DAT}	POSS	SUBJ	SUBJ/POSS
DP_{NOM}	POSS	NCOMP	SUBJ/POSS
DP_{OBL}/PP	OBL	OBL	OBL

Laczkó (1995) uses GFS standardly employed in noun phrases (POSS and OBL). Assuming that POSS is a semantically unrestricted function, he develops an LMT approach in which there is a POSS Condition that is the nominal domain counterpart of the SUBJ Condition in the verbal domain. The SUBJ Condition requires that every (verbal) predicator must have a Subject, see Bresnan (1990), for instance. Laczkó's (1995: 85) POSS Condition states: 'every event nominal predicator must have a Possessor'.

Rather exceptionally in the generative literature on Hungarian noun phrases, Chisarik & Payne (2003) assume that the two possessor constituents bear distinct GFS, both of which are taken to be semantically unrestricted. The dative realizes the SUBJ function in the nominal domain, while the nominative expresses a new, DP-specific function: NCOMP. SUBJ is considered to be discourse-related, while NCOMP is not.

Laczkó (2004) assumes that both the dative possessor and the nominative possessor can overtly realize either the SUBJ or the POSS GFS, both of which are regarded as semantically unrestricted. Furthermore, the SUBJ argument can also be expressed by an LFG-style PRO. Given this nature and distribution of these GFS, Laczkó's LMT analysis can adopt the SUBJ Condition from the verbal domain. In addition, his approach can formally handle (anaphoric) control into possessive DPs in Hungarian with the standard LFG mechanism even in the case of CENS

---

[45] Charters (2014) proposes a new DF in Hungarian possessive DPs: ANCHOR.

derived from transitive verbs, which Laczkó's (1995) system cannot do. Consider the following examples.

(87) Hungarian:

a. Péter elkezdte a kiabál-ás-t.
Peter.nom started the shout-Ás-acc
'Peter started the shouting.'

b. Péter elkezdte a dal enekl-és-é-t.
Peter.nom started the song.nom sing-Ás-poss.3sg-acc
'Peter started the singing of the song.'

In Laczkó's (1995) system, the f-structure of the DP in (87a) contains a poss pro, which is anaphorically controlled by the matrix subject, and in (87b) *a dal* 'the song' has the poss function, and (in the absence of any other available gf for the agent controllee) Laczkó is forced to assume that control takes place in a different dimension. By contrast, in Laczkó's (2004) approach there is a controlled pro subj in both cases, and in (87b) *a dal* 'the song' has the poss function. Laczkó's (2004) subj & poss theory receives further independent support from Laczkó & Rákosi (2019), who argue that this gf inventory is necessary for the adequate LFG handling of certain binding facts in Hungarian DPs. Laczkó (2008b, 2009b), in response to Kenesei (2005), proposes that both t participial constructions and cen constructions should have a dual pro & suppression analysis for an adequate treatment of binding and control phenomena.

8.3 Possessives

8.3.1 Finnish

Toivonen (2000) develops an analysis of the morpho-syntax of Finnish possessive noun phrases. This language has the widely attested poss pro-drop in the case of first and second person possessors, see a 1sg example in (88), and Toivonen's lexical representation of the pronoun and the possessive suffix (glossed as poss) in (89) and (90), respectively.

(88) Finnish:
Pekka näkee (minun) ystävä-ni.
Pekka sees my friend-poss.1sg
'Pekka sees my friend.'

(89) *minun:*

$$\left[\begin{array}{ll} \textsc{poss} & \left[\begin{array}{ll} \textsc{pred} & \text{‘}\textsc{pro}\text{’} \\ \textsc{pers} & 1 \\ \textsc{num} & \textsc{sg} \end{array}\right] \end{array}\right]$$

(90) *-ni:*

$$\left[\begin{array}{ll} \textsc{poss} & \left[\begin{array}{ll} (\textsc{pred} & \text{‘}\textsc{pro}\text{’}) \\ \textsc{pers} & 1 \\ \textsc{num} & \textsc{sg} \end{array}\right] \end{array}\right]$$

In the third person there is an interesting split between the possessive pronoun and the possessive suffix when the latter provides the PRED feature (i.e. in the case of pro-drop). The pronoun must not be bound by the matrix subject, while the POSS-PRO must, cf. (91) and (92).

(91) Finnish:
Pekka näkee hänen ystävä-nsä.
Pekka sees his/her friend-POSS.3SG
‘Pekka sees his/her$_{*i/j}$ friend.’

(92) Finnish:
Pekka näkee ystävä-nsä.
Pekka sees friend-POSS.3SG
‘Pekka sees his/her$_{i/*j}$ friend.’

Furthermore, the 3SG.POSS suffix cannot agree with a non-human possessor:

(93) Finnish:
sen ruokaa(*-nsa)
its food-POSS.3SG
‘its food’

Toivonen captures these facts by means of the following lexical forms.[46]

(94) *hänen:*

$$\left[\begin{array}{ll} \textsc{poss} & \left[\begin{array}{ll} \textsc{pred} & \text{‘}\textsc{pro}\text{’} \\ \textsc{pers} & 3 \\ \textsc{gend} & \textsc{hum} \\ \textsc{num} & \textsc{sg} \\ \textsc{sb} & - \end{array}\right] \end{array}\right]$$

(95) *pron. -nsA:*

$$\left[\begin{array}{ll} \textsc{poss} & \left[\begin{array}{ll} \textsc{pred} & \text{‘}\textsc{pro}\text{’} \\ \textsc{pers} & 3 \\ \textsc{sb} & + \end{array}\right] \end{array}\right]$$

---

[46] SB stands for obligatorily subject bound.

(96) *agr. -nsA:* $\left[\textsc{poss}\ \left[\textsc{pers}\ 3\right]\right]$, GEND$=_c$ HUM

Toivonen also compares corresponding possessive noun phrase constructions in Estonian and Northern Saami. Toivonen (2001) provides a historical context for her analysis in Toivonen (2000), and she also discusses dialectal variation in Finnish with respect to these phenomena. Her proposal involves the erosion of features other than PRED 'pro', which makes it very similar to Coppock & Wechsler's (2010) analysis of Ostyak and Hungarian in Section 7.1.2.

8.3.2 Hungarian

Laczkó (2001) develops an LFG approach to the inflectional phenomena in Hungarian possessive DPs in the spirit of Item and Arrangement morphology.[47] Consider the following examples.

(97) Hungarian:

a. a toll-a-i-nk
the pen-POSS-PL-1PL
'our pens'

b. a toll-a-i
the pen-POSS-PL.3SG
'her pens'

c. a toll-a
the pen-POSS.3SG
'her pen'

d. a hajó-i
the ship-POSS.PL.3SG
'her ships'

Laczkó postulates the following sets of functional annotations in the lexical forms of *-a* and *-i*, the main point being that the same morphological form (morph) can encode fewer or more features depending on what other morphs it is combined with, see the optional features in (98).

(98) a. *-a* (↑ POSS) [97a, 97b]
(↑ POSS PERS) = 3 [97]
(↑ POSS NUM) = SG
((↑ POSS PRED) = 'PRO')

---

[47] By contrast, Laczkó (2018) proposes a Word and Paradigm approach, arguing that it has considerable implementational advantages.

b. *-i* (↑ poss) [97a]
(↑ num)
(↑ poss pers) = 3 [97b, 97d]
(↑ poss num) = sg
((↑ poss pred) = 'pro')

9 Further reading

Limitations of space have prevented us from discussing additional phenomena in Finno-Ugric languages and their analyses. Below we provide references to further works that we recommend to the interested reader.

On predicate-argument relationships in Hungarian, see Komlósy (1992, 1994) and Rákosi (2008). On causatives in Hungarian, see Komlósy (2000). On argument realization alternations in Finnish and Estonian, see Ackerman & Moore (1999), in Hungarian, see Ackerman (1992) and Laczkó (2013b). On Uralic conjugation classes and verbs imposing restrictions on argument structure, see Abondolo (1998), Nikolaeva (2014) and Tamm & Vainikka (forthcoming). On argument vs. (thematic) adjunct issues in Hungarian, see Rákosi (2003, 2006a,b, 2012). On the grammaticalization of the Estonian perfective particles, see Tamm (2004b). On scalar verb classes, aspect and partitive and total case assignment in Estonian, see Tamm (2012c). On the pragmatics of morphological case in the verbal domain of Finnic languages, see Tamm (2011b). On Estonian object and adverbial case marking with verbs of motion, see Tamm (2007b). On case and aspectuality in Estonian, see Tamm (2008, 2012b). On raising and equi constructions in Estonian, see Tamm (2004c, 2008). On a variety of analyses of *wh*-questions in Hungarian, see Mycock (2004, 2006, 2010, 2013), Gazdik (2010) and Laczkó (2014b, 2021). On two Finno-Ugric contributions to the comp debate in LFG,[48] see Belyaev et al. (2017) for comp on the basis of Moksha Mordvin phenomena and Szűcs (2018a) against comp on the basis of Hungarian facts. On 'operator raising' in Hungarian, see Coppock (2003) and Szűcs (2013, 2014, 2018b). On binding and control relations of anaphors in Hungarian, see Rákosi (2009, 2010), Laczkó & Rákosi (2019), Szűcs (2019) and Laczkó et al. (2020). On reflexivity and binding in Uralic languages, see Volkova (2014, forthcoming). On participial constructions in Hungarian, see Komlósy (1992, 1994) and Laczkó (1995, 2000a, 2005). On derived and inherent relational nouns in Hungarian, see Laczkó (2008a, 2009b). On elliptical noun phrases in Hungarian, see Laczkó (2007). On modelling (in)definiteness

---

[48] For instance, see Dalrymple & Lødrup (2000) and Lødrup (2012) for comp, and Alsina et al. (2005) and Patejuk & Przepiórkowski (2016) against comp, and the references in these papers.

and (typological) variation in Hungarian possessive DPs, see Laczkó (2017). On a special system of person and number marking in possessive noun phrases in Northern Ostyak, see Ackerman & Nikolaeva (1997). On natural and accidental coordination in Finnish noun phrases, see King & Dalrymple (2004) and Dalrymple & Nikolaeva (2006). On a lexical analysis of a Hungarian phrasal adjectival derivational suffix, see Laczkó (1997). On extraction from partitive DPs in Hungarian, see Chisarik (2002).

10 Conclusion

In this chapter we have discussed some salient, sometimes competing, LFG analyses of a variety of (morpho-)syntactic phenomena in Finno-Ugric languages, with occasional glimpses at alternative generative approaches, on the one hand, and at some related phenomena in languages belonging to Samoyedic, the other major branch of Uralic languages, on the other hand. We have dealt with clausal c-structure representational issues, verbal modifiers, focused constituents, negation, copula constructions, argument realization, subject-verb agreement, differential object marking, evidentiality and a set of noun phrase phenomena related to event nominalization.

On the basis of the interim conclusions at the end of various sections, we can make the following overall concluding remarks at the end of this chapter. On the one hand, LFG provides an appropriate and suitably flexible formal apparatus for a principled analysis of all the phenomena in all the Finno-Ugric languages discussed here. The range of these phenomena is considerably wide and varied, see above, containing several cases that pose serious challenges for generative grammar at large, for instance, the treatment of complex predicates, negation, copula constructions, discourse functions, agreement and event nominalization. On the other hand, the analysis of some of these phenomena can also contribute to LFG-internal theorizing, see, for instance, the choice between LFG treatments of complex predicates involving PVCs and clause negation.

Acknowledgements

Work on this chapter was supported by a research grant obtained from the Faculty of Humanities and Social Sciences, Károli Gáspár University of the Reformed Church in Hungary (*Theoretical and Experimental Research in Linguistics*, reg. no. 20736B800). We are grateful to our three anonymous reviewers, who at a later stage identified themselves as Anne Tamm, Ida Toivonen and Péter Szűcs. The comments of all our reviewers have greatly contributed to improving both the content and the presentational aspects of this chapter. Our special thanks go to Anne Tamm for generously providing us with a large amount of information about phenomena in several Uralic languages that are comparable to the phenomena whose LFG analyses are discussed in this chapter and for calling our attention to a great number of additional relevant works on Uralic languages. As usual, all remaining errors are our sole responsibility.

Abbreviations

Besides the abbreviations from the Leipzig Glossing Conventions, this chapter uses the following abbreviations.

ADE	adessive case (marker)	PAR	partitive case
ÄRA	Estonian particle	TOT	total case
ÁS	Hungarian event nominalizer suffix	VALÓ	Hungarian adjectivalizing participle
INE	inessive case	VM	verbal modifier

Chapter 32

LFG and Romance languages

Alex Alsina
Universitat Pompeu Fabra

This chapter is an overview of the main topics in the Romance languages that have been the object of analysis within LFG. The topics reviewed include the analysis of verbal clitics, considering their morphological and c-structure status, their role in f-structure, and the role of the anaphoric reflexive clitics in a-structure, the grammatical function of direct and indirect objects and of clausal complements, passive and impersonal constructions, and complex predicates such as the causative construction.

1 Introduction

This section consists of a brief presentation of the Romance languages and an overview of the chapter.

1.1 Brief presentation of the Romance languages

The Romance languages developed out of the varieties of Latin spoken in the areas under Roman domination as a result of the expansion of Latin throughout the territories around the Mediterranean Sea from the fifth century BC to the sixth century AD. The main present-day Romance languages with a standard form and/or official status in some state or region within a state are:

- The closely related Portuguese and Galician;
- Spanish, or Castilian;
- Catalan, with Valencian as a regional name;

Alex Alsina. 2023. LFG and Romance languages. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 1533–1596. Berlin: Language Science Press. DOI: 10.5281/zenodo.10186016

- French;
- Occitan, with a variety of regional names including Provençal, Langue d'Oc, Gascon, Limousin, etc.;
- Sardinian;
- Italian;
- Raeto-Romance, with Romansh, Ladin and Friulian as regional names;
- Romanian.

In addition, there are a number of languages without an official status, such as Asturian and Aragonese in Spain, Walloon, Picard and Bourguignon in France, the Italo-Romance varieties Piedmontese, Ligurian, Lombard, Sicilian, Neapolitan in Italy, and Corsican in France, and the Daco-Romance varieties Aromanian, Istro-Romanian, and Megleno-Romanian, to name just a few. As a consequence of the colonial policies of European states from the fifteenth to the nineteenth centuries, some of the Romance languages have large numbers of speakers outside Europe; this is the case of Spanish, Portuguese, and French, which are, in this order, the Romance languages with the largest numbers of speakers.

Because of their (relatively recent) common ancestry, the Romance languages share many structural patterns, but they also have significant differences. Readers interested in finding more information about any aspect of this language family should consult Ledgeway & Maiden (2016).

1.2 Overview of the chapter

The choice of topics dealt with in this chapter is conditioned by the existence of LFG work on specific topics, theoretical interest, and space limitations. Most of the LFG work on Romance is on Spanish, French, Italian, Catalan, and Portuguese. Consequently, this chapter will deal mostly with these languages.

Section 2 focuses on so-called clitics in Romance. First, it addresses the debate about their morphological status: are clitics affixes or independent words? Second, it addresses their syntactic status: do they fill a grammatical function (GF) and, if so, what GFs can they fill? Can they be agreement markers? Do they have other roles? And, finally, the status of the anaphoric reflexive clitic is debated. Section 3 discusses arguments, GFs, and case and addresses issues such as the inventory of GFs in LFG and what GFs should be used for objects in the

Romance languages, subject-object alternations, passivization, etc. Section 4 discusses complex predicate constructions such as the causative construction and the restructuring construction.

Following are some topics not discussed in detail in this chapter:

- The phenomena that, in Rizzi (1997) and subsequent works, are known as corresponding to the structure of the left periphery. Although there is not much LFG work on this topic within the Romance languages, Estigarribia (2005, 2013) analyses clitic left dislocation in Spanish; Gazdik (2008, 2010) studies interrogatives and multiple questions in French; and Zipf & Quaglia (2017) discuss word order and information structure in Italian matrix wh-questions. See Zaenen 2023 [this volume] for a general discussion.

- Determiners and the structure of the NP. A salient feature of the Romance languages in general is the existence of a clitic-like definite article. In many of these languages it is homophonous (or partially so) with the third person pronominal accusative clitic. Article-preposition contracted forms in French are analyzed in Wescoat (2007) as lexical items involving lexical sharing. Alsina (2010) takes this idea a step further and assumes that the definite article in Catalan is always an affix that attaches to a word with lexical sharing. Alsina (2011) identifies three types of determiners in Catalan depending on whether they must co-occur with a head noun, may (but need not) co-occur with a head noun, or cannot do so, and provides an analysis within LFG.

- Agreement. Verb agreement is generally taken to be agreement with the subject. However, Alsina & Vigo (2014) show that the finite verb may agree with a non-subject (a nominative complement) in Catalan and Spanish, as can be seen in copular constructions; Alsina & Yang (2018) extend this assumption to intransitive clauses with an indefinite postverbal logical subject. Carretero García (2017) proposes an analysis of the special form of adjectives used for agreement with non-count nouns in Asturian.

- Diachrony. The diachronic development of infinitival complements from Latin to the Romance languages is discussed by Vincent (2019).

- Finiteness and tense, in connection with the morphology-syntax interface, are dealt with in Barron (2000) and Schwarze (2001a), using data from Italian and French, respectively.

- Auxiliaries. Butt et al. (1996) develop the idea of having a level of representation different from f-structure, called m-structure, for the analysis of auxiliaries in French, as well as in English and German. Schwarze (1996) proposes an analysis of auxiliaries in Spanish, Italian and French, including auxiliary selection in the latter two languages.

2 Clitics

The term "clitic" in this chapter is used as a purely descriptive term (without any theoretical implications) to refer to the class of phonologically dependent particles that attach to a verb and generally provide information about a GF of the clause. Section 2.1 focuses on the debate as to whether clitics are syntactically independent words (though phonologically dependent) or affixes, what their correct analysis should be, and what implications this analysis has. In Section 2.2, we examine the f-structure status of clitics as the expression of an argument, as an agreement marker, and as the expression of a non-argument of the verb. The reflexive clitic, in its "anaphoric" use, is discussed in Section 2.3.

2.1 Morphological status

One of the central issues in the analysis of clitics is their morphological status: are they independent syntactic constituents or are they affixes? If they are affixes, should we treat them as morphemes – linguistic signs consisting of a phonological representation and a semantic and f-structure representation – or should we treat them as the overt realization of particular bundles of morphological or syntactic features within a realizational approach to morphology?

2.1.1 Affixes vs. independent words

The most common assumption in connection with this issue in LFG is that they are independent syntactic constituents. This is not only the oldest approach, as it is found in the earliest analyses of clitics within LFG, as in Grimshaw (1982), but it is a very prevalent one, as it is found up to the present (see, for example, Schwarze (2001b) for French and Italian, Estigarribia (2005, 2013) for Spanish, Quaglia 2012 for Italian, and Barbu & Toivonen 2018 for Romanian). Grimshaw (1982: 90) posits the following c-structure rule in order to account for the position of clitics in French:

(1) $\mathrm{V}' \longrightarrow (\mathrm{CL})_1\ (\mathrm{CL})_2\ (\mathrm{CL})_3\ (\mathrm{AUX})\ \mathrm{V}$

In this approach, clitics are a special grammatical category (CL) that occupies a position in the c-structure. By a rule such as (1), the position of clitics is restricted to being adjacent to a verb (or an auxiliary).

However, proponents of clitics as syntactic constituents generally do not present arguments in favor of their position and against treating clitics as affixes, presumably because that position is seen as the default assumption, given that the standard orthographies in general separate clitics from their hosts by means of spaces, hyphens or apostrophes, at least in preverbal position, which induces the belief that clitics are words. (But see Schwarze 2001b, who makes an explicit defense of clitics as c-structure constituents, in French and Italian.)

On the other hand, proponents of treating clitics as affixes have presented evidence in favor of this assumption that is highly problematic for the assumption that clitics are independent syntactic constituents. Evidence that clitics are morphological units (not c-structure constituents) has been presented, within different frameworks, by Bonet (1991, 1995); Miller (1992); Crysmann (1997); Miller & Sag (1997); Monachesi (1999); Luís & Sadler (2003); Luís & Spencer (2005), among others. Some of the evidence, of a strictly syntactic nature, is that clitics cannot be topicalized, cannot be substituted by full pronouns, cannot be coordinated, and cannot be modified. The following Portuguese examples illustrate the failure of coordination of clitics:[1]

(2) Portuguese (Crysmann 1997)

a. * eu vi o e Paulo.
I saw.1SG 3SG.M.ACC and Paul
'I saw him and Paul.'

b. * eu não o e a conheço.
I not 3SG.M.ACC and 3SG.F.ACC know.1SG
'I do not know him and her.'

There is also evidence that can be classified as morphophonological. Clitics exhibit a high degree of selection with respect to their host: in most Romance languages, the clitic cluster must be adjacent to the verb. This is always the case

---

[1] Examples, including cited ones, are glossed according to the Leipzig glossing rules, replacing the original glosses, if necessary. Unreferenced examples reflect the author's judgments. Clitics are glossed indicating only the corresponding features of person, number, gender, and case that are morphologically relevant. The reflexive clitic (*se*, *si*, *s'*, and cognate forms) is glossed as REFL (even when its meaning is not reflexive). Forms that cannot be glossed in a simple way are glossed with the form in small caps; example: the genitive and partitive clitic *en* in Catalan or French is glossed as EN.

when the clitic cluster is postverbal. The exception to the adjacency requirement of the verb and the clitic cluster is only found when the clitic cluster is preverbal in modern Portuguese (Crysmann 1997, Luís & Otoguro 2004), as well as in medieval Spanish and Portuguese (Fontana 1993, 1996, Fischer 2002), and only in very restricted contexts. There are morphophonological alternations that are restricted to clitic combinations. For example, in Portuguese, when a third person accusative clitic (*-o,-a,-os,-as*) is in a clitic combination (either with a verb or with another clitic) following an oral coronal continuant (/s/, /z/, /r/), this consonant is replaced by [l] (see Crysmann 1997): *comprar + o* → *comprá-lo* buy.inf it, *nos o dão* → *no-lo dão* us-it give.3pl, etc. This alternation does not occur across word boundaries: *todos os alunos* 'all the students'. The same clitics are preceded by /n/ when suffixed to a verb form ending in a nasal vowel, as in *eles conhecem + o/a* → *eles conhecem-no/na* 'they know him/her' (see Crysmann 1997), but this nasal insertion does not occur across word boundaries: *eles conhecem o aluno/a aluna* vs. **eles conhecem no aluno/na aluna* 'they know the student.m/the student.f'.

One of the most compelling sources of morphophonological evidence for the affixal nature of clitics is the existence of opaque clitic combinations, i.e. combinations of clitics that do not coincide with the form of the corresponding clitics used in isolation (Bonet 1995). One of the clearest examples of opaque clitic combinations is the so-called "spurious *se*" in Spanish. While the clitic form of the third person singular indirect object is *le* in isolation, as in (3b), when it combines with a third person accusative object, such as *lo* in (3a), it adopts the form *se*, as in (3c), elsewhere used only as a third person reflexive clitic. The transparent combination **le lo* (or **lo le*) does not exist.

(3) Spanish (Bonet 1995: 608)

a. El premio, lo dieron a Pedro ayer.
the price 3sg.m.acc gave.3pl to Pedro yesterday
'The price, they gave it to Pedro yesterday.'

b. A Pedro, **le** dieron el premio ayer.
to Pedro, 3sg.dat gave.3pl the price yesterday
'Pedro, they gave him the price yesterday.'

c. A Pedro, el premio, **se lo** dieron ayer.
A Pedro the price se 3sg.m.acc gave.3pl yesterday
'Pedro, the price, they gave it to him yesterday.'

Another instance of an opaque clitic combination, among those reported in Bonet (1995), is the combination in standard Italian of the impersonal clitic *si* with the third person reflexive clitic *si*: instead of the expected *si si* sequence (possible in certain dialects of Italian), the sequence *ci si* is found:

(4) Italian (Bonet 1995: 609)

a. Lo si sveglia.
3sg.m.acc impers wake.up.3sg
'One wakes him/it up.'

b. Se lo compra.
refl 3sg.m.acc buy.3sg
'S/he buys it for herself/himself.'

c. Ci si lava
refl impers wash.3sg
'One washes oneself.'

These opaque clitic combinations are completely unexpected under the treatment of clitics as words and very difficult to explain in that approach. On the other hand, if clitics are affixes, this kind of allomorphy is much more natural.

In addition, there is phonological evidence for the affixal status of clitics. One of the sources of such evidence is word stress. While clitics in most cases are stressless and have no effect on the stress pattern of the word they are attached to, there are some Romance varieties in which clitics affect the stress pattern of their host. This is the situation in the Catalan dialects of Mallorca and Minorca: the first column in (5) illustrates verb forms without postverbal clitics and the second column shows the same verb forms with postverbal clitics:

(5) Mallorcan Catalan (Colomina i Castanyer 2002: 579)

dona 'give' [ˈdonə]	dona'm 'give me' [doˈnəm]
agafa 'pick up' [əˈɣafə]	agafa'l 'pick it up' [əɣəˈfəl]
entra 'enter' [ˈəntrə]	entra-hi 'enter there' [ənˈtrəj]

In these dialects, the presence of a clitic in postverbal position causes stress to be placed on the final syllable of the verb form, instead of on the penultimate syllable. Given that word stress in Catalan does not depend on elements external to the word, one must conclude that clitics are part of the word at the point in the derivation in which word stress placement rules apply. In other dialects, clitics are affixes that do not affect stress placement.

All of these facts argue conclusively for treating clitics as word parts, specifically, affixes.

2.1.2 Alternative analyses of clitics as affixes

The affixal status of clitics is consistent with two approaches to morphology, in particular, to inflectional morphology: the morpheme-based approach and the realizational approach. Within the morpheme-based approach, an affix is a linguistic sign, consisting of a phonological representation and a semantic and/or syntactic representation. Under this view, an affix is very much like a word, only, instead of being an element that can appear as a terminal node in the c-structure, it is part of a word and combines with other word parts in a tree structure to form a word. Within the realizational approach, an affix is the phonological realization or spell-out of semantic and/or syntactic features of a word, possibly mediated by morphological features. In inflectional morphology, for every lexeme there are as many feature combinations as there are possible forms in the paradigm of the lexeme and there are rules spelling out specific features or feature combinations as particular affixes.[2]

To compare the two approaches, consider the form *lo* that appears in Italian examples such as (4a), (4b). In a morpheme-based approach, the form *lo* would have a dictionary entry that, instead of specifying its grammatical category, as it would for a word, indicates what kind of word part it is.[3] For the purpose of illustration, we can assume that form would be classified as a special kind of affix, which we can call *cl* (for clitic), as in (6):

(6) *lo* *cl* (↑ PRED)=‘PRO’
(↑ CASE)=ACC
(↑ PERS)=3
(↑ GEND)=M
(↑ NUM)=SG

Affixes of type *cl* combine with other *cl* elements to form a clitic cluster (CCL). In Italian, a CCL attaches preverbally (as a prefix) to finite verb forms except for imperatives and postverbally (as a suffix) to imperatives and non-finite verb forms.

---

[2] These two approaches are mutually exclusive within LFG, although they are not necessarily so in a derivational framework such as Minimalism. As pointed out by a reviewer, this would be the case with Distributed Morphology (Halle & Marantz 1993), which is claimed to be both morpheme-based and realizational. In this framework, morphemes are bundles of morphosyntactic features as terminal nodes in the syntax without a phonological representation and are subsequently assigned a phonological form.

[3] Standardly, in LFG the term “lexical entry” refers to the information associated with a fully inflected word, as it appears in the syntax. Since clitics, as affixes, are not fully inflected words, I avoid using the term “lexical entry” to refer to the phonological, morphological, f-structure, and semantic information that characterizes a sublexical element such as an affix, but use the term “dictionary entry” instead.

There has to be some mechanism to place clitics in the right order within a CCL: as we see in (4), *lo* precedes the impersonal clitic *si* but follows the third person reflexive *si* (which takes on the form *se* in this context). This can be achieved by having a template with several clitic positions and having each clitic subclassified as to the position it occupies in the template. Alternatively, there can be linear precedence rules that are sensitive to the syntactic features of the clitics (such as person, case, reflexivity, etc.) and order the clitics within a CCL according to these features.

In a realizational approach, there are rules that spell out bundles of f-structure features (or the corresponding morphological features) as the appropriate clitic form. So, if a verb form has the f-structure features in (6), a rule is triggered that introduces the form *lo* in a CCL, along the following lines:

(7) [PRED 'PRO', CASE ACC, PERS 3, GEND M, NUM SG] ⟶ CCL {...lo...}

As in the previous approach, there would also have to be a mechanism such as a template, linear precedence rules, or ordered blocks of rules to obtain the right order of clitics when more than one is present in a CCL.

At first sight there might seem to be little difference between the two approaches. Both approaches can account with a similar degree of success for the strictly syntactic evidence for the affixal nature of clitics noted in Section 2.1.1 (such as the failure to be topicalized, substituted by full pronouns, coordinated or modified): these processes affect c-structure units, which clitics are not in either approach. The phonological evidence for the affixal status of clitics (e.g. instances in which stress assignment applies to the word structure that includes clitics) is accounted for in a similar way whether affixes are viewed as morphemes or as the product of spell-out rules.

Many of the morphophonological arguments for the affixal status of clitics can also be accounted for in either approach. To account for an allomorphic alternation such as the *o/lo/no* alternation in Portuguese noted earlier, within the morpheme-based approach, we would have to assume that the third person singular accusative masculine clitic morpheme has three allomorphs that are phonologically conditioned; within the realizational approach, we would have to assume that there are three different spell-out rules for the same syntactic (or morphological) feature bundle each one with a different phonological context. The existence of opaque clitic combinations, such as the ones illustrated in (3) and (4), is probably the strongest argument in favor of the realizational approach. From the morphemic perspective, these can be thought of simply as instances of allomorphic alternations. To use the example of the Spanish spurious *se*, illustrated in (3), the third person dative clitic morpheme would have two allomorphs: *se*, when it co-occurs with another third person clitic; and *le*, elsewhere. A problem with this approach is that it fails to explain the observation by Bonet (1995) that, in opaque clitic combinations, the unexpected form always coincides with a clitic that exists independently in the language. If the third person dative *se* is an allomorph of the more general *le*, it is just an accident that it is homophonous with the third person reflexive *se*; it could just as easily be *che*, *je*, *na*, or any other form that does not coincide with an existing clitic. On the other hand, the realizational approach has the means of capturing that observation, as in Bonet (1995); see also Grimshaw (1997) using Optimality Theory.[4]

2.1.3 Proclisis and enclisis in European Portuguese

This subsection illustrates to what extent Romance data can call standard LFG assumptions into question, in particular, the way the Lexical Integrity Principle is to be interpreted. The position of clitics (or, more exactly, of the CCL) in European Portuguese (EP) with respect to the verb of their clause poses an important problem for theories of syntax, morphology, and the syntax-morphology interface. Two properties that distinguish EP from the other modern Romance languages are relevant in this context:[5]

- With finite verb forms, the CCL can appear after the verb (enclisis) or before it (proclisis), depending on the kind of syntactic constituent, if any, that precedes the verb.
- When it appears before the verb, it need not be adjacent to it, but may be separated from it by words such as some adverbs and the negation *não* (interpolation) (see Section 2.1.1).

These properties are a problem for the affixal treatment of clitics. If we assume that clitics are affixes in both preverbal and postverbal position, the fact that the choice between the two positions is dependent on a syntactic property (the presence or absence of certain types of syntactic constituents before the verb)

---

[4] The facts involving the expression and omission of the reflexive clitic in Catalan presented in Alsina (2020) are further evidence for the realizational treatment of clitics in Romance.

[5] An additional specificity of the positioning of CCL in EP is the phenomenon of mesoclisis: with future and conditional verb forms, the enclitic position is not after the tense, aspect and person affixes, but before them. See Luís & Spencer (2005) for an analysis within LFG and realizational morphology. When a present tense form such as *mostramos* ‘we show’ combines with the clitic complex *lho* (3.DAT+3SG.M.ACC) in enclitic position, the result is *mostramos-lho* ‘we show it to him’, but, if instead we use a future tense form such as *mostraremos* ‘we will show’, the enclitic attachment of *lho* results in *mostrar-lho-emos*, not **mostraremos-lho*.

is a prima facie problem for that assumption. The standard view of the syntax-morphology interface in a lexicalist framework assumes that the morphology may impose constraints on the syntax, but the syntax cannot impose constraints on the morphology. But, in the case in point, a particular morphological property – the linearization of CCL before or after V – is determined by the syntax.

Example (8) shows that the same finite verb form, here *vê*, can take a clitic before it, as in *me vê*, or after it, as in *vê-me*, depending on what precedes it.

(8) Portuguese (Luís & Otoguro 2004)

a. O João raramente me vê.
the João rarely 1SG see.3SG

b. O João vê-me raramente.
the João see.3SG-1SG rarely
'João rarely sees me.'

The accepted assumption in work such as Luís & Sadler (2003), Luís & Otoguro (2004, 2005), and Luís & Spencer (2005), among others, is that enclisis is the default linearization of CCL and the verb in EP, whereas proclisis is triggered by the presence of certain c-structure constituents in preverbal position, which can be referred to as proclisis-triggers. So, for example, a non-quantified preverbal subject, such as *o João* in (8), is not a proclisis-trigger, which implies that the default option of enclisis is chosen in (8b); on the other hand, the adverb *raramente* in preverbal position is a proclisis-trigger, which explains the proclitic sequence *me vê* in (8a).

The approach adopted in Luís & Sadler (2003) is that all syntactic constituents that are proclisis-triggers are associated with the f-structure feature (↑ TYPE) = NON-NEUTRAL (or with the morphological feature [Restricted:Yes] in Luís & Otoguro 2004). For example, the negative element *não* is associated with this feature. (It has not been possible to find a common configurational or semantic/discourse denominator for the set of syntactic contexts that trigger proclisis; hence the proposal of having an f-structure feature for proclisis.)

The linearization rule 'Proclitic-LR', which ensures that CCL is placed preverbally, applies only under the existence of the (↑ TYPE)=NON-NEUTRAL feature in the f-structure of the verb. In the absence of this feature, the linearization rule that places CCL postverbally applies. So, the TYPE feature reflects the idea that proclisis is the marked option in EP.

However, the two alternative sequences *vê-me* and *me vê* are not identical from the syntactic point of view: even though they are both assumed to be a word from the morphological point of view, the form with enclisis, *vê-me*, is assumed to constitute a single X^0 (either I or V), whereas the form with proclisis, *me vê*, is assumed to correspond to two different c-structure positions. This assumption is necessary in order to account for two phenomena: scope over coordinated VPs and so-called interpolation. Focusing on interpolation, we find that certain words, which are clearly independent syntactic constituents, can appear between the proclitic CCL and the verb. These words can be the negative element *não*, certain adverbs like *ainda* 'yet', subject pronominals, and a combination of them, as in (9):

(9) Portuguese (Luís & Otoguro 2005)
... acho que ela o ainda não disse.
... think.1sg that she 3sg.m.acc yet not told.3sg
'... I think that s/he hasn't told it to him/her/them yet.'

The clitic *o* in (9) is separated from the verb *disse* by two words: *ainda* and *não*. This indicates that *o* and *disse* must be two independent c-structure elements (c-structure words). On the other hand, according to Luís & Sadler (2003), Luís & Otoguro (2004, 2005), and Luís & Spencer (2005), these two elements constitute a single unit at the morphological level (a morphological word). This is a departure from the standard idea in LFG that words – the minimal units of c-structure – are the output of the morphological component and, so, there should be no reason to distinguish between a c-structure word and a morphological word.

The exact implementation of the syntactic representation of the form with proclisis varies depending on the work. In Luís & Sadler (2003), the proclitic CCL attaches to the left of the VP headed by the verb that constitutes a morphological word with the preverbal CCL. In Luís & Otoguro (2004), it is assumed that, in certain cases, i.e. proclisis, a morphological token may correspond to two or more c-structure terminals.

In both approaches, a morphological unit is decomposed into two elements in the c-structure, which is a clear violation of the Lexical Integrity Principle – the idea that the internal structure of words is invisible to the c-structure. More specifically, this treatment of proclisis in Portuguese can be seen as a violation of Zwicky's Principle of Morphology-Free Syntax, according to which "syntactic rules cannot make reference to the internal morphological composition of words or to particular rules involved in their morphological derivation" (Zwicky 1987: 650), which he considers equivalent to the Lexicalist Hypothesis or the belief that syntax is blind to morphology (O'Neill 2016: 244).

2.2 F-structure status

In this subsection we address the issue of the GF that the clitic corresponds to, if any, and its status as a pronoun or an agreement marker, leaving aside the reflexive clitic, to be discussed in Section 2.3 and Section 3.2.

2.2.1 The GF the clitic corresponds to

In most cases, a clitic corresponds to a GF in its clause. In some languages (e.g., Spanish, Portuguese, Catalan, Italian), a clitic cannot correspond to the subject; it can correspond to an object only, both accusative and dative, as in Spanish and Portuguese, or to an object, as well as an oblique, as in Catalan and Italian. In French, clitics can correspond to a subject, in addition to objects and obliques.[6]

The most common situation with clitics is that in which the clitic is in complementary distribution with the phrasal expression of the GF that the clitic corresponds to. As Grimshaw (1982: 88) notes for French, "accusative clitics are in complementary distribution with NP objects." With a verb like *voit* 'sees', which requires a direct object, either an NP object or an accusative clitic satisfies this requirement, as in (10b) and (10c) respectively, but they cannot co-occur, as in (10d):

(10) French (Grimshaw 1982: 88)

a. * Jean voit.
John see.3SG
'John sees.'

b. Jean voit l'homme.
John see.3SG the.man
'John sees the man.'

c. Jean le voit.
John 3SG.M.ACC see.3SG
'John sees him.'

d. * Jean le voit l'homme.
John 3SG.M.ACC see.3SG the.man
'John sees him the man.'

---

[6] Some Northern Italian languages also require a subject clitic, in a wide range of modalities (see Renzi & Vanelli 1983 and Cardinaletti & Repetti 2010). See Poletto & Tortora (2016) for variation in subject clitics in the different Romance languages that are claimed to have subject clitics.

How these facts are explained depends in part on whether we treat clitics as c-structure constituents or as affixes and, within the affixal treatment, as morphemes or as exponents of morphological or syntactic features. We shall consider the different approaches to clitics in explaining distributional facts such as those illustrated in (10).

Grimshaw (1982) takes the position that clitics are c-structure constituents belonging to the CL (clitic) grammatical category – let us call it the clitic-as-word approach. The observation that the direct object requirement is satisfied by either an NP following the verb or an accusative clitic before the verb is explained: (a) by annotating as an obj both the NP daughter of VP and one of the CL (clitic) positions daughters of V'; (b) by assuming that both nouns and pronouns, including pronominal clitics, have a pred feature in their lexical entries and that the clitic *le* has the lexical entry in (11); and (c) by appealing to the standard well-formedness conditions of Consistency, Completeness, and Coherence.

(11) *le* CL (↑ pred) = ‘pro’
(↑ case) = acc
(↑ num) = sg
(↑ pers) = 3
(↑ gend)=m

This clitic, in the appropriate CL position, satisfies the obj requirement of the verb and provides the necessary pred feature to satisfy Completeness. It is an alternative to the NP realization of the object, in which a noun provides the pred feature. This explains the alternative expression of the object illustrated in (10b) and (10c). In addition, if both ways of expressing the obj are used in the same clause, a violation of Consistency results, as the obj would have two pred values, given the convention that pred values are not unifiable, which accounts for (10d).

The affixal treatment of clitics is common to the two approaches in Section 2.1.2. In the morpheme-based approach, the main difference with the clitic-as-word approach is that clitics are not joined to a verb in the c-structure, but are joined to it in the lexicon. A clitic such as *le*, being a morpheme, has a “sublexical” entry identical or very similar to that in (11), except that “CL” is not a c-structure category, but a type of affix. One could either assume that there is a word template with different clitic affix positions, one of which would be annotated as the obj, and then a sublexical entry like that in (11) would fit into that position providing the f-structure features to the obj. Alternatively, the clitic-affix *le* would be specified in its sublexical entry with features indicating the GF they correspond to, such as (↑ obj pred) = ‘pro’, (↑ obj case) = acc, etc. The concatenation of a clitic (or clitic cluster) with a verb yields a word whose f-tructure information is the union of that of the clitic and that of the verb, so that a word such as *le voit* carries the f-structure information of the clitic and the f-structure information of the verb *voit*. This would be an instance of pronominal incorporation similar to the analysis of object markers in Chicheŵa by Bresnan & Mchombo (1987).

Within the realizational approach, the phonological representation of the clitic – *le*, in the French example (10b) – is the result of exponence rules and linearization rules, to use the concepts of Luís & Sadler (2003). Adapting the approach of Luís & Sadler (2003) to the present example, we can assume that one of the forms of the paradigm of the verb *voit* has the morphological feature (or m-feature) bundle {ACC,3,SG,M}. This feature bundle is realized phonologically as *le* and this exponent is linearized preceding the verb stem, giving the form *le voit*. In addition, there is a mapping between the m-features and f-structure features. Specifically, the m-feature bundle {ACC,3,SG,M} corresponds to the same f-structure features of the OBJ as those in (11). This is shown schematically in (12a) for the phonological realization and in (12b) for the f-structure correspondence.

(12) a. {ACC,3,SG,M} → /lə/, preceding *voit*
b. {ACC,3,SG,M} → (↑ OBJ PRED)=‘PRO’
(↑ OBJ CASE)=ACC
(↑ OBJ NUM)=SG
(↑ OBJ PERS)=3
(↑ OBJ GEND)=M

So, in this view, the word *le voit* is lexically assigned the syntactic features of *voit*, as well as the syntactic features in (12b). Since this word carries the f-structure information of the object, the use of this word satisfies the object requirement of the verb and precludes the appearance of an NP object for the same reasons noted for the clitic-as-word approach.

2.2.2 Agreement vs. pronoun; clitic doubling

In many cases, a clitic is not in perfect complementary distribution with the corresponding phrasal expression, but some amount of clitic doubling is found. In European Spanish, clitic doubling with direct objects (or accusative objects) is found only with pronominal expressions: a definite pronominal direct object is obligatorily expressed as a clitic, optionally doubled by the phrasal expression, as in (13):

(13) European Spanish (Andrews 1990: 540)

a. Lo vimos (a él).
3SG.M.ACC see.PST.1PL A HIM
'We saw him/HIM.'

b. *vimos a él.

In contrast, Rioplatense Spanish (also called Porteño and River Plate Spanish), as well as other varieties of South American Spanish, has a much more general use of direct object clitic doubling, as in (14):

(14) Rioplatense Spanish (Estigarribia 2005)

a. Yo las tenía guardadas las cartas.
I 3PL.F.ACC have.PST.1SG stored the letters
'I had the letters stored.'

b. ¿La vas a llamar a Marta?
3SG.F.ACC go.2SG A call A Marta
Are you going to call Marta?

In these cases, there is a single GF corresponding to the direct object, which is encoded in the c-structure by both the direct object clitic and by its phrasal expression: *las* and *las cartas* in (14a) and *la* and *a Marta* in (14b). The standard way of analyzing clitic doubling is to assume that it is a kind of agreement: the clitic in examples such as (14) merely specifies the formal features of person, number and gender of the object, while the corresponding phrasal expression contributes, in addition, the semantic PRED feature of the object. This means that there are two sets of specifications associated with clitics that have the dual function exemplified in (13a): as the sole expression of the object, the clitic is lexically associated with the [PRED 'PRO'] feature needed to satisfy Completeness; as an agreement marker, the clitic lacks this feature in its set of lexical specifications, enabling it to satisfy Uniqueness. This choice is assumed regardless of whether clitics are treated as words, as morphemes, or as exponents.

This analysis follows the treatment given in Bresnan & Mchombo (1987) to subject markers (SM) in Chicheŵa, in contrast with object markers (OM). (See also Fassi Fehri 1984, 1988.) OMs in Chicheŵa are assumed to be always incorporated object pronouns and thus are lexically associated with the [PRED 'PRO'] feature. SMs in Chicheŵa are claimed to be alternatively pronouns and agreement markers, which follows from the optional [PRED 'PRO'] feature in the sublexical entry of the SM. Andrews (1990) adapts this idea to the analysis of clitic doubling in

Spanish. This way of analyzing the dual function of clitics is used in Mayer (2006) for Limeño Spanish, in Estigarribia (2013) for Rioplatense Spanish, and in Barbu & Toivonen (2018) for Romanian, among others.[7]

The two sets of lexical specifications associated with clitics that have the dual function just mentioned may differ in more features that in the presence or absence of the [PRED ‘PRO’] feature. In Estigarribia (2013), it is proposed that the doubling use of the direct object clitic in Rioplatense Spanish not only lacks the pronominal feature, but carries a constraint that the object cannot be non-specific. The pronominal (or non-doubling) use of the clitic is necessarily definite and specific, but a direct object clitic can double (or agree with) an NP with specific reference (not necessarily definite).

Andrews (1990) explains the facts of European Spanish illustrated in (13) by assuming that direct object clitics also have two lexical entries: the pronominal entry, with the [PRED ‘PRO’] feature, and the doubling entry, which has a constraining [PRED ‘PRO’] specification, instead of the defining one. This constraining specification effectively restricts the doubling use to situations in which the clitic doubles a pronominal phrase (such as *a él*, in (13a)). The obligatoriness of the clitic double with pronominal NPs is explained by appealing to Andrews’s Morphological Blocking Principle. Without this principle, the clitic double would just be an option with pronominal object NPs.

Given two lexical items L1 and L2 such that L1’s f-structure specifications are a proper subset of those of L2, the Morphological Blocking Principle requires the use of L2 – the more highly specified lexical item – in a structure in which both L1 and L2 are compatible. In order for this principle to be able to choose between a verb form with a clitic and the same verb form without that clitic, it is necessary to assume that a verb form with a clitic is a lexical item. In other words, the Morphological Blocking Principle presupposes the affixal status of clitics. Given that a clitic is always associated with a set of f-structure features not present in the verb form to which it attaches, a lexical item consisting of a verb and a clitic is always going to be more highly specified in terms of f-structure features than the same lexical item without the clitic. So, if the lexical item with the clitic can be used, it must be used. This explains the obligatoriness of the clitic double in cases like (13).

---

[7] Although this section deals with object clitics, it should be mentioned that subject clitics, in those languages that have them (e.g. French and Northern Italian languages), also vary as to whether they function as pronouns or as agreement markers, depending on the language and on the context (Poletto & Tortora 2016). See Cardinaletti & Repetti (2010) for the claim that subject clitics in Northern Italian languages should be analyzed as pronouns.

Constructions that are similar to clitic doubling but which need to be distinguished from it are clitic left dislocation and clitic right dislocation. Languages that do not have clitic doubling or make a very restricted use of it allow these dislocation constructions quite freely. Catalan, which only allows clitic doubling of the direct object in pronominal cases, does not allow a doubling clitic with a neutral intonation in an example like (15a), but allows a direct object clitic, and in fact requires it, when the apparent direct object is fronted, as in (15b), or postposed, with a clear intonational break, as in (15c):[8]

(15) Catalan (Vallduví 2002: 1233–1237)

a. (*El) va regalar el llibre a la biblioteca.
3sg.m.acc pst.3sg give.inf the book a the library
'She/he gave the book to the library.'

b. El llibre, el va regalar a la biblioteca.
the book 3sg.m.acc pst.3sg give.inf a the library
'The book, she/he gave it to the library.'

c. El va regalar a la biblioteca, el llibre.
3sg.m.acc pst.3sg give.inf a the library the book
'She/he gave it to the library, the book.'

The left or right dislocations in (15) fulfill functions at the information-structure level, but from the f-structure point of view the dislocated phrase does not fill an in-clause GF, but should be analyzed as a udf (unbounded dependency function). In other words, the phrase *el llibre* 'the book' is not an object in either (15b) or (15c), but a udf anaphorically bound to the object clitic *el*. It is this element that fulfills the accusative object function in these examples.

2.2.3 Non-argument clitics

While clitics in most cases either fulfill a GF that is an argument of the clause or agree with it, there are many instances in which clitics are neither an argument nor a marker of agreement with an argument. This is the case with the reflexive clitic, which can have an inherent use (see Section 2.2.3.1), an anaphoric use

---

[8] The periphrastic past perfect tense in Catalan consists of an auxiliary form, such as *va* in (15), and an infinitive. The auxiliary is diachronically descended from the present indicative tense of *anar* 'go', but synchronically it is not the same form. The past tense auxiliary has the forms *vaig* or *vàreig* (1sg), *vas* or *vares* (2sg), *va* (3sg), *vam* or *vàrem* (1pl), *vau* or *vàreu* (2pl), and *van* or *varen* (3pl), whereas the present indicative of *anar* 'go' has the forms *vaig* (1sg), *vas* (2sg), *va* (3sg), *anem* (1pl), *aneu* (2pl), and *van* (3pl). For this reason, the past tense auxiliary is not glossed as if it were a form of *anar* 'go'.

(Section 2.3), and a use as a marker of passivization or impersonalization (Section 3.2). We shall focus here on two non-argument uses of clitics, leaving aside the reflexive clitic: (a) inherent clitics; and (b) clitics as adjuncts.[9]

2.2.3.1 Inherent clitics

Inherent clitics cannot alternate with a phrasal expression and their semantic contribution is not compositional: the predicate consists of a verb and a specific clitic or clitic combination. Examples of verbs with inherent clitics in Catalan include the following: *dinyar-la* 'die', *tocar-hi* 'have a grasp of things', *anar-se'n* 'go away', *jugar-se-la* 'take a risk', etc. Without the clitic or clitics, the verb either does not exist (e.g. *dinyar*) or has a different meaning and argument structure (e.g. *tocar* 'touch'). While one might like to think of these clitics as affixes attached to their verb, they cannot be treated as inseparable affixes, since they can appear separated from the verb by a number of auxiliaries and restructuring verbs, as in the following examples, where the verb and its associated clitics are underlined:

(16) Catalan

a.

L'	hauries	poguda	dinyar.
3sg.f.acc	have.cond.2sg	could.ptcp.f.sg	die.inf

'You could have died.'

b.

Se	l'	està	començant	a	jugar.
refl	3sg.f.acc	be.3sg	beginning	to	play.inf

'He is beginning to take a risk.'

These examples show that the word to which the inherent clitics attach is not the verb that must be used in combination with these clitics. The string of auxiliaries and restructuring verbs in (16) is clearly not a word, but a sequence of verbs, each one imposing a form requirement on the next. For example, the auxiliary *haver*, in the form *hauries* in (16a), requires the following verb to be in the past participle form, and the verb *poder*, in the form *poguda*, requires the following verb to be in the infinitive form. In addition, *poguda* is in the feminine singular

---

[9] In addition, one can argue that the clitic *en/ne* found in Catalan, French, and Italian has two other non-argument uses: the partitive use and the genitive use. In the partitive use, the clitic appears instead of the head noun of an object of the verb (see Alsina & Yang 2018 for an analysis of the partitive clitic in Catalan) and cannot be argued to substitute for the whole object. In the genitive use, it fills the complement of a nominal or adjectival complement of the verb and therefore does not correspond to an argument of the verb. Because of space limitations, I will not discuss these uses further.

form (as opposed to the unmarked *pogut*) showing agreement with the feminine singular clitic *la*, which in this respect behaves like a direct object. The position in which inherent clitics are realized and the possibility of triggering past participle agreement, among other facts, are the same as with any other clitic.

One might assume that verbs with inherent clitics are listed in the lexicon with one or more fully specified GFs that have no semantic content. For example, *dinyar-la* would fully specify an accusative object with no correspondence to an argument at a-structure or to a semantic participant.[10] It would be listed as the verb *dinyar* taking a feminine singular accusative object, as indicated in (17):

(17) *dinyar* V
$$\left[\begin{array}{ll} \textsc{pred} & \text{‘}\textsc{die}\langle\textsc{arg}\rangle\text{’} \\ \textsc{obj} & \left[\begin{array}{ll} \textsc{case} & \textsc{acc} \\ \textsc{pred} & \text{‘}\textsc{pro}\text{’} \\ \textsc{pers} & 3 \\ \textsc{num} & \textsc{sg} \\ \textsc{gend} & \textsc{fem} \end{array}\right] \end{array}\right]$$

Under a realizational approach to clitic morphology, we can assume that the features of the object in (17) are mapped onto the clitic *la*. As for the position of this clitic in a string of restructuring verbs, it is no different from that of any clitic. The syntactic dependents of the most embedded verb following a string of restructuring verbs can cliticize onto the highest verb in the string of verbs.

One of the uses of the reflexive clitic is as an inherent clitic. In this use, there is no reflexive interpretation. Following Grimshaw (1982), we can distinguish two classes of verbs within the class of verbs that take an inherent reflexive clitic: the lexically stipulated class of reflexive verbs and the class of inchoative verbs (in Grimshaw's terminology). The first class consists of verbs that are lexically required to take a reflexive clitic and either do not exist in a non-reflexive form or are not related in a systematic way with their non-reflexive counterpart. Examples of this class in Catalan are *desmaiar-se* 'faint' or *penedir-se* 'repent', which do not exist without a reflexive clitic. In the second class we find the intransitive alternant of the causative alternation, such as *trencar-se* 'break.INTR' or *obrir-se* 'open.INTR' in Catalan. See Alsina (2020) for a treatment of inherently reflexive verbs.

---

[10] One could debate whether this object should have a [PRED 'PRO'] feature. Depending on how one views the syntax-morphology mapping for clitics, this feature might be necessary. On the other hand, the presence of this feature on a non-semantic GF would yield a violation of Coherence, according to some definitions of this condition which require a PRED feature on all and only those GFs with semantic content.

2.2.3.2 Clitics as adjuncts

Although clitics generally correspond to objects (or subjects, in languages with subject clitics, such as French), in some languages they can also correspond to obliques: this is the case of *en* and *y* in French, *en* and *hi* in Catalan, and *ne* and *ci* or *vi* Italian. The clitic *y/hi/ci*(*vi*) may correspond either to an argument of the verb or to an adjunct, as we see in (18) for French and in (19) for Catalan:

(18) French (Schwarze 2001b)

a. J' y ai pensé.
I Y have.1SG thought
'I have thought of it.'

b. Je l' y ai vu.
I 3SG.F.ACC Y have seen
'I saw him there.'

(19) Catalan (Todolí 2002)

a. Encara no s' hi han acostumat.
still not REFL HI have.3PL accustomed
'They haven't got used to it yet.'

b. No es pot circular sense casc, però molts motoristes hi circulen.
Not REFL can ride.INF without helmet, but many motorcyclists HI ride.3PL
'You cannot ride without a helmet, but many motorcyclists do so.'

In (18a) and (19a), *y/hi* corresponds to an argument, but in the (b) examples it is an adjunct: in (18b) it expresses the location in which an event takes place, and in (19b) it expresses the means or manner. One can take this to mean that *y/hi* has a double function, being alternatively an oblique or an adjunct, as in Schwarze (2001b). Or one can take this as evidence that there is no adjunct grammatical function, as argued in Alsina (1996b). According to Alsina (1996b), the distinction between argument and adjunct is made at the level of a-structure: a GF that corresponds to a position at the a-structure is an argument, whereas a GF with semantic content that does not is an adjunct. This distinction need not be duplicated at the level of GFs by increasing the inventory of GFs with ADJ, and adjuncts are simply obliques (OBL) at the level of GFs. Consequently, all we need to say about *hi/y* is that it corresponds to an OBL. By not restricting it to arguments, it follows that it can correspond to either an argument or an adjunct.

2.3 The anaphoric reflexive clitic

We can define reflexive clitics as those that show agreement in person and number with the logical subject[11] of the predicate that the clitic combines with. First and second person clitics do not have a special reflexive form distinct from their non-reflexive form. The third person does have a specific form for the reflexive use, *se* (and cognate forms), which, however, does not distinguish singular from plural. The third person form, being the only one that is unambiguously reflexive, will be normally used to illustrate the behavior of reflexive clitics.

In this section, we will only consider what we might call the anaphoric use of the reflexive clitic, by which the predicate has a semantically reflexive or reciprocal interpretation. In Section 2.3.1, we compare the pronominal analysis and the valence-reducing analysis of the anaphoric reflexive. And in Section 2.3.2, we consider three variants of the valence-reducing analysis.

The other uses of the reflexive clitic are the inherent use (Section 2.2.3) and the passive and impersonal use (Section 3.2).[12]

2.3.1 The reflexive clitic as an argument or as a marker of valence-reduction

In general, any verb that can take an object (direct or indirect) can also take a reflexive clitic instead of the phrasal object, so that the logical subject and another direct argument of the verb are interpreted as being the same set of participants: this is the anaphoric use of the reflexive clitic. The interpretation is reflexive or reciprocal depending on whether the same participant (individual or group) is involved in the relation – reflexive interpretation – or a different participant of the set is involved – reciprocal. Using Catalan to exemplify the anaphoric use of the reflexive clitic, (20a) is a transitive sentence in which the direct, or accusative, object is expressed as an NP; (20b) shows that a reflexive clitic can be used instead of the NP object, in this case with a reflexive interpretation; and this sentence resembles (20c), where a pronominal non-reflexive clitic is used instead of the object NP. The examples in (21) show the possibility of the reflexive

---

[11] See the glossary for the definition of *logical subject.*

[12] The homonymy or syncretism of the anaphoric reflexive with the passive/impersonal reflexive is complete in some Romance languages (e.g. Spanish, Catalan, or French), but is not complete in some others, specifically, in Italian. In Italian, in both uses, it has the form *si* when it is not in combination with another clitic, but, when the two uses co-occur in the same clause, we obtain the combination *ci si*, as in *ci si lava* in (4c). In addition, the anaphoric reflexive precedes a third person accusative clitic, whereas the impersonal reflexive follows it, as shown in (4). This indicates that they are different morphs in Italian, which explains the possibility of their co-occurrence together with another clitic, as *ce lo si compra* ‘one buys it for oneself’, as pointed out by an anonymous reviewer.

clitic appearing instead of a dative object and yielding a reciprocal or reflexive interpretation.

(20) Catalan

a. Mira com contradiu el director.
look how contradict.3SG the manager
'See how she contradicts the manager.'

b. Mira com es contradiu.
look how REFL contradict.3SG
'See how she contradicts herself.'

c. Mira com el contradiu.
look how 3SG.M.ACC contradict.3SG
'See how she contradicts him.'

(21) Catalan

a. Avui els estudiants enviaran regals a la professora.
today the students send.FUT.3PL presents A the teacher
'Today the students will send the teacher presents.'

b. Avui els estudiants s' enviaran regals.
today the students REFL send.FUT.3PL presents
'Today the students will send each other/themselves presents.'

c. Avui els estudiants li enviaran regals.
today the students 3SG.DAT send.FUT.3PL presents
'Today the students will send her presents.'

This pattern of facts lends itself to an analysis in which the reflexive clitic only differs from pronominal object clitics in its anaphoric properties, being obligatorily bound by some antecedent in a local domain, and is the realization of an argument of the clause. This is in fact the analysis proposed in Alencar & Kelling (2005), which we can call the "pronominal analysis." In examples like (20b) and (21b), the reflexive clitic would be argued to realize an accusative object or a dative object, just like the non-reflexive clitics do. However, this analysis has been shown to be problematic since Grimshaw (1982). Grimshaw (1982, 1990) gives compelling evidence for the claim that the reflexive clitic in its anaphoric use should be treated as not realizing an argument of the clause but as valence-reducing morphology.

The clearest evidence presented by Grimshaw (1982, 1990) for the valence-reducing analysis of the reflexive clitic concerns the behavior of the causative construction. The logical subject of the infinitive in a causative construction, with *faire* in French, is realized differently depending on the transitivity of the infinitive: indirect object if the infinitive has a direct object, and direct object otherwise, as shown in (22):

(22) French (Grimshaw 1990: 153)

a. Il fera boire un peu de vin *(à) son enfant.
he make.FUT.3SG drink.INF a bit of wine A his child
'He will make his child drink a little wine.'

b. Il fera partir {les/*aux} enfants.
he make.FUT.3SG leave.INF the/*A.the children
'He will make the children leave.'

When the infinitive has a reflexive clitic corresponding to its direct object, it behaves like an intransitive verb and its logical subject is realized as a direct object, as in (23a). In contrast, if the direct object of the infinitive is expressed as a non-reflexive clitic, its logical subject is an indirect object, as in (23b).

(23) French (Grimshaw 1990: 153)

a. La crainte du scandale a fait se tuer {le/*au} frère
the fear of.the scandal has made REFL kill.INF the/*A.the brother
du juge.
of.the judge
'Fear of scandal made the brother of the judge kill himself.'

b. La crainte du scandale l'a fait tuer {au/*le}
the fear of.the scandal 3SG.M.ACC.has made kill.INF A.the/*the
juge.
judge
'Fear of scandal made the judge kill him.'

If we assume that the reflexive clitic is not an object, unlike the non-reflexive clitic, but an element of the morphology that signals the binding of two arguments so that there is only one open argument position, we explain that the verb behaves like an intransitive verb.

Grimshaw (1982) also presents NP extraposition in French as evidence for the intransitive behavior of reflexivized verbs, i.e., verbs with an anaphoric reflexive clitic. French allows arguments that can normally appear as subjects, as in (24a), to alternatively appear as objects with a dummy *il* in subject position, as in (24b):

(24) French (Grimshaw 1982: 112)

a. Un train passe toutes les heures.
A train passes all the hours

b. Il passe un train toutes les heures.
IL passes a train all the hours
'A train goes by every hour.'

However, the construction of NP extraposition, illustrated in (24b), is restricted to intransitive verbs. In addition, there are semantic constraints on NP extraposition, but the intransitivity requirement is independent of these semantic restrictions. A reflexivized verb behaves like an intransitive verb in allowing NP extraposition, unlike verbs with non-reflexive object clitics, as the contrast in (25) illustrates:

(25) French (Grimshaw 1982: 113)

a. Il s' est dénoncé trois mille hommes ce mois-ci.
IL REFL is denounced three thousand men this month
'Three thousand men denounced themselves this month.'

b. * Il l' a dénoncée trois mille hommes.
IL 3SG.F.ACC has denounced three thousand men
'Three thousand men denounced it.'

2.3.2 Three alternative valence-reducing analyses

Having shown that reflexive cliticization turns a transitive verb into an intransitive one, three possibilities emerge as to how the two argument roles involved in the binding relation signaled by the reflexive clitic map onto only one GF (typically the subject, but not necessarily, as shown in (25a)). The three analyses, described in (26), have in common the idea that the anaphoric reflexive clitic signals the binding at the level of argument structure of the logical subject and another core argument of the same predicate:

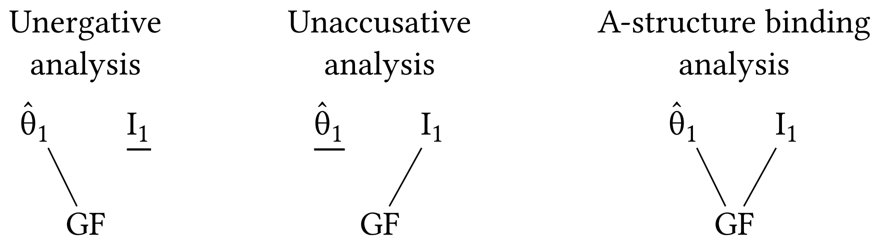
(26) a. *The unergative analysis*: the lower argument is lexically bound and therefore unable to be expressed as a GF; only the logical subject is expressed as a GF. Proposed by Grimshaw (1982).

b. *The unaccusative analysis*: the logical subject is lexically bound and therefore unable to be expressed as a GF; only the lower argument in the binding relation is expressed as a GF. Proposed by Grimshaw (1990).

c. *The a-structure binding analysis*: both arguments involved in the binding relation are expressed as a GF and are expressed as the same GF. Proposed by Alsina (1993, 1996b).

Schematically, the three analyses can be depicted as in (27), where “$\hat{\theta}$” represents logical subject, “I” represents internal argument, co-subscripting signifies binding of arguments, and underlining of an argument signifies that the argument has no mapping to GF:

(27)



Grimshaw (1982) does not present evidence specifically for the unergative analysis. The evidence presented in Grimshaw (1990) for the unaccusative anaysis rests primarily on the facts of auxiliary selection in Italian, as we shall see. Some of the evidence presented in favor of this analysis is really neutral with respect to the other two analyses in competition. Since, according to Grimshaw (1990: 154), reflexivization satisfies an external argument (by binding), it cannot apply to predicates that do not have an external argument or have a suppressed external argument. It follows that it cannot apply to passives or subject-raising predicates. This explains the contrast between English and French with subject-raising verbs (from Grimshaw 1990: 155):

(28) a. They appear to each other to be intelligent.
b. * Jean se semble intelligent. (French)
Jean REFL seems intelligent.
‘Jean seems intelligent to himself.’

Grimshaw (1990) takes the ungrammaticality of (28b) to follow from the assumption that a raising verb like *sembler* ‘seem’ does not have an external argument. However, it can also be attributed to the observation that this verb does not have two arguments that can be involved in binding: the subject in (28b) is not an argument of the raising verb, but of its complement, so that the two arguments that would be involved in binding in (28b) belong to two different predicates. And the three analyses described in (26)–(27) require that the two arguments involved in reflexive cliticization be arguments of the same predicate.

As for auxiliary selection in Italian, unergative verbs select *avere* 'have' as the auxiliary in perfective compound forms and unaccusative verbs select *essere* 'be' (following Perlmutter 1978, 1983, 1989 and Rosen 1984; see Loporcaro 2016 for an update), as shown in (29). The fact that reflexivized verbs select *essere*, as in (30), even though their non-reflexive counterparts select *avere*, is taken as evidence in Grimshaw (1990) that reflexivized verbs are unaccusatives:

(29) Italian (Katerinov 1975)
a. Avete viaggiato bene?
have.2PL travelled well
'Have you travelled well?'
b. Sono uscito.
be.1SG gone.out
'I have gone out.'

(30) Italian (Katerinov 1975)
a. Maria e Paola si sono salutate.
Maria and Paola REFL be.3PL greeted.F.PL
'Maria and Paola greeted each other.'
b. Mi sono comprato una casa nuova.
1SG be.1SG bought a house new
'I bought myself a new house.'

If the expressed argument in reflexivized verbs is the internal argument, and the external argument is not assigned to a GF, as in the unaccusative analysis in (27), it is clear that reflexivized verbs are like unaccusative verbs. However, let us suppose that the relevant notion for auxiliary selection is that verbs whose highest GF maps onto an internal argument select *essere* (where SUBJ ranks higher than OBJ, and OBJ than OBL). Then, both the unaccusative analysis and the a-structure binding analysis fare equally in predicting that both unaccusative verbs and reflexivized verbs select *essere*.

But the a-structure binding analysis does not treat reflexivized verbs as unaccusatives, since the highest GF of the former is an external argument, as well as an internal argument. This has an advantage over the unaccusative analysis as it allows us to explain two facts that the unaccusative analysis fails to explain. First, the highest GF of reflexivized verbs, being an external argument, tends to be a subject much more so than that of unaccusative verbs, which is not an external argument. This contrast between reflexivized verbs and unaccusative verbs can be clearly illustrated by using the same verb with a reflexive clitic yielding a potential ambiguity between the anaphoric and the passive interpretations. Using Catalan data, a sentence like (31a) is ambiguous between these two interpretations, whereas (31b) only allows the anaphoric interpretation:

(31) Catalan

a. Es defensaran dos diputats al parlament.
REFL defend.FUT.3PL two deputies at.the parliament
'Two deputies will defend themselves at the parliament.'
'Two deputies will be defended at the parliament.'

b. Dos diputats es defensaran al parlament.
two deputies REFL defend.FUT.3PL at.the parliament
'Two deputies will defend themselves at the parliament.'
*'Two deputies will be defended at the parliament.'

The preverbal position of the NP, with no object clitic anaphorically dependent on it attached to the verb, unambiguously signals that the NP is the subject – or, more exactly, a topic anaphorically linked to the null pronominal subject. While an internal argument, especially if expressed as an indefinite NP, is assigned the object function, an external argument favors the assignment to the subject function.

The contrast between the reflexivized verb and the reflexive passive form is even clearer, when, under the appropriate discourse conditions, we omit the noun *diputats* from (31). If the NP *dos* is postverbal, with obligatory presence of the partitive clitic *en*, only the passive interpretation is allowed; if the NP *dos* is preverbal, with no partitive clitic, only the reflexivized reading is possible:

(32) Catalan

a. Se' n defensaran dos al parlament.
REFL EN defend.FUT.3PL two at.the parliament
*'Two will defend themselves at the parliament.'
'Two will be defended at the parliament.'

b. Dos es defensaran al parlament.
two REFL defend.FUT.3PL at.the parliament
'Two will defend themselves at the parliament.'
*'Two will be defended at the parliament.'

If, as assumed in Grimshaw (1990), the reflexive passive and the reflexivized verb have the same syntactically expressed arguments, namely, the internal argument in both cases, the difference shown in (31) and (32) would be completely unexpected. On the other hand, under the a-structure binding analysis of reflexivized forms, these forms have a GF that is both an internal and an external argument, contrasting with reflexive passive forms, in which the highest GF is only an internal argument.

The second fact that favors the a-structure binding analysis is found in triadic predicates: when the binding relation involves an argument that in the non-reflexivized form of the verb is a dative object, the corresponding GF is not dative in the reflexivized form, but nominative. If argument realization with reflexivized verbs were the same as with unaccusative or passive verbs, we would not expect dative case to disappear. Dative case is retained under passivization, blocking the dative expression from being the passive subject. We see this not only with participial passives, but also with reflexive passives, as in (33b). The goal argument is dative and cannot be expressed as a nominative phrase in a reflexive passive, as in (33c). However, in the reflexivized form, in (33d) with a reciprocal interpretation, the goal argument is nominative and the subject.[13]

(33) Catalan

a. El metge va ensenyar els resultats al pacient.
the doctor PST.3SG show.INF the results A.the patient
'The doctor showed the patient the results.'

b. Es van ensenyar els resultats al pacient.
REFL PST.3PL show.INF the results A.the patient
'The patient was shown the results.'

c. * El pacient es va ensenyar els resultats.
the patient REFL PST.3SG show.INF the results
'The patient was shown the results.'

---

[13] The phenomenon is illustrated with Catalan data, but the facts are essentially the same in French, Italian, and Spanish. See, for example, the Italian reflexivized form (30b), where the first person singular reflexive clitic signals the binding of the agent and the goal, which are encoded as the (null) subject.

d. Els pacients es van ensenyar les cicatrius.
the patients REFL PST.3PL show.INF the scars
'The patients showed each other the scars.'

Under the unaccusative analysis, the NP *els pacients* in (33d) is the goal internal argument, just as the phrase *al pacient* in (33b); so, it is very unclear why it has dative case in the passive example, which prevents it from being the subject, as in (33c), but not in the reflexivized form, in which the goal argument is nominative.[14] On the other hand, within the a-structure binding analysis, the phrase *al pacient* in the passive example (33b) is the goal internal argument and no other argument, whereas the phrase *els pacients* in the reflexivized structure (33d) is both the goal internal argument and the external argument. Here there are two arguments that map onto the same GF. If we assume, as in Alsina (1996b), that dative case is assigned to the GF that maps onto the more prominent of two internal arguments, as long as it is **not an external argument**, it follows that dative case will be assigned to the goal internal argument in the active and passive forms (33a) and (33b), but not in the reflexivized form (33d).

The a-structure binding analysis of the anaphoric use of the reflexive clitic just described relies on the idea essential to LFG that grammatical information is factored into different levels of representation, allowing for mismatches among these levels. In particular, the distinction between argument roles at a-structure and GFs at f-structure plays a crucial role in this analysis. If we allow for the possibility that a given GF corresponds to two different argument roles, as schematized in (27) for the a-structure binding analysis, we can explain not only the valence-reducing effect of the anaphoric reflexive clitic, but those properties of the GF that group it with an internal argument, as in the unaccusative analysis, and those properties that group it with an external argument, as in the unergative analysis.

Following the proposal in Alsina (1996b), we can illustrate this by comparing the non-reflexive use of a dyadic predicate such as *defensar* 'defend' in Catalan with the same predicate with the anaphoric reflexive clitic. This predicate has an external argument and an internal argument, represented by [Ext] and [Int] respectively at a-structure. Each argument has its linking index, represented as a subscripted number, which, in the default case, is different for each argument, entailing a different mapping to GF. This is the situation in (34a), where the external argument maps onto the subject and the internal argument onto the object.

---

[14] Grimshaw (1990: 184) points out this problem in an endnote and essentially leaves it unsolved, although one of the solutions she sketches involves precisely a-structure binding.

The effect of the anaphoric reflexive clitic is to coindex the logical subject of a predicate with an internal argument, so that they have the same linking index and therefore map onto the same GF, as shown in (34b). The principles mapping argument roles to GFs are satisfied in (34b): the external argument is required to map onto the subject and the internal argument is required to map onto a direct GF (either subject or object) and, since the subject is a direct GF, both mapping requirements are met. The a-structure is represented as the value of the feature PRED in (34).

(34) a. Non-reflexive use of *defensar* 'defend':

$$\begin{bmatrix} \textsc{pred} & \text{`}\textsc{defend}\langle[\textrm{Ext}]_1\ [\textrm{Int}]_2\rangle\text{'} \\ \textsc{subj}_1 & \\ \textsc{obj}_2 & \end{bmatrix}$$

b. Reflexivized use of *defensar-se* 'defend-REFL':

$$\begin{bmatrix} \textsc{pred} & \text{`}\textsc{defend}\langle[\textrm{Ext}]_1\ [\textrm{Int}]_1\rangle\text{'} \\ \textsc{subj}_1 & \end{bmatrix}$$

3 Arguments, grammatical functions, and case

This section deals with the morphosyntactic expression of arguments in terms of grammatical functions and case. Section 3.1 considers the inventory of GFs, especially the GFs of subjects, objects, and clausal complements. The passive and impersonal reflexive constructions are examined in Section 3.2.

3.1 Objects and their realization

3.1.1 Direct and indirect objects: GF and case

Traditional grammar, as well as Relational Grammar, distinguishes two kinds of objects in the Romance languages: direct object (DO) and indirect object (IO). DOs, in their phrasal expression, are generally NPs without any case marker or preposition, except that in some languages a subset of DOs are marked by a preposition,[15] whereas IOs, as phrases, are PPs introduced by the preposition *a*. Both kinds of objects can be expressed as clitics and all Romance languages have different sets of pronominal clitics in the third person for the two kinds of objects. First and second person clitics do not distinguish between the two

---

[15] The prepositional marking of the DO, also known as differential object marking, is found in Spanish, Catalan, southern Italian dialects, and Sardinian, which use the same preposition as for IOs, and in Romanian, in which the preposition *pe* is used (Dragomirescu & Nicolae 2016: 920–921). See Barbu & Toivonen (2018) for the distribution of DO *pe* in Romanian.

kinds of objects.[16] Given that LFG does not have a DO and an IO in its standard inventory of GFs, researchers have accommodated this distinction into the LFG inventory of GFs in different ways. The proposals that restrict themselves to the standard LFG inventory of GFs have in common the assumption that the DO is OBJ and differ in the GF attributed to the IO, which is one of the following three: OBL, OBJ_θ, and OBJ.[17]

3.1.1.1 IO as OBL

This proposal is found in Schwarze (2001b) and Sells (2013: 185–194), although no motivation is given for adopting it instead of the available alternatives. Alsina (1996b: 150–160) enumerates eight properties that group IOs with DOs, in the class of direct functions, together with subjects, contrasting them with obliques: (1) doubling of independent personal pronouns in the verbal morphology (as clitics); (2) expression of person and number distinctions in the verbal morphology; (3) the ability to be bound at a-structure (by means of the reflexive clitic); (4) the ability to launch a floating quantifier; (5) disjoint reference of pronouns; (6) the ability to bind quantifiers; (7) the ability of independent (or strong) pronouns to function as resumptive pronouns; and (8) the ability to be the target of secondary predication. All of these properties argue against treating the IO as an oblique and show that it belongs to the class of direct GFs, together with subjects and objects.[18]

3.1.1.2 IO as OBJ_θ

This proposal is found in Falk (2001: 115–118), Alencar & Kelling (2005), Aranovich (2012), Quaglia (2012), and Carretero García (2018). Grimshaw (1982) can

---

[16] Neither do third person reflexive clitics, but then, according to Section 2.3, they are not object clitics. Instances of DO-IO syncretism are found even in third person non-reflexive clitics: this is the case of Spanish *leísmo*, in which the clitic *le* is used for both IOs and human masculine DOs. Other forms of DO-IO syncretisms in third person clitics are found in regional varieties of Spanish (Tuten et al. 2016: 398).

[17] Some exceptions to this observation are found. Luís & Otoguro (2004: 344–349) treat the single object of a clause as OBJ, whether it is direct or indirect (i.e., accusative or dative) and, in ditransitive clauses, treat the DO as OBJ_θ and the IO as OBJ. Luís & Spencer (2005) use the GFs OBJ1 and OBJ2 for the IO and the DO respectively, where we can assume that OBJ1 is another name for OBJ and OBJ2 replaces OBJ_θ. No argumentation is presented for these proposals.

[18] To these properties we could add the IO-DO syncretism in first and second person and reflexive clitics in Romance in general, the partial IO-DO syncretism in third person non-reflexive clitics in Spanish (see footnote 16), and the partial syncretism in the phrasal expression of IO and DO in those languages that use the same preposition for both objects (see footnote 15).

be grouped in this proposal, as she assumes that the DO is OBJ and uses the GF A OBJ, instead of OBJ$_\theta$, for the IO. The main argument for this proposal is the observation that dative arguments cannot be encoded as subjects: they are never the subject of a passive form, with verbs that can be passivized, and are not the subject of psychological verbs of the 'like'-type. While this is true, there are many reasons for rejecting this proposal. In languages such as Chicheŵa (asymmetrical object languages), in which the OBJ-OBJ$_\theta$ distinction is strongly motivated, the OBJ has the ability to be expressed as a morphologically incorporated pronominal, can be accessed by an a-structure binding operation (reciprocalization), and alternates with the SUBJ in a passive form, whereas the OBJ$_\theta$ lacks all of these properties (see Baker 1988a,b, Alsina & Mchombo 1990, Bresnan & Moshi 1990, Alsina 1996a, among others).[19] The IO, like the DO, in Romance is able to be expressed as a morphologically incorporated pronoun, as illustrated in examples (3b), (3c) and (21c) (see also (35)), and, like the DO, can be accessed by an a-structure binding operation (by means of the reflexive clitic), as in (21b), (30b), and (33d). The only property that the IO shares with the OBJ$_\theta$ is the fact that it cannot be a subject. To focus on this one feature of the IO in order to claim that it is an OBJ$_\theta$ is to ignore the fact that there is a cluster of properties associated with the OBJ-OBJ$_\theta$ distinction, as has been mentioned, and the fact that DO and IO are distinguished by grammatical case, unlike OBJ and OBJ$_\theta$ in most asymmetrical languages.

In addition to this, there is a difference in the thematic roles that map onto OBJ$_\theta$ in the subclass of asymmetrical languages of the Chicheŵa type termed non-alternating in Alsina (1996a) and the thematic roles that correspond to IO in the Romance languages. In Chicheŵa, only thematic roles below goal in the thematic hierarchy (i.e., instrumental, theme, patient, locative) can map onto OBJ$_\theta$, as the higher roles in the hierarchy (agent, beneficiary, goal) cannot map to OBJ$_\theta$. In contrast with this, the IO in Romance typically corresponds to the higher roles in the hierarchy (agent, beneficiary, goal, experiencer).

In other words, to assume that IO is OBJ$_\theta$ implies abandoning the idea that there is a cluster of properties associated with OBJ$_\theta$ and assuming that the only necessary and sufficient condition for the OBJ$_\theta$ function is the failure of alternating with the SUBJ function, which is clearly an undesirable loss of predictive

---

[19] In addition, in Chicheŵa, the OBJ precedes the OBJ$_\theta$ when both are expressed as NPs in the VP. However, this is not a necessary property of asymmetrical object languages, as there are languages of this type, including other Bantu languages, that allow either order of the objects. Also, the fact that the DO precedes the IO in Romance in the unmarked order is simply a consequence of the different grammatical category of the two objects, the DO being an NP and the IO being a PP.

power of the theory. And it also requires assuming that the mapping of argument roles to OBJ$_\theta$ may vary radically from language to language.

3.1.1.3 IO as OBJ

This proposal is argued for in Alsina (1996b) and is also found in Vanhoe (2002). It places a lot of importance on the observation that DO and IO are distinguished primarily by means of grammatical case. Both DO and IO are the GF OBJ and are distinguished because IO is dative and DO is non-dative (i.e., accusative, although nominative is also an option, see Section 3.1.3). What needs to be accounted for in this approach is case assignment, particularly, the assignment of dative case. Alsina (1996b) notes that dative case is assigned either on the basis of the semantics, specifically, the thematic role involved, or on the basis of the a-structure configuration. In the first case, dative is claimed to be assigned to arguments whose thematic role is goal and this assignment does not depend on there being a non-dative object in the clause, as illustrated in (35a). In the second case, dative is assigned to the GF corresponding to the more prominent of two internal arguments, as in (35b). As there need to be two internal arguments each mapping to a different GF for the latter type of dative case assignment, dative fails to be assigned to the single internal argument of a clause (unless it meets the semantic requirement), as in (35c). The dative-accusative case alternation in (35b)–(35c) also occurs with the causee in causative constructions depending on transitivity of the embedded infinitive (see (22) and Section 4.1).

(35) Catalan (Alsina 1996b: 172)

a. En Ferran li ha escrit (una carta).
ART Ferran 3SG.DAT has written a letter
'Ferran has written him (a letter).'

b. Li ensenyen llatí.
3SG.DAT they.teach Latin
'They teach him Latin.'

c. L' ensenyen.
3SG.M.ACC they.teach
'They teach him.'

The only property that seems to indicate that IO behaves like OBJ$_\theta$ is the claim that dative arguments are never subjects in Romance, but must be objects instead. Alsina (1996b) claims that this fact is best accounted for through a constraint prohibiting subjects with dative case. This constraint is active in the Romance languages, which do not allow dative subjects,[20] but is not active in languages such as Icelandic or Hindi (see Zaenen et al. 1985 and Mohanan 1994, respectively, among others), in which dative subjects are possible. The thematic roles to which dative case is assigned are very similar across these different languages, but Romance differs from Icelandic and Hindi basically because dative blocks the assignment of the subject function in the former, but not in the latter. Introducing the OBJ-OBJ$_\theta$ distinction in the description of the facts would just obscure the differences and similarities among these languages.[21]

Accepting the idea that IO is OBJ implies that a given clause may have more than one GF OBJ, since clauses often have an IO and a DO and sometimes even more than one IO. In this respect, OBJ would not be different from OBJ$_\theta$ or OBL$_\theta$, of which clauses may have more than one. This requires modifying the framework, which, in its standard form, does not allow multiple GFs with the same attribute, unless the GF in question is assumed to take a set of f-structures as its value rather than a single f-structure. Alsina (1996b) assumes that the only GF that is unique in a clause is the subject, whereas the other two GFs, namely, object and oblique (in a reduced inventory of GFs with only the three named GFs), are not required to be unique and can have multiple instantiations. This proposal can be implemented by assuming that both OBJ and OBL take a set of f-structures as their value, whereas SUBJ takes an f-structure as its value. See also Patejuk & Przepiórkowski (2016) for a different implementation of the idea that the inventory of GFs consists of only the three GFs mentioned.[22]

3.1.2 The GF of clausal complements

The debate about the inventory of GFs in LFG has also addressed the issue of the GF COMP, a GF that in standard LFG is reserved for clausal complements, typically finite. Alsina et al. (2005) (AMM) argue that this GF is not necessary and, in fact, complicates the statement of generalizations and that clausal complements

---

[20] However, some authors have claimed that dative experiencers can be subjects, e.g. Cardinaletti (2004) for Italian and Fernández-Soriano (1999) for Spanish.

[21] Certain verbs take a dative object as their sole object. This occurs in Latin with verbs such as *subvenire* 'help', *parcere* 'spare', etc., as well as in the Romance languages. This is unlike the OBJ$_\theta$ in languages such as Chicheŵa, where it occurs only in a double object construction.

[22] This idea is also valid for asymmetrical languages like Chicheŵa, since the distinction between primary and secondary object (OBJ and OBJ$_\theta$, respectively, in standard LFG) needs to be made at the level of a-structure, as argued in Alsina (1993, 2001), by means of a feature (R) that marks secondary objects, and only at that level, so that both primary and secondary objects are simply objects at the level of GFs.

should be assumed to be either objects or obliques.[23] The argument based on Catalan is as follows. Catalan has two types of clausal complements introduced by the complementizer *que*, without a preposition: those that alternate with a nominal complement, which can be expressed by the object clitic *ho*, and that can passivize, and those that alternate with a prepositional complement, that can be expressed by one of the oblique clitics *hi* or *en*, and that cannot passivize. (36) exemplifies a complement of the first type: the verb *entendre* 'understand' can take a nominal complement, as in (36a), can cliticize its clausal complement by means of *ho*, as in (36b), and can passivize with the dependent clause as the subject, as in (36c):

(36) Catalan (AMM)

a. (La teva explicació) no l' he entesa.
the your explanation not 3sg.f.acc have.1sg understood.f
'(Your explanation$_i$) I didn't understand it$_i$.'

b. (Que hagis arribat tan tard) no ho he entès.
that have.2sg arrived so late not ho have.1sg understood
'(That you should have arrived so late$_i$) I didn't understand it$_i$.'

c. Que votessis a favor de la proposta no va ser
that vote.sbjv.2sg in favor of the proposal not pst.3sg be
entès per una part del públic.
understood by a part of-the audience
'That you should have voted in favor of the proposal was not understood by part of the audience.'

Convèncer 'convince' is a verb that takes a clausal complement of the second type: it alternates with a PP, as in (37a), but does not take a preposition, as in (37b), and can be expressed by means of the oblique clitic *en*, as in (37c):

(37) Catalan (AMM)

a. M' heu de convèncer **de** les seves possibilitats.
me have.2pl to convince of the 3poss possibilities
'You have to convince me of his possibilities.'

b. M' heu de convèncer (***de**) que torni a casa.
me have.2pl to convince of that return.1sg to home
'You have to convince me to return home.'

---

[23] A defense of the GF comp can be found in Dalrymple & Lødrup (2000), Lødrup (2004, 2012), and Belyaev et al. (2017).

c. Me n' heu de convèncer.
me en have.2pl of convince
'You have to convince me of that.'

Another class of verbs that take a clausal complement introduced by *que* is illustrated by *estar d'acord* 'agree', which takes a different preposition, *en*, when the complement is not clausal, and a different clitic form, *hi* (see relevant examples in AMM).

The choice of oblique clitic (*en* vs. *hi*) is related to the choice of oblique preposition: oblique complements introduced by the preposition *de* can be expressed by means of the clitic *en*, whereas other obliques alternate with the clitic *hi*. Replacing one oblique clitic by the other one renders the sentences ungrammatical. In addition, neither of the two classes of verbs allows the dependent clause introduced by *que* to be the subject of a passive form, as illustrated in (38) for *convèncer*.

(38) Catalan (AMM)
* Que tornés a casa va ser convençut en Martí.
that return.sbjv.3sg to home past.3sg be convinced the Martí
'That he return home was convinced Martí.'

A possible LFG approach to these facts using the comp function would assume that a clausal complement can be either an obj or a comp: it is an obj in cases like (36b), where it alternates with an NP, with object clitics, and with the subject in a passive clause, whereas it is a comp in (37b), where it has none of these properties. This means that predicates like *convèncer* and *estar d'acord* have two different subcategorization frames depending on whether the complement is nominal or clausal: they take an obl for sentences such as (37a) and a comp for sentences such as (37b) and, to complicate matters further, the clitic that corresponds to the obl and to the comp is unique for each verb regardless of whether it corresponds to the obl or to the comp, as in (37c). No generalization can be made regarding the choice of clitic, given that some comps are expressed as *en* and some others are expressed as *hi*, and the choice does not depend on the comp but on the obl that appears on the alternative subcategorization frame of the verb.

If, on the other hand, we assume that there is no such GF as comp, as claimed in AMM, but clauses can be the c-structure realization of either obj or obl (just as they can be of subj), the different behavior of the clausal complements shown in (36)–(38) simply follows from their being either obj or obl, together with a constraint preventing clausal complements from taking a preposition. This constraint (let us call it *P+CP) is active in languages like Catalan or French (see

Forst 2006 for relevant data on French) and English, where clausal complements are not preceded by a preposition, but not in languages like Spanish, where complements take their required preposition regardless of the category of the complement (nominal or clausal).[24]

In languages with an active *P+CP, a verb selecting an oblique with a particular case feature (say genitive) will normally require this case feature to be overtly realized (by means of the preposition *de* or by means of the clitic *en*, which are alternative ways of realizing genitive case), but, if the realization of the oblique should cause a violation of *P+CP, an alternative expression is chosen that does not cause this violation, even though it fails to realize the case requirement. This can be done in an OT framework, although other ways of obtaining prepositionless oblique clauses are possible.

In this way, eliminating COMP from the inventory of GFs not only results in a simplification of the framework (it is preferable to have fewer theoretical constructs), but also in a simplification of the analysis (verbs that alternate between taking a PP complement and a plain clausal complement, such as *convèncer*, have only one subcategorization frame, with an OBL, rather than two, one with an OBL and one with a COMP) and it reduces the redundancy in the theory (the c-structure realization of COMP is predictably clausal, i.e., CP or IP, but not NP or PP, whereas in the framework without COMP, both OBL and OBJ can map onto either a nominal or a clausal category) and makes it possible to state generalizations that are obscured in the framework with COMP (e.g., the fact that the clitic realization that corresponds to a clausal complement is the one that corresponds to the object or oblique complement of the verb).

3.1.3 Mixed subject-object properties

It is generally assumed that the single core argument of unaccusative verbs alternates between subject and object.[25] It can be shown that this argument sometimes has objecthood properties and sometimes has subjecthood properties. A paradox arises when we observe that this argument can have both types of properties in the same structure.

---

[24] Danish, according to Nigel Vincent (p.c.), is another language where the *P+CP constraint is not active: e.g. *det endte med at han blev fyret* 'it ended with that he was fired'.

[25] The Unaccusative Hypothesis – the idea that intransitive verbs are classified into two classes depending on whether their core argument has some objecthood properties or not – was originally proposed by Perlmutter (1978) within the framework of Relational Grammar and subsequently adapted to other frameworks. See Section 2.3.2 for the different behavior of unaccusative and unergative verbs with respect to auxiliary selection in Italian.

Evidence for assuming that the single core argument of unaccusative verbs can be expressed as an object is provided by the possibility of encoding this argument by means of the partitive clitic in those languages that have it, such as Catalan, French, and Italian. Since Perlmutter (1983), Rosen (1984), and Burzio (1986) for Italian (see also Alsina 1996b for Catalan), the claim is that this clitic must correspond to a direct object.[26] Example (39) shows that the unaccusative verb *sortir* 'go out' in Catalan allows its single core argument to be expressed by means of the partitive clitic, which, in this example, corresponds to the postverbal NP *un*. Given the claim just noted, this NP has to be a direct object.

(39) Catalan (Alsina & Yang 2018: 48)
Cada dia surten molts trens, però avui només n' ha sortit un.
every day leave.3PL many trains but today only EN has left one
'Every day many trains leave, but today only one has left.'

Additional evidence supporting the claim that the argument partially encoded by the partitive clitic is an object comes from past participle agreement. In Catalan, the past participle optionally agrees in gender and number with a third person object clitic, when co-occurring with the perfective auxiliary *haver* 'have'. The partitive clitic is one of the third person object clitics that can trigger past participle agreement, as in (40):

(40) Catalan (Fabra 1912: 160)
N' han arribats molts.
EN have.PL arrive.PTCP.M.PL many.M.PL
'Many have arrived.'

In addition, the possibility of expressing the single direct argument of an intransitive verb as a bare indefinite NP provides further evidence for the objecthood of this argument, given the observation that this type of expression is excluded for the subject of transitive verbs.

---

[26] The claim that, among intransitive verbs, only unaccusatives allow the partitive clitic, though commonly accepted, has been questioned by various scholars, who have pointed out that unergative verbs also allow the partitive clitic corresponding to their single core argument, at least under certain circumstances, such as Lonzi (1986) and Saccon (1995) for Italian, Cortés & Gavarró (1997) and Alsina & Yang (2018) for Catalan. Regardless of the correctness of this claim, the shared assumption is that the partitive clitic in these languages corresponds to a DO, which implies that the single core argument of an intransitive verb can be encoded as an object.

Alongside the object encoding of the single direct argument in examples like (39)–(40), it is also possible for this argument to be expressed as the subject. The clearest evidence for this alternative encoding is the possibility of subject pro-drop. In a subject pro-drop language such as Catalan, a subject (and only a subject) can be null and be interpreted as having a definite referent, which indicates that, in (41), the missing argument, the logical subject of *sortir* 'leave', is its subject:

(41) Catalan (based on Alsina & Yang 2018: 50)
Avui Ø surten tard.
today leave.3PL late
'Today they are leaving late.'

If we should take verb agreement to be a subjecthood diagnostic in Catalan, we would have a problem in examples like (39)–(40). We find that the verb does not only agree with the subject, as is the case in (41), but also with the argument that is claimed to be an object. In (40), for example, the single core argument of *arribar* 'arrive' is expressed as the NP *molts* 'many', which has been argued to be an object, and yet this object agrees with the finite verb form *han*. But there is no need to assume that the agreement trigger is a subject. The verbal agreement facts of languages like Icelandic or Hindi indicate that the verb can agree with a grammatical function other than the subject, provided that it is in nominative case. And there is independent evidence that this is the case in Catalan as well. As shown in Alsina & Vigo (2014), in copular constructions with a predicative NP in Catalan, which are characterized by having two nominative phrases, the verb agrees with the nominative phrase that is higher in a person-number hierarchy where first and second person outrank third person and, among third persons, plural outranks singular (similar facts are found in Spanish and Italian). This indicates that what is necessary is for the agreement trigger to be a nominative expression.

Alsina & Yang (2018) propose an argument realization theory in which case is assigned to arguments independently of their GF and has the effect of constraining the GF assigned to an argument. According to their case assignment principles, nominative is assigned as a default to a core argument: a core argument that is not assigned dative or accusative case receives nominative. A constraint disallowing subjects with a case value other than nominative ensures that subjects in Catalan, and in the Romance languages in general, are nominative. Crucially, while all subjects are nominative, not all nominative arguments are subjects. The single core argument of an unaccusative verb is assigned nominative case and maps either onto the subject or the object.[27]

Thus, the paradox noted at the beginning of this subsection disappears. The single core argument of an unaccusative seems to have simultaneous subjecthood and objecthood properties: in examples like (39)–(40) it is encoded by the partitive clitic and triggers past participle agreement, which are properties of objects, and it triggers finite verb agreement, which is usually assumed to be a property of subjects. However, once we observe that finite verb agreement is triggered by the nominative argument, all we need to assume is that the single core argument of a verb is always nominative and alternates between the subject and the object functions. As a nominative object, it has the standard objecthood properties, shared with accusative objects, and triggers finite verb agreement, a property of nominative arguments.

3.2 Passive and impersonal constructions

In this subsection we deal with passive and impersonal constructions. In Section 3.2.1, we compare the participial passive (or passive with auxiliary ESSE 'be') and the reflexive passive. And in Section 3.2.2, we review the evidence for considering the reflexive passive and the reflexive impersonal as the same or different constructions.

3.2.1 Two passive constructions

All Romance languages have two passive constructions, which we will call the participial passive and the reflexive passive. (The reflexive impersonal construction will be discussed in Section 3.2.2.) The participial passive is characterized by having the main predicate in the past participial form,[28] by the agreement in gender and number of this participle with its subject, by the fact that this subject has the same thematic role as the accusative object of the corresponding active

---

[27] Alsina & Yang (2018) assume that this nominative argument maps onto the subject, when it is definite, and onto the object, when it is indefinite. This follows from treating the Subject Condition as a constraint in an OT setting and ranking it below an Indefinite Subject Ban, which penalizes an indefinite subject, in subject pro-drop languages like Catalan. So, the single core argument is a subject in an example like (41), but is an object in examples like (39)–(40).

[28] The assumption that past participles (of transitive verbs) can be passive and that it is the participial morphology that signals that the construction is passive is made in Bresnan (1982: 9–10) for English and in Loporcaro et al. (2004) for Romance, among others. The syntactic structure in which the participle is used (e.g., whether the auxiliary is 'be' or 'have') constrains the choice of the active or passive reading of the participle.

form, and by the fact that the thematic role of the subject of the corresponding active form is either unexpressed or expressed by means of an oblique phrase (introduced by the preposition *da* in Italian, *par* in French, *por* in Spanish and Portuguese, *per* in Catalan, etc.). The passive participle can be used heading an adjunct clause, modifying either a clause or a noun, or as the main predicate of the clause along with a special auxiliary for passive clauses – the equivalent of *be* in the different languages (*ser*, *être*, *essere*, etc., although some languages have additional passive "auxiliaries," such as *venire* or *andare* in Italian), as in the Catalan examples in (42):

(42) Catalan

a. Examinada la situació pels experts, la solució
examine.PTCP.F.SG the.F.SG situation by.the experts the solution
arribarà aviat.
arrive.FUT.3SG soon
'Once the situation has been examined by the experts, the solution will arrive soon.'

b. La situació serà estudiada pels experts fins a
the.F.SG situation be.FUT.3SG study.PTCP.F.SG by.the experts until A
l' últim detall.
the last detail
'The situation will be studied by the experts up to the last detail.'

Participial passives are also known as periphrastic passives, as they require an auxiliary in order to function as the main predicate of a clause other than an adjunct clause; however, since they can occur without an auxiliary in adjunct clauses such as in (42a), the term "participial passive" seems more appropriate.

The reflexive passive (or "Middle se" to use Grimshaw's (1982) term) is characterized by the use of the reflexive clitic in the third person. The effects of this clitic on the mapping between arguments and GFs are very similar to those of the participial passive: the logical subject is suppressed, i.e., not expressed as a direct GF, and the direct object of the active form is the nominative GF, typically the subject. However, with the reflexive passive, the suppressed logical subject is generally not expressible as an oblique phrase. Morphologically, the reflexive passive is identical to the anaphoric and inherent uses of the reflexive reviewed in Section 2.2.3 and Section 2.3 and, potentially, gives rise to ambiguities with those uses of the reflexive. Two examples of reflexive passives in Catalan are given in (43), using verbs that, without the reflexive clitic, are transitive (i.e. take a direct, or accusative, object).

(43) Catalan

a. Aquesta obra s' estrenarà demà.
this play REFL premiere.FUT.3SG tomorrow
'This play will be premiered tomorrow.'

b. Es preparen moltes pizzes en aquest local.
REFL prepare.3PL many pizzas in this establishment
'Many pizzas are prepared in this establishment.'

The direct object of the non-reflexive form corresponds to the nominative GF in the reflexive passive. As a nominative GF, it shows agreement with the verb: singular in (43a) vs. plural in (43b). It can be the subject, and often is (see Section 3.1.3): as such, it can appear in clause-initial position without an agreeing clitic on the verb, as in (43a), can be omitted with a definite interpretation, as in (44a), and cannot be expressed by means of a definite clitic, as in (44b):[29]

(44) Catalan

a. S' estrenarà demà.
REFL premiere.FUT.3SG tomorrow
'It will be premiered tomorrow.'

b. * Se les preparen en aquest local.
REFL 3PL.F.ACC prepare.3PL in this establishment
'They are prepared in this establishment.'

In subject pro-drop languages, like Catalan, subjects can be omitted with a definite interpretation, accounting for (44a). And definite object clitics such as *les* can only correspond to objects, which explains (44b).

Whereas the anaphoric and inherent uses of the reflexive clitic are compatible with all person features (first, second, and third), the reflexive passive can only occur with the third person clitic. It is not possible to have a reflexive passive with a first or second person subject, as that would require a first or second person reflexive clitic. Compare a well-formed participial passive with a first person subject, (45a), with the corresponding ill-formed reflexive passive, (45b).

(45) Catalan

a. He estat vist passant per la plaça.
have.1SG been seen passing by the square
'I have been seen walking across the square.'

---

[29] (44b) is grammatical with an anaphoric interpretation, irrelevant here: 'They prepare them for themselves in this establishment.'

b. * M' he vist passant per la plaça.
me have.1sg seen passing by the square
'I have been seen walking across the square.'

The two passive constructions are different morphologically, but share the definitional properties of a passive construction: the logical subject cannot be encoded as a direct GF and there is an internal argument encoded as a nominative GF, often the subject.

3.2.2 Reflexive passive and reflexive impersonal: one or two constructions?

The construction that we may call the impersonal reflexive, which is common at least in Spanish, Catalan, and Italian, like the reflexive passive also involves the reflexive clitic. It has a passive-like interpretation, as the argument that would be the subject without the reflexive clitic is unexpressed and interpreted as an arbitrary or unspecified human. It is found with intransitive predicates of both agentive and non-agentive types, as in (46). It also occurs with transitive verbs, in which case the internal argument should be analyzed as an accusative object because it does not agree with the verb and can be expressed by means of a definite object clitic, as in (47).

(46) Catalan

a. Demà no es treballa.
tomorrow not refl work.3sg.
'There is no work tomorrow.'

b. No se surt fins que ho digui jo.
not refl go.out.3sg until that ho say.sbjv.1sg I
'No one goes out until I say so.'

c. S' ha de ser tossut per fer això.
refl have.3sg of be.inf stubborn to do.inf this
'You've got to be stubborn to do this.'

(47) Catalan

a. S' ha seguit els sospitosos fins al seu pis.
refl have.3sg followed the suspects until a.the their flat
'The suspects have been followed up to their flat.'

b. Se' ls ha seguit fins al seu pis.
refl 3pl.m.acc have.3sg followed until a.the their flat
'They have been followed up to their flat.'

There are clear similarities between the reflexive passive and the impersonal reflexive constructions that make it desirable to assume that the reflexive clitic performs the same function in both cases. The two constructions share the fact that the logical subject is not expressed and is interpreted as an arbitrary or unspecified human and that they can only be used with the third person form of the reflexive clitic. For this reason it is not possible to distinguish them semantically. This has led some researchers, such as Cardona (2015), to claim that both constructions should be treated as a passive construction.[30]

However, no attempt to derive the two constructions from a single operation performed by the reflexive clitic has successfully explained all the facts of both constructions. The main objections to such a reductionist approach, which would assume that the reflexive clitic is the morphological exponent of a passive operation in both constructions, have been pointed out in Yang (2019). The first objection concerns the conditions on accusative case assignment. Accusative case can only be assigned in an argument structure that contains an external argument expressed as a direct function. This explains the observation that passive sentences in Romance, including reflexive passive sentences, do not have accusative objects: for this reason the reflexive passive (44b) is ungrammatical, as it has an object clitic that corresponds to an accusative object. But if the impersonal reflexive were also a passive form, we would not be able to explain the grammaticality of (47b), which does contain a clitic corresponding to an accusative object. As a passive form, it would not have a direct function mapped onto the external argument and accusative case should not be assigned.

The second objection has to do with the observation that the impersonal *se* can occur in constructions in which one cannot argue that a logical subject is being suppressed, either because the argument that is interpreted as a generic or arbitrary human is not a thematic argument of the predicate or because it is not the logical subject. This is arguably the situation with copular sentences, such as (46c), on the assumption that the subject of the copula is not an argument of the copula, but of its predicative complement. And it is definitely the case when impersonal *se* is attached to a participial passive sentence, as in (48). Although such examples are rare and hard to contextualize, they are not ungrammatical.

---

[30] See Bentley (2006) for an attempt to capture both the differences and the commonalities between the anaphoric, passive and impersonal uses of the reflexive clitic in Italian, within the framework of Role and Reference Grammar.

(48) Catalan (Institut d'Estudis Catalans 2016: 895)
Passava això quan s' era expulsat del partit.
happened this when REFL was expelled from.the party
'This is what happened when one was expelled from the party.'

The reflexive clitic cannot be the exponent of the suppression of the logical subject of the verb in participial form, because this argument is already suppressed by the participial morphology. If anything is suppressed by the reflexive morphology, it is the subject of the copula, a non-thematic GF of this verb that controls the subject of the participial verb, which is not its logical subject.

Given these two objections to the unified analysis of the reflexive passive and the reflexive impersonal, it seems necessary to assume that they are two different constructions, as concluded in Yang (2019): the reflexive passive is a passive construction, in which the logical subject is suppressed, whereas the reflexive impersonal licenses a null, 3rd person singular subject, with an arbitrary human interpretation. This is also the proposal in Kelling (2006).

The reflexive passive and the reflexive impersonal, although different constructions, are in competition. According to Aranovich (2009), with dyadic predicates, in Spanish, the choice between the two constructions is determined by the animacy features of the internal argument. If this argument is animate, the reflexive impersonal construction is employed, but if it is inanimate the reflexive passive is preferred:[31]

(49) Spanish (Aranovich 2009: 623–624)

a. Ayer se atrapó a los ladrones.
yesterday REFL caught.3SG A the thieves
'The thieves were caught yesterday.'

b. Ayer se atraparon las pelotas.
yesterday REFL caught.3PL the balls
'Yesterday, the balls were caught.'

(50) Spanish (Aranovich 2009: 623–624)

a. * Ayer se atraparon los ladrones.
yesterday REFL caught.3PL the thieves
'The thieves were caught yesterday.'

---

[31] While there might be a strong preference for the choice between the two constructions to depend on the animacy of the internal argument, sentences such as (50) are generally not considered to be ungrammatical.

b. * Ayer se atrapó las pelotas.
yesterday REFL caught.3SG the balls
'Yesterday, the balls were caught.'

Aranovich (2009) develops an analysis using Optimality Theory (OT) and Lexical Mapping Theory (LMT). In this analysis, the alternation between the reflexive impersonal and the reflexive passive is the result of a conflict between two constraints, one favoring the assignment of the subject function to the reflexive clitic and another one penalizing inanimate objects. The difference between the two constructions is reflected in the GF assigned to the reflexive clitic, which is a subject in the reflexive impersonal and an oblique in the reflexive passive. The reflexive passive avoids the marked configuration of an inanimate object by allowing the inanimate internal argument to be realized as the subject. See Aranovich (2009) for the details of the analysis.

4 Complex predicates

Complex predicates have been the object of investigation within LFG in a variety of languages since work such as Mohanan (1990, 1994), Matsumoto (1992), Alsina (1993, 1996b), and Butt (1993, 1995). For present purposes we can follow Butt's (1995: 2) definition and take a complex predicate to be a construction whose argument structure is complex, in the sense that two or more semantic heads contribute to it, and whose GF structure is that of a simple predicate. The Romance languages have made a significant contribution to this investigation, as they have several constructions that are analyzed as complex predicates, particularly, the causative construction and restructuring constructions. In Section 4.1 we examine the facts of these constructions and, in Section 4.2, we review some of the analyses that have been proposed for them.

4.1 The causative and restructuring constructions

4.1.1 The causative construction

In contrast with languages where causative verb forms are a single word consisting of a stem and a causative affix (as in Chicheŵa and many Bantu languages), causative constructions in the Romance languages comprise two verb forms (leaving aside the fact that they can also be accompanied by auxiliaries):

the causative verb and an infinitive complement.[32] There are two causative verbs, which behave alike in most respects syntactically: *fare* 'make' and *lasciare* 'let' in Italian, and the corresponding pairs in French (*faire* and *laisser*), Spanish (*hacer* and *dejar*) or Catalan (*fer* and *deixar*);[33] see examples (51)–(54).

What distinguishes the causative construction in Romance from other constructions in which a verb takes an infinitival complement is what we might call the monoclausality of the causative construction, that is, the fact that the causative verb and the infinitive behave as if they were part of one and the same clause from the point of view of the f-structure. As shown in Alsina (1997), the causative verb and the infinitive are a unit at the level of f-structure, very much like causative verbs in Chicheŵa, but are clearly two different units (i.e., two separate verbs) at the level of c-structure, unlike causative verb forms in Chicheŵa, which are a unit at both levels.

Following is some of the evidence in favor of the monoclausality of the causative construction:

4.1.1.1 The case alternation on the causee

(I use the term causee here to refer to the logical subject of the infinitive, or embedded predicate, in the causative construction.) As shown in Section 2.3.1, example (22), repeated here as (51), the case of the causee depends on the transitivity of the embedded predicate: it is dative if the embedded predicate has an accusative object, and it is accusative otherwise.

(51) French (Grimshaw 1990: 153)
a. Il fera boire un peu de vin *(à) son enfant.
he make.FUT.3SG drink.INF a bit of wine A his child
'He will make his child drink a little wine.'

---

[32] The Romance languages also include many verbs that are causative in meaning but cannot be considered to be complex predicates in the sense intended here as they are not decomposable into a base predicate and a causative predicate (whether bound morpheme or independent word). This is the case of *romper* 'break' or *abrir* 'open' in Spanish, or *chiudere* 'close' or *raffreddare* 'cool' in Italian. Some of these verbs, including the examples given, undergo the causative-anticausative alternation, which is signaled morphologically by means of the reflexive clitic on the anticausative member of the alternation (e.g. *romperse* or *abrirse* in Spanish and *chiudersi* or *raffreddarsi* in Italian). It is, therefore, an *anticausative* alternation, in Haspelmath's (1993) terms (see also Cennamo 2016: 971), in contrast with the Bantu pattern, where the alternation is causative.

[33] Some of these verbs also admit a biclausal raising-to-object construction, in which both the causative verb and the dependent infinitive head their own clause and the object of the causative verb functionally controls the subject of the infinitival clause. This is the case of a French example such as *Elle a laissé Jean laver la voiture* 'She let John wash the car.' Since these constructions are not complex predicates, they will not be discussed here.

b. Il fera partir {les/*aux} enfants.
he make.FUT.3SG leave.INF the/*A.the children
'He will make the children leave.'

This case alternation would be unexpected if the infinitive were the f-structure head of an embedded clause. By viewing the two verbs in the construction as forming a unit, a PRED, at f-structure, this case alternation can be made to follow from a theory of argument realization in which dative case is assigned only as a marked option, that is, to the more prominent of two internal arguments (as proposed in Alsina 1996b and Alsina & Yang 2018).

4.1.1.2 Clitic climbing

Clitics that correspond to argument roles of the embedded predicate usually appear attached to the causative verb (or to a higher auxiliary or restructuring verb), as in (52):

(52) Catalan

a. Això m' hi ha fet pensar.
that me HI has made think.INF
'That made me think about it.'

b. Aquests documents, els faré enquadernar.
these documents 3PL.M.ACC I.will.make bind.INF
'These documents, I will have them bound.'

The clitic *hi* in (52a) corresponds to the oblique complement of *pensar* 'think' and yet appears attached to the auxiliary of the causative verb; likewise in (52b), where the clitic *els* corresponds to the accusative object of *enquadernar* 'bind'. This property is not found with verbs that take an infinitival clausal complement, such as *semblar* 'seem', *caldre* 'be necessary', *convenir* 'be convenient', *insistir* 'insist, etc., in which case the clitics dependent on the infinitive appear attached to the infinitive.

4.1.1.3 Reflexivization

The reflexive clitic can encode the binding of the logical subject of the causative predicate and an argument of the embedded predicate, as in (53a).

4.1.1.4 Reflexive passive

A reflexive passive of the causative predicate, encoded by the reflexive clitic, can have an argument of the embedded predicate as its nominative argument, agreeing with the causative verb (or a higher auxiliary or restructuring verb), as in (53b).

(53) Catalan

a. S' ha fet criticar durament.
REFL has made criticize.INF hard
'She has got herself criticized severely.'

b. S' han fet arreglar les façanes del carrer principal.
REFL have.3PL made fix.INF the façades of.the street main
'The façades of the main street have been made to be repaired.'

4.1.1.5 Passivization

Some Romance languages allow participial passivization of the causative construction, in which an argument of the embedded predicate is the subject of the passivized causative structure. This possibility is illustrated for Italian in (54a), from Frank (1996), whereas French is a language that does not allow it.

4.1.1.6 Past participle agreement

Among those Romance languages in which the past participle of compound tenses agrees with the accusative object expressed as a clitic (or, depending on the language, in other cases as well), Italian has this phenomenon in causative constructions, as in (54b), although French does not.

(54) Italian

a. Questo libro è stato fatto leggere a Mario da Giovanni.
this book is been made read.INF A Mario by Giovanni
'This book has been made to be read by Mario by Giovanni.'

b. Le tavole, le ho fatte riparare a Gianni.
the.F.PL table.F.PL 3PL.F.ACC have.1SG make.PTCP.F.PL repair.INF A Gianni
'The tables, I have made Gianni repair them.'

Other phenomena that support the monoclausal treatment of the causative construction include *tough* movement, which in Romance is a clause-bound phenomenon: as it can affect the object of the embedded predicate in a causative construction, it shows that the causative predicate and the embedded predicate constitute a single complex predicate. Although the facts are quite compelling in this respect, there are some attempts to explain them adopting a biclausal approach, as in Yates (2002).

4.1.2 The restructuring construction

The restructuring construction, present in many of the Romance languages, but absent in modern French, is similar to the causative construction in that it also involves two verbs (not counting auxiliaries) that form a complex predicate and behave as if they belonged to the same clause, but differs from it in not increasing the valence of the embedded predicate. The list of restructuring verbs varies somewhat from language to language, and even from one speaker to another, but it typically includes verbs such as (using Catalan for the examples) *voler* 'want', *poder* 'can, be able', *saber* 'know', *venir a* 'come to', *anar a* 'go to', *tornar* 'do again', *començar a* 'begin', *acabar de* 'finish', etc. The construction was first described by Aissen & Perlmutter (1976) and Rizzi (1976),[34] who proposed an optional process of clause union or restructuring, respectively, in order to explain that a restructuring verb, such as those just mentioned, and a dependent verb can behave as if they were a single verb from the point of view of their GFs.

As with the causative construction, one of its salient features is the possibility of clitic climbing. Reflexivization and the reflexive passive are also possible with the restructuring construction. Some verbs allow participial passive and languages that have past participle agreement with the object in compound tenses also exhibit this phenomenon in the restructuring construction. In languages that have auxiliary selection, like Italian, the choice of auxiliary is determined by the embedded verb. To illustrate just some of these phenomena in Italian, *dovere* 'have to', as a verb taking an infinitival phrase, allows clitic climbing, as the position of the clitic *gli* illustrates in (55), and also allows, but does not require, the choice of auxiliary to be determined by the infinitive, as shown in (56):

(55) Italian (Rizzi 1982: 4)

a. Gianni ha dovuto parlargli personalmente.
Gianni has had.to speak.3SG.M.DAT personally

---

[34] Although these works are better known through later publications, specifically Aissen & Perlmutter (1983) and Rizzi (1982), the fact that the first version of these works has the same date of publication suggests that they were developed independently of each other.

b. Gianni gli ha dovuto parlare personalmente.
Gianni 3sg.m.dat has had.to speak personally
'Gianni has had to speak with him personally.'

(56) Italian (Rizzi 1982: 19)
Piero ha / è dovuto venire con noi.
Piero has / is had.to come with us
'Piero has had to come with us.'

Interestingly, when clitic climbing takes place from an infinitive such as *venire* 'come', which selects *essere*, the option of using the *avere* auxiliary disappears, as shown in (57):

(57) Italian (Rizzi 1982: 21)
a. Maria c' è dovuta venire molte volte.
Maria ci is had.to.f.sg come many times
b. *? Maria ci ha dovuto venire molte volte.
Maria ci has had.to come many times
'Maria has had to come there many times.'

Restructuring is optional, accounting for the options in (55)–(56). When restructuring occurs, clitic climbing is required and auxiliary choice is determined by the dependent infinitive, which accounts for the contrast in (57).

4.2 Analyses of the Romance complex predicates

Alsina (1996b), adapting Alsina's (1992) proposal for the causative predicate in Chicheŵa, assumes that the causative predicate in Romance has a three-place argument structure, in which there is a causer, an affected (or acted-upon) argument, and a caused event. In addition, the affected argument is fused with an argument of the caused event, so that there is a GF that corresponds to two argument roles: the affected argument of the causative predicate and another role of the caused event. The caused event position in the causative argument structure is filled by the predicate of the infinitive in the causative construction.

In this way, the causative complex predicate is formed in the syntax in Romance, whereas it is formed in the lexicon in Chicheŵa. As argued in Alsina (1997), the causative complex predicate is the same in the two languages as far as the argument structure is concerned, but they differ in that it corresponds to a single word in Chicheŵa (containing a verb stem and a causative suffix), but it corresponds to two words in Romance (the causative verb and the infinitive). If the lexicon is the linguistic component in which words are formed, as well as stored, and the syntax operates with fully formed words, the difference between the two languages concerning causative predicates resides in the component in which this complex predicate is formed: the lexicon in Chichewa̓, the syntax in Romance. Given that this proposal implies some departure from classical LFG assumptions (such as the idea that the list of GFs that a predicate requires is fixed in the lexicon and cannot be altered in the syntax), there are alternative proposals that assume that the causative complex predicate is formed in the lexicon, as in Frank (1996), in spite of the fact that it corresponds to two distinct words in the syntax.

The treatment of causatives in Alsina (1996b) can be adapted to handle restructuring constructions. The only difference is that a restructuring verb either takes an event argument as its sole argument, as would be the case of *dovere*, or takes an additional argument role that is fused with the logical subject of the event argument, as would be the case of *volere* 'want' or *venire* 'come'. In either case, the resulting restructuring construction has no more expressed arguments than the base predicate, the infinitive. When restructuring takes place, the auxiliary selection properties of the construction are determined by the base predicate and the highest verb in the sequence of restructured verbs, including auxiliaries, is the one to which clitics are attached.

The idea that predicate formation may take place in the syntax, as opposed to the lexicon, has been met with some resistance by some LFG practitioners. Yet, the alternative, namely, that complex predicate formation with restructuring and causative verbs takes place in the lexicon, is hard to maintain given that the sequence of such verbs is potentially unlimited. Following are two examples with a long sequence of restructuring and causative verbs in Catalan:

(58) Catalan

a. La va haver de tornar a començar a escriure.
3sg.f.acc past.3sg have.inf to repeat.inf to begin.inf to write.inf
'She had to start writing it again.'

b. L' hi he volgut fer acabar de recitar.
3sg.m.acc 3.dat have.1sg want.ptcp make.inf finish.inf of recite.inf
'I wanted to make him finish reciting it.'

In both examples the clitics (*la* in (58a) and *l'hi* in (58b)) are thematically related to the base predicate, but appear attached to the matrix verb (the past tense auxiliary *va* in (58a) and the perfective auxiliary *he* in (58b)), indicating that there is complex predicate formation involving all the verbs from the auxiliary to the base predicate.

An issue that Alsina (1996b, 1997) does not address is how the light verb (the causative, restructuring, or auxiliary verb) in a complex predicate imposes form requirements on the dependent verb. Some verbs, such as the causative verbs and restructuring verbs like *poder* 'can' and *voler* 'want', require a prepositionless infinitive, as seen in (58b) and preceding examples. Other verbs require a specific preposition before the infinitive: *haver* in (58a) and *acabar* in (58b) require the preposition *de* before the infinitive; *tornar* and *començar* in (58a) require the preposition *a* before the infinitive.

The traditional LFG way to capture these dependencies is through the f-structure. However, if the f-structure is "flat" so that there is no feature structure corresponding to the dependent verb that is distinct from that of the embedding verb, this mechanism is no longer available. Andrews & Manning (1999) notice this problem and propose a way to capture the monoclausality of complex predicates, while retaining an embedding relation between the light verb and its dependent verb. The leading idea in Andrews & Manning (1999) is that the features traditionally assumed to be part of f-structure are grouped into three classes: ρ: grammatical relations (SUBJ, OBJ, …); α: argument structure features such as PRED and others; and μ: morphosyntactic features (GEND, NUM, TENSE, etc.). In addition, every node in the c-structure specifies which of these feature classes is shared with its mother node. In this way, it is possible to achieve a flat f-structure as far as GFs are concerned by having the two verbs in the complex predicate share the ρ class with the mother, but having only the light verb share its α and μ features with the mother, whereas the dependent verb would contribute its α and μ features to an ARG attribute. ARG is not a grammatical relation, but one of the features on the α-projection. Having this ARG feature allows the light verb to specify form features on its dependent verb (whether it is an infinitive or a gerund, what preposition it requires, if any, etc.). The embedding at the α-projection allows Andrews & Manning (1999) to capture the fact that the order of the light verbs is reflected in the meaning of the complex predicate, as in the following Catalan examples:

(59) Catalan (Alsina 1997)

a.

Li	acabo	de	fer	llegir	la	carta.
3SG.DAT	I.finish	of	make.INF	read.INF	the	letter

'I finish making him read the letter.' or 'I just made him read the letter.'

b. Li faig acabar de llegir la carta.
3sg.dat I.make finish.inf of read.inf the letter
'I make him finish reading the letter.'

This proposal is not very different from the proposal in Butt et al. (1996), which is designed to account for structures with auxiliaries, but can easily be applied to the analysis of complex predicates. Butt et al. (1996) propose to split the traditional f-structure into two structures, or projections: the grammatical features of verb forms (having to do with whether the form is an infinitive, a gerund, etc.) are removed from the f-structure and placed in the m-structure, which allows the f-structure of an auxiliated structure, and of complex predicates, to be "flat", i.e., not containing an embedding relation between the auxiliary or restructuring verb and its dependent verb. The dependent verbs in auxiliated structures, and by extension in complex predicates, provide their form features to a dep attribute. In this way, the auxiliary, or the light, verb can impose form requirements on their dep (the dependent verb) achieving a similar result to that achieved by Andrews & Manning (1999). More recent LFG developments in the analysis of complex predicates include Andrews (2007), Homola & Coler (2013), and Lowe (2016), which shift the burden of explanation onto the semantics.

Acknowledgments

I am very grateful to Nigel Vincent and two anonymous reviewers for their comments, which have helped improve this chapter in many ways.

Chapter 33

LFG and Scandinavian languages

Helge Lødrup
University of Oslo

This chapter gives an overview of some of the LFG literature on the Scandinavian languages: Danish, Swedish, Norwegian, Icelandic and Faroese. LFG has been used to investigate these languages ever since the framework was launched in the eighties. Important work has been done by researchers both inside and outside Scandinavia.

1 Introduction to the Scandinavian languages

The North Germanic languages are referred to in English as the Scandinavian languages. The modern languages are usually divided into Mainland Scandinavian: Danish, Swedish[1] and Norwegian, and Insular Scandinavian: Icelandic and Faroese. The literature on Faroese is limited, and Icelandic will usually have to represent Insular Scandinavian in this chapter.

In Danish, Swedish and Norwegian, the term *skandinavisk* is often used in a different way, to denote only Danish, Swedish and Norwegian. The English use will be applied in this chapter.

Danish, Swedish and Norwegian are by and large mutually intelligible. When Danes, Swedes and Norwegians talk to each other, they can come a long way using their own language. Danish, Swedish and Norwegian are grammatically similar in many respects, but there are also differences that can be more or less subtle.

---

[1] The variety spoken in Älvdalen in Sweden, known as *älvdalska* in Swedish, and Elfdalian or Övdalian in English, is often considered a separate language (Garbacz 2009). It has hardly been mentioned in the LFG literature, and it is not discussed in this chapter.

Helge Lødrup. 2023. LFG and Scandinavian languages. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 1597–1650. Berlin: Language Science Press.
DOI: 10.5281/zenodo.10186018

Mainland Scandinavian and Insular Scandinavian are not mutually intelligible. There are a number of grammatical differences. For example, morphological case on nouns and agreement on finite verbs can be found in Insular Scandinavian, but not in Mainland Scandinavian (except for relics in archaic dialects).

Older forms of the Scandinavian languages will be mentioned occasionally. In medieval times, the most important dividing line was between Eastern Scandinavian: Old Danish and Old Swedish, and Western Scandinavian: Old Norwegian and Old Icelandic. The latter two are sometimes referred to together as Old Norse.

There is an interesting LFG literature on various topics in the Scandinavian languages. For more general overviews of their syntax (independently of LFG), the following can be recommended: Faarlund (2004) on Old Norse, Thráinsson et al. (2004) on Faroese, Thráinsson (2007) on Icelandic, and Faarlund (2019) on Mainland Scandinavian.

2 C-structure phenomena

2.1 Basic sentence structure: V2

The architecture of LFG gives an excellent point of departure for studying c-structure. With parallel levels of representation, insights about c-structure can be obtained without necessarily involving the analysis of phenomena that could be argued to belong to other levels.

The Scandinavian languages have a relatively rigid word order, with the well known V2 requirement: the finite (auxiliary or main) verb must be in second position in main clauses.[2] This is a classical topic within various approaches to syntax.

Examples of V2 are (1) and (2).[3] Example (1) has the subject in the initial position, while example (2) has an adverb in the initial position, and the subject following the finite verb.

(1) Swedish (Sells 2001: 34)
Anna läste bok-en.
Anna read book-DEF
‘Anna read the book.’

---

[2] The concept of finiteness is discussed and refined in Sells (2007) and Heinat (2012).

[3] The source of example sentences is indicated when available. Examples that do not indicate a source have been provided by the author.

(2) Swedish (Sells 2001: 34, modified)
Igår läste hon bok-en.
Yesterday read she book-DEF
‘Yesterday she read the book.’

In Mainland Scandinavian, there is no V2 requirement in subordinate clauses. An example is (3).

(3) Swedish
Om Anna inte läser bok-en …
if Anna not reads book-DEF
‘If Anna doesn’t read the book …’

Icelandic usually has V2 in subordinate clauses (Thráinsson 2007: 58–64), while Faroese subordinate clauses are in the process of changing from V2 to non-V2 (Heycock et al. 2012).

V2 was an important motivation for the field grammar that Paul Diderichsen proposed for Danish (Diderichsen 1946). His approach was later taken up by Ahrenberg (1992), who proposed an LFG-like system in which the c-structure is given in the format of a field grammar.

Functional categories were used in LFG from the nineties. They were inspired by work in the Principles and Parameters framework, but the architecture of LFG made a more restricted use possible. A common Principles and Parameters assumption was that all main clauses in Scandinavian have a CP - IP - VP structure, with C as the designated V2 position.

Sells (2001) is an important work on Swedish c-structure in LFG.[4] The account proposed by Sells is based on the general principles that a subject is typically in SpecIP, and a constituent associated with a discourse function typically in SpecCP. He assumes that subject initial sentences are IPs (when the subject does not have a discourse function), while other sentences are CPs. This means that there is no designated V2 position – the finite verb is either in I or in C in main clauses.

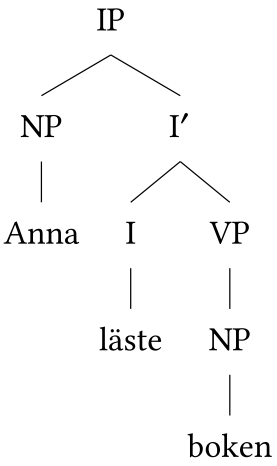
This analysis might seem to allow sentences with more than one main verb. This is not the case, however. CP and IP are functional projections, which correspond to the same f-structure as VP, and this f-structure can only have one PRED.

---

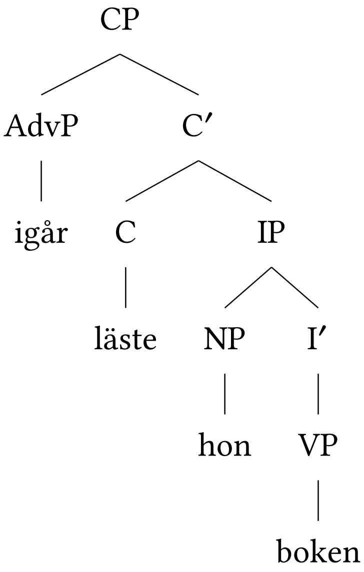
[4] Sells (2001) includes a component with restrictions stated in Optimality Theory, like some of the work that proposes alternatives to his analysis (Börjars et al. 2003, Andréasson 2007, 2010). For simplicity, these aspects of the analyses are put aside here.

The c-structure trees for examples (1)–(2) are from Sells (2001: 34). Note that the tree for (1) is an IP with the finite verb in I, while the tree for (2) is a CP with the finite verb in C.

(4)



(5)



2.2 Object shift

Another c-structure phenomenon that has often been discussed is object shift in Mainland Scandinavian. Examples are (6)–(7).

(6) Swedish (Sells 2001: 54)
Anna såg den inte.
Anna saw it not
‘Anna didn’t see it.’

(7) Swedish (Sells 2001: 54)
Såg Anna den inte?
saw Anna it not
‘Didn’t Anna see it?’

Object shift means that a weak pronominal object is not realized in the regular object position within the VP, but in a position closer to a finite main verb.[5] It can then precede a sentence adverb, as in (6)–(7). Object shift requires that the main verb is not in the VP, but in a higher functional projection. This is often called “Holmberg’s generalization” (Holmberg 1999). When the non-finite main verb is in VP, as in (8), then object shift cannot apply.

(8) Swedish
Anna har inte sett den.
Anna has not seen it
‘Anna has not seen it.’

Sells (2001: 54–56) assumes that a weak pronoun does not project in syntax. He assumes that a shifted pronoun adjoins to the I node. The adjunction is syntactic, and not morphological or phonological incorporation.

Below are the c-structure trees for (6)–(7), from Sells (2001: 62). The finite verb is in I, as in (9), or in the higher C position, as in (10). When the verb is in C, the pronoun is still under I, following the post-verbal subject.[6] Negation and other sentence adverbs are under I′.[7]

---

[5] Icelandic also allows object shift with full nominal phrases (Thráinsson 2007: 31–37). This will not be discussed further here.

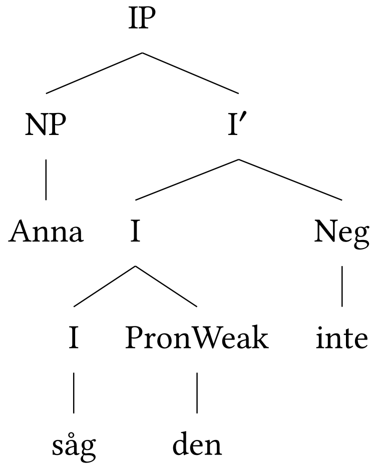
[6] The reader might find it strange that the pronoun is the only element under I when the verb is in C, as in (10). This follows from the adjunction rule X → X Y, combined with the optionality of phrase structure nodes and an economy principle which requires “tree pruning”

[7] Negation is always expressed outside the VP. An interesting effect of this is that an argument with a negative quantifier cannot be inside VP, cf. the contrast (i)–(ii). This is discussed in Sells (2000) and Sells (2001: 93–101).

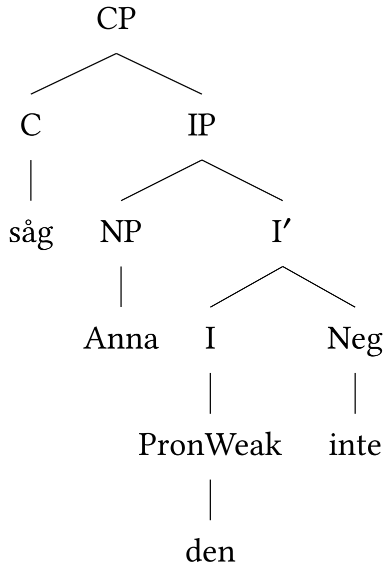
(i) Swedish (Sells 2001: 93)
Jag såg ingen.
I saw nobody
‘I saw nobody.’

(ii) Swedish (Sells 2001: 93)
*Jag har sett ingen.
I have seen nobody
‘I have seen nobody.’ [intended]

(9)



(10)

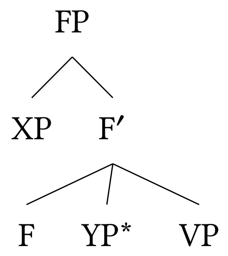


Restrictions on object shift have been discussed several times, see e.g. Andréasson (2008, 2010), Ørsnes (2013), and Engdahl & Zaenen (2020).

2.3 How much hierarchy?

Some researchers have argued that the c-structure proposed by Sells is more hierarchical than necessary, and inconsistent with the principle of Economy of expression (see Bresnan et al. 2016: 90 for this principle). They propose a basic sentence structure with one functional category above VP. The head position of this functional category is then the V2 position. The category is called IP in Dyvik (2000) (on Norwegian), and FP – Finiteness Phrase – in Börjars et al. (2003) and Andréasson (2007, 2010) (on Swedish). The structure they propose is as in (11).

(11)



F is the position of the finite verb. An initial subject has the same position as an initial non-subject, namely SpecFP. In the middle field between F and the VP there can be a subject (when not in SpecFP), one or more sentence adverbs, and pronominal objects.

One motivation for this kind of structure is the relative flexibility of the constituent order in the middle field. Sentence adverbs can precede or follow the subject, conditioned by scope and information structure. Examples are (12), with the subject scoping over the sentence adverb, and (13), with the sentence adverb scoping over the subject.

(12) Swedish (Börjars et al. 2003: 54)
Då skulle alla grod-or-na antagligen dö.
then should all frog-PL-DEF probably die
'All the frogs should probably die then.'

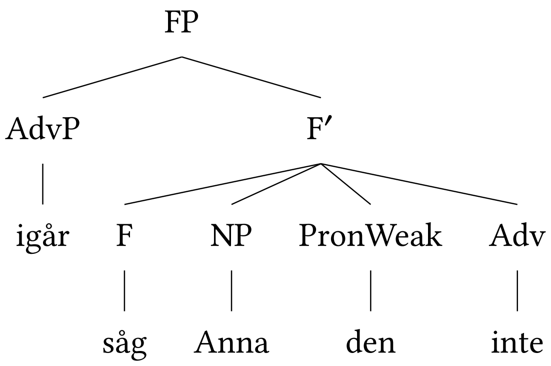
(13) Swedish (Börjars et al. 2003: 54)
Då skulle antagligen alla grod-or-na dö.
then should probably all frog-PL-DEF die
'All the frogs should probably die then.'

Example (12), with the subject preceding the adverb, requires that frogs have been mentioned in the discourse. There is no such requirement in example (13), with the adverb preceding the subject.

With the FP analysis, a sentence with object shift such as (14) would have the c-structure tree (15).

(14) Swedish (Sells 2001: 54)
Igår såg Anna den inte.
yesterday saw Anna it not
'Yesterday, Anna didn't see it.'

(15)



2.4 Is Icelandic different?

While the clausal hierarchy of Mainland Scandinavian has been discussed within LFG, there has been no parallel discussion of Insular Scandinavian. All newer LFG work on Icelandic seems to assume a c-structure that has one functional category above VP, e.g. Sells (2001: 190–92, 2003, 2005), Booth et al. (2017), Booth (2018). This analysis is also given for Old Norse in Kristoffersen (1996: 69). Icelandic then has the same basic structure that is assumed for Mainland Scandinavian in the work discussed in Section 2.3 above (the name of the functional projection aside).

Only Sells (2001: 190–92, 2003, 2005) assumes that Icelandic is different from Mainland Scandinavian concerning its basic sentence structure. His motivation seems to be that Icelandic differs from Mainland Scandinavian in being a "symmetric" V2 language with embedded V2. Sells here follows ideas from Diesing (1990), which cannot be discussed further in this context.

2.5 Expletives

The Scandinavian languages have several constructions that involve expletives. However, Icelandic expletives are very different from those of Mainland Scandinavian. Expletives in Mainland Scandinavian have the c-structure properties of subjects, preceding or following the finite verb in main clauses. Examples (16)–(17) show expletives preceding and following the finite verb.

(16) Norwegian
Det ble danset til midnatt.
EXPL became danced to midnight
'People danced until midnight.'

(17) Norwegian
Ble det danset til midnatt?
became EXPL danced to midnight
'Did people dance until midnight?'

Some Mainland Scandinavian varieties distinguish between expletive *det* 'it' and *der* 'there' in a way comparable to expletive *it* and *there* in English (Larsson 2014). This is the case in Danish and in some dialects of Swedish and Norwegian. Other varieties use only *det* 'it'.

Icelandic also has one expletive only, namely *það* 'it' (see Booth 2018 for an LFG account of Icelandic expletives). This expletive can occur in the first position of the clause, but it cannot follow the finite verb. Examples are (18)–(19).

(18) Icelandic (Thráinsson 2007: 310)
það var dansað til miðnættis.
EXPL was danced to midnight
'People danced until midnight.'

(19) Icelandic (Thráinsson 2007: 312)
Var (*það) dansað til miðnættis?
was (*EXPL) danced to midnight
'Did people dance until midnight?'

The position following the finite verb should be considered the basic subject position in Scandinavian main clauses, in the sense that only this position is reserved for subjects. The fact that the Icelandic expletive cannot occur there motivates the common view – inside and outside LFG – that it is not a subject.

Sells (2005) gives a different analysis in which the expletive is treated as a subject. He shows that the Icelandic expletive is not limited to the first position of a main clause. It can occur in the first position in an embedded clause. Some speakers also allow it as a raised subject in the subject-to-object raising construction, as in (20).

(20) Icelandic (Thráinsson 1979: 481–2)
Jón telur (það) vera mýs í baðker-inu.
Jón believes EXPL be mice in bathtub-DEF
'Jón believes there to be mice in the bathtub.'

In Sells' analysis, the expletive is a subject without a PRED. There can be another subject in the sentence, as in (21).

(21) Icelandic (Thráinsson 2007: 327)
Það höfðu einhverjir stúdentar stolið smjör-inu.
EXPL had some students stolen butter-DEF
'Some students had stolen the butter.'

Both the expletive and the logical subject then map to subject in f-structure, where the expletive is only reflected by a feature such as [EXPL +] (see also Section 3.4).

2.6 Verbal particles

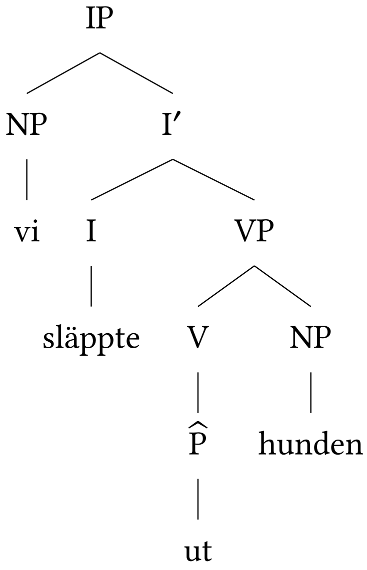
The Scandinavian languages differ as to the placement of verbal particles (Lundquist 2014d). Particles precede the object in Swedish, while they follow the object in Danish. Norwegian and Icelandic allow both word orders. Swedish and Danish examples are (22) and (23).

(22) Swedish (Toivonen 2003: 160)
Vi släppte ut hund-en.
we let out dog-DEF
'We let the dog out.'

(23) Danish (Toivonen 2003: 160)
Vi slap hund-en ud.
we let dog-DEF out
'We let the dog out.'

Toivonen (2003) discusses Swedish verbal particles. They precede the object, as mentioned. To be more exact, they follow the verb, and precede all other VP-internal constituents. Toivonen argues that these particles are non-projecting words in c-structure. They are adjoined to V, which explains the word order. The c-structure for (22) is then as in (24), where the "hat" on P means that it is non-projecting (Toivonen 2003: 21–22). Note that the finite verb is in I in (24).

(24)



It was mentioned above that the other Scandinavian languages are different with respect to the position of the particle. Toivonen proposes that Danish differs from Swedish in that words such as ‘out’ have a different status in Danish. They are prepositions that project a PP, and PPs generally follow objects.

Norwegian and Icelandic would be more difficult to account for within Toivonen’s proposal, since they allow particles to either precede or follow the object. The Norwegian situation is analysed in Dyvik et al. (2019). They consider particles a c-structure category, and particles can precede or follow the object. Particle verbs have lexical entries in which the verb and the particle are represented as one PRED. For example, the particle verb *skrive opp* ‘write up’ has the PRED (25).

(25) PRED ‘skrive*opp ⟨(↑SUBJ) (↑OBJ)⟩’

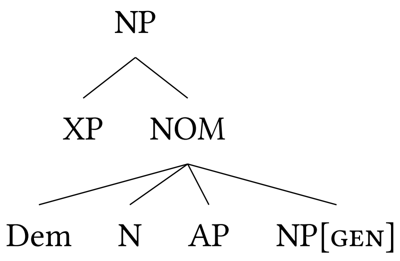
The presence of the relevant particle is secured by a requirement in the lexical entry of the particle verb. A constraining equation requires a feature contributed by the relevant particle. This equation is independent of the position of the particle in c-structure.

2.7 The structure of nominal phrases

Nominal phrases in modern Scandinavian have a rigid word order. Old Norse is very different, with free word order in nominal phrases.

Börjars et al. (2016) study the development of nominal phrases from Old Norse to Modern Faroese. They argue that the Old Norse nominal phrase is a non-configurational NP. There are no syntactic constraints on word order, but the first position is information structurally privileged. The rest of the phrase has a flat structure. They give the schematic c-structure tree (26) (Börjars et al. 2016: e17).

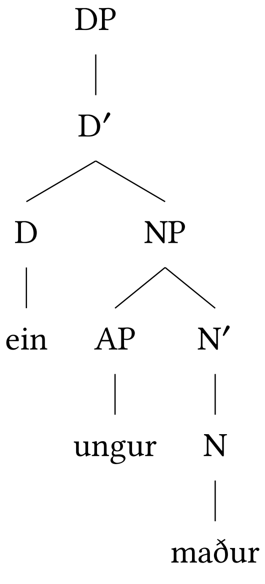
(26)



In Modern Faroese – as in the other modern Scandinavian languages – the word order is no longer free. The first position in a referential nominal phrase contains an element that marks it as ±DEFINITE, such as an indefinite or definite article, a demonstrative, or a noun with the bound definiteness marker.

Börjars et al. (2016) argue that what has happened between Old Norse and Modern Faroese is that a category D has developed, which heads a DP. The c-structure tree for Modern Faroese *ein ungur maður* 'a young man' is then as in (27) (Börjars et al. 2016: e25).

(27)



This is a change from a non-configurational to a configurational nominal phrase.

2.8 Non-projecting possessive pronouns

Standard Swedish and Danish have one position for possessive pronouns in the nominal phrase, preceding the noun and AP (if any). In other Scandinavian varieties, possessive pronouns in addition have the option of immediately following the noun. Examples are (28)–(29).

(28) Norwegian
min ny-e bil
my new-DEF car
'my new car'

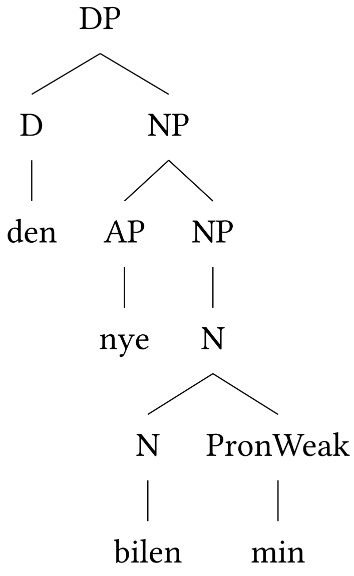
(29) Norwegian
den ny-e bil-en min
the new-DEF car-DEF my
'my new car'

Lødrup (2011) gives a lexicalist analysis of postnominal possessive pronouns in Norwegian, where the main point is that they are non-projecting weak pronouns. They are adjoined to N in syntax, comparable to the weak object pronouns that are adjoined to I in Sells' analysis (see Section 2.2). A noun preceding a possessive pronoun always has the definite form. The noun is either under N, as in (29), or in the higher head position D, as in (30) (following Hankamer & Mikkelsen 2002).

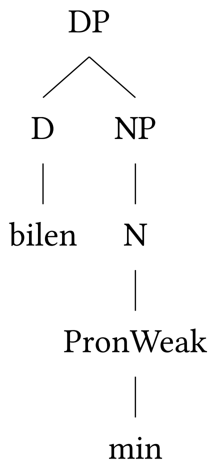
(30) Norwegian
bil-en min
car-DEF my
'my car'

The c-structure trees for (29) and (30) are given in (31) and (32).

(31)



(32)



3 F-structure phenomena

3.1 Oblique subjects in Icelandic

The relation between morphological case and syntactic function is complicated in some languages. The situation in Icelandic has been the object of interesting discussion within different grammatical frameworks. Especially the fact that a number of verbs take an oblique (i.e. non-nominative) subject has been the topic of much attention. Some examples are (33)–(36).

(33) Icelandic (Andrews 1982: 461)
Bát-inn rak á land.
boat-DEF.ACC drifted to land.ACC
'The boat drifted to shore.'

(34) Icelandic (Andrews 1982: 461)
Dreng-ina vantar mat.
boys-DEF.ACC lack food.ACC
'The boys lack food.'

(35) Icelandic (Andrews 1982: 462)
Barn-inu batnaði veik-in.
child-DEF.DAT recovered.from disease-DEF.NOM.
'The child recovered from the disease.'

(36) Icelandic (Zaenen et al. 1985: 100)
Henni hefur alltaf þótt Ólaf-ur leiðinleg-ur.
she.DAT has always thought Ólaf-NOM boring-NOM
'She has always found Ólaf boring.'

The verbs that take an oblique subject are all non-agentive. There are some tendencies concerning the correlation between verb meaning and subject case, but the option of an oblique subject must be seen as idiosyncratic. Important groundwork on oblique subjects was carried out within the framework of LFG. The very first mention of the phenomenon was in Andrews (1976); an LFG analysis was later proposed in Andrews (1982). His proposal is to treat an oblique subject in a way that resembles the treatment of a lexically selected preposition. There is an extra "layer" in their f-structure, in the sense that e.g. a dative subject is the value of the attribute DAT, and this f-structure is the value of SUBJ. Below is the simplified f-structure that Andrews (1982: 472) gives example (35).

(37)
$$\left[\begin{array}{ll}
\text{PRED} & \text{`BATNA}\langle\text{SUBJ DAT,OBJ}\rangle\text{'} \\
\text{SUBJ} & \left[\begin{array}{ll}\text{DAT} & \left[\begin{array}{ll}\text{PRED} & \text{`BARN'}\\ \text{CASE} & \text{DAT}\\ \text{DEF} & +\end{array}\right]\end{array}\right]\\
\text{OBJ} & \left[\begin{array}{ll}\text{PRED} & \text{`VEIK'}\\ \text{DEF} & +\end{array}\right]
\end{array}\right]$$

One argument for this analysis is that an oblique subject doesn't trigger agreement the way a nominative subject does. Regular agreement is blocked by the extra layer. In sentences without a nominative argument, such as (33)–(34) above, the verb occurs in the default third person singular. In sentences with a nominative object, the object can agree with the verb. An example is (38), with a singular oblique subject and a plural nominative object that triggers agreement.

(38) Icelandic (Thráinsson 2007: 156)
Mér hafa alltaf leiðst þessir kjölturakk-ar.
me.DAT have.PL always bored these poodle-NOM.PL
'I have always found these poodles boring.'

Another classic article on non-nominative subjects is Zaenen et al. (1985), who discuss case-preservation in passive sentences. Consider (39)–(40).

(39) Icelandic (Zaenen et al. 1985: 96)
Ég hjálpaði honum.
I helped him.DAT
'I helped him.'

(40) Icelandic (Zaenen et al. 1985: 98)
Honum var hjálpað.
him.DAT was helped
'He was helped.'

Zaenen et al. (1985) show how various syntactic criteria for subjecthood give evidence for non-nominative subjects in passive sentences such as (40). They also compare Icelandic to German. German has superficially similar sentences, but Zaenen et al. (1985) show that the non-nominative arguments in question do not show subject properties.

Zaenen et al. (1985) assume that idiosyncratic case is assigned to arguments at the level of a-structure. One important reason for this assumption is that idiosyncratic case is preserved independently of the syntactic function that realizes the argument position. It is not affected by valency alternations such as passive or raising, as can be seen in (40).

The diachrony of oblique subjects in Icelandic is discussed in Schätzle et al. (2015) and Booth et al. (2017).

3.2 Control and complementation in Icelandic

Control and complementation have been important research topics in LFG since Bresnan (1982a). These topics are intertwined in some ways. LFG distinguishes between two main types of control. One is anaphoric control of a PRO subject (an f-structure subject with a pronominal PRED). The other is functional control, in which the subordinate subject is structure shared with the subject or the object of the governing verb. Functional control is restricted in several ways. It is limited to complements with the function XCOMP and adjuncts with the function XADJ. This means that if an infinitive can be shown to have a syntactic function other than XCOMP or XADJ, control must be anaphoric.

Andrews (1982) assumes that finite *that*- and *wh*-clauses in Icelandic have the external syntactic properties of nominal phrases, realizing nominal syntactic functions such as subject and object (following Thráinsson 1979). Andrews argues that this is also true of infinitival clauses with the infinitival marker *að*. This analysis gives a prediction about how the subject of these infinitival clauses is controlled. Because they are subjects or objects, there must be anaphoric control of a PRO subject.

An interesting question is what case a PRO subject can have. Icelandic verbs can take oblique subjects, as was discussed in Section 3.1. One should expect, then, that PRO can be oblique when required by the infinitival verb. This expectation is true, as can be seen from example (41).

(41) Icelandic (Andrews 1982: 474)
Ég vonast til að vanta ekki ein-an í tím-anum.
I.NOM hope toward to lack not alone-ACC in class-DEF
'I hope not to be the only one missing from class.'

The main verb *vonast* 'hope' takes a regular nominative subject, while the infinitive *vanta* 'lack' requires an accusative subject. In (41), the case of PRO can be seen from the case on *einan* 'alone.ACC', which is an XADJ that agrees with the subject. If control were functional in (41), the accusative subject of *vanta* would have to structure share with the nominative subject of *vonast* 'hope'. This would be impossible, however, because structure sharing shares all grammatical properties, and the values for CASE would be incompatible.

3.3 Control and complementation in Mainland Scandinavian

The function and control of complement clauses have also been discussed for Mainland Scandinavian. Dalrymple & Lødrup (2000) proposed that a finite complement is an object if it shares external syntactic properties with nominal objects, and a COMP if it doesn't. (See Alsina et al. 2005 for criticism.)

Icelandic is a language with finite complements that are objects (see Section 3.2). Examples of languages that have both types of finite complements are English and Swedish (Dalrymple & Lødrup 2000). Norwegian also shows this split, even if object complements represent the dominant option (Lødrup 2004). For example, Norwegian *bevise* 'prove' takes a complement that alternates with a nominal phrase, and corresponds to a subject in the passive. Its complement is then assumed to be an object. The verb *anse* 'consider', on the other hand, takes a complement that lacks these properties, and it is therefore assumed to be a COMP. Examples (42)–(45) show the differences.

(42) Norwegian (Lødrup 2004: 65)
Han har endelig bevist [at jord-en er rund] / dette
he has finally proved that earth-DEF is round / this
'He has finally proved that the earth is round / this.'

(43) Norwegian (Lødrup 2004: 65)
[At jord-en er rund] er endelig blitt bevist.
that earth-DEF is round is finally become proved
'That the earth is round has finally been proved.'

(44) Norwegian
Komitee-en anser [at fordel-ene oppveier
committee-DEF considers that advantage-PL.DEF compensate
ulemp-ene] / *dette
disadvantage-PL.DEF / this
'The committee considers that the advantages compensate for the disadvantages / this.'

(45) Norwegian
*[At fordel-ene oppveier ulemp-ene] blir
that advantage-PL.DEF compensate disadvantage-PL.DEF becomes
ansett.
considered

Lødrup (2004) shows that infinitival complements in Norwegian also show this split, with object complements as the dominant option. For example, the infinitival complement of *akseptere* 'accept' alternates with a nominal object, as shown in (46), and it corresponds to a subject in the passive, as shown in (47).

(46) Norwegian (Lødrup 2004: 70, modified)
De har akseptert [å betale høyere skatt] / dette
they have accepted to pay higher tax / this
'They have accepted to pay higher taxes / this.'

(47) Norwegian (Lødrup 2004: 71)
[Å betale høyere skatt] er blitt akseptert.
to pay higher tax is become accepted
'To pay higher taxes has been accepted.'

As for Icelandic (see Section 3.2), the object analysis implies that the infinitival complements have a PRO subject, and not functional control with structure sharing. In the active (46), the controller of the infinitival subject is the subject of *akseptere* 'accept'. In the passive (47), on the other hand, the infinitive has no controller. This situation rules out functional control, because there is nothing that the subject of the infinitive can structure share with. PRO, on the other hand, can do without a controller, so the infinitive must be assumed to have a PRO subject. A corresponding analysis of the Danish verb *forsøge* 'try' is given in Ørsnes (2006).

3.4 Subject vs object in presentational sentences

All the Scandinavian languages have what could be called a presentational construction, in which a verb takes an expletive and a so-called logical subject. Examples are (48) and (49).

(48) Norwegian
Det kom fire studenter på forelesning-en i går.
EXPL came four students on class-DEF in yesterday
'Four students came to class yesterday.'

(49) Icelandic (Thráinsson 2007: 310)
Það kom-u fjór-ir nemend-ur í tím-ann í gær.
EXPL came-3PLUR four-NOM students-NOM.PL in class-DEF in yesterday
'Four students came to class yesterday.'

The grammatical properties of the presentational construction are rather different in Mainland Scandinavian and Icelandic, and there is some discussion concerning its analysis.

For the Icelandic construction, there seems to be agreement that the logical subject is a grammatical subject. As mentioned in Section 2.5, Icelandic expletives are usually assumed not to be subjects. They can occur in first position, but not in the subject position following the finite verb, as shown in (50).

(50) Icelandic (Thráinsson 2007: 313)
Kom-u (*Það) fjór-ir nemend-ur í tím-ann í gær?
came-3PLUR (EXPL) four-NOM student-NOM.PL in class-DEF in yesterday
'Did four students come to class yesterday?'

However, Sells (2005) assumes that the expletive and the logical subject both map to subject in f-structure. The expletive has no PRED, and no other features that cannot unify with those of the logical subject. Its only reflex in f-structure is then a feature such as [EXPL +].

The Mainland Scandinavian presentational construction is rather different from the Icelandic one. The expletive can occur in all subject positions in c-structure, including the position following the finite verb, as shown in (51).

(51) Norwegian
Kom det fire studenter på forelesning-en i går?
came EXPL four students on class-DEF in yesterday
'Did four students come to class yesterday?'

The logical subject has the same c-structure position as a regular object. The grammatical status of the logical subject has been discussed several times, both inside and outside LFG. Lødrup (1999b, 2020) argues that it is an object in f-structure, following Askedal (1982), Platzack (1983) and others. This view has been criticized by Börjars & Vincent (2005), Zaenen et al. (2017), and Hellan & Beermann (2020). Börjars & Vincent (2005) propose the same kind of analysis for Swedish that Sells (2005) gives for Icelandic: both the expletive and the logical subject correspond to the subject in f-structure. Zaenen et al. (2017) are more agnostic concerning the correct analysis.

Arguments have been given for both subject and object analyses of the logical subject. The presentational construction is not possible with a syntactically realized object role in Mainland Scandinavian, as shown in (52).

(52) Norwegian
Det spiser mange studenter (*pølser) i denne kafe-en.
expl eats many students (sausages) in this cafeteria-def
‘Many students eat (sausages) in this cafeteria.’

This gives an argument for the object analysis, which assumes that the direct object function (LFG’s obj) is taken by the logical subject. Icelandic, on the other hand, allows transitive verbs, see example (21) above.

Another argument for the object analysis is given by subject-to-object raising. Consider (53).

(53) Swedish (Zaenen et al. 2017: 268)
Johan anser det ha varit för många hästar på kyrkogård-en.
Johan considers expl have been too many horses in churchyard-def
‘Johan considers there to have been too many horses in the churchyard.’

Subject-to-object raising leaves the logical subject in the embedded object position, as shown by (53). It is the expletive that raises. This gives an argument that the expletive must be the f-structure subject of ‘to have been’.

Reflexive binding has been used as argument that the logical subject is a grammatical subject. The logical subject not only allows, but seems to require a coreferring proform to be reflexive. An example is (54), in which the reflexive possessive *sin* is acceptable, while the non-reflexive *hans* is not.

(54) Swedish (Börjars & Vincent 2005)
Det kom en man med sin / *hans fru.
expl came a man with refl.poss / his wife
‘There came a man with his (own) wife.’

The arguments that have been given for the competing analyses of presentational sentences are discussed by Lødrup (2020) who concludes that there are no acceptable arguments for the subject analysis.

3.5 Auxiliaries – verbs or functional heads?

The analysis of auxiliary verbs has often been discussed, both outside and inside LFG. In early LFG, they were treated as raising verbs (Falk 1984). In newer LFG, the tendency has been to see them as functional heads without a PRED. With this analysis, they only contribute grammatical features (Butt et al. 2004, Frank & Zaenen 2002). The f-structures (56) and (57) show the different analyses of example (55), with an auxiliary that expresses future tense.

(55) Norwegian
Jeg skal komme.
I shall come
'I will come.'

(56)
$$\left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{skulle}\langle\textsc{xcomp}\rangle\textsc{subj}\text{'} \\ \textsc{subj} & \left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{pro}\text{'} \\ \textsc{pers} & 1 \\ \textsc{numb} & \textsc{sg} \\ \textsc{case} & \textsc{nom} \end{array}\right] \\ \textsc{xcomp} & \left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{komme}\langle\textsc{subj}\rangle\text{'} \\ \textsc{subj} & \underline{\qquad\qquad} \\ \textsc{form} & \textsc{infinitive} \end{array}\right] \\ \textsc{tense} & \textsc{future} \end{array}\right]$$

(57)
$$\left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{komme}\langle\textsc{subj}\rangle\text{'} \\ \textsc{subj} & \left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{pro}\text{'} \\ \textsc{pers} & 1 \\ \textsc{numb} & \textsc{sg} \\ \textsc{case} & \textsc{nom} \end{array}\right] \\ \textsc{tense} & \textsc{future} \end{array}\right]$$

The analysis of auxiliaries raises several difficult questions, and it is not clear that all verbs that are traditionally called auxiliaries should get the same analysis (Falk 2008). Dyvik (1999) discusses Norwegian modals, and criticizes the functional head analysis. His point of departure is the status of f-structure as a grammatical level of representation. He rejects the idea that semantics gives an argument for parallel f-structure representations of morphological and periphrastic expression of, for example, the future.

If one accepts the functional head analysis, there are phenomena that must be accounted for in a different way than in traditional LFG. For example, an auxiliary restricts the form of its dependent verb. When the auxiliary selects an XCOMP, it can restrict the form of the verb heading the XCOMP with the equation (↑XCOMP FORM) = INFINITIVE. To account for this kind of phenomena with the functional head analysis, Butt et al. (2004) propose a separate morphological projection, m-structure, (see also Frank & Zaenen 2002). However, Wedekind & Ørsnes (2003) argue that a simpler description is possible, using the so-called restriction operator. They also use the restriction operator in their account of VP-topicalization (Wedekind & Ørsnes 2004).

3.6 "*do*-support" in Scandinavian

The Scandinavian languages differ from English in not having *do*-support in interrogative and negative sentences. There is, however, a kind of *do*-support that is used in three contexts: When the main verb VP is topicalized, as in (58), elided, as in (59), or pronominalized as in (60). The support verb in these examples is the present form of (Danish) *gøre* 'do'.

(58) Danish (Ørsnes 2011: 410)
Venter gør han ikke.
waits does he not
'He doesn't wait.'

(59) Danish (Ørsnes 2011: 410)
Han venter. Nej, han gør ej.
he waits no he does not
'He'll wait. No he won't.'

(60) Danish (Ørsnes 2011: 410)
Han venter. Nej, det gør han ikke.
he waits no that does he not
'He is waiting. No he is not.'

A VP is pronominalized with the pronoun *det* 'it/that' (Lødrup 1994). This construction often corresponds to VP ellipsis in English, which is a rather restricted option in Scandinavian.

Ørsnes (2011) discusses the use of the non-finite form of the support verb. A non-finite support verb is optional when a VP or a VP anaphor is topicalized. An example of the former is (61).

(61) Danish (Ørsnes 2011: 420)
Hørt efter har han aldrig (gjort).
listened PARTICLE has he never done
'Listen! he never did that.'

Ørsnes (2011) shows that the non-finite support verb in Danish can be obligatory with a post-verbal VP anaphor in some cases, as in (62) (see also Ørsnes 2013).

(62) Danish (Ørsnes 2011: 419)
Peter plejer aldrig ??/*(at gøre) det.
Peter used never to do that
'Peter never used to do that.'

The support verb is considered an auxiliary in Lødrup (1990, 1994). Ørsnes (2011) argues against auxiliary status. A difference from regular auxiliaries is that the support verb cannot take a verbal complement in its complement position. Another difference is that it does not impose restrictions on the shape of its complement. This can be seen in examples (58) and (61) above; a topicalized VP can have its head in the infinitive or in the same form as the support verb (with some variation within Scandinavia). Ørsnes (2011) sees the support verb as a main verb – a subject-to-subject-raising verb that takes an object complement.

3.7 Varieties of raising and control

Raising and control have been importent research topics within LFG. They are related phenomena, and the border between them can be thin (see e.g. Lødrup 2008c). This section will illustrate how raising can be more constrained in Scandinavian as compared to English, and show how the analysis of raising and control has been applied to other constructions in Scandinavian. Note that the discussion of passives in Section 3.8 also covers two constructions that have been given a raising analysis: pseudopassives and complex passives.

3.7.1 Raising to object with *believe* type verbs

Norwegian is traditionally assumed not to have raising to object with *believe* type verbs (sometimes called the ECM construction). Lødrup (2008b) shows that even if sentences such as (63) are possible, sentences such as (64) are not.

(63) Norwegian
Dette antar jeg å være en menneskelig forsvarsmekanisme.
this assume I to be a human defense.mechanism
'This I assume to be a human defense mechanism.'

(64) Norwegian
*Jeg antar dette å være en menneskelig forsvarsmekanisme.
I assume this to be a human defense.mechanism
'I assume this to be a human defense mechanism.' [intended]

The relevant difference between (63) and (64) is that the raised object is in the canonical object position in (64), and in SpecCP in (63). Norwegian requires that the raised object be in a topic or focus position. This constraint was called the Derived Object Constraint in Postal (1974) (see also Kayne 1981). In Lødrup (2008b) the relevant verbs are equipped with a constraint in the lexicon which says that the raised object is realized as a discourse function.

Danish and Swedish are not exactly like Norwegian concerning raising to object with *believe* type verbs. In Danish, it seems to be rather marginal (Brandt 1995: 26). In Swedish, on the other hand, this kind of raising seems to be somewhat less restricted, at least in writing (Teleman et al. 1999: 576–78).

Passive raising sentences with *believe* type verbs, such as (65), are not affected by the Derived Object Constraint.

(65) Swedish (Ramhöj 2016: 583)
Hon säg-s vara en utpräglad målskytt.
she says-PASS be a specialized goal-scorer
'She is said to be a specialized goal scorer.'

However, these passive sentences also raise some questions.

First, there is a restriction on the realization of the passive. Mainland Scandinavian has two ways of realizing the passive – with a suffix or with an auxiliary and a participle. Passive raising sentences with *believe* type verbs differ from other passives in being reluctant to take the periphrastic passive, cf. (66).

(66) Swedish (Ramhöj 2016: 583)
*Hon blir sagd vara en utpräglad målskytt.
she becomes said be a specialized goal-scorer
'She is said to be a specialized goal scorer.'

Second, there are passive *believe* type raising sentences that do not correspond to actives, in the sense that there is no acceptable equivalent active with the passive subject as an object. An example is (65) above. These properties could be taken to indicate that the relevant sentences should not be seen as passives of raising sentences with *believe* type verbs. However, Ramhöj (2016) argues that they should.

3.7.2 Copy raising

Asudeh & Toivonen (2012) discuss so-called copy raising in Swedish and English. An example is (67).

(67) Swedish (Asudeh & Toivonen 2012: 323)
Tina verkar som om hon har hittat choklad-en.
Tina seems as if she has found chocolate-DEF
'Tina seems as if she has found the chocolate.'

Copy-raising differs from regular subject to subject raising in that there is a finite complement clause with a pronominal representation of the raised subject. In the analysis of Asudeh & Toivonen (2012), the *som om* 'as if' complement is an XCOMP whose subject is raised. This raised subject anaphorically binds the copy pronoun in the complement.

3.7.3 Pseudocoordination as control

A favorite topic in both traditional and modern Scandinavian grammar is so-called pseudocoordination (see e.g. Lødrup 2019a and references there). An example is (68).

(68) Norwegian
Da satt han og arbeidet.
then sat he and worked
'Then he sat working.'

A pseudocoordination contains two verbs with the same inflectional form, and the conjunction *og* 'and' between them. The first verb is often a posture verb, as in (68), but some verbs of other types are also possible. A pseudocoordination has grammatical properties that distinguish it from a coordination of two verbs or verb phrases (Lødrup 2019a). Two important properties are the following:

The two verbs cannot occur together in the V2 position in a sentence such as (69).

(69) Norwegian
*Da satt og arbeidet han.
then sat and worked he
'Then he sat working.' [intended]

The first verb in a pseudocoordination allows the presentational construction without involving the second verb, cf. (70).

(70) Norwegian (Lødrup 2019a: 92)
Nå sitter det en mann her og skriver om en ny type maskin.
now sits EXPL a man here and writes about a new type machine
'A man is sitting here now, writing about a new type of machine.'

Lødrup (2002) discusses the analysis of pseudocoordination, and argues that most pseudocoordinations are complement constructions with functional control of the complement headed by the second verb. In Lødrup (2017) this analysis is revised, with anaphoric instead of functional control. When the second verb heads a verbal complement, the properties illustrated in (69) and (70) above follow. In true coordination two verbs can occur in the V2 position, but in pseudocoordination, the first verb cannot 'bring with it' the second verb since it is the head of its complement. In (70), the object *en mann* 'a man' can be understood as the subject of the second verb because it is the controller of its PRO subject.[8] With true coordination, a presentational construction involving the first verb only is not possible. The reason is that a preceding object cannot be understood as a subject of a second coordinated VP – only a preceding subject can.

3.7.4 The preposition *med* 'with' as a control predicate

The preposition *med* 'with' (and to some extent *uten* 'without') has interesting control properties. Lødrup (1999a) showed that it must be assumed to select a subject in one of its uses. His argument was based upon example (71), which requires a subject in the complement of *med* to bind the reflexive.

(71) Norwegian (Lødrup 1999a: 376)
En dame med en hund foran seg kom løpende.
a lady with a dog in.front.of REFL came running
'A lady with a dog in front of her came running.'

---

[8] The observant reader will notice that the author here takes sides in the discussion of the analysis of the presentational construction, calling the controller an object (see Section 3.4).

The preposition *med* 'with' in (71) takes a subject, a non-thematic object and an XCOMP. Haug (2009) argues that *med* can take a subject also when there is no XCOMP. The argument is again based upon binding. Haug gives example (72), in which the object 'car' must be interpreted as the possessor of the prepositional object 'tank'.

(72) Norwegian (Haug 2009: 343)
Han leverte bil-en med full tank.
he returned car-DEF with full tank
'He returned the car with the tank full.'

In Norwegian, this kind of null possessor is generally bound in the same way as a simple reflexive (Lødrup 1999a, 2010, see also Section 3.11). This means that it cannot be bound by an object (Lødrup 2010: 95), so it is necessary to assume that *med* takes a subject.

The subject of *med* is always an anaphorically bound PRO. The controller is often an argument of the matrix verb, but other controllers are also possible – even a participant implied by a verbal noun, as in example (73).

(73) Norwegian (Haug 2009: 340)
Fødsel-en foregår med ski på bein-a.
birth-DEF takes.place with skis on legs-DEF
'The birth takes place with (the mother or the baby) wearing skis.'

Haug (2009) gives a semantic account of *med* using Glue semantics.

3.7.5 "Backward" possessor raising

Lødrup (2009b, 2018) discusses Norwegian sentences such as (74), with a body part noun and a possessor with the preposition *på* 'on'. This construction corresponds to the dative external possessor construction, which is found in e.g. French and German, cf. (75).

(74) Norwegian
Jeg brekker arm-en på ham.
I break arm-DEF on him
'I break his arm.'

(75) French
Je lui casse le bras.
I him.DAT break DEF arm
'I break his arm.'

In the French and German dative external possessor construction, the external possessor is understood to be affected by the verbal action. The external possessor is not included in the verb's basic valency, however. This means that the dative external possessor realizes an "extra" thematic role that must be added by a lexical rule.

The dative external possessor construction is often seen as possessor raising – the dative OBJ$_\theta$ is structure shared with the possessor function in the body part noun phrase. Alternatively, the relation between the possessor and the body part noun could be seen as binding, see e.g. Deal (2017).

Old Norse had the dative external possessor construction. In Modern Norwegian, there is no dative case, and the possessor is expressed as a PP. This construction is rather similar to the dative external possessor construction, but there is one important difference: The PP can be a part of the body part noun phrase, due to reanalysis (Lødrup 2009b, 2018). Example (74) can have 'the arm on him' as one or two constituents.

The two constituent construction can be analyzed in the same way as the dative external possessor construction, when the PP is considered an OBJ$_\theta$. The one constituent construction is more challenging. Lødrup (2018) proposes that the noun phrase-internal possessor should be considered a so-called prominent internal possessor (see e.g. Ritchie 2017). The possessor is structure shared with the verb's OBJ$_\theta$ function. This could be considered a case of "backward" possessor raising. It could be compared to cases of raising and control in which a shared subject is realized in the lower subject position (Polinsky & Potsdam 2006), schematically as in (76).

(76) tried [John to leave]

The structure sharing equation on the main verb accounts for both forward and backward raising. The lexical entry of the verb in example (74) is given in (77).

(77) 'break <(↑SUBJ) (↑OBJ$_{\text{affected}}$) (↑OBJ)>'
(↑OBJ$_{\text{affected}}$) = (↑GF POSS), where GF is a local function

3.7.6 Possessor raising with unergatives

A different type of possessor raising with body part nouns can be found with transitive and unaccusative verbs in many languages. An example is (78).

(78) Norwegian (Lødrup 2019b: 562)
Hun vasket baby-en i ansikt-et.
she washed baby-DEF in face-DEF
'She washed the baby's face.'

The possessor is raised from the prepositional object, and realized as an OBJ with transitive verbs, or as a subject with unaccusatives. This kind of possessor raising can also be seen as structure sharing – the OBJ is structure shared with the possessor function in the prepositional object. (As mentioned in Section 3.7.5, the relation between an external possessor and a body part noun could alternatively be seen as binding. See e.g. Deal 2017.)

Lødrup (2009c, 2019b) shows that sentences seemingly similar to (78) also occur with unergative verbs in Norwegian. An example is (79).

(79) Norwegian (Lødrup 2019b: 563)
Hun spyttet ham i ansikt-et.
she spat him in face-DEF
'She spat in his face.'

This option is completely productive. The only restriction is the same for transitive and unergative verbs: they must denote some form of physical contact. Lødrup (2019b) sees the raised argument with unergatives as a thematic object. It realizes the same role as the PP with *på* 'on' in sentences such as (74) above. Example (79) can alternatively take this PP, cf. (80).

(80) Norwegian (Lødrup 2019b: 563)
Hun spyttet i ansikt-et på ham.
she spat in face-DEF on him
'She spat in his face.'

However, the raised argument shows the syntactic properties of an OBJ, and not of an OBJ$_\theta$ in sentences such as (79) (Lødrup 2019b). We see, then, that the affected role can be realized as either an OBJ$_\theta$ PP or an OBJ DP/NP with unergatives. The OBJ option follows from the syntactic features assigned to arguments by Lexical Mapping Theory. The affected role will usually be treated as a secondary patientlike role by Lexical Mapping Theory. It then gets the syntactic feature [+*o*], and is realized as an OBJ$_\theta$. However, with an unergative verb, the affected role can alternatively be treated as a regular patientlike role. It then gets the syntactic feature [−*r*], and is realized as a direct object. This option does not exist with unaccusatives or transitives. The reason is that their subject is [−*r*], and a verb can only take one [−*r*] argument in Norwegian, as in many other languages (Bresnan & Moshi 1990).

3.8 Varieties of the passive

The passive has been a favorite topic in lexicalist frameworks. Scandinavian has a rich and interesting variety of passives. Mainland Scandinavian has two ways of realizing the passive: a periphrastic passive with an auxiliary and a participle, or a morphological passive with a suffix (see e.g. Engdahl 2006). Icelandic only has periphrastic passives (Thráinsson 2007: 10–11). Icelandic passives with oblique subjects were mentioned in Section 3.1.

3.8.1 Different passives of ditransitives

Norwegian, Swedish and to a lesser extent Danish allow both internal arguments of a ditransitive verb to be realized as the passive subject, as shown in (81)–(83).

(81) Norwegian
De overrakte ham medalj-en.
they presented him medal-DEF
'They presented him with the medal.'

(82) Norwegian
Han ble overrakt medalj-en.
he became presented medal-DEF
'He was presented with the medal.'

(83) Norwegian
Medalj-en ble overrakt ham.
medal-DEF became presented him
'The medal was presented to him.'

These data create problems for theories of the mapping of arguments in passives. It is generally assumed that only one of the internal arguments can correspond to a passive subject. Lexical Mapping Theory assumes that only one internal argument can be classified as an unrestricted function, and thus be realized as a passive subject. Bresnan & Moshi (1990) show that some Bantu languages are "symmetrical" in the sense that either object role can correspond to a passive subject. Lødrup (1995) argues that their analysis cannot be transferred to Mainland Scandinavian, because objects in ditransitives are not symmetrical outside the passive. However, no solution to the problem is presented.

Icelandic is both similar and different from Norwegian and Swedish concerning the passivization of ditransitives (Zaenen et al. 1985). The central group of ditransitives are those that take a dative object and an accusative object, such a *gefa* 'give'. They allow both internal arguments to be realized as the passive subject, as shown in (84) and (85). When the dative is realized as a subject, as in (84), the object gets nominative case and can trigger agreement on the verb (compare example (38) above).

(84) Icelandic (Zaenen et al. 1985: 460)
Konung-inum voru gef-nar ambátt-ir.
king-DEF.DAT were given-PL female.slave-NOM.PL
'The king was given female slaves.'

(85) Icelandic (Zaenen et al. 1985: 460)
Ambátt-in var gef-in konung-inum.
female.slave-DEF.NOM.SG was given.SG king-DEF.DAT
'The female slave was given to the king.'

Zaenen et al. (1985) argue that both internal objects with these verbs can be either object or second object [i.e. OBJ or OBJ$_\theta$]. The option of being an object makes it possible for them to change to subject by the (then current) lexical rule of passive, which replaces OBJ by SUBJ in the linking of roles and functions in the verb's lexical entry.

Ditransitives with other case frames only allow the linearly first internal argument to be realized as a subject.

3.8.2 Pseudopassives

The Mainland Scandinavian languages all have pseudopassives, i.e. passives in which the subject corresponds to the object of a preposition in the active; Engdahl & Laanemets (2015) show that claims to the contrary are not correct. An example is (86).

(86) Norwegian
Skildringer av norsk natur se-es ofte ned på.
depictions of Norwegian nature see-PASS often down on
'People often look down upon depictions of Norwegian nature.'

Bresnan (1982c) pointed out that pseudopassives create a potential problem for a lexical treatment of the passive. She proposed a rule which incorporates the verb and the preposition into one complex verb (Bresnan 1982c: 50–59). This analysis accounts for the fact that the verb and the preposition behave as a unit in English pseudopassives. The preposition must be adjacent to the verb, and it can be a part of a derived participle-based adjective. Examples are (87)–(88).

(87) English (Bresnan 1982c: 54)
*Everything was paid twice for.

(88) English (Bresnan 1982c: 53)
Each unpaid for item will be returned.

Scandinavian pseudopassives are different from the English ones. The preposition does not have to be adjacent to the verb, as (86) shows, and derived adjectives with a preposition following the verb do not exist. Scandinavian grammarians have therefore been skeptical of preposition incorporation (see e.g. Christensen 1986).[9] Lødrup (1991) proposes a raising to subject analysis, in which the subject and the prepositional object are structure shared (see also Alsina 2009).

3.8.3 Complex passives

The so-called complex passive is exemplified in (89).

(89) Danish (Ørsnes 2006)
Bil-en bed-es flyttet.
car-DEF ask-PASS moved
'You are asked to move your car.'

This construction has a passive verb followed by a passive or unaccusative participle. One of its interesting properties is that there is no directly corresponding active sentence. It is impossible to realize the theme argument *bilen* 'car.DEF' as the object of the active verb *bede* 'ask'.

The complex passive is possible with a small number of first verbs in Danish and Norwegian. It is more marginal in Swedish. Ørsnes (2006) gives an LFG account in which the complex passive is a subject-to-subject raising construction.

---

[9] These arguments rule out an analysis in which the verb and the preposition are one lexical item. However, given later developments within LFG, one could imagine a different analysis that makes the verb and the preposition one unit. They could be one PRED in f-structure in the same way as complex predicates consisting of two verbs (see the discussion following example (90) below).

3.8.4 Long passives

Another type of passive that involves two verbs is exemplified in (90).

(90) Norwegian
Dette forsøk-es å gjør-e(-s).
this try-PASS to do-INF(-PASS)
'One tries to do this.'

This construction can be found in Norwegian, Swedish and Danish, even if speakers' intuitions vary. It sounds best with a passive second verb (Lødrup 2014). The subject of (90) realizes the internal argument of the second verb. This is a passive of a complex predicate consisting of two verbs (Butt 1995, Alsina 1996, Sells 2004, Andrews 2023 [this volume]), a so-called long passive (Lødrup 2014).

There is independent evidence for the complex predicate analysis. Verbs that take the long passive also allow verbal feature agreement in the active, in the sense that a second verb takes on the form of the preceding verb, instead of the expected infinitive. Verbal feature agreement is a complex predicate phenomenon, for reasons discussed in Niño (1997) and Sells (2004). Mainland Scandinavian can (to varying degrees) have this kind of agreement with imperatives and participles, as in (91)–(92) (Havnelid 2015, Aagaard 2016).

(91) Norwegian
Forsøk å gjør ditt beste.
try.IMP to do.IMP your best
'Try to do your best.'

(92) Norwegian
Hadde forsøk-t å gjor-t samtal-en kort.
had try-PTCP to do-PTCP conversation-DEF short
'(I) would have tried to make the conversation short.'

3.8.5 The new passive/impersonal construction

Icelandic has a construction that has been called the new passive construction or the new impersonal construction (see Maling & Sigurjónsdóttir 2002). An example is (93).

(93) Icelandic (Kibort & Maling 2015)
Loks var fund-ið stelp-una eftir mikla leit.
finally was found-N.SG girl.(F)-DEF.ACC after great search
'They finally found the girl after a long search.'

This construction seems to have passive morphology. There is no realized subject. (There can be an expletive in first position, but these are usually not considered subjects, see Section 2.5.) The external role cannot be realized as a subject, and there is no "promotion to subject" of an internal role.

The analysis of this construction has been discussed several times, but the only LFG discussion is in Kibort & Maling (2015). Some authors see it as a real passive (e.g. Eythórsson 2008). Maling and her co-authors argue that despite its morphology, the construction is not a passive. They see it as an impersonal active construction, comparable to the Irish autonomous form and the Polish -*no/to* construction. This means that the verbal morphology introduces a PRO subject with an unspecified, typically human interpretation. This PRO is argued to behave like other subjects syntactically. For example, it can control a subject-oriented adjunct, as shown in (94).

(94) Icelandic (Maling & Sigurjónsdóttir 2002: 125)
Það var kom-ið skellihlæjandi í tím-ann.
EXPL was come-N.SG laughing.out.loud into class-DEF
'People came into class laughing out loud.'

3.9 Directed motion – rules or constructions

Toivonen (2002) and Asudeh et al. (2013) discuss the Swedish directed motion construction, in which a verb takes a reflexive and a directional PP. An example is (95).

(95) Swedish (Asudeh et al. 2013: 13)
Sarah armbågade sig genom mängd-en.
Sarah elbowed REFL through crowd-DEF
'Sarah elbowed her way through the crowd.'

Toivonen (2002) discusses how this kind of sentence should be described, with a construction or with a lexical rule. An argument for using a construction is that "it is difficult to pin its meaning to any one of its individual parts" (Toivonen 2002: 342). The relevant sentences denote traversal, but the verb does not need to be a motion verb. There is no special word or morpheme that is uniquely associated with the construction.

Asudeh et al. (2013) discuss this and similar expressions further. They point out that assuming a directed motion construction would violate the Lexical Integrity Principle:

> "Morphologically complete words are leaves of the c-structure tree and each leaf corresponds to one and only one c-structure node." (Bresnan et al. 2016: 92)

This principle entails that units smaller or bigger than words cannot be inserted in c-structure. Asudeh et al. (2013) propose templates to factor out grammatical information that can be invoked by words or construction-specific phrase structure rules. This makes it possible to capture the constructional effects, without giving up the Lexical Integrity Principle.

3.10 Definiteness and pronouns

3.10.1 Double definiteness

So-called double definiteness can be found in Norwegian, Swedish and Faroese, but not in Danish and Icelandic. Examples are (96)–(97).

(96) Norwegian
denne hest-en / ??hest
this horse-DEF / horse
'this horse'

(97) Norwegian
den hvit-e hest-en / ??hest
the white-DEF horse-DEF / horse
'the white horse'

Double definiteness means that the definiteness of the nominal phrase is expressed by two elements: both the determiner and the definite suffix on the noun.[10] In (97), the adjective makes the determiner *den* obligatory. When there is no adjective, a definite noun such as *hesten* 'horse.DEF' can be a nominal phrase on its own.

Double definiteness is usually obligatory in the colloquial language. There are, however, certain options for semantic differences with and without double definiteness, especially in literary style. Some researchers assume that the two definite elements give different semantic contributions to the phrase (e.g. Julien 2005: 35–44).

---

[10] The definite (or "weak") form of the adjective in (98) is conditioned by the definiteness of the nominal phrase. This will not be discussed further here.

The LFG formalism makes it easy to account for double definiteness by letting both definite elements introduce [DEF +]. A problem is then how to avoid double definiteness in languages where it is ungrammatical, such as Danish. Cf. example (98).

(98) Danish
den hvid-e hest / *hest-en
the white-DEF horse / horse-DEF
'the white horse'

One way of accounting for Danish is to use so-called instantiated values (Strahan 2008: 213–14). The Danish determiner *den* 'the' is then specified as [↑ DEF = +_], where the underscore indicates that this specification cannot unify with anything else. The Danish definite noun *hesten* 'horse.DEF' also has this specification, so (98) is ruled out with a definite noun.

A different analysis of double definiteness can be found in Romero (2015). He assumes that the determiner is the only element that has definiteness as an inherent property, while the noun simply agrees with it. The definite form of the noun then carries a constraining equation [↑ DEF $=_c$ +]. This analysis gives raise to a problem with nominal phrases such as *hesten* 'horse.DEF', which can be used in all argument positions. Romero's solution is that *hesten* is really *den hesten* 'the horse.DEF', where the elements undergo lexical sharing (in the sense of Wescoat 2002).

Börjars & Harries (2008) discuss the history of double definiteness, and make the following remark on its analysis:

> All analyses of the difference between double and single definiteness appear to be somewhat stipulative […] This may be because it is a relatively superficial phenomenon, not associated with deep semantic properties, and hence there may not be any fundamental principled explanation. (Börjars & Harries 2008: 341)

3.10.2 Pronominal demonstratives

Norwegian and Danish can use a pronoun as a demonstrative in sentences such as (99)–(100).

(99) Norwegian (Strahan 2008: 193)
Se på han mann-en!
look at he.NOM man-DEF
'Look at that man!'

(100) Danish (Strahan 2008: 193)
Se på ham mand-en!
look at he.acc man-def
‘Look at that man!’

Johannessen (2008) says that the use of the demonstrative is linked to what she calls psychological distance, and names it the pronominal psychological demonstrative. The form of the pronoun is invariable in each language, not depending upon the function of the nominal phrase. Norwegian always uses the nominative, while Danish uses the accusative. It is striking that Danish can have the definite form of the noun in this construction when double definiteness is not allowed otherwise.

A nominal phrase with a pronominal demonstrative always has specific reference (while the regular distal demonstrative *den* is neutral in this respect). Strahan (2008) sees the relation between the specificity of the pronominal demonstrative and the definiteness of the noun as a kind of agreement.

A difference between Norwegian and Danish is that Danish needs a determiner following the pronominal demonstrative when there is an adjective preceding the noun, as in (101). The noun is then indefinite. The Norwegian equivalent cannot have this determiner following the pronominal demonstrative, as shown in (102).

(101) Danish (Strahan 2008: 213)
Det er ham den store mand.
it is he.acc the big-def man
‘It is that big man.’

(102) Norwegian
Det er han (*den) store mann-en.
it is he.nom the big-def man-def
‘It is that big man.’

This difference between Norwegian and Danish shows that the pronominal demonstrative must be at different levels in c-structure in the two languages. Strahan (2008) assumes that it is under NP in Norwegian, and under DP in Danish.

Varieties of Swedish are similar to Danish in allowing sentences parallel to (101). On the other hand, Swedish is like Norwegian in using the nominative form of the pronoun.

3.10.3 Nominative and accusative of Danish pronouns

Personal pronouns in Danish have, like English, the accusative form as the default form, while the nominative is reserved for subjects. Ørsnes (2002) discusses a special feature of Danish: The nominative is only used for local subjects, as in (103). A non-local subject is realized in the accusative form, as in (104).

(103) Danish (Ørsnes 2002)
Peter tror han vinder.
Peter thinks he.NOM wins
'Peter thinks he is going to win.'

(104) Danish (Ørsnes 2002)
Ham / *han tror Peter vinder.
he.ACC / he.NOM thinks Peter wins
'Peter thinks he is going to win.'

Ørsnes (2002) gives the following conditions for nominative and accusative pronouns:

Nominative The DP is the subject of the immediately containing f-structure.

Accusative The DP is *not* the subject of the immediately containing f-structure (but possibly the subject of an embedded f-structure).

The constructive case formalism (Nordlinger 1998) makes it possible to state these conditions in a simple way. Ørsnes (2002) proposes that the accusative *ham* is equipped with the restriction (105), and the nominative *han* with (106).

(105) *ham* $\{\neg\ (\textsc{subj}\uparrow) \vee$
$((\textsc{comp}^{+}\ \textsc{subj}\uparrow)\ \textsc{df}) = \uparrow\}$

(106) *han* $(\textsc{subj}\uparrow)$
$((\textsc{comp}^{+}\ \textsc{subj}\uparrow)\ \textsc{df}) \neq \uparrow$

3.11 Reflexive binding

3.11.1 The classical LFG approach

The basic facts about binding of reflexives are rather similar in the Mainland Scandinavian languages (but see Lundquist 2014a for some nuances).

Norwegian data has played an important role in the development of binding theory in LFG. Dalrymple (1993) was influenced by the pioneer work of Hellan (1988) (see also Hestvik 1991). Her work is followed up in Bresnan et al. (2016: 227–85). Two general introductions to LFG also discuss binding in Norwegian and Swedish: Falk (2001: 173–91) and Börjars et al. (2019: 152–175).

Anaphoric elements in Norwegian give a nice illustration of different kinds of binding requirements. Their properties are shown in table 1 (from Dalrymple 1993: 34). A nucleus is a PRED and the functions that it selects. A complete nucleus is a nucleus that contains a SUBJ.

Table 1: Anaphoric elements in Norwegian

	Bound to:	Disjoint from:
seg selv	subject in coargument domain	–
ham selv	argument in minimal complete nucleus	subject in minimal complete nucleus
seg	subject in minimal finite domain	subject in minimal complete nucleus
sin	subject in minimal finite domain	–

Examples are (107)–(110).

(107) Norwegian (Dalrymple 1993: 29, from Hellan 1988: 67)
Jon fortalte meg om seg selv.
Jon told me about REFL SELF
'Jon told me about himself.'

(108) Norwegian (Dalrymple 1993: 29, from Hellan 1988: 104)
Vi fortalte Jon om ham selv.
We told Jon about him SELF
'We told Jon about himself.'

(109) Norwegian (Dalrymple 1993: 31, from Hellan 1988: 73)
Jon hørte oss snakke om seg.
Jon heard us talk about REFL
'Jon heard us talk about him.'

(110) Norwegian (Dalrymple 1993: 33, from Hellan 1988: 75)
Jon ble arrestert i sin kjøkkenhave.
Jon became arrested in REFL.POSS kitchen-garden
'Jon was arrested in his kitchen garden.'

Dalrymple shows how anaphoric elements can be equipped with binding requirements in their lexical entries. Binding is described as an inside-out phenomenon in f-structure. Intuitively, we start at the anaphoric element, and go outwards to find a possible binder to co-index with. The path outward is restricted in different ways for different elements. For example, *seg selv* is bound to the subject in its coargument domain, which means that the path cannot go through an f-structure that contains a subject. Possessive *sin* is bound to a subject in a minimal finite domain, which means that the path cannot go through an f-structure that contains TENSE.

The relation between the anaphoric element and the binder can be non-local, as shown by the long distance use of the simple reflexive *seg* (example (109)). This is a case of functional uncertainty.

3.11.2 Some questions of data and interpretation

The Norwegian binding data used by Dalrymple have been the basis of theoretical discussion within different frameworks. They are not without their problems, however. The Hellan/Dalrymple assumptions were criticized in Lødrup (1999a, 2007, 2008a). Three problems for the Hellan/Dalrymple assumptions will be mentioned here: object binders, the status of the simple reflexive *seg*, and binding into a finite clause.

3.11.2.1 Object binders

Hellan and Dalrymple assume that only subjects are possible binders. This might be considered a somewhat brutal idealization of the data, because speakers accept object binders as well in some cases, such as (111) (Lødrup 2008a).

(111) Norwegian
Regl-ene er til for å beskytte dem mot seg selv.
rules-DEF are PARTICLE for to protect them against REFL SELF
'The rules exist to protect them against themselves.'

3.11.2.2 The status of the simple reflexive *seg*

Hellan and Dalrymple assume that the simple reflexive *seg* is not used in local binding, only in long distance binding as in example (109) above. A difficult question concerns the status of the simple reflexive when it is not long distance bound. It is uncontroversial that it can be a non-argument, e.g. with inherently reflexive verbs (such as *skynde seg* 'hurry'). The problem concerns sentences such as (112), in which the simple reflexive seems to be locally bound.

(112) Norwegian
Jon vasker seg.
Jon washes REFL
'Jon is washing himself.'

In the Hellan/Dalrymple approach, one has to say that this is not an argument reflexive, but a lexical reflexive that is used to detransitivize the verb. Lødrup (1999a, 2007) argues that the simple reflexive is a thematic object in sentences such as (112). He claims that a locally bound simple reflexive is possible in what he calls a physical contexts (see also Bresnan et al. 2016: 279–282). This means that the reflexive is the object of a verb that denotes an action directed towards the body of the subject, or the object of a locational preposition.

Physical contexts are also the contexts that allow body part nouns and other nouns in the "personal domain" to occur in the definite form without a possessive pronoun, as in (113) (Lødrup 1999a, 2010). The subject is then understood as the possessor. This use of the definite form is independent of the regular conditions on definiteness, such as being previously known or mentioned.

(113) Norwegian
Jon vasker ansikt-et.
Jon washes face-DEF
'Jon is washing his face.'

Lødrup assumes that both simple reflexives and the relevant group of definite nouns can be bound in physical contexts. Outside physical contexts, the complex reflexive is required – and a body part noun needs a possessive pronoun (or a definite form that satisfies the regular conditions on definiteness). This is shown in (114)-(115).

(114) Norwegian
Jon elsker seg *(selv).
Jon loves REFL (SELF)
'Jon loves himself.'

(115) Norwegian
Jon elsker ansikt-et *(sitt).
Jon loves face-DEF (REFL.POSS)
‘Jon loves his face.’

3.11.2.3 Binding into a finite clause

Mainland Scandinavian allows non-local binding into a non-finite clause, as in example (109) above. Varieties of Mainland Scandinavian also allow binding into a finite clause to some extent. Lødrup (2009a) shows that this can be acceptable when the subject of the embedded clause is low prominent: expletive, non-animate or non-specific. Examples are (116)-(117). Note that the complex reflexive is used in (117).

(116) Norwegian (Lødrup 2009b: 116)
Alle kan føle det er en del av seg…
all can feel it is a part of REFL
‘Everybody can feel that it is a part of them.’

(117) Norwegian (Lundquist 2014b)
Folk leser vel bare de brev-ene som er til seg selv.
people read presumably only the letters-DEF that are to REFL SELF
‘People presumably only read the letters which are for them.’

The Norwegian (117) is accepted by a majority of informants, and the same is true of its Swedish equivalent (Lundquist 2014b).

The conditions on binding into a finite clause in Mainland Scandinavian seem to be complicated, and there has been some discussion about their nature (Strahan 2009, 2011, Lødrup 2009a, Lundquist 2014b,c, Julien 2020).

3.11.3 Long distance binding in Insular Scandinavian

Icelandic allows binding into a finite clause when the subordinate verb is subjunctive (Thráinsson 1976). Icelandic long distance reflexives are usually considered logophoric (see e.g. Maling 1984). An example is (118).

(118) Icelandic (Thráinsson 1976)
Jón segir að María elsk-i sig.
Jón says that María loves-SBJV REFL
‘Jón says that María loves him.’

Sentences corresponding to (118) are also possible in Faroese (Strahan 2011), even though this language does not have a subjunctive mood.

Strahan (2009, 2011) compares long distance binding in Mainland and Insular Scandinavian, and discusses the formalization of relevant binding conditions. An original idea is the use of outside-in (in addition to inside-out) functional uncertainty, to account for the role of the binder as a perspective-holder

3.12 Binding of distributive possessors

The Scandinavian languages can use prenominal distributive possessors to express distance distributivity. Examples are (119)–(120).

(119) Swedish
Vi har ätit varsitt äpple.
we have eaten each.3.REFL.POSS.NEUT apple
'We have eaten one apple each.'

(120) Eastern Norwegian
Vi har spist hver-t vår-t eple.
we have eaten each-NEUT 1.REFL.POSS-NEUT apple
'We have eaten one apple each.'

These distributive elements are composed of a distributive quantifier and a reflexive possessor (at least from a historical point of view). Lødrup et al. (2019) compare the grammar of these expressions in Standard Swedish and Eastern Norwegian, and find a number of differences. Eastern Norwegian has agreement that is lacking in Standard Swedish: The distributive quantifier agrees with the following noun in number and gender, and the possessor agrees with the subject in person and number. Another difference is that the Eastern Norwegian expression follows standard binding requirements, while this is not always necessary in Swedish.

Lødrup et al. (2019) give an analysis which is based upon an idea from Vangsnes (2002): The Swedish *varsitt* 'each.3.REFL.POSS.NEUT' is a single lexical unit, while its Eastern Norwegian correspondent is syntactically complex. They also give a semantic analysis in which the distributive possessor has the semantics of a Skolemized Choice Function.

4 Computational work

Computational approaches to Scandinavian grammar are not covered in this chapter. It could be mentioned, however, that seminal work on Norwegian grammar within LFG has been conducted in several computational linguistics projects at the University of Bergen. NorGram is a broad-coverage LFG grammar for Norwegian implemented on the XLE platform (Dyvik 2000, see also Forst & King 2023 [this volume]). Extensive online documentation of NorGram covers inter alia basic clause structure, lexical categories, phrase structure categories, and f-structure features.[11] NorGram has been used in the construction of the LFG treebank NorGramBank (Dyvik et al. 2016, see also Rosén 2023 [this volume]). For the treebank there is detailed documentation (in Norwegian) on how to search for various grammatical phenomena; it provides not only c- and f-structures, but also comments on the analyses.[12]

5 Conclusion

There is a rich LFG literature on various aspects of the Scandinavian languages, and it was impossible to do justice to it all in this chapter. Scandinavian data have played a role in the development of LFG, for example when it comes to binding conditions and functional categories. Chomskyan approaches have had a dominating position in Scandinavian syntax, and research in LFG has given alternative perspectives. It has produced results that are important both for Scandinavian and international linguistics.

Acknowledgments

For thorough and constructive comments I would like to thank the three anonymous reviewers, the editor, and Nigel Vincent. Thanks are also due to Victoria Rosén.

Chapter 34

LFG and Semitic languages

Louisa Sadler
University of Essex

This chapter surveys the work in LFG on the Semitic languages of Arabic, Hebrew and Maltese. The overview is structured around a number of themes and topics where there is LFG work on one or more of the Semitic languages. Successive sections look at basic clause structure, verbal complementation (including temporal and aspectual auxiliaries, phasal verbs, and perceptual report verbs), copula constructions, construct state nominals, mixed categories, negation and unbounded dependency constructions.

1 Introduction

The Semitic languages are part of the Afro-Asiatic family and the genus includes Arabic, Amharic, Tigrinya, Hebrew, Tigré, Maltese, Mehri and Jibbali *inter alia*. Of these, Arabic (including its many modern vernaculars, and the codified, formal variety Modern Standard Arabic (MSA)) is spoken over a very extensive geographical area with in the order of 250–300 million native language speakers, while Amharic, Tigrinya, Hebrew and Tigré all have numbers of speakers in excess of 1 million. Most work in LFG on this family is on (Modern) Hebrew, Arabic (Modern Standard (MSA) and the modern vernaculars) and Maltese (a mixed language with a Maghrebi/Siculo-Arabic stratum). Kifle (2007) and Kifle (2011) are concerned respectively with differential object marking and the applicative construction in Tigrinya, a Semitic language of Eritrea and Ethiopia; see Bodomo & Che 2023 [this volume] for further discussion of Tigrinya.[1]

---

[1] Example sentences in this chapter have been taken from a number of different sources. In each case, the examples are given using the author's own transcription, with the exception of long vowels, where the notation has been standardised. On the other hand, some standardisation of glossing has been adopted to increase transparency.

Louisa Sadler. 2023. LFG and Semitic languages. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 1651–1702. Berlin: Language Science Press. DOI: 10.5281/zenodo.10186020

2 Basic clause structure

Word order is relatively free in Arabic: there are two basic word orders generally claimed for msa (svo and vso), while svo structures predominate in the spoken vernaculars. Beyond LFG, a considerable literature has addressed the question of whether the preverbal position in svo structures is a genuine subject position or alternatively a dislocated or topicalised position, in particular in connection with msa which exhibits full agreement in the svo order and partial agreement in the vso order. While none of the LFG work on Arabic has a primary focus on matters of constituent structure (unlike quite a considerable volume of the theoretical work in other frameworks), basic clause structure for Arabic is covered to some extent in the theses by Alsharif (2014) (msa), Alotaibi (2014) (Hijazi), ElSadek (2016) (Egyptian), Alruwaili (2019) (Turaif) and Camilleri (2016) (Maltese). This work generally reflects the view that Arabic has two structural subject positions, [Spec, IP] and a lower position, and places the tensed verb in I.

Alsharif (2014) adopts an I+S (subject-predicate) analysis for the two basic word orders of msa, in which the subject appears in a different position in each word order, as shown in (2) (Alsharif 2014: 49–50),[2] and a similar position is adopted for vso and svo structures in Hijazi Arabic in Alotaibi (2014).

(1) msa (Alsharif 2014: 49;50)

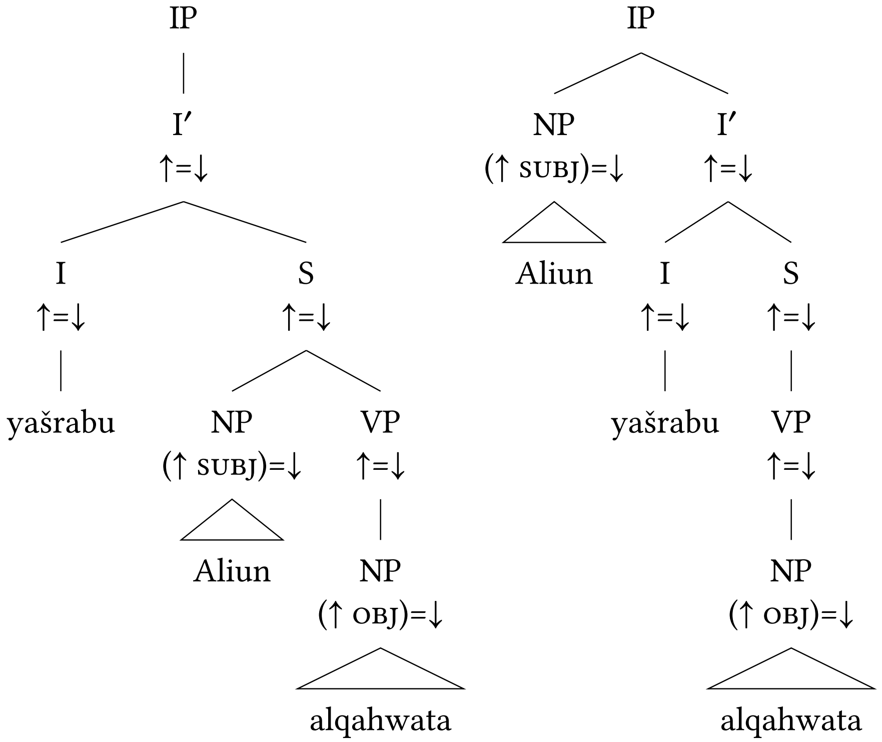
a. ya-šrab-u Ali-un al-qahwat-a
3m-drink.ipfv-sg.ind Ali-nom def-coffee-acc
'Ali drinks the coffee.'

b. Ali-un ya-šrab-u al-qahwat-a
Ali-nom 3m-drink.ipfv-sg.ind def-coffee-acc
'Ali drinks the coffee.'

---

[2] Alsharif (2014) claims that for msa the subject in Spec of IP is associated with additional pragmatic information, but this is not explored further. The agreement asymmetry between SVO and VSO structures in msa where we find full agreement in SVO structures and partial agreement (person and gender) in VSO structures is not discussed but see Fassi Fehri (1988) for an early discussion of this issue. Many vernacular varieties lack this agreement asymmetry, but this is not the place to discuss this somewhat complex issue.

(2)



In a slight variant, both ElSadek (2016) and Alruwaili (2019) assume an I+VP structure for the basic neutral SVO word order in Egyptian Arabic and Turaif Arabic respectively.[3]

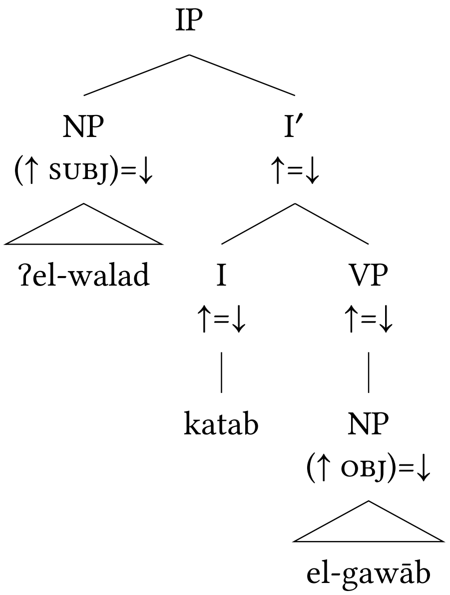
(3) Egyptian Arabic (ElSadek 2016: 90)
ʔel-walad katab el-gawāb
DEF-boy write.PFV.3M.SG DEF-letter
'The boy wrote the letter.'

(4) Turaif Arabic (Alruwaili 2019: 100)
ʕali kitɛb l-wāǧib
Ali write.PFV.3M.SG DEF-homework
'Ali wrote the homework.'

---

[3] As with many other vernaculars, VSO is a possible but less common variant in Turaif Arabic.

(5) (ElSadek 2016: 91)



In all of this work, an important motivation for the assumption that the verb expressing tense is in I is the fact that the very same (perfective and imperfective) forms express aspectual information when they occur in a lower position, in the compound tenses of Arabic (the examples (1a) and (6) provide a simple illustration of this property). There is some discussion of compound tenses in Arabic (involving forms of the ‘be’ verb as a temporal auxiliary) in a number of LFG sources and this literature includes both Aux-feature and Aux-PRED analyses for broadly comparable data across the dialects.

Alsharif (2014) adopts a single-tier or Aux-feature analysis for MSA examples such as (6), and a fuller development of this approach to compound tense formation in MSA is given in Alsharif & Sadler (2009).[4]

(6) MSA (Alsharif 2014: 52)

kāna	Ali-un	ya-šrab-u	al-qahwat-a
be.PFV.3M.SG	Ali-NOM	3M-drink.IPFV-SG.IND	DEF-coffee-ACC

‘Ali was drinking the coffee.’

---

[4] In the simple tenses of Arabic, the imperfective and perfective forms of the lexical verb are associated with TENSE. The compound tenses of Arabic and Maltese are formed by combining imperfective and perfective verb forms of the auxiliary ‘be’ (associated with TENSE) with perfective and imperfective forms of the lexical verb, which are then associated with ASPECT. Note that these forms still show subject agreement in their (embedded) aspectual use.

(7) MSA (Alsharif & Sadler 2009: 18)
kun-tu ʔaktub-u t-taqrīr-a
be.PFV-1SG write-IPFV.1SG the-report-ACC
'I was writing the report.'

(8)
$$\begin{bmatrix} \text{PRED} & \text{`WRITE}\langle\text{SUBJ,OBJ}\rangle\text{'} \\ \text{ASP} & \text{PROG} \\ \text{TENSE} & \begin{bmatrix} \text{PAST} & + \end{bmatrix} \\ \text{SUBJ} & \begin{bmatrix} \text{PERS} & 1 \\ \text{NUM} & \text{SG} \end{bmatrix} \end{bmatrix}$$

(Alsharif & Sadler 2009: 18)

The Aux-feature account is also adopted by Alotaibi (2014) for Hijazi (Taif) Arabic and Alruwaili (2019) for Turaif Arabic, and by Camilleri (2016) for Maltese. In (10) the auxiliary elements *kont* 'be.PFV.1SG' and *qed* respectively contribute TENSE=PAST and ASPECT=PROG to the f-structure of the predicate *wash*.

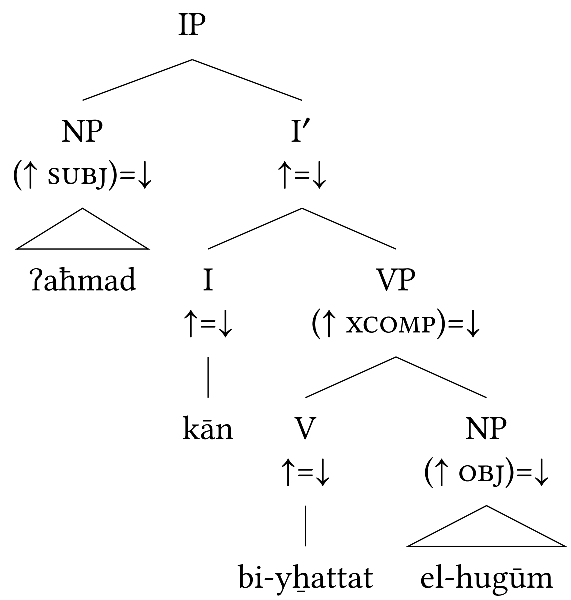
(9) Hijazi (Taif) Arabic (Alotaibi 2014: 37)
ʔaħmad kān yiğri fī al-ħadīqah ʔams
Ahmad be.PFV.3M.SG run.IPFV.3M.SG in DEF-garden yesterday
'Ahmad was running in the garden yesterday.'

(10) Maltese (Camilleri 2016: 19)
Kon-t qed n-a-ħsel il-karozza
be.PFV-1SG PROG 1-FRM.VWL-wash.IPFV.SG DEF-car
'I was washing the car.'

On the other hand, ElSadek (2016) presents some arguments in favour of the Aux-PRED analysis for Egyptian Arabic, in which the tense-aspect auxiliary *kān* is treated as a raising verb taking a VP XCOMP complement. The c-structure for (11) and f-structure for (13) below illustrate this approach. In work on the aspectual system of Libyan Arabic, Börjars et al. (2016) also provide arguments in support of an Aux-PRED approach to the facts which they discuss.

(11) Egyptian Arabic (ElSadek 2016: 91)
ʔaħmad kān bi-yẖattat el-hugūm
Ahmed be.PFV.3M.SG BI-plan.IPFV.3M.SG DEF-attack
'Ahmed was planning the attack.'

(12) (ElSadek 2016: 91)

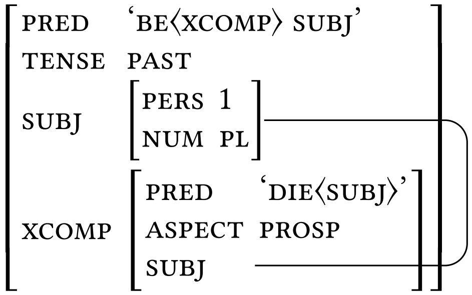


(13) Egyptian Arabic (ElSadek 2016: 90)

konna	ħa-nmūt
be.pfv.1pl	fut-die.ipfv.1pl

‘We were going to die.’

(14) (ElSadek 2016: 90)



3 Aspects of verbal complementation

Various further aspects of verbal complementation in the Arabic vernaculars are discussed in the LFG literature. Camilleri (2016) provides a detailed exploration of temporal and aspectual auxiliation in Maltese, articulating an unusually large set of features and values for this domain at f-structure. She also explores the use of the pseudo-verbs *għodd-* ‘almost’ *il-* ‘to’ and *għad-* ‘still’ as aspectual auxiliaries expressing the perfect aspect. The term pseudo-verb is used descriptively in work on the Arabic vernaculars to refer to a form which plays the role of a finite verb in the syntax but which is derived from a participle, preposition or nominal stem and usually retains many aspects of morphosyntactic realization reflecting this origin, such as exhibiting non-canonical forms of subject agreement. These forms raise many interesting issues for analysis, not least regarding their synchronic categorial identity. Camilleri argues that the universal perfect and the perfect of recent past are expressed syntactically in Maltese by the pseudo-verbs *il-* and *għad-* respectively (see (15) and (16)), while *għodd* provides an avertive construction. Applying a range of standard tests, she argues for an Aux-pred, raising analysis of these forms, along the lines shown in (18) and (19) for (16) and (17) respectively. Note that Maltese, like Arabic, lacks an infinitival form, and makes use of the imperfective form of the verb in these non-finite complements.

(15) Maltese (Camilleri 2016: 205)

(Camilleri 2016: 214)

(19)

$$\begin{bmatrix} \text{PRED} & \text{`GĦODDNI}\langle\text{XCOMP}\rangle\text{SUBJ'} \\ \text{CL-TYPE} & \text{AVERTIVE} \\ \text{TENSE} & \text{PAST} \\ \text{SUBJ} & \begin{bmatrix} \text{PRED} & \text{`PRO'} \\ \text{PERS} & 1 \\ \text{NUM} & \text{SG} \end{bmatrix} \\ \text{XCOMP} & \begin{bmatrix} \text{PRED} & \text{`XTRAJT}\langle\text{SUBJ,OBJ}\rangle\text{'} \\ \text{SUBJ} & \underline{\qquad\qquad} \\ \text{ASPECT} & \text{PERFECTIVE} \\ \text{OBJ} & \begin{bmatrix} \text{PRED} & \text{`LIBSA'} \\ \text{DEF} & + \end{bmatrix} \end{bmatrix} \end{bmatrix}$$

(Camilleri 2016: 214)

The syntax and morphosyntax of phasal verbs, that is verbs which denote the inception, duration, continuation, completion or termination of a state or event (such as (20)), in the Arabic vernaculars is addressed in Alotaibi et al. (2013) (see also Camilleri 2016 and ElSadek 2016 for more extensive discussion of Maltese and Egyptian respectively). These verbs take verbal complements (or, particularly in Modern Standard Arabic, nominalised verbal complements) and typically disallow intervening material between the aspectual verb and its verbal complement (which generally lacks a complementising particle). The aspectual verb and the embedded verb have the same subject, which is not expressed as an NP in the lower clause. The embedded verb shows subject agreement and is usually an imperfective form (Arabic lacks an infinitive form). Using standard tests, Alotaibi et al. (2013) show that a raising analysis is motivated for these verbs in examples such as (20) and (21) below.[5]

(20) Egyptian Arabic (Alotaibi et al. 2013: 17)

a.

el-walad	ma-badaʔ-š	ya-kul
def-boy	neg-start.pfv.3m.sg.neg	3-eat.ipfv.m.sg

‘The boy didn’t start to eat.’

b.

el-walad	badaʔ	ma-ya-kul-š
def-boy	start.pfv.3m.sg	neg-3-eat.ipfv.3m.sg.neg

‘The boy started to not eat.’

---

[5] In addition to occurring in a raising structure, some of the class of phasal verbs also occur in a ‘subjectless’ variant with a default 3m.sg phasal verb and a subject expressed within the embedded complement, a structure which provides an expletive subject counterpart to the raising structure.

(21) a. Hijazi Arabic (Alotaibi et al. 2013: 20)
al-maḥṣūl bada ya-n-ğimʕ
DEF-harvest start.PFV.3M.SG 3-PASS-gather.IPFV.M.SG
'The harvest started being gathered.'

b. Maltese (Alotaibi et al. 2013: 20)
L-iltiema bde-w j-i-n-ġabr-u
DEF-orphans begin.PFV.3-PL 3-FRM.VWL-PASS-gather.IPFV-PL
'The orphans started being gathered (together).'

Camilleri et al. (2014b) discuss perceptual report predicates in MSA and in Maltese. The MSA verb *yabdū* 'seem, appear' occurs in an expletive subject (or 'subjectless') construction taking a complement introduced by the declarative complementising particle *ʔanna*. While it does not permit subject raising (SSR) they argue that it does permit copy raising (CR) with the complementising particle *kaʔanna* 'as if'. In the CR construction, the copy pronoun is not restricted to the embedded SUBJ role and may occur in a wide range of nominal GFS in the embedded complement.

In Maltese the perceptual report predicates include the verb *deher* 'seem/appear' and the pseudo-verbs *donn*+PRN (diachronically the imperative of 'believe/think') and *qis*+PRN, both meaning 'seem/appear/taste/sound as.though/as.if'. (22) exemplifies the expletive construction with the verb *deher*, in which the verb appears in the default 3M.SG form and the subject is expressed only in the embedded COMP. In (23) the subject is in the matrix clause and both matrix and embedded verbs agree with it. Camilleri et al. (2014b) argue that evidence from standard tests for raising (idiom chunks, meaning preservation under passivisation, expletives, etc) suggests that (23) and similar examples are SSR.

(22) Maltese (Camilleri et al. 2014b: 191)
J-i-dher t-tfal sejr-in tajjeb
3-FRM.VWL-appear.IPFV.M.SG DEF-children going.ACT.PTCP-PL good.M.SG
'It seems the children are doing well.'

(23) Maltese (Camilleri et al. 2014b: 191)
It-tfal dehr-u qed j-ieħd-u gost
DEF-children appear.PFV.3-PL PROG 3-take.IPFV-PL pleasure
'The children seem (as though) they are enjoying themselves (lit: taking pleasure).'

However, Maltese *deher* also occurs in what looks like a copy raising (cr) construction, in which a pronominal coreferential with the subj of the raising predicate *deher* occurs as an argument within the embedded complement. This is illustrated in (24) where the obj pronominal inflection *-ha* in the form *weġġagħ-ha* 'hurt.caus.pfv.3m.sg-3f.sg.acc' is coreferential with the (inflectionally-expressed) matrix subj (indicated by the dashed line between anaphor and antecedent in (25)).

(24) Maltese (Camilleri et al. 2014b: 195)

Marija	t-i-dher	weġġagħ-ha	sew,	Mario
Mary	3-frm.vwl-appears.f.sg	hurt.caus.pfv.3m.sg-3f.sg.acc	well	Mario

'Mary seems as though Mario hurt her a lot.'

(25)
$$\begin{bmatrix} \textsc{pred} & \text{`}\textsc{seem}\langle\textsc{comp}\rangle\textsc{subj}\text{'} \\ \textsc{subj} & \begin{bmatrix} \textsc{pred} & \text{`Marija'} \\ \textsc{num} & \textsc{sg} \\ \textsc{gend} & \textsc{fem} \\ \textsc{pers} & 3 \end{bmatrix} \\ \textsc{comp} & \begin{bmatrix} \textsc{pred} & \text{`}\textsc{hurt}\langle\textsc{subj,obj}\rangle\text{'} \\ \textsc{subj} & \begin{bmatrix} \textsc{pred} & \text{`}\textsc{mario}\text{'} \end{bmatrix} \\ \textsc{obj} & \begin{bmatrix} \textsc{pred} & \text{`}\textsc{pro}\text{'} \end{bmatrix} \end{bmatrix} \end{bmatrix}$$

(Camilleri et al. 2014b: 196)

The analysis which Camilleri et al. (2014b) develop of the syntax and semantics of these perceptual report predicates builds on Asudeh & Toivonen's (2012) work on English and Swedish. Because Maltese (and Arabic in general) is both a pro-drop language and uses the imperfective form of the verb in non-finite complement clauses (lacking an infinitive form), examples such as (23) could in principle involve either raising or copy raising. They argue that there is a clear contrast between ssr examples such as (23), in which any aspect of the eventuality can be the perceptual source, and cr examples such as (26) in which it is the raised subj itself that is necessarily the individual psource. In the Maltese cr construction, the pronominal copy can correspond to a very wide range of embedded functions. It is also not limited to the immediately embedded comp but within the topmost embedded comp it is restricted to non-subject functions.

(26) Maltese (Camilleri et al. 2014b: 192)
T-i-dher ġa ta-w-ha xebgħa
3-FRM.VWL-seem.IPFV.F.SG already give.PFV.3-PL-3F.SG.ACC smacking
xogħol x't-a-għmel!
work what.3-FRM.VWL-do.IPFV.F.SG
'She$_i$ seems like they already gave her$_i$ a whole load of work to do!'

While Camilleri et al. (2014b) are concerned with canonical verbal perceptual report predicates in MSA and Maltese, ElSadek & Sadler (2015) look at the expression of perceptual reports in Egyptian Arabic using the active participle *bāyen* 'show, appear' and in particular at the use of the (noun-derived) pseudo-verb *šakl* (>'form, shape') as a perceptual report predicate. *bāyen* can occur in a construction in which the active participle is followed by a PP which expresses the (visible) individual PSOURCE with either the standard sentential complementiser *ʔin* (corresponding to the MSA complementiser *ʔanna*) or the 'evidential' complementiser *kaʔin* (cognate with MSA *kaʔanna*). The active participle must be in the default form but a temporal auxiliary may agree with the nominal PSOURCE in the PP, as illustrated in (27), in what may be a case of parasitic or miscreant agreement.

(27) Egyptian Arabic (ElSadek & Sadler 2015: 92)
konti bāyen ʕalē-ki ʔinn-ik
be.PFV.2F.SG show.ACT.PCTP.M.SG on-2F.SG that-2F.SG
mabsūt-a
happy.PASS.PTCP.SG-F
'You seemed happy.'

With *šakl*, there is rather clearer evidence of raising. (28) illustrates a very common means of expressing a perceptual report. It involves what appears morphosyntactically to be a nominal form *šakl* 'form, shape' with a dependent 'possessor' corresponding to the individual about whom the report is made. Notice in (28) that it is the dependent 'possessor' (the pronominal affix) which controls agreement on the ACT.PTCP, and similarly in an example such as (29). Synchronically, this form appears to operate as a pseudo-verb here, in a raising structure.

(28) Egyptian Arabic (ElSadek & Sadler 2015: 95)
šakl-ohom mestaney-īn ħāga mohemma
form-3PL wait.ACT.PTCP-PL thing important
'They seem to be waiting for an important thing.'
'It seems they're waiting for an important thing.'

(29) Egyptian Arabic (ElSadek & Sadler 2015: 98)
šakl el-welād kānu biyitderbo
form DEF-boys be.PFV.3PL beat.BI.IPFV.PASS.3PL
'The boys seem to have been (being) beaten.'

In structures such as (28) and (29) the dependent NP or pronoun is not obligatorily interpreted as the individual PSOURCE. In a different structure, illustrated in (30), we find a sentential complement introduced by the complementising particle *kaʔin*, with no requirement that the dependent NP/pronoun be co-referential with the subject of the (embedded) predication, and these structures *are* associated with a clear individual PSOURCE interpretation.

(30) Egyptian Arabic (ElSadek & Sadler 2015: 98)
šakl el-welād kaʔenn-aha darabet-hom
form DEF-boys as.if-3F.SG beat.PFV.3F.SG-3PL
'The boys seem as if she's beaten them.'

Other work on aspects of complementation includes the following. ElSadek (2016) discusses the causative *χalla* 'make', aspectual/phasal verbs and modal verbs, proposing analyses involving functional and anaphoric control. Alotaibi et al. (2013) concerns the description and analysis of experiencer-object psychological predicates (*frighten* or *please* class – EOPVS) in Hijazi Arabic, Egyptian Arabic and Maltese and proposes that the interaction of EOPVS with aspectual raising predicates involves copy raising (CR). An analysis of aspectual object marking in Libyan Arabic is provided in Börjars et al. (2016). In Libyan Arabic, the presence of the preposition *fi* before the direct object of a transitive verb in the imperfective form provides a continuous or habitual aspectual value to the clause (see (31)), which Börjars et al. (2016) model by means of a clause feature INTERIOR=+.

(31) Libyan Arabic (Börjars et al. 2016: 126)

a. aħmed kle el-koski
Ahmed eat.PST.3M.SG DEF-couscous
'Ahmed ate couscous.'

b. aħmed yākil fi el-koski
Ahmed eat.IPFV.3M.SG FI DEF-couscous
'Ahmed eats/is eating couscous.'

4 Copula sentences

Both Hebrew and Arabic have copula sentences without an overt copula head, as well as copula sentences with a 'pronominal copula', and a variety of copula-type elements which mark existential constructions of various sorts. Predicative (copula) sentences with no copula receive present tense interpretations, while an appropriate form of *be* signals other temporal interpretations. The examples in (32) illustrate this alternation between the 'null' and overt copula in Hebrew with adjectival, nominal and prepositional predicates.

(32) a. Hebrew (Falk 2004: 227)
Pnina nora xamuda/ tinoket/ b-a-bayit
Pnina awfully cute.f/ baby.f/ in-def-house
'Pnina is awfully cute/a baby/in the house.'

b. Pnina hayta nora xamuda/ tinoket/ b-a-bayit
Pnina be.pst.3f.sg awfully cute.f/ baby.f in-def-house
'Pnina was awfully cute/a baby/in the house.'

As well as the zero realisation in the predicative clauses in (32), the so-called pronominal copula also occurs with predicative complements in Hebrew, as well as with a definite NP complement in an equative copula construction, in paradigmatic opposition with forms of *be* giving temporal interpretations other than the present.[6]

(33) a. Hebrew (Falk 2004: 227)
Pnina hi nora xamuda/ ha-tinoket
Pnina pron.3f.sg awfully cute.f/ def-baby.f
'Pnina is awfully cute/the baby.'

b. Pnina hayta nora xamuda/ ha-tinoket
Pnina be.pst.3f.sg awfully cute.f/ def-baby.f
'Pnina was awfully cute/the baby.'

---

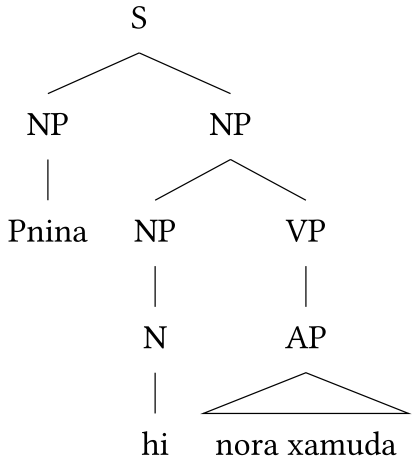
[6] The distribution of the null copula and the pronominal copula strategy in Arabic is similar, but not identical. For example, in Hebrew examples with predicative nominals and PPs are well-formed in the complement of the pronominal copula, but these structures are not found in (most) Arabic vernaculars.

(i) Hebrew (Sichel 1997: 296)
Rina hi talmid-a/xaxam-a/b-a-bayit
Rina pron.3f.sg student-f/intelligent-f/in-def-house
'Rina is a student/intelligent/at home.'

The pronominal copula forms of Hebrew and Arabic have received considerable analytic attention outside LFG. Within LFG, Falk (2004) develops a mixed category analysis of the pronominal copula *hi* and its inflectional counterparts in Hebrew, taking it to be categorially nominal but functionally verbal. It is argued to have categorially mixed properties in taking 'verbal' complements (e.g. accusative objects) and heading a constituent with a clausal distribution, but occurring in an N position.[7] (34) is the lexical entry for the copula use of *hi*; the c-structure and f-structure for (33) are shown in (35) and (36) respectively.[8] The final line in (34) is satisfied if the category VP is a member of the set of c-structure nodes mapping to the f-structure denoted by ↑. This requirement is satisfied in the c-structure shown in (35).

(34) *hi* N (↑ PRED)='BE⟨SUBJ,PREDLINK'⟩ (Falk 2004: 233)
(↑ TENSE)=PRES
(↑ SUBJ GEND)=F
(↑ SUBJ NUM)=SG
VP ∈ CAT(↑)

(35)



---

[7] In Hebrew, the sentential negator *lo* appears before a verb but between the pronominal copula and the following predicative element, which is taken to support the conclusion that the pronominal copula is not a V in c-structure.

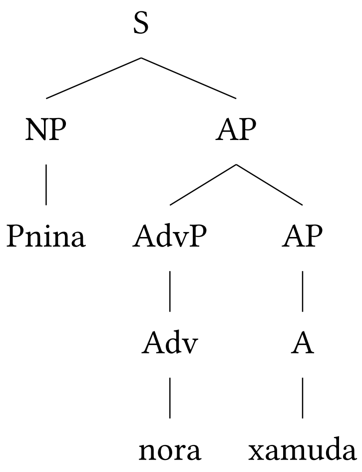
[8] Note that although this is a mixed category analysis, because Falk (2004) assumes an NP node dominating the N *hi*, the N is not the extended head of VP and AP, according to the standard definition of extended head (Bresnan et al. 2016: 136).

(36)
$$\left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{be}\langle\textsc{subj}, \textsc{predlink}\ \rangle\text{'} \\ \textsc{tense} & \textsc{pres} \\ \textsc{subj} & \left[\begin{array}{ll}\textsc{pred} & \text{`Pnina'} \\ \textsc{gend} & \textsc{f} \\ \textsc{num} & \textsc{sg}\end{array}\right] \\ \textsc{predlink} & \left[\begin{array}{ll}\textsc{pred} & \text{`}\textsc{cute}\text{'} \\ \textsc{adj} & \left\{\left[\text{“}\textsc{awfully}\text{”}\right]\right\}\end{array}\right]\end{array}\right]$$

(Falk 2004: 234)

While the pronominal copula is treated as a PRED-bearing element with a PREDLINK complement (see (34) above), giving a closed, two-tier analysis of these copula sentences, those with no copula are treated as simple single-tier predications (“such sentences are most naturally analysed as involving an exocentric S, with direct predication by the non-verbal element” (Falk 2004: 235)). The analysis of an example such as (32a) which lacks the pronominal copula is along the lines shown in (37–38). On this analysis, non-verbal predicational elements which appear in both the null copula and the pronominal copula constructions must be associated with two lexical entries, the predicational (i.e. SUBJ-subcategorising) PRED value (for the null copula construction) being a lexical extension of the non-predicational one (as can be seen by comparing the relevant PRED values in (36) and (38) respectively).

(37)



(38)
$$\left[\begin{array}{ll} \textsc{tense} & \textsc{pres} \\ \textsc{subj} & \left[\begin{array}{ll}\textsc{pred} & \text{`Pnina'} \\ \textsc{gend} & \textsc{f} \\ \textsc{num} & \textsc{sg}\end{array}\right] \\ \textsc{pred} & \text{`}\textsc{cute}\langle\textsc{subj}\rangle\text{'} \\ \textsc{adj} & \left\{\left[\text{“}\textsc{awfully}\text{”}\right]\right\}\end{array}\right]$$

(Falk 2004: 235)

An interesting consequence of this analysis is that the distinction between individual level predication and stage-level predication is reflected in f-structure. Individual level predication uses the pronominal copula and therefore is associated with a two-tier analysis, while stage-level predication (with no copula) is associated with a single simple f-structure (Falk 2004: 236). This contrast in interpretation is illustrated in (39).

(39) Hebrew (Falk 2004: 236–237)

a. ha-dinozaur hu vsikor
def-dinosaur pron.m.sg drunk.m.sg
'The dinosaur is a drunkard.'

b. ha-dinozaur vsikor
def-dinosaur drunk.m.sg
'The dinosaur is drunk.'

Copula clauses with forms of the verb *haya* 'be' are functionally equivalent to both the zero and the pronominal copula constructions, as shown in (32b) and (33b) above. This means that the lexical entry for *haya* must have an optional pred value (see (40)). As a consequence, a sentence such as (41) will be associated with one c-structure and the two f-structure analyses shown in (42) and (43), that is, it will be analysed as functional ambiguous.

(40) *hayta* N ((↑ pred)='be⟨subj, predlink⟩')
(↑ tense)=past
(↑ subj gend)=f
(↑ subj num)=sg

(41) Hebrew (Falk 2004: 227)
Pnina hayta nora xamuda
Pnina be.pst.3f.sg awfully cute.f
'Pnina was awfully cute.'

(42)
$$\left[\begin{array}{ll} \textsc{tense} & \textsc{past} \\ \textsc{subj} & \left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{Pnina}\text{'} \\ \textsc{gend} & \textsc{f} \\ \textsc{num} & \textsc{sg} \end{array}\right] \\ \textsc{pred} & \text{`}\textsc{cute}\langle\textsc{subj}\rangle\text{'} \\ \textsc{adj} & \left\{\left[\text{``}\textsc{awfully}\text{''}\right]\right\} \end{array}\right]$$

(Falk 2004: 237)

(43)
$$\left[\begin{array}{ll} \textsc{pred} & \text{‘}\textsc{be}\langle\textsc{subj, predlink}\ \rangle\text{’} \\ \textsc{tense} & \textsc{past} \\ \textsc{subj} & \left[\begin{array}{ll} \textsc{pred} & \text{‘}\textsc{Pnina}\text{’} \\ \textsc{gend} & \textsc{f} \\ \textsc{num} & \textsc{sg} \end{array}\right] \\ \textsc{predlink} & \left[\begin{array}{ll} \textsc{pred} & \text{‘}\textsc{cute}\text{’} \\ \textsc{adj} & \left\{\left[\text{“}\textsc{awfully}\text{”}\right]\right\} \end{array}\right] \end{array}\right]$$

(Falk 2004: 237)

For MSA, Attia (2008) discusses predicative and locational copula clauses lacking an overt copula form and associates a *be* PRED with the absence of a copula, treating the predicative complement as a PREDLINK. His contention is that the adjective cannot be the head because the subject and the adjective both take what is considered to be default nominative case, while in the presence of an overt copula the adjective will have accusative case. (44) and (45) show this contrast.

(44) MSA (Attia 2008: 94)
al-marʔat-u karīmat-un
DEF-woman.F.SG-NOM generous.F.SG-NOM
‘The woman is generous.’

(45) MSA (Attia 2008: 100)
kāna ar-rağul-u karīm-an
was DEF-man.M.SG-NOM generous.M.SG-ACC
‘The man was generous.’

While agreement between the adjective and the clausal subject could be captured simply and transparently by a local SUBJ agreement statement on a two-tier analysis with an open predicational complement (that is, an XCOMP analysis along the lines of a raising predicate) this mechanism is not available on the (closed complement) PREDLINK analysis, since the PREDLINK does not contain a SUBJ. Attia (2008) suggests that agreement specifications should be associated with the c-structure rules, as in (46), adapted from Attia (2008: 104).

(46)
$$\text{S} \longrightarrow \begin{array}{c} \text{NP} \\ (\uparrow \textsc{subj}){=}\downarrow \end{array} \left\{ \begin{array}{c} \text{VCop} \\ \uparrow{=}\downarrow \\ \end{array} \middle| \begin{array}{c} \epsilon \\ (\uparrow \textsc{pred}){=}\text{‘}\textsc{null-be}\langle\textsc{subj, predlink}\rangle\text{’} \\ (\uparrow\textsc{tense}){=}\textsc{pres} \end{array} \right\} \begin{array}{c} \{\ \text{NP} \mid \text{AP}\ \} \\ (\uparrow \textsc{predlink}){=}\downarrow \\ (\downarrow \textsc{gend}){=}(\uparrow \textsc{subj gend}) \\ (\downarrow \textsc{num}){=}(\uparrow \textsc{subj num}) \end{array}$$

The f-structure of a simple predicative copula sentence such as (47) is (48) on this analysis.

(47) MSA (Attia 2008: 107)
huwa ṭālib-un
he student.NOM
‘He is a student.’

(48)
$$\begin{bmatrix} \text{PRED} & \text{`NULL-BE}\langle\text{SUBJ, PREDLINK }\rangle\text{'} \\ \text{TENSE} & \text{PRES} \\ \text{SUBJ} & \begin{bmatrix}\text{PRED `HE'}\end{bmatrix} \\ \text{PREDLINK} & \begin{bmatrix}\text{PRED `STUDENT'}\end{bmatrix} \end{bmatrix}$$
(Attia 2008: 107)

The ‘null-be⟨SUBJ, PREDLINK⟩’ analysis is not adopted across the board for the Arabic copula clause. Alsharif (2014) treats verbless predication in MSA with a single-tier analysis and no ‘null-be’ PRED, as does Alruwaili (2019) for Turaif Arabic. In these analyses the lack of an overt verb is associated simply with TENSE=PRES. Alruwaili (2019) treats the Arabic pronominal copula of equational sentences, illustrated in (49), as an element in I with the PRED value ‘hi⟨SUBJ,OBJ⟩’, though without providing much discussion of this analytic choice.

(49) Turaif Arabic (Alruwaili 2019: 109)
huda hī l-mudīr-a
Huda COP.3F.SG DEF-director-F.SG
‘Huda is the director.’

5 Construct state nominals

A considerable theoretical literature addresses the syntax of the *construct state nominal* (or *construct*) (CSN) in Modern Hebrew and Arabic, a construction of central importance in the grammar of these languages. This construction, illustrated in (50)–(52), has a range of distinctive properties: it is left-headed, the head cannot be inflected for definiteness and may occur in a bound form, the *construct state*, depending on language and inflectional class. In MSA the dependent is genitive. A further key property is lack of interruptibility of the head-dependent construction, so that any adjectival modifiers of the head noun follow the entire construct (including any modifiers of the non-head dependent itself), as in example (53). A range of different relations may hold between the head and the non-head or dependent, including possession, partitivity, kinship, identity, measurement and composition, though the range of the construction differs between languages and dialects.[9]

(50) Hebrew (Falk 2007: 106)
mamlexet norvegia
kingdom.CONSTR Norway
‘the kingdom of Norway’

(51) Lebanese Arabic (Ouwayda 2012: 77)
sayyaret l-estez
car.F.SG.CONSTR DEF-teacher
‘the teacher’s car’

(52) Syrian Arabic (Hallman 2018: 258)
ʕamm l-ʕrāus
uncle DEF-bride
‘the uncle of the bride’

(53) Hebrew (Falk 2007: 106)
dodat ha-balšan ha-generativi ha-zkena
aunt.CONSTR DEF-linguist DEF-generative.M DEF-old.F
‘the generative linguist’s old aunt’

(54) Jordanian Arabic (Alhailawani 2018: 152)
bait il-mara il-jdīd
mouse.M.SG DEF-woman.F.SG DEF-new.M.SG
‘the woman’s new house’

As well as the CSN, Hebrew and the Arabic vernaculars have an analytic or free state genitive construction with a distribution which partially overlaps that of the CSN. The following examples illustrate (note that a variety of different “linking elements” are found in the various Arabic vernaculars).

---

[9] There are also modificational constructs which get a kind reading as in (i). These are not discussed in any detail in the LFG literature.

(i) Lebanese Arabic (Ouwayda 2012: 77)
abbouʕet sherti
hat cop
‘a cop’s type of hat’

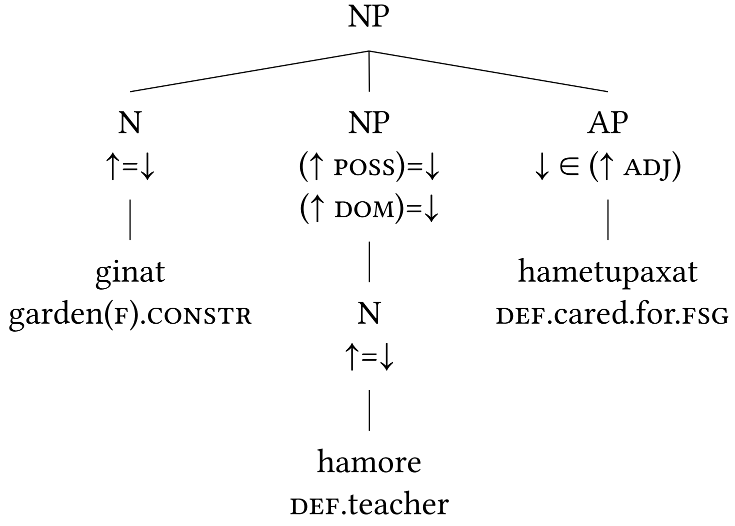
(55) Lebanese Arabic (Ouwayda 2012: 77)
l-sayyara tabaʔ l-estez
DEF-car of DEF-teacher
‘the teacher’s car’

(56) Hebrew (Falk 2007: 104)
ha-doda ha-zkena šel ha-balšan
DEF-aunt DEF-old of DEF-linguist
‘the old aunt of the linguist’

Falk (2001) provides a detailed examination of the constituent structure of NPs containing a *construct* in Hebrew, concluding that despite the closely bound nature of the CSN[10] the N+possessor/dependent does not form a constituent to the exclusion of the head-modifying AP; the c-structure proposed for (57) is thus (58).[11] The c-structure rule is shown in (59): the ↓ ∈(↑ ADJ) annotation is for the sort of modificational example noted in footnote 9 above which also occur in Hebrew e.g. *bigdey yeladim* ‘clothing.CONSTR children’ (children’s clothing), and is not directly relevant to our discussion below.

(57) Hebrew (Falk 2001: 85)
ginat ha-more ha-metupax-at
garden(F).CONSTR DEF-teacher(M) DEF-cared.for-F.SG
‘the teacher’s tended garden’

(58) (Falk 2001: 85)



---

[10] The construct state (of the head noun) is a morphophonological form limited to occurrence within this construction, and within compounds.

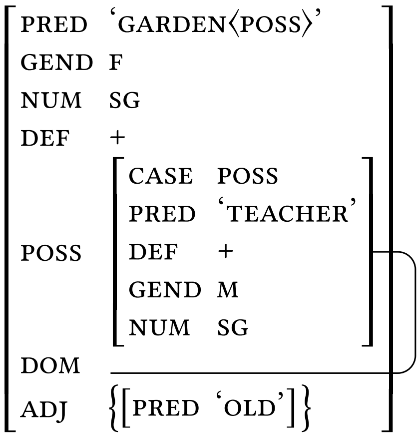
[11] Falk (2007) assumes that any PP modifiers or arguments of the head N are adjoined to the NP, citing a similar proposal developed for Welsh NP structure in Sadler (2000).

(59) $$\begin{array}{llll} \text{NP} \longrightarrow & \text{N} & \text{NP} & \text{AP*} \\ & \uparrow=\downarrow & (\uparrow \textsc{dom})=\downarrow & \downarrow \in (\uparrow \textsc{adj}) \\ & & \{\, (\uparrow \textsc{poss})=\downarrow \mid & \\ & & \downarrow \in (\uparrow \textsc{adj}) \,\} & \end{array}$$ (Falk 2001: 91)

The c-structure rule annotations state that the dependent NP is the value of both a POSS function and a DOM attribute. Nouns are treated as optionally subcategorising for a POSS, which may be expressed by means of the dependent NP in a CSN, or by means of the alternative free genitive construction. The basic property of the construct form is the tight bond it forms with the dependent (reflected in the choice of a particular variant form of the head noun). Modelling his analysis in part on Wintner's (2000) use of a DEP attribute in his HPSG analysis, Falk introduces a DOM attribute associated with the immediately post-head constituent. The dependency between the head in the construct state and the dependent NP is thus captured in the f-structure – the construct form (and only this form) selects a DOM attribute, which is also the value of the POSS feature (the f-description (↑ DOM) is an existential constraint, requiring the presence of a DOM attribute in the satisfying f-structure). Construct forms cannot occur in other syntactic environments. In a CSN the definiteness value of the construction as a whole is "inherited" from the dependent nominal. This is captured in the lexical entry shown in (60) for the construct form of the noun *gina* 'garden', i.e. *ginat* by the f-description (↑ DEF)=(↑ DOM DEF). The f-structure is shown in (61). In contrast to nouns in construct form, free form nouns are specified as ¬(↑ DOM).

(60) *ginat* (↑ PRED)='GARDEN⟨(POSS)⟩' (Falk 2001: 92)
(↑ NUM)=SG
(↑ GEND)=F
(↑ DOM)
(↑ DEF)=(↑ DOM DEF)

(61)



(Falk 2001: 92)

Adjectival modifiers in Hebrew and Arabic show definiteness agreement, in addition to agreement in more canonical agreement features such as num and gend. In a csn the definiteness value of the construction as a whole is determined by that of the poss or dependent NP, as illustrated in (53), (54) and (57) above. Definiteness agreement is simply captured by associating the relevant inside-out statement (e.g. ((adj ↑) def=+) with the attributive adjective.

Simply put, the essence of Falk's (2001) analysis is a lexical distinction between construct forms of nouns, which are specified as (↑ dom) and free forms, which are ¬(↑ dom) by default, a special ps rule which takes care of the adjacency requirement, and the association of the dependent NP with the poss function. Notice that the occurrence of a poss function and the use of the construct form are not co-extensive: some dependent NPs are adj, rather than poss functions, as noted above, and some poss functions are realised by means of the free genitive construction illustrated in (56) above. It is for this reason that Falk's account separates the requirement for a dependent (dom) from the function of the dependent (normally poss).

Falk (2007) further develops the analysis of the csn presented in Falk (2001), providing more extensive discussion of the distribution of the 'short' (i.e csn-internal) and 'long' (i.e. *šel*-PP) possessor constructions (i.e. examples such as (56) above). For example, while both constructions are available for relational nouns, true possession in Hebrew is normally expressed by using the *šel* construction (use of the csn being limited to more formal registers). By contrast, for naming places and periods of time, Hebrew uses only the short construction (see (50)). There are two main theoretical developments, concerning the identification of grammatical functions and the treatment of definiteness and definiteness inheritance.

While Falk (2001) calls the grammatical function of the dependent NP poss, Falk (2007) offers a more articulated account, replacing this function by $\widehat{\text{GF}}$. The notation $\widehat{\text{GF}}$ stands for the most prominent argument in an f-structure (typically the subj in a clausal f-structure); Falk (2006) introduces this notation, arguing that the grammatical function subj should be deconstructed into the most prominent function, notated $\widehat{\text{GF}}$ and an 'overlay' function, pivot, a function of cross-clausal connection. The dependent in examples such as (62) involving a relational noun then is treated as the $\widehat{\text{GF}}$ (rather than poss), and the overlay function is argued to be def (replacing the dom of the earlier account), licensed through structure-sharing (with $\widehat{\text{GF}}$) as stated in (65). As noted above, the head noun in a construct nominal cannot itself be inflected for definiteness and it is the possessor, or $\widehat{\text{GF}}$ dependent which determines the definiteness of the construction as a whole. (59) is replaced by (63), but expresses essentially the same analysis.[12]

(62) Hebrew (Falk 2007: 104)
dodat ha-balšan ha-zkena
aunt.CONSTR DEF-linguist DEF-old.F
'the linguist's old aunt'

(63) $$\begin{array}{lllll} \text{NP} \longrightarrow & \text{N} & \text{NP} & \text{AP}^* & \text{Falk (2007: 113)} \\ & \uparrow{=}\downarrow & (\uparrow \text{DEF}){=}\downarrow & \downarrow \in (\uparrow \text{ADJ}) & \\ & & (w\ (\lessdot)\ \text{MORPHTYPE}){=}\text{BND} & & \end{array}$$

(64) $$\begin{bmatrix} \text{PRED} & \text{'AUNT}\langle\widehat{\text{GF}}\rangle\text{'} \\ \text{GEND} & \text{F} \\ \text{NUM} & \text{SG} \\ \widehat{\text{GF}} & \\ \text{DEF} & \begin{bmatrix} \text{PRED} & \text{'TEACHER'} \\ \text{DEF} & + \\ \text{NUM} & \text{SG} \end{bmatrix} \\ \text{ADJ} & \left\{ \begin{bmatrix} \text{PRED} & \text{'OLD'} \end{bmatrix} \right\} \end{bmatrix}$$ (Falk 2001: 92)

(65) $(\uparrow\text{DEF}){=}(\uparrow \widehat{\text{GF}}) \mid (\uparrow \text{OBL}_{\text{CON}}) \mid (\uparrow \text{OBL}_{\text{THEME}}) \mid (\uparrow \text{OBL}_{\text{NAME}})$ (Falk 2007: 120)

The re-entrancy stated in (65) takes account of the range of functions which can be expressed within the CSN (replacing the POSS of the previous analysis). An example such as (66) is associated with an OBL_{CON} function (as well as being the value of DEF): other functions which can be expressed by the dependent nominal in a CSN are OBL_{NAME} and $\text{OBL}_{\text{THEME}}$ – the latter for concrete nouns with a Theme argument as in (67).

(66) Hebrew (Falk 2007: 117)
kos kafe
cup coffee
'a cup of coffee'

'the library's translation of the Odyssey'

---

[12] The annotation (w ($\lessdot$) MORPHTYPE)=BND on the dependent NP specifies that the left sister of the NP's word structure is a bound form.

6 Mixed categories

An analysis of the Hebrew action nominal (and NP structure more generally) is offered in Falk (2001) and further developed in Falk (2007). These papers treat action nominals such as (68) as displaying a ‘verbal’ mapping to arguments, signalled by the existence of the ACC-marked OBJ, while others display a purely nominal mapping. In the ‘verbal’ action nominal, the agent argument is realized within the CSN (i.e. as a ‘short’ possessor) or in a *šel*-PP (‘long’ possessor). In each case, it is argued that the c-structure of the action nominal is mixed.

(68) Hebrew (Falk 2007: 117)

a. sgirat ha-mankal [et ha-misrad]
closure.CONSTR DEF-director ACC DET-office
‘the director’s closure of the office’

b. ha-sgira šel ha-mankal [et ha-misrad]
DEF-closure of DEF-director ACC DET-office
‘the director’s closure of the office’

The analysis of an example such as (68a) in Falk (2001) is as follows. The nominal has a mixed c-structure captured in (69), where λ is the category labelling function. A c-structure with both NP and VP projections is required to satisfy this set of constraints, motivating the c-structure rule in (70). Alongside this is the assumption that Hebrew actional nominals have the specification (↑ POSS)=(↑ SUBJ) and hence the f-structure in (71) arises for the accusative Hebrew actional nominal such as (68a) (given the treatment of dependent NP within the CSN developed in Falk 2001). The fundamental insight concerning the f-structure of ‘verbal’ action nominals is that they have a verbal argument structure mapping (e.g. to SUBJ and OBJ) but realise their SUBJ as a POSS.[13] The c-structure proposed by Falk for the ‘verbal’ action nominal is shown in (72).[14]

(69) (↑PRED)=‘close$< < x, y >_v >_n$ (Falk 2001: 96)
v: VP $\in \lambda\ (\phi^{-1}\ (\uparrow)\ )$
n: NP $\in \lambda\ (\phi^{-1}\ (\uparrow)\ )$

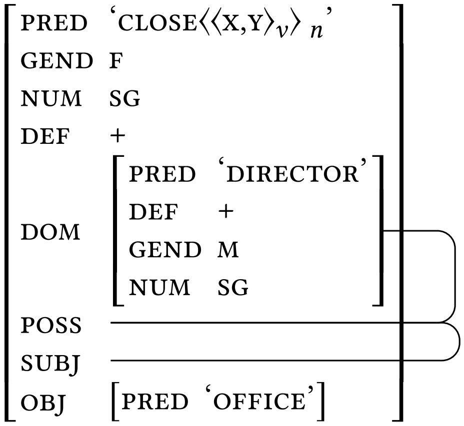
---

[13] The argument mapping for (68b) will be similar although there will be no DOM feature because the POSS is not realized within a CSN.

[14] As a technical aside, note that although this is a mixed category analysis, according to the standard definition of extended head (Bresnan et al. 2016: 136) the N is not the extended head of the VP, because of the intervening NP node which dominates the CSN, a matter which is not discussed in Falk (2001, 2007).

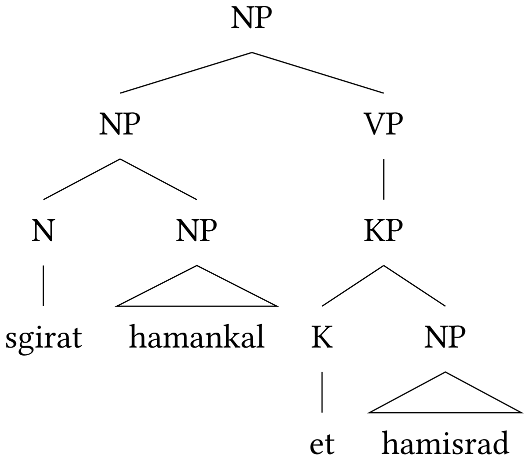
(70) $\text{NP} \longrightarrow \underset{\uparrow=\downarrow}{\text{NP}} \quad \underset{\uparrow=\downarrow}{\text{VP}}$ (Falk 2001: 94)

(71)



(Falk 2001: 96)

(72)



As well as the 'verbal' mapping (with an ACC-marked OBJ), Hebrew action nominals may realize their arguments as shown in (73). In (73a) the arg2 or theme is the dependent NP in the construct state nominal, and hence corresponds to a POSS (on the analysis of Falk 2001). This variant has a purely nominal mapping in which the other argument (if present) is an OBL. Hence the PRED value is as shown in (74).

(73) Hebrew (Falk 2001: 94, 118)

a. sgirat	ha-misrad	(alyedey	ha-mankal)
closure.CONSTR	DEF-office	by	DET-director

b. ha-sgira šel ha-misrad (alyedey ha-mankal)
DEF-closure of DEF-office by DET-director
'the closure of the office by the director'

(74) (↑PRED)='close⟨(OBL_{AG}), POSS⟩ (Falk 2001: 97)

Evidence that the purely nominal variant also has a mixed c-structure comes from the observation that it can be modified by AdvP as well as by AP, as shown in (75).[15]

(75) Hebrew (Falk 2001: 98)

a. ibud ha-kolot yadanit alyedey ha-mumxim
processing DEF-votes manually by DEF-experts

b. ibud ha-kolot ha-yadani alyedey ha-mumxim
processing DEF-votes DEF-manual by DEF-experts
'the manual processing of the votes by the experts'

In summary, Falk argues that both "verbal" and "nominal" action nominals in Hebrew have a mixed c-structure. In Falk (2001) the NP realized as the dependent within a CSN nominal (or as a *šel* phrase in the case of 'long' possession) is analysed as a POSS, leading to the mappings shown in (76) for the action nominal. Falk (2007) develops a more articulated view of the range of GFs associated with the CSN, as discussed in the previous section, leading to the mappings show in (77) for the action nominals.

(76)

	subcategorisation lexical description	additional functions (in CSN) from the PS rules
verbal mapping	⟨SUBJ, OBJ⟩ SUBJ=POSS	POSS=DOM
nominal mapping	⟨OBL_{AG}, POSS⟩	POSS=DOM

(77)

	subcategorisation lexical description	additional functions from the PS rules
verbal mapping	⟨ $\widehat{\text{GF}}$, OBJ⟩	$\widehat{\text{GF}}$=DEF
nominal mapping	⟨OBL_{AG}, $\widehat{\text{GF}}$ ⟩	$\widehat{\text{GF}}$=DEF

---

[15] Although there is less discussion, Falk (2001) also provides examples showing AP modification of the verbal variant (with the POSS/SUBJ expressed as a *šel* PP), as well as modification by AdvP.

There is relatively little detailed discussion in the LFG literature of the corresponding Arabic NPs, which are headed by maṣdars. The msa examples (78) and (79) illustrate the ‘verbal’ and ‘nominal’ mappings respectively.[16]

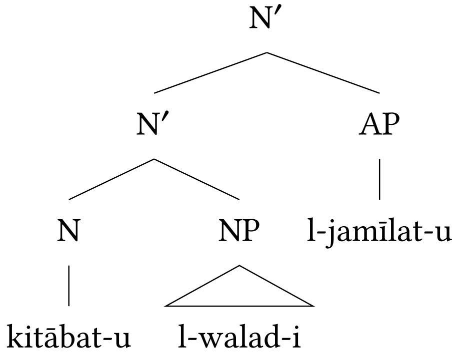
(78) msa (Börjars et al. 2015: 49)
ʔakl-u l-walad-i it-tufāhat-a
eat.msd-nom def-boy-gen def-apple-acc
‘the boy’s eating the apple’

(79) msa (Börjars et al. 2015: 55)
ʔakl-u l-walad-i as-sarīʕ-u li-t-tufāhat-i
eat.msd-nom def-boy-gen def-fast-nom of-def-apple-gen
‘the boy’s fast eating of the apple’

In connection with his treatment of negation in maṣdar-headed structures in msa, Alsharif (2014) adopts Falk’s (2001) analysis of the csn dependent as a poss (re-entrant with the dom feature) and using the additional functional equation poss=subj for cases in which the head N is a maṣdar, and a mixed category c-structure (at least for the ‘verbal’ maṣdar structures). However he argues for a structure in which the csn is recognised as a constituent to the exclusion of any adjectival modifiers, as shown in (81) (in contrast to Falk’s (59) above). Börjars et al. (2015) provide agreement data from msa in support of the same conclusion.

(80) msa (Alsharif 2014: 291)
kitābat-u l-walad-i l-jamīlat-u
write.msd-nom def-boy-gen def-beautiful-nom
‘the boy’s beautiful writing’

(81)



---

[16] The occurrence of acc case in (78) is often taken to indicate a mixed categorial status for this construction, with the ‘verbally-marked’ dependent(s) appearing within a VP node.

In contrast to the mixed category analysis of Hebrew action nominals developed in Falk (2001, 2007), Börjars et al. (2015) propose a purely nominal c-structure, reflecting the fact that the maṣdar has nominal morphosyntax and may have the external distribution of a NP. The gen and acc NPs in the transitive 'verbal' maṣdar are both sisters of N – the idea is essentially that of extending the constituent containing the cs to include acc objects in the case of the 'verbal' mapping (all rhs categories are to be interpreted as optional in this rule).[17] The nominal structure in (79) is more hierarchical, with the *li*-PP (corresponding to the second argument of the verb 'eat') adjoined at a higher level NP constituent in the structure as an obl, and the AP also licensed as an adjunct by a recursive NP → NP XP rule.

(82)
$$\text{NP} \longrightarrow \begin{array}{cccc} \text{N} & \text{NP} & \text{NP} & \text{NP} \\ \uparrow=\downarrow & (\downarrow \textsc{case})=\textsc{gen} & (\downarrow \textsc{case})=\textsc{acc} & (\downarrow \textsc{case})=\textsc{acc} \\ & (\uparrow \textsc{subj})=\downarrow & (\uparrow \textsc{obj})=\downarrow & (\uparrow \textsc{obj}_{\theta})=\downarrow \end{array}$$

(Börjars et al. 2015: 53)

Lowe (2020) points out a number of empirical problems with this analysis, notably in relation to ensuring the correct ordering of any AP and AdvP modifiers in the nominal maṣdar constructions and in ruling out the occurrence of adjectival modifiers in the 'verbal' maṣdar structures; and also takes issue with it on theoretical grounds. He argues for an approach to mixed category constructions in which internal syntax, rather than morphosyntax or external distribution, is taken to be a sufficient criterion for syntactic categorisation. This leads to a mixed projection (VP over NP) analysis for both types of maṣdar construction (the VP node is motivated by the presence of an obj under the 'verbal' mapping and the possibility of adverbial modifiers under both 'nominal' and 'verbal' mappings). The structures which he proposes, (84) and (86), are rooted in a VP node, despite the nominal nature of the external distribution of these structures.[18]

---

[17] Börjars et al. (2015) do not provide an analysis of definiteness inheritance (from the genitive dependent) for the general case of construct state nominals. For the maṣdar-headed structures of msa which they are concerned with in this paper they assume the equation (↑ def)=(↑ subj def) in the lexical entry of the maṣdar.

[18] To address this issue, Lowe (2020: 333) proposes the use of a complex category $\text{V}_{[msd]}$ and a metacategory in the phrase structure rules to capture the distributional similarity between NPs and maṣdar-headed VPs. Recall that the meta-category label does not itself give rise to a node in the tree representation, being merely an abbreviatory device.

(i) $\text{NomP} \equiv \{\text{NP} \mid \text{VP}_{[msd]}\}$ (Lowe 2020: 333)

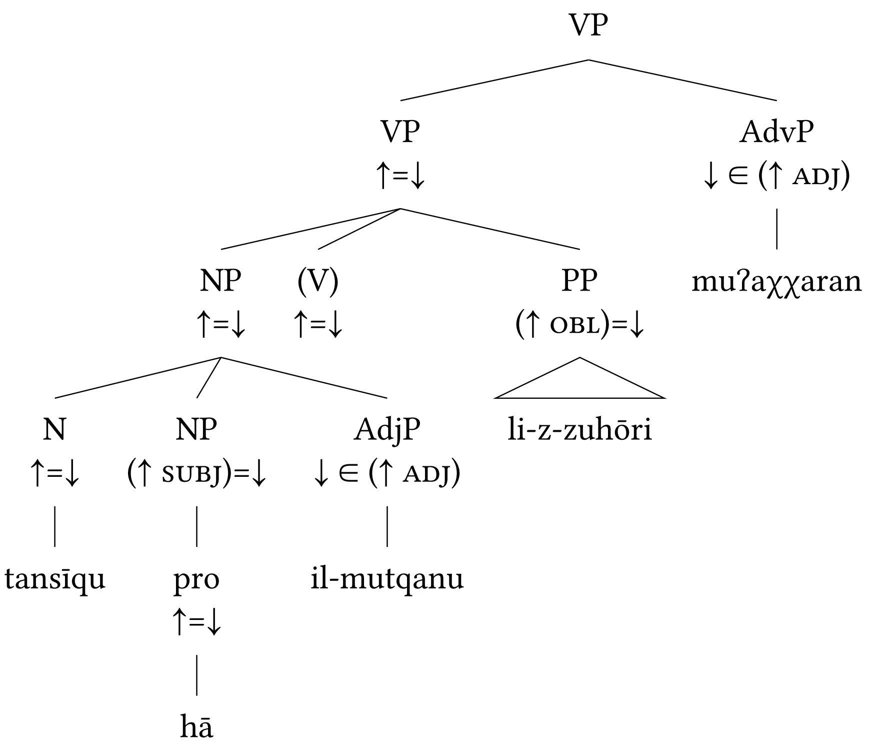
(86)



7 Negation

Sentential negation in MSA is expressed by means of the particles *mā*, *lā*, *lan* and *lam* and the inflecting form *laysa* which occurs with both verbal and non-verbal predicates (see (87) and (88)). *laysa* (and its inflectional variants) gives rise to present tense interpretations and shows partial agreement when it precedes the subject and full agreement with a preceding subject, typical verbal behaviour. Accordingly, Alsharif & Sadler (2009) treat *laysa* as a negative (present) tensed verbal element in I.

(87) MSA (Alsharif & Sadler 2009: 10)

a. al-awlad-u lays-ū ya-ktub-ūn
the-boys-NOM NEG-3M.PL 3M-write.IPFV-3M.PL-IND
‘The boys do not write.’

b. lays-a al-awlad-u ya-ktub-ūn
NEG-3M.SG the-boys-NOM 3M-write.IPFV-3M.PL-IND
‘The boys do not write.’

(88) MSA (Benmamoun 2000: 53)
laysa ʔaḫii muʕallim-an.
NEG.3M.SG brother.my teacher-ACC
‘My brother is not a teacher.’

The particles *lā*, *lam* and *lan* are strictly verb-adjacent, and do not exhibit agreement with the subject. While *lā* occurs with a verb in the indicative imperfective, *lam* occurs with the jussive imperfective expressing negation in the past, and *lan* with the subjunctive imperfective, expressing negation in the future: thus *lam* and *lan* are negative particles which carry temporal information.

(89) MSA (Benmamoun 2000: 95)
a. ṭ-ṭullāb-u laa ya-drus-uu-n
the-students NEG 3M-study.IPFV-3M.PL-IND
‘The students do not study/are not studying.’
b. lan ya-ḏhab-a ṭ-ṭullāb-u
NEG.FUT 3M-go.IPFV-M.SG.SBJV the-students-NOM
‘The students will not go.’
c. ṭ-ṭullāb-u lam ya-ḏhab-uu
the-students-NOM NEG.PST 3M-go.IPFV-M.PL.JUSS
‘The students did not go.’

Alsharif & Sadler (2009) analyse these negative particles as non-projecting words of category I (notated $\widehat{\mathrm{I}}$) in the sense of Toivonen (2003), forming a small construction with the immediately following verbal element. The notion of non-projecting word captures the uninterruptibility of the Neg+V sequence, but still treats the negative marker and the verb as separate morphological words. The particles *lam* and *lan* contribute PAST and FUT tense values respectively (and select (tenseless) forms of the verb in a dependent mood), while *lā* cannot co-occur with PAST tense. The negative particle *lan* can also occur as a non-projecting word under V where it contributes not FUT but PROSP aspect. They consider the interaction of these negative particles with both simple and compound tenses in MSA.[19]

(90) $\mathrm{I} \longrightarrow \begin{array}{cc} \hat{\mathrm{I}} & \mathrm{I} \\ \uparrow=\downarrow & \uparrow=\downarrow \end{array}$ (Alsharif & Sadler 2009: 14)

(91) *lam* $\hat{\mathrm{I}}$ $(\uparrow \text{TENSE PAST})=+$ (Alsharif & Sadler 2009: 16)
$(\uparrow \text{POL})=\text{NEG}$
$(\uparrow \text{MOOD}) =_c \text{JUSS}$

As for MSA *mā*, this marker of sentential negation occurs in sentences with both verbal and non-verbal predicates. It always precedes the predicate but is not required to be immediately adjacent to it. Alsharif (2014) argues that it is a negative complementiser (Arabic has a reasonably extensive range of complementising particles), so that (92) is associated with the c-structure shown in (94).

(92) MSA (Alsharif 2014: 169)
mā qal-a maher-un l-ħaqq-a
NEG say.PFV-3M Maher-NOM DEF-truth-ACC
'Maher did not say the truth.'

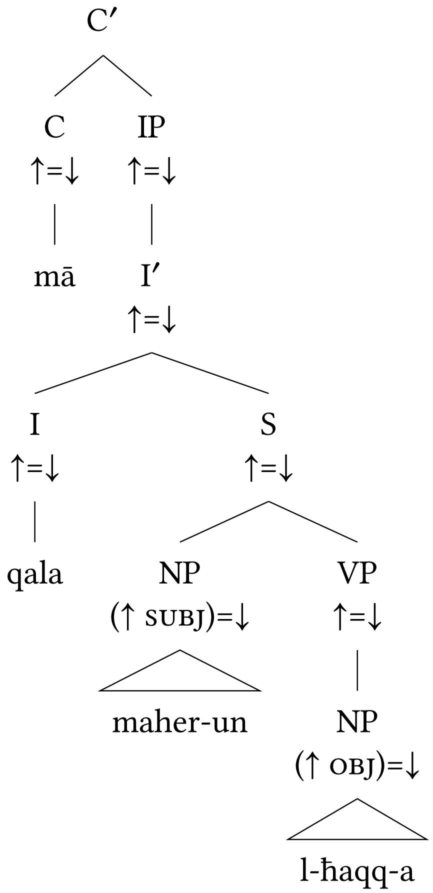
(93) MSA (Alsharif 2014: 132)
mā mohammad-un kātib-un
NEG Mohammad-NOM writer-NOM
'Mohammad is not a writer.'

---

[19] A complex TENSE feature with boolean-valued attributes PAST and FUT is adopted in this approach because of the compositional nature of certain periphrastic verb forms. For example, a future tense may be formed periphrastically by combining the imperfective indicative form (which otherwise received a present tense interpretation), with the preverbal particle *sawfa* as in (i), and hence the imperfective indicative is associated with the (underspecified) TENSE PAST=−.

(i) MSA (Fassi Fehri 1993: 82)
sawfa lā y-aḥdur-u
FUT NEG 3M-present.IPFV-3M.SG.IND
'He will not come.'

(94) msa (Alsharif 2014: 170)



Adopting the idea that it may mark some sort of contrastive focus as well as negation, (see Ouhalla 1993 and Benmamoun 2000, *inter alia*)), Alsharif (2014) also argues that in examples such as (95), the focussed element immediately following the negative complementiser, is in [Spec,IP] (in (95) this is the PP *bi-s-sikkīn-i*) (hence this position must host various discourse functions, including that of subj).

(95) msa (Alsharif 2014: 173)

mā	bi-s-sikkīn-i	jaraħ-a	χālid-un	bakr-an
neg	p-def-knife-gen	wound.pfv-3m.sg	Khalid-nom	Bakr-acc

‘It is not with a knife that Khalid wounded Bakr.’

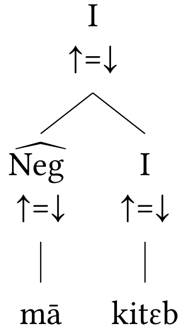
The Arabic vernaculars typically use *mā* for negation in verbally-headed sentences, and a set of forms which combine *m-* with pronominal affixes for sentential negation in non-verbal sentences.[20]

A major split is found across the dialects (roughly between Eastern and Western) according to whether they use a single negative element or bipartite negation, combining an *m-* form with a second marker *-š/-x* which results from grammaticalisation of an earlier form corresponding to *šayʔ* 'thing' in Classical Arabic.

The vernacular verbal negative marker *mā* illustrated in (96) is treated as a non-projecting word in Alsharif (2014) (for Hijazi) and Alruwaili (2019) (for Turaif Arabic), that is, as a syntactic element appearing strictly adjacent to a verbal element.[21]

(96) Turaif Arabic (Alruwaili 2019: 162)
ʕali mā kitɛb l-wāǧib
Ali NEG write.PFV.3M.SG DEF-homework
'Ali did not write the homework.'

(97) Turaif Arabic (Alruwaili 2019: 162)



Alruwaili (2019) shows that *mā* can occur before either the the auxiliary (*kān* 'be.PFV') or the lexical verb in compound tenses (and hence can form a small

---

[20] The occurrence of verbal negation with many pseudo-verb forms, as in (i), where the literal, prepositional meaning of *l-* is 'to', shows that their reanalysis from their original category into a verbal category is well advanced.

(i) Turaif Arabic (Alruwaili 2019: 121)
ṭ-ṭullāb mā l-hum χaṣam
DEF-student.PLM NEG have-3M.PL.GEN discount
'The students do not have a discount.'

[21] Clearly, an affixal analysis of the negative markers might be argued to be appropriate for some other dialects.

construction with either I or V), and argues in favour of the ternary branching rule (99) as the negator must precede the tense/aspect particle *rāħ* when they co-occur. As a marker of sentential negation, *mā* specifies ENEG=+ (eventuality negation, see Przepiórkowski & Patejuk 2015).

(98) Turaif Arabic (Alruwaili 2019: 166)
huda mā rāħ t-sāfar bukra
Huda NEG FUT 3F.SG-travel.IPFV tomorrow
'Huda will not travel tomorrow.'

$$\begin{array}{lclll} \mathrm{I}' & \longrightarrow & \widehat{\mathrm{Neg}} & \widehat{\mathrm{I}} & \mathrm{I} \\ & & \uparrow=\downarrow & \uparrow=\downarrow & \uparrow=\downarrow \end{array}$$

The example in (100) illustrates the marker of sentential negation for non-verbal predicates (and in equational sentences). Both Alsharif (2014) and Alruwaili (2019) treat this marker (and its inflectional variants) as a negative copula (the lexical entry in (101) is from Alruwaili (2019: 170)).

(100) Turaif Arabic (Alruwaili 2019: 169)

(101) *mū* I (↑ ENEG) = + Turaif Arabic (Alruwaili 2019: 170)
VP ∉ CAT(↑)
(↑ TENSE)=PRES

Camilleri & Sadler (2017a) look at sentential negation in Maltese and the syntactic behaviour of a group of negative sensitive indefinite items (n-words, NSI) in Maltese. In common with many Western dialects of Arabic, Maltese is a language with bipartite negation, as can be seen in the double marking *ma ...-x* in (102). Synchronically, they argue for Maltese that it is *m-/ma* which realizes negation in Maltese, while the *-x* is essentially some sort of NSI. The strategies for sentential negation of clauses with verbal and non-verbal predicates (including the active participle) respectively are shown in (102) and (103) respectively.

(102) Maltese (Camilleri & Sadler 2017a: 147)
Ma qraj-t-x il-ktieb.
NEG read.PFV-1SG-NEG DEF-book

(103) Maltese (Camilleri & Sadler 2017a: 147)
Mhux ~ mhumiex sejr-in.
NEG.3M.SG.NEG ~ NEG.3PL.NEG go.ACT.PTCP-PL
'They are not going.'

The paper proposes an analysis of the *xejn* 'nothing' series of negative indefinites (including *ħadd* 'no one', *ebda* 'no(ne)' and *imkien* 'nowhere') which occur in negative sentences. As the examples in (104) show, the negative marker *ma* is required to express sentential negation, irrespective of the linear order of the n-word vis-à-vis the predicate. This behaviour, and the fact that these n-words may provide negative fragment answers, supports the view that Maltese is a strict negative concord language and the classification of these indefinites as simple NCIs. However, although Maltese uses the bi-partite (*ma …-x*) strategy for negation, as shown in (102) above, *-x* is in fact incompatible with these n-words in the same clause, as shown in (105).

(104) Maltese (Camilleri & Sadler 2017a: 150)

a. Ilbieraħ ħadd *(ma) ġie.
yesterday no.one NEG come.PFV.3M.SG
'No one came yesterday.'

b. Ilbieraħ *(ma) ġie ħadd.
yesterday NEG come.PFV.3M.SG no.one
'No one came yesterday.'

(105) Maltese (Camilleri & Sadler 2017a: 151)
It-tifla ma ra-t(*-x) xejn.
DEF-girl NEG see.PFV-3F.SG-x nothing
'The girl saw nothing.'

Long-distance licensing of n-words is felicitous in Maltese (depending on the nature of the subordinate clauses), as in (106), and the same incompatibility with the suffix *-x* is observed.[22]

---

[22] As an alternative to (106), bi-partite negation and a positive proform (replacing *xejn* 'nothing' by *xi ħaġa* 'something' in (106)), is also grammatical, retaining the same interpretation.

(106) Maltese (Camilleri & Sadler 2017a: 153)
Ma smaj-t [li qal-u [li
NEG hear.PFV-1SG COMP say.PFV.3-PL COMP

j-i-xtr-u xejn.]]]
3-FRM.VWL-buy.IPFV-PL nothing
'I didn't hear that they said she told them they have to buy anything.'

Camilleri & Sadler (2017a) argue that the n-word proforms like *xejn* are not in fact simply NCIs but have the broader distribution of weak NPIs, a view supported by the fact that they occur in a range of non-veridical contexts, as shown in (107), and unlike NCIs are not limited to negative or anti-veridical contexts. Equally, the *-x* of bipartite negation shares the wider distribution of an NPI, occurring in a range of contexts including conditionals, interrogatives, rhetorical interrogatives, embedded interrogatives and counterfactuals.

(107) Maltese (Camilleri & Sadler 2017a: 154)
Kil-t xejn ċikkulata?
eat.PFV-2SG nothing chocolate
'Did you eat any chocolate?'

As part of the analysis they provide an approach to bi-partite negation in Arabic dialects (primarily found in the dialects westward from the Levant to Morocco). There is both a dependency and an essential asymmetry in the distribution of *ma* and *-x*: *ma* realizes sentential negation but requires the presence of either *-x* or one or more NCI items within an appropriate domain, while *-x* itself is incompatible with the presence of (other) NCI items within that domain. Following Przepiórkowski & Patejuk (2015), Camilleri & Sadler (2017a) propose that *ma* introduces an ENEG feature. Because *ma* cannot stand alone it also introduces a constraining equation requiring a positive value of a NVM (for non-veridical marker) feature within an appropriate domain, which can be satisfied by a strictly local *-x* or by NC items in the N-series, within a certain domain.[23] The lexical entry for the sentential negation marker *ma* is in (108). The first line provides a value for the sentential negation feature ENEG, treating it as a feature with

---

[23] Because both *-x* and the N-series proforms occur in the wider set of non-veridical contexts they cannot simply be associated with an inside-out statement limiting them to contexts containing ENEG=+.

instantiated values, with the consequence that it is required to be uniquely contributed, so expressed only once. The somewhat complicated uncertainty statement requires that there either be a feature NVM=+ in the local f-structure (which will be introduced by *-x*, see example (102) and the entry for *-x* in (109)) or that some dependent within the domain specified by the functional uncertainty path be specified as NVM=+ (e.g. examples (104a), (106), where NVM=+ is associated with an n-word dependent, see the entry for *xejn* in (110)). This path rules out *ma* satisfying its requirement for a NVM=+ dependent in a subordinate negative domain, ruling out (111). The non-veridicality affix *-x* defines NVM=+ and is incompatible with NVM=+ on any local dependent or any more deeply embedded dependent which is not itself inside an f-structure marked as ENEG=+, thus ruling out (112). The entry for an N-series word simply defines the NVM feature in the local f-structure, as in (110).

(108) *ma* ENEG $(\uparrow \textsc{eneg})=+$

(113)
$$\begin{bmatrix} \text{ENEG} & + \\ \text{PRED} & \text{`HEAR}\langle\text{SUBJ,COMP}\rangle\text{'} \\ \text{COMP} & \begin{bmatrix} \ldots \\ \begin{bmatrix} \text{COMP} & \begin{bmatrix} \text{PRED} & \text{`BUY}\langle\text{SUBJ,OBJ}\rangle\text{'} \\ \text{OBJ} & \begin{bmatrix} \text{PRED} & \text{`NOTHING'} \\ \text{NVM} & + \end{bmatrix} \end{bmatrix} \end{bmatrix} \end{bmatrix} \end{bmatrix}$$

Alruwaili & Sadler (2018) look at negation, n-words and the combination of negation and coordination in a construction similar to the English *neither … nor* construction in the vernacular Arabic of Turaif in the Northern region of Saudi Arabia. Turaif Arabic does not use the bipartite negation illustrated above for Maltese. Also unlike Maltese, the n-words which can occur as fragment answers, including the negative proform *māhad* 'no one' and the scalar focus particle *wala* 'not even one' can occur (*preverbally*) without the negation marker, giving rise to a negative interpretation, as shown in (114a). Hence a preverbal n-word in combination with the sentential negation marker *mā* results in a double negation reading, as in (115). Alruwaili & Sadler (2018) treat these negative arguments as contributing CNEG adopting the distinction between ENEG and CNEG introduced by Przepiórkowski & Patejuk (2015), and proposing the f-structure in (116) for (115).[24]

(114) Turaif Arabic (Alruwaili & Sadler 2018: 30)

a. māħad ǧa l-yōm
no.one come.PFV.3M.SG DEF-today.M.SG

'Every student came today.'
(= Not even a single student didn't come today.)

---

[24] The feature SFOC is associated with the scalar focus determiner *wala*.

(116)

$$\left[\begin{array}{ll}\textsc{pred} & \text{‘}\textsc{come}\langle\textsc{subj}\rangle\text{’}\\ \textsc{eneg} & +\\ \textsc{subj} & \left[\begin{array}{ll}\textsc{pred} & \text{‘}\textsc{student}\text{’}\\ \textsc{cneg} & +\\ \textsc{num} & \textsc{sg}\\ \textsc{sfoc} & +\end{array}\right]\\ \textsc{adj} & \left\{\left[\textsc{pred}\ \ \text{‘}\textsc{today}\text{’}\right]\right\}\end{array}\right]$$

(Alruwaili & Sadler 2018: 31)

The main focus of this paper is on the bipartite negative coordination marker *lā … wala* illustrated in (117b) (and found across many dialects of Arabic).

(117) Turaif Arabic (Alruwaili & Sadler 2018: 32–33)

a. mansōr mā gaʕad min n-nōm, w ʕali mā ǧa min d-dawām
Mansour NEG wake.PFV.3M.SG from DEF-sleep, CONJ Ali NEG come.PFV.3M.SG from DEF-work
‘Mansour did not wake up and Ali didn’t come (back) from work.’

b. lā mansōr gaʕad min n-nōm, wala ʕali ǧa min d-dawām
NEG Mansour wake.PFV.3M.SG from DEF-sleep, NEG.CONJ Ali come.PFV.3M.SG from DEF-work
‘Mansour did not wake up and nor did Ali come (back) from work.’

Alruwaili & Sadler (2018) analyse both the negative conjunction *wala* (which rather transparently combines the conjunction *wa* and a negative formative) and the negative marker *lā* as elements which adjoin to (and mark) a conjunct, postulating special coordination schema for *neither … nor* coordination – the rules in (118) and (119) (Alruwaili & Sadler 2018: 38) illustrate for sentential coordination.

(118) *Negative Coordination Schema*

$$\begin{array}{lccc}\text{XP} & \longrightarrow & \text{XP} & \text{XP}^{+}\\ & & \downarrow\in\uparrow & \downarrow\in\uparrow\\ & & (\downarrow\textsc{eneg}) =_c +\_ & (\downarrow\textsc{conjform}) =_c \textsc{wala}\\ & & (\downarrow\textsc{conjform}\ ) \neq \textsc{wala} & \end{array}$$

(119)

$$\begin{array}{lccc}\text{XP} & \longrightarrow & \text{Neg} & \text{XP}\\ & & \uparrow=\downarrow & \uparrow=\downarrow\\ & & (\in\uparrow) & \end{array}$$

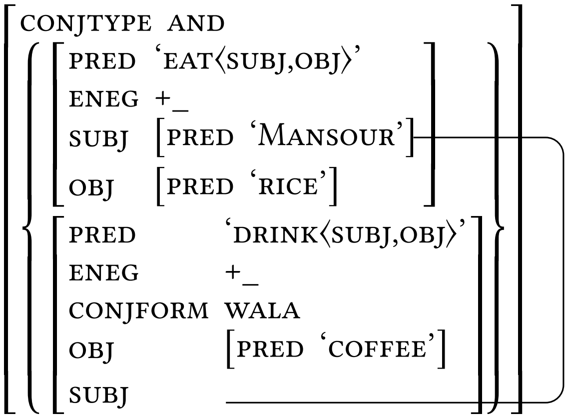
(120) *wala* Neg (↑CONJFORM)=WALA (Alruwaili & Sadler 2018: 38)
(↑ENEG)=+_
((∈ ↑) CONJTYPE)=AND

(121) *lā* Neg (↑CONJFORM)=LĀ (Alruwaili & Sadler 2018: 39)
(↑ENEG)=+_
((∈ ↑) CONJTYPE)=AND

The f-structure for (122) on this analysis is shown in (123), from Alruwaili & Sadler (2018: 38).

(122) Turaif Arabic (Alruwaili & Sadler 2018: 32)
mansōr **mā** akal l-ruz **wala** šarab l-gahwa
Mansour.M NEG eat.PFV.3M.SG DEF-rice NEG.CONJ drink.PFV.3M.SG DEF-coffee
'Mansour neither ate the rice nor drank the coffee.'

(123)



The *neither … nor* construction may also be used to coordinate arguments, where it shows the weak NCI behaviour noted above for negative elements such as *maħad* 'no one' and determiner *wala*. That is, occurring preverbally, it expresses negation (and hence can give rise to double negation readings) while postverbally, it behaves like a NCI.

(124) Turaif Arabic (Alruwaili & Sadler 2018: 34,40)

a. lā ʔaħmad wala mhammad ǧ-aw
NEG Ahmad NEG.CONJ Mohamamd come.PFV-3M.PL
'Neither Ahmad nor Mohammad came.'

b. lā ʔaħmad wala mhammad **mā** ǧ-aw
NEG Ahmad NEG.CONJ Mohammad NEG come.PFV-3M.PL
'Both Ahmad and Mohammad came.'

c. mā ǧ-aw lā ʔaħmad wala ʕali
neg come.pfv-3m.pl neg Ahmad.m neg.conj Ali.m
‘Neither Ahmad nor Ali came.’

In previous work, Przepiórkowski & Patejuk (2015) associate the Polish strict nci *nikt* ‘nobody’ with an inside-out constraint requiring eneg=+ to be defined in the appropriate containing f-structure. Building on this approach, Alruwaili & Sadler (2018) formulate a complex lexical constraint to capture the dependency between the cneg/nci alternation and the existence and linear position of a eneg marker.

8 Unbounded dependency constructions

Hebrew and Arabic both make extensive use of resumptive strategies as well as gap strategies in unbounded dependency constructions, and formalisation of the resumptive strategy for Hebrew is a major concern of Asudeh (2012), the most important reference for this section (see also Asudeh 2011). Falk (2002) also discusses the resumptive strategy for Hebrew udcs. Camilleri & Sadler (2011) looks at restrictive relative clauses and resumption in Maltese (see also Camilleri & Sadler 2012a), building on Asudeh’s approach to resumption. Further work on Maltese is descriptively oriented (Camilleri & Sadler 2016, Sadler & Camilleri 2017).

Hebrew resumptives occur in all NP positions except that of the highest subject. (125) illustrates an optional obj resumptive and (126) illustrates a resumptive within a complex NP island (note that there is no *wh*-item in these Hebrew relative clauses).

(125) Hebrew (Borer 1984: 220)
raʔiti ʔet ha-yeled she/ʔasher rina ʔohevet (ʔoto)
saw.1sg acc def-boy comp Rina love.3f.sg him
‘I saw the boy that Rina loves.’

(126) Hebrew (Borer 1984: 221)
raʔiti ʔet ha-yeled she-/asher dalya makira ʔet ha-ʔisha
saw-I acc def-boy comp Dalya knows acc def-woman
she-ʔohevet ʔoto
comp-loves him
‘I saw the boy that Dalya knows the woman who loves him.’

It is well established in the literature beyond LFG that the resumptives of Hebrew have the interpretational properties of pronouns rather than those of gap. The diagnostics distinguishing those which are interpretationally identical to gaps from those which behave semantically as pronouns include differences in behaviour with respect to island phenomena, weak crossover, across-the-board extraction, parasitic gaps and reconstruction (McCloskey 2017: 106). In line with this work, Asudeh (2011, 2012) distinguishes two types of true resumptives, which he refers to as *syntactically active resumptives* (SARS) and *syntactically inactive resumptive* (SIRS). Both types of resumptive receive the same treatment in the syntax-semantics interface, that is, they are removed by a manager resource. SARS do not display gap-like properties in the syntax and are simply anaphorically bound pronouns in the syntax: the RPS of Hebrew are of this type, as shown in (128). On the other hand, SIRS are syntactically gap-like (i.e. they are functionally controlled): the RP is treated as the bottom of a filler-gap dependency by restricting out the pronominal PRED, so that syntactically, the RP is equivalent to a gap (this analysis is given for Swedish in Asudeh 2012).

On the view that Asudeh develops, Hebrew resumptives are pronouns at f-structure, and are licensed in the complementiser system of Hebrew.[25]

That is, members of the class of C elements are lexically associated with the (optional) information shown in (127).

(127) *C* % RP=(↑GF^{+}) (Asudeh 2012: 221)
(↑UDF)$_{\sigma}$=(%RP$_{\sigma}$ ANTECEDENT)
@MR(%RP)
@RELABEL(%RP)

Abstracting away from many technical details, (127) states an equality between the semantics of a discourse function (↑UDF) in the f-structure which contains the complementiser and the value of the ANTECEDENT attribute of some grammatical function within the structure (identified by means of the local name %RP). The template call in the third line introduces the semantic resource which removes the surplus pronominal resource in the course of semantic composition, using the Resource Management Theory of Resumption developed in Asudeh (2012).

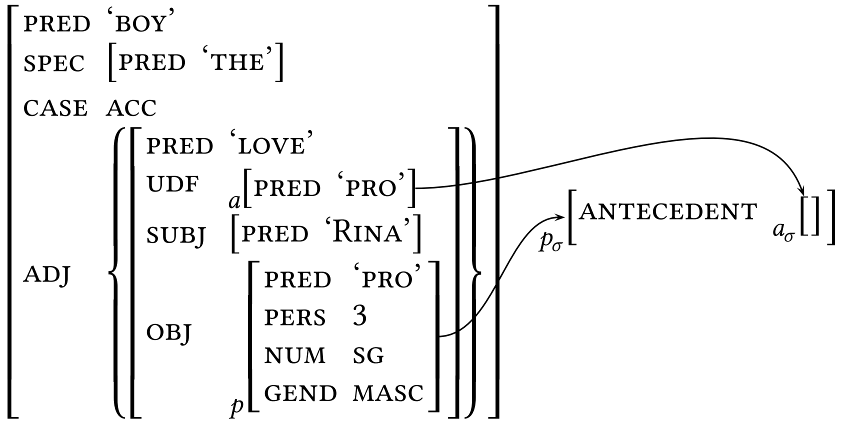
---

[25] An alternative view of the resumptive pronouns is taken in Falk (2002), namely that pronouns may lack a PRED value just in case they are functionally identified with a discourse function: functional identification is introduced lexically (by the pronoun itself) and mediated by reference to a *p* projection containing the referential elements in the discourse as shown in (i).

(i) $f \in p^{-1}(\uparrow_{p}) \wedge (\textsc{df}\ f) \Rightarrow \uparrow = f$ (Falk 2002: 163)

The example in (125) with the resumptive has the f-structure in (128) (Asudeh 2012: 227).[26] The (standard) CP rule is shown in (129) (Asudeh 2012: 224) where ϵ is not an empty node in the c-structure but the absence of a node associated with the collection of constraints specified.

(128)



(129)

$$\mathrm{CP} \longrightarrow \left\{ \begin{array}{c} \mathrm{XP} \\ (\uparrow \textsc{udf}){=}\downarrow \end{array} \middle| \begin{array}{c} \epsilon \\ (\uparrow \textsc{udf pred}){=}\text{`}\textsc{pro}\text{'} \\ (\textsc{adjunct} \in \uparrow) \\ REL_\sigma \end{array} \right\} \begin{array}{c} \mathrm{C}' \\ \uparrow{=}\downarrow \end{array}$$

Asudeh (2012) provides detailed coverage of many aspects of the syntax of Hebrew UDCs. For example (130) contains a fronted resumptive and no complementiser. The former is treated as an adjunction to C and the latter by means of a lexical entry for a null complementiser. *ʔašer* is a complementiser which can only appear in relative clauses, a restriction which is captured by an inside-out constraint in the lexical entry (132)

(130) Hebrew (Borer 1984: 220)

'I saw the boy that Rina loves.'

(131) (Asudeh 2012: 223)

$$\mathrm{C} \longrightarrow \begin{array}{c} \mathrm{C} \\ \uparrow{=}\downarrow \end{array} \quad \begin{array}{c} \widehat{\mathrm{D}} \\ (\uparrow \textsc{gf}){=}\downarrow \end{array}$$

(132) *ʔasher* C (ADJUNCT ∈ ↑) (Asudeh 2012: 223)

---

[26] Asudeh does not represent the subcategorised arguments within the PRED value, which is a simple, argument-less semantic form.

Camilleri & Sadler (2011) provide an analysis of Maltese restrictive relative clauses. In Maltese a resumptive is not permitted in the highest subject function or, in relative clauses with definite or quantified heads, the highest object position. They suggest the underlying distribution of resumptive and gap is essentially free but subject to some additional restrictions (for example, only a resumptive is possible as the argument of a preposition).

(133) Maltese (Camilleri & Sadler 2011: 113)
Ir-raġel li bgħatt-(lu) l-ittra
def-man comp send.pfv.1sg.(-dat.3m.sg) def-letter
weġib-ni
respond.pfv.3m.sg-1sg.acc
'The man that I sent (him) the letter responded.'

As well as complementiser-introduced relatives such as (133), Maltese also has *wh*-relatives, which involve a gap rather than a resumptive pronoun, although these are subject to quite severe restrictions. (134) is an example.

(134) Maltese (Camilleri & Sadler 2011: 114)
It-tifel 'l min n(a)-ħseb j-għallem-*u
def-boy acc.who 1sg-think.ipfv 3-teach.ipfv.3m.sg-3sg.acc
'the boy who I think he teaches'

Building on standard assumptions, Camilleri & Sadler (2011) provide a syntactic analysis of both complementiser and *wh*- relatives. The example in (135) with either a complementiser or a *wh*-item is associated with the f-structure in (136) (assuming the pred value of *'l min* is 'pro').

(135) Maltese (Camilleri & Sadler 2011: 116)
Rajt lit-tifel li /'l min j-af Pawlu
see.pfv.1sg acc.def-boy comp /who 3m.sg-know.ipfv Paul

\textsc{pred} & \text{`KNOW}\langle\textsc{subj,obj}\rangle\text{'} \\
\textsc{compform} & \textsc{decl} \\
\textsc{subj} & \left[\begin{array}{ll} \textsc{pred} & \text{`Paul'} \\ \textsc{pers} & 3 \\ \textsc{num} & \textsc{sg} \\ \textsc{gend} & \textsc{masc} \end{array}\right] \\
\textsc{topic} & \left[\textsc{pred}\ \text{`PRO'}\right] \\
\textsc{obj} &
\end{array}\right]\right\}
\end{array}\right]$$

(Camilleri & Sadler 2011: 116)

Camilleri & Sadler (2011) show that Maltese also has true resumptives (as opposed to intrusive pronouns), and that the available tests indicate that (in the terminology of Asudeh 2012) they are SARs and hence anaphorically bound pronouns in the syntax. For example, they can be used felicitously in circumstances which would induce weak crossover violations. In (137) the dependency between the antecedent (*ir-raġel*) (or the TOPIC) and the RP 'crosses over' the possessive in *martu* ('his wife'), but the sentence is completely grammatical, while the corresponding sentence with a gap would be ungrammatical, despite the fact that RPs are normally excluded in wh-relatives in Maltese. Note that the POSS function is not accessible to relativisation by the wh-strategy and so it is clear that (137) involves relativisation on the OBJ, and therefore constitutes a case of crossover. (138) provides a similar example using the less restricted complementiser strategy for relativisation.

(137) Maltese (Camilleri & Sadler 2011: 19)
Ir-raġel 'l min n-af li t-elq-it-u
DEF-man ACC.who 1SG-know.IPFV COMP 3F.SG-leave.PFV-3M.SG.ACC
l-mara/mart-*(u)
DEF-woman/woman-3M.SG.ACC
'the man who I know that his wife left him'

(138) Maltese (Camilleri & Sadler 2011: 19)
Ir-raġel li n-af li ħallie-t-u
DEF-man COMP 1SG-know.IPFV COMP leave.PFV-3F.SG-3M.SG.ACC

wife-3M.SG.ACC stay.PFV.3M.SG NEG go out.3M.SG-NEG from.DEF-house
'The man who I know that his wife left him, has not left the house since.'

(139) illustrates the Complex Noun Phrase Constraint, with a (second) relative dependency into a CNP created by relativisation: although the relativised position is one which is normally accessible to the gap strategy, the resumptive is obligatory here as a gap would cause a syntactic constraint violation.[27]

9 Other work

Alotaibi (2014) looks at conditional sentences in Hijazi Arabic and provides an LFG analysis of the syntax of these constructions. Camilleri et al. (2014a) discusses the dative alternation in Hijazi Arabic, ECA and Maltese and develops an account of the mapping to GFs using the mapping approach of Kibort (2008). Camilleri & Sadler (2012b) looks at non-selected datives in Maltese. Alzaidi (2010) on gapping constructions in Hijazi (Taif) Arabic. Sadler (2019) provides an analysis of mixed agreement in adjectival relatives in MSA. Clausal possession in Hebrew is discussed in Falk (2004). For an early discussion of agreement in MSA see Fassi Fehri (1988). Camilleri & Sadler (2017b) discusses the grammaticalisation of a progressive construction in the Arabic vernaculars from a posture verb ACT.PTCP and also provides a synchronic account of the progressive construction. Camilleri & Sadler (2018) concerns the grammaticalisation of both the universal perfect (see also Camilleri 2016) and the progressive in Arabic.

---

[27] The distribution of resumptives in Maltese does raise some potentially puzzling issues. Camilleri & Sadler (2011) show that there may be evidence from the distribution of gaps and RPs in across-the-board constructions that Maltese also has *syntactically inactive resumptives* (SIRs) (functionally controlled RPs or 'audible' gaps) since gaps and resumptives occur together in ATB constructions, but that simply assuming that ATB constructions in Maltese (and in Arabic more widely) involve SIRs rather than SARs is also problematic.

Acknowledgements

I am grateful to the reviewers for their very helpful comments on earlier versions of this chapter.

Abbreviations

Besides the abbreviations from the Leipzig Glossing Conventions, this chapter uses the following abbreviations.

CONJ	conjunction	JUSS	jussive
CONSTR	construct form	MSD	maṣdar
EPENT.VWL	epenthetic vowel	PRN	pronoun
FRM.VWL	formative vowel	SFP	scalar focus particle

Chapter 35

LFG and Sinitic languages

Olivia S.-C. Lam

Sophia Y.-M. Lee
The Hong Kong Polytechnic University

The assumptions of LFG have been applied to the research on a number of grammatical phenomena in Chinese languages. In this chapter, we present an overview of some of the studies devoted to investigating the syntactic patterns of two varieties of Chinese: Mandarin and Cantonese. This chapter includes a discussion on the expression and identification of grammatical functions, *ba*, *bei* and related constructions, the dative alternation, compounds (VO compounds and resultative compounds), the locative inversion, and classifiers and measure words. The chapter concludes with a brief overview of the applications of LFG in Chinese language processing.

1 Introduction: Chinese or Sinitic Languages

LFG is a lexicon-driven, unification-based linguistic theory aiming to account for both variations and universals found in human languages. The well-known parsimony of morpho-syntactic markings in Chinese poses an interesting challenge to the theory, but at the same time provides an opportunity to showcase

Olivia S.-C. Lam, One-Soon Her, Jing Chen & Sophia Y.-M. Lee. 2023. LFG and Sinitic languages. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 1703–1751. Berlin: Language Science Press. DOI: 10.5281/zenodo.10186026

the explanatory adequacy of LFG. The term ‘Chinese’ is commonly replaced by ‘Sinitic languages’ or ‘Chinese languages’ in the linguistics literature. These two terms refer to a family of varieties which are genetically related but are, very often, not mutually intelligible (Handel 2015, Huang & Shi 2016). Wurm & Liu (1987) list 10 varieties under ‘Chinese’ in the *Language Atlas of China*, while the *Ethnologue* lists 16 (Eberhard et al. 2020). The more prominent varieties are traditionally known as *fangyan* 方言 (literally ‘regional speech’ or ‘dialect’), and are classified into 7 groups: Mandarin, Xiang, Gan, Wu, Yue, Hakka and Min. Drawing data from both Mandarin and Cantonese (a Yue dialect), we will be using the term ‘Chinese’ to loosely refer to the Sinitic family, and reserve the terms ‘Mandarin’ and ‘Cantonese’ for these two individual varieties.

LFG has been adopted to study Chinese since 1985. Earlier studies, such as Huang (1985, 1986, 1987, 1988, 1989b,a, 1990) and Huang & Mangione (1985), present LFG accounts of a wide range of grammatical structures in Mandarin Chinese, including the internal structure of NPs, the subcategorized topic, and lexical discontinuity. Her (1990) investigates the grammatical functions in Mandarin, while Tan (1991) focuses on the subject in Mandarin. Bodomo & Luke (2003), the monograph resulting from the first LFG Workshop dedicated to the analysis of Chinese languages in 2001, contains studies on Mandarin, Cantonese, and other Sinitic languages.

It is important to note that, although this chapter focuses on Cantonese and Mandarin, LFG has in fact been successfully applied to a wide range of varieties in China. For instance, Huang (1991) provides an account of adjectival reduplication in Taiwan Southern Min. Studies on Zhuang, a Tai-Kadai language spoken in southern China, include Pan (2010), Bodomo (2011), and Burusphat & Qin (2012).

There is also a well-established collection of LFG literature written in Chinese, with most of them providing an introduction to the framework. These include Huang (1988, 1989b), Fu (1990a,b), Fu (1993), Feng (2004), Gao & Li (2009) and Wei (2014).

In the following sections, we first outline the prominent grammatical properties of Chinese from an LFG perspective (Section 2). Section 3 discusses the encoding of grammatical functions in Chinese, while Sections 4–10 provide an overview of the major grammatical phenomena which have been analyzed in LFG. Section 11 concludes the chapter by highlighting LFG analyses which have contributed to the understanding of Sinitic languages, and how the studies on Sinitic languages have contributed to the development of LFG.

2 Grammatical properties: An LFG Perspective

This section introduces important grammatical features of Chinese from an LFG perspective, including the morpho-syntactic encoding of grammatical functions (Section 2.1); the classifier system (Section 2.2); and the canonical word order and the role of information structure (Section 2.3). For more in-depth and recent discussions on issues in Chinese linguistics, see Huang et al. (2009), Wang & Sun (2015), Huang & Shi (2016), and Huang et al. (2022), among others.

2.1 Morpho-syntactic encoding

Chinese has been described in the literature as being 'morphologically impoverished' (e.g. Packard 2000, Hsieh et al. 2022). This, however, does not mean that there is no morpho-syntactic encoding. In (1a), TENSE is not encoded on the verb, but in (2), aspect is.[1,2]

(1) a. Cantonese
Zoengsaam kam jat/ gam jat/ ting jat faangung.
Zoengsaam yesterday/ today/ tomorrow work
'Zoengsaam went to work yesterday/ is going to work today/ will go to work tomorrow.'

b. Mandarin
Zhangsan zuotian/ jintian/ mingtian shangban.
Zhangsan yesterday/ today/ tomorrow work.
'Zhangsan went to work yesterday/ goes to work today/will go to work tomorrow.'

(2) a. Cantonese
Zoengsaam tai-zo/ -gan/ -gwo bun syu.
Zoengsaam read-PFV/ -PROG/ -EXP CLF book
'Zoengsaam has read/is reading/read the book.'

b. Mandarin
Zhangsan du-le/ zhengzai du/ du-guo (yi) ben shu.
Zhangsan du-PRF/ ZAI read/ read-EXP (NUM) CLF book.
'Zhangsan has read/is reading/read a book.'[3]

---

[1] Tones are omitted unless they are relevant to the discussion.

[2] Examples in Cantonese are romanized using the scheme developed by LSHK (2002).

[3] The marker *-gwo*, and the Mandarin equivalent *-guo*, express the 'experiential aspect' in Chinese.

There is no person, number or gender agreement between a verb and its arguments.

(3) Cantonese

a. Zoengsaam gin-dou keoidei.
Zoengsaam see-dou 3pl
'Zoengsaam saw them.'

b. ngo gin-dou Zoengsaam.
I see-dou Zoengsaam
'I saw Zoengsaam.'

Note that the changes in person and number do not affect the verb forms in (3). Note also that *-dou* (到; *-dao* in Mandarin) is not a tense marker – it marks accomplishment and is part of a verb-result compound.

There is no case-marking in Chinese. Pronouns are not case-marked, either:

(4) Cantonese

a. ngo gin-dou keoi.
1sg see-dou 3sg
'I saw him/her.'

b. keoi gin-dou ngo.
3sg see-dou 1sg
'S/he saw me.'

2.2 Number-marking, classifiers and the expression of quantities

Most nouns are not number-marked. The only marker which codes number in Mandarin is the plural marker *-men* (Hsieh et al. 2022). Yet, even for human nouns, a bare noun is unspecified for number, allowing both a singular and a plural reading, as exemplified in (5).

(5) Mandarin
Gebi de xuesheng hen chao.
next.door de student very noisy
'The student(s) next door is/are very noisy.'

Classifiers are a significant feature of the Chinese languages. As number is not explicitly encoded in Chinese, nouns can only be enumerated when they are individuated by classifiers in the [num clf n] structure. Some scholars believe that classifiers ‘serve to profile an essential or inherent feature of the head noun...and contribute no additional meaning to the head noun’ (Her 2012a; see also Cheng & Sybesma 1999). Others (e.g. Huang & Ahrens 2003, Chen et al. 2022), however, argue that classifiers make a crucial contribution to the meaning through coercion.

(6) Mandarin

a. san ben shu
three CLF book
‘three (volumes/copies of) books’

b. san xiang shu
three CLF book
‘3 boxes of books’

Cantonese, among other varieties of Chinese and unlike Mandarin, allows the omission of the numeral one. Whether ‘one’ is expressed depends on the information structure and the grammatical function of the noun. The structure [CLF N] receives a definite, or contextually retrievable, interpretation when it serves as the SUBJ, but when it is an OBJ, either a definite or an indefinite reading is possible:

(7) Cantonese

a. [CLF N] as SUBJ
(Context: What happened to the book?)
[bun syu] laan-zo.
CLF book damage-PFV
‘The book is damaged.’

b. [CLF N] as OBJ

i. With a definite reading
(Context: Where is the book?)
ngo m gin-zo [bun syu].
1SG not see-PFV CLF book
‘I have lost the book.’

ii. With an indefinite reading
ngo kam jat maai-zo [bun syu].
1SG yesterday buy-PFV CLF book
‘I bought a book yesterday.’

2.3 Canonical word order

Different views can be found in the literature regarding the canonical word order in Chinese languages. While there is a long tradition of analyzing Chinese as having a canonical SVO word order (e.g. Light 1979, Mei 1980, Sun & Givón 1985, Dryer 2005), there are also arguments for treating the SOV order as the canonical word order (see, for instance, Tai 1973, Li & Thompson 1974). The empirical and theoretical arguments for both the SVO and SOV accounts can be found in Liu (2022) and Xu & Dong (2022) respectively. In some Wu varieties, it has also been observed that the SOV or OSV orders occur more frequently than the SVO order, especially in cases where obj expresses the patient role (Yue 2003).

Despite the ongoing debate on the canonical word order, it is generally accepted that word order variations in Chinese can be accounted for in terms of information structure (Shyu 2016). Chinese has been well-established as a topic-prominent language since Li & Thompson (1976). Constituents bearing almost any grammatical function can be easily placed in the sentence-initial position as long as they are topics. Kroeger (2004) provides a clear overview on the grammatical functions which can be topicalized in Chinese, including the possessor (Xu & Langendoen 1985). Identifying grammatical functions in Chinese is thus far from being straight-forward – grammatical functions may be expressed in various syntactic positions depending on the discourse context, and they are not morphologically encoded. The obj *pingguo* can appear in the canonical object position (8a), sentence-initially if it is topical (8b), and between the subj and the V, where the marker *ba* is optional:[4]

(8) Mandarin
    a. ta chi le [pingguo].
       3sg eat pfv apple
       'S/he ate the apple/apples.'
    b. [pingguo] ta chi le.
       apple 3sg eat pfv
       'S/he ate the apple/apples.'

---

[4] Whether the marker *ba* is required depends on the semantic features of the displaced NP. A displaced human NP must be marked:

(i) Ta *(ba) laoshi tuidao le.
    3sg.m ba teacher push.over pfv
    'He pushed over the teacher.' (Yang & van Bergen 2007: 1622)

c. ta (ba) [pingguo] chi le.
3SG BA apple eat PFV
'He ate the apple/apples.' (Yang & van Bergen 2007: 1622)

Other word order variations are found in Chinese. These will be discussed in Section 4.

Chinese is also well-known for having 'Chinese-style topics' (Chafe 1976), or 'dangling topics'. These topics are unique in that they are not subcategorized for by the predicate in the comment (Pan & Hu 2008). In (9), the predicate in the comment is *lai* 'come', which is intransitive and only subcategorizes for a subject, *xiaofangdui* 'fire-brigade'. The topic [*nei chang huo*] 'that fire' is not related to the predicate-argument structure of *lai* 'come', and is thus considered a 'dangling' topic.

(9) Mandarin
[nei chang huo], xingkui xiaofangdui lai de kuai.
that CLF fire fortunately fire-brigade come DE quick
'As for that fire, fortunately the fire-brigade came quickly.'
(Li & Thompson 1976)

It is also possible and entirely natural to have more than one topic at the beginning of a sentence in Chinese, i.e. 'topic-chain constructions':

(10) Mandarin
[zhei jian shi], (Zhangsan), ta mei you cuo.
this CLF matter Zhangsan 3SG not have fault
'Regarding this matter, Zhangsan is not at fault.'
(Her 1990; glosses modified)

We provide a more detailed discussion on the TOPIC as a grammatical function in Section 3.

3 Grammatical functions and word order variations in Chinese

We provide a synopsis of the state-of-the-art LFG research on Chinese in this section and Sections 4–10. We begin with the fundamental issue of encoding grammatical functions in Chinese.

Identifying grammatical functions in Chinese can be challenging due to the lack of morphological encoding of grammatical functions, and to the fact that Chinese has relatively free word order. We offer an overview of the grammatical functions in Mandarin (Section 3.1), and in Cantonese (Section 3.2).

3.1 Mandarin

Almost all early LFG studies on Chinese have included a classification of grammatical functions. Interestingly, although there are no obligatory morphological encodings of GFs, there is general consensus as to the grammatical functions which can be identified for Chinese. Huang (1989b, 1993a), adopting the assumptions of classical LFG (Bresnan 1982b, Bresnan & Kanerva 1989), shows that GFs in Mandarin can be identified by their unambiguous syntactic positions at the surface level, and can be classified into four types based on two features: [±*r*estricted] and [±*o*bjective]. Her (1990, 2008) presents an expanded set of GFs in Mandarin, and recognizes SUBJ, OBJ, OBJ2, OBL_θ (oblique function which includes subtypes $\text{OBL}_{\text{THEME}}$ (theme), OBL_{GOAL} (goal), OBL_{BEN} (beneficiary), OBL_{LOC} (location), and COMP (complement function that includes subtypes XCOMP, SCOMP, and NCOMP) as subcategorizable GFs, while TOPIC, ADJunct (adjunct function that has two subtypes ADJ and XADJ), and POSS are identified as non-subcategorizable, as shown in Figure 1. It should be noted that, in the current LFG literature, the restricted object function OBJ_θ has replaced OBJ2, while grammatical function labels such as SCOMP and NCOMP, which make reference to c-structure categories, are no longer adopted.

The syntactic encoding of GFs is via both the c-structure and the predicate argument structure (AS). Take the lexical verb *da* 'hit', for example: it has a predicate argument structure of ⟨AGENT, THEME⟩, and subcategorizes for ⟨SUBJ, OBJ⟩, where the linking between the argument roles and the grammatical functions is constrained by the Lexical Mapping Theory (LMT; Bresnan & Kanerva 1989).

(11) Mandarin
Lisi da Zhangsan.
Lisi hit Zhangsan
'Lisi hit Zhangsan.'

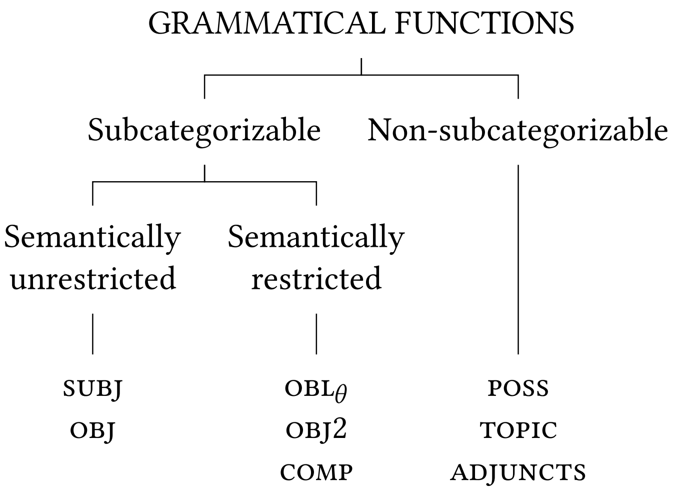

Figure 1: Classification of grammatical functions in Mandarin (Her 1990, 2008)

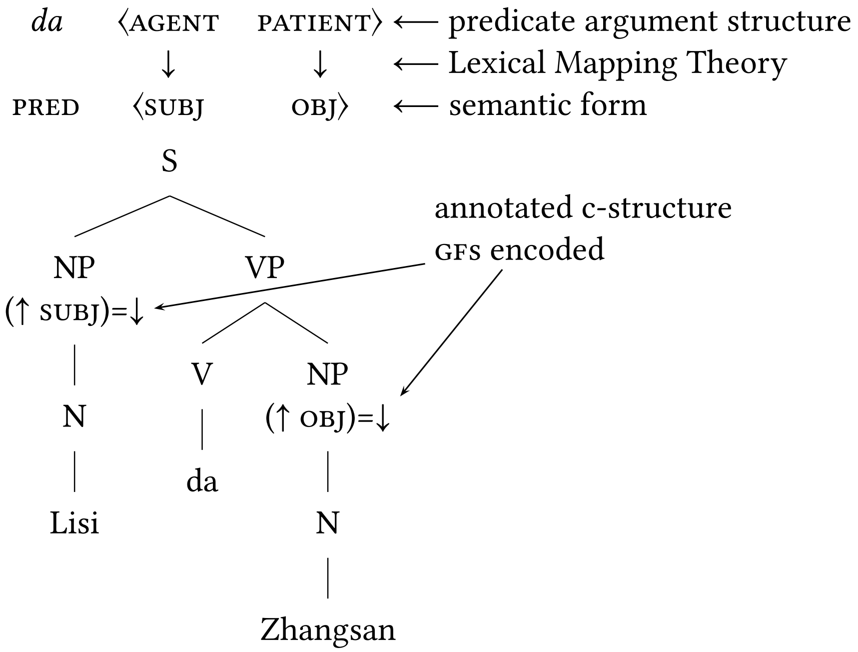


The treatment of TOPIC above touches on a fundamental issue related to the universal properties of GFs. Recall that Chinese is a topic-prominent language (see, for instance, Tsai (2022), for a discussion on the syntactic approaches to the phenomenon, and Tao (2022), among others, for a discussion on the functional approaches). Thematic TOPICS may be 'preposed', while non-thematic TOPICS may remain *in situ*. A set of frequently used constructions known as 'Pseudo-transitive constructions' (Chang et al. 1988) pose challenges to the grammatical status of topic, and this has been treated in detail in Huang (1989a). In these constructions, an NP which is clearly an argument of the verb may only occur in the pre-verbal topic position or some obl positions, but never in the postverbal obj position. The following two examples are from Huang (1989a).

(12) Mandarin

a. zeijian shi, ni zuozhu.
this matter 2sg make.master
'You'll take charge of this matter.'

b. *2sg zuozhu zeijian shi.
you make.master this matter

(13) Mandarin

a. yuyanxue, ta nashou.
linguistics 3sg take.hand
'S/he is good at linguistics.'

b. *ta nashou yuyanxue.
3sg take.hand linguistics

Huang (1989a) has made the following observations: (i) the topical NPs have clearly subcategorizable semantic roles; (ii) these constructions involve a large set of compound verbs, including some V+N compounds which are practically all disyllabic in Chinese, and all of the quadrisyllabic compounds, and (iii) topics can be regarded as being subcategorized (Bresnan 1982a). Based on these three observations, Huang shows that the most efficient account is to treat the topical NPs as subcategorized topics. Mo (1990) has proposed a new grammatical function stopic (s for 'subcategorized') to differentiate them from the non-thematic topics.

According to Huang (1989a), the subcategorizable topic achieves parsimony in terms of lexical encoding and mapping to c-structure, but this would introduce complexities to the LMT. Her (1991, 2010), based on the same LMT considerations, argues that topics should be regarded as strictly non-subcategorizable. To deal with the fact that pseudo-transitive verbs do not allow the stipulated objs to be realized in the canonical obj position, a feature-value pair [frame +] is assigned to those verbs. The [frame +] feature can only be obtained by way of unification with the topic. The annotated PSR in (14b) specifies that topic receives the feature [frame +] and it must be associated with some gf in the f-structure to fulfill the Extended Coherence Condition.

(14) Her (2010):

a. *nashou* V (↑ pred) = ‘be-good-at⟨subj obj⟩’
(↑ obj frame) $=_c$ +

b. S′ ⟶ NP S
(↑ topic)=↓ ↑=↓
(↑ frame)=+

It is important to note that neither account explicates how it will account for the NPs occurring in other non-obj positions, such as in (15).

(15) Mandarin
[[Mali zui nashou] de kemu] shi shuxue.
Mary most take.hand de subject be math
‘The subject that Mary is best at is math.’

In (15), a gap in the relative clause is linked to the head noun, and is then linked to the complement of the verb *shi* ‘be’. In Huang’s (1989a) account, the subcategorized subj will have to be linked to other gfs following the same mechanisms for control and complementation (Bresnan 1982a). See Her (2010) for a different account. In both cases, however, there is neither a clear solution to the entailed complexities for LMT, nor an answer to the question of why such a high-level solution is needed for what seems to be a parochial fact limited to a set of predicates in a specific language.

In sum, the pseudo-transitive verbs in Mandarin, where the obj-like arguments can only occur in the topic position, pose a great challenge to the theory of gf-encoding in LFG. The two existing proposals (Huang 1989a and Her 2010) both have their strengths and weaknesses. The fact that the set of verbs involved are some of the verbs currently undergoing changes in transitivity (Jiang & Huang 2018) suggests that the ultimate solution may involve a theory which takes historical changes involving gfs into consideration.

3.2 Cantonese

In contrast to the issue-driven discussion on gfs in Mandarin in the last section, this section will provide a survey on subj (Lee 2003), obj (Lam 2008), and the complement (Bodomo & Lee 2003, Lee 2002) in Cantonese.

3.2.1 Subject in Cantonese

Lee (2003) shows that two syntactic properties are of particular relevance in the identification of the subject in Cantonese. The first is the binding of the reflexive pronoun *zigei* 'self' to the subject *Mary* within the same clause, or to the subject *John* in the clause containing the local clause. This, following Tan (1991), clearly distinguishes the subject from the topic, both of which can be found preverbally.

(16) Cantonese
John$_i$ zi1 Mary$_j$ sik6-zo2 keoi5-zi6gei2$_{i/j}$ haap6 faan6.
John know Mary eat-PFV 3SG-self CLF rice
'John knows that Mary ate his/her lunch box.' (Lee 2003: 30)

The second distinctive property of the subject is that the possessor of the subject can be easily relativized with the gap strategy (17a), but the possessor of the object cannot be relativized in the same way (17b):

(17) Cantonese

a. [_ sing4zik1] ji5ging1 gung1bou3-zo2 ge3 hok6saang1
grades already announce-PFV REL students
'the students whose grades have been announced.' (Lee 2003: 37)

b. *hok6haau6 ji5ging1 gung1bou3-zo2 [_ sing4zik1] ge3 hok6saang1
school already announce-PFV grades REL students
(Intended meaning: 'the student whose grades have been announced by the school') (Lee 2003: 38)

Luke et al. (2001) discuss the Subject Condition in Cantonese. As with Sinitic languages in general, Cantonese allows pro-drop even without agreement morphology or case-marking. This poses a challenge to the identification of grammatical functions at f-structure. Luke et al. (2001) show that apparently 'subjectless' sentences, in fact, do have a subject, but discourse-pragmatic criteria, such as the speech context, must be taken into consideration in order to retrieve the subject. See also Liao (2010) for a discussion on the pro-drop patterns in Mandarin Chinese, and for an analysis within LFG.

3.2.2 Object in Cantonese

Lam (2008) investigates the syntax of objects in Cantonese, in particular, their syntactic behaviours in double object constructions (DOCs). Without morphological marking, the structural position of each object becomes an important clue in the identification of the different object functions – in (18), the recipient-object is found immediately postverbally, with the theme-object following it:

(18) Cantonese

a. Recipient-NP < Theme-NP
ngo gaau siupangjau zungman.
1sg teach children Chinese
'I teach children Chinese.'

b. *Theme-NP < Recipient-NP
*ngo gaau zungman siupangjau.
1sg teach Chinese children
'I teach children Chinese.'

This, however, is not the canonical order of objects for the verb GIVE – it is the theme-object that must be immediately postverbal.

(19) Cantonese

a. Theme-NP < Recipient-NP
ngo bei-zo bun syu ngo gaaze.
1sg give-pfv clf book 1sg elder.sister
'I gave the book to my elder sister.'

b. *Recipient-NP < Theme-NP
*ngo bei-zo ngo5 gaaze bun syu.
1sg give-pfv 1sg elder.sister clf book

A related question is – which one of these objects is the unrestricted object obj, and which is the restricted one obj$_{\theta}$? In LFG, the object in a DOC which grammatically patterns with the monotransitive object is obj, while the one which does not is obj$_{\theta}$. Passivization is often seen as *the* diagnostic for unrestricted objecthood, but in Cantonese, as in Mandarin Chinese, passivization is often constrained - the passive is associated with a meaning of adversity. As a result, not all verbs, even monotransitive ones, can be involved in passivization (20). It is therefore not a very helpful test for the unrestricted object. We shall return to a discussion of passivization in Section 4.

(20) Mandarin

a. Zhangsan gei ren du-si le.
Zhangsan give people poison-die prt
'Zhangsan was poisoned to death by people.'

b. *Zhangsan gei ren yi-hao le.
Zhangsan give people cure prt
'Zhangsan was cured by people.' (Lefebvre 2011: 257)

Patterns of relativization and pro-drop show that it is the theme-object which behaves like the monotransitive object. Lam (2008) thus concludes that the theme-object is the unrestricted object in Cantonese, while the recipient-object is the restricted object.

3.2.3 Complement in Cantonese

Lee (2002) and Bodomo & Lee (2003) show that Cantonese verbs such as *zidou* 'think' may take either a comp (21a) or an obj (21b), while other verbs subcategorize for only a comp (22a) but not an obj (22b):

(21) Cantonese

a. ngo zi dou $_{\text{S}}$[keoi hai hou jan].
1sg know 3sg be good person
'I know that s/he is a good person.'

b. ngo zi dou $_{\text{DP}}$[li gin si].
1sg know this clf matter
'I know (about) this.'

(22) Cantonese

a. ngo hei mong $_{\text{S}}$[keoi hai hou jan].
1sg hope 3sg be good person
'I hope that s/he is a good person.'

b. *ngo hei mong $_{\text{DP}}$[keoi].
1sg hope 3sg
['I hope him/her.']

They therefore argue that Cantonese is a 'mixed language', along the lines of Dalrymple & Lødrup (2000).

4 *Ba*, *Bei*, and Related Constructions

4.1 Mandarin

The Mandarin *bei* construction is considered to be the equivalent of the English *by* passive in the literature. The discussion of the *bei* passive is frequently compared to the *ba* construction, as they share almost identical surface structures. Note that in (23), the agent *gemi* 'fans' is optional, much like the *by*-agent phrase in English. A *bei* construction with the agent phrase is known as the 'long' passive, while a *bei* construction with the agent phrase omitted is the 'short' passive (Huang et al. 2009, Huang & Shi 2016).

(23) Mandarin
Amei bei (gemi) weizhu.
Amei BEI fans encircle
'Amei was encircled (by the fans).'

(24) Mandarin
gemi ba *(Amei) weizhu.
fans BA Amei encircle
'The fans encircled Amei.'

Several important and controversial issues have been raised over the passive analysis of the *bei* construction. The first is whether *bei* is a preposition like the English *by* (Huang 1982, Li 1990, Li & Thompson 1981, Lü 1980, McCawley 1992, Tsao 1996) or a verb (Bender 2000, Feng 1995, Her 1989, 2009, Hsueh 1989, Huang 1999). The current dominant view of *bei* as higher verb is heralded by Huang & Mangione's (1985) formal semantic account, and was first adopted in LFG syntactic studies (e.g. Huang & Mangione 1985, Bender 2000).

The second issue is whether there is one or two passive constructions. The dominant GB analysis treats the passive in Mandarin as having 'split' into two different constructions: the agentless short passive versus the long passive with an overt agent. This is motivated by the observation that the long passive allows a much wider range of syntactic behaviours than the short passive. Yet Her (2009) shows, with corpus data from Sinica Corpus (Chen et al. 1996), that the short passive in fact exhibits the same range of syntactic behaviours, and argues that the two should receive exactly the same analysis, with the only difference being whether the agent is overt or covert. The evidence is presented below. First, Her (2009) shows that short passives (26), just like long passives (25), allows long-distance gaps:

(25) Mandarin
bei ta qitu nuyi de ziyou renmin.
BEI 3SG attempt enslave DE free people
'the free people who were "attempted-to-enslave" by him'

(26) Mandarin

a. gongsi-de wanglu bei qitu ruqin.
company-POSS network BEI attempt hack
'The company network has been "attempted-to-hack".'

b. ziliao bei shefa kaobei le.
document BEI manage copy PRF
'The documents have been "managed-to-copy".'

Second, the claims in the literature that a long passive, but not a short passive, allows a resumptive pronoun to fill a gap are also incorrect, as in (27) and (28).

(27) Mandarin
Zhangsan$_i$ bei wo piping-le ta$_i$ yidun.
John BEI 1SG criticize-PFV 3SG once
'John was criticized once by me.'

(28) Mandarin
ta ba$_i$ pa bei renwei ta$_i$ wufa guanjiao haizi.
3SG father afraid BEI consider 3SG fail discipline children
'His father was afraid to be considered that he failed to discipline his children.'

Third, the split view claims that the pronominal particle *suo* is allowed in the long passive only, as in (29), and not the short passive. The corpus example in (30) shows that *suo* can be found in the short passive as well:

(29) Mandarin
ni hui bei ren suo chixiao.
2SG will BEI person SUO sneer
'I'm afraid your recent behavior toward him will be sneered at.'

(30) Mandarin
ni nanmian bu bei suo pian.
2SG unavoidably not BEI SUO trick
'Unavoidably you would be tricked.'

Finally, the split view claims that only the long passive allows an adverbial PP, as in (31), but not in the short passive. This is again shown to be wrong by the corpus example in (32).

(31) Mandarin
Zhangsan bei Lisi zai xuexiao pian-zou le.
John BEI Lee at school abduct PFV
'John was abducted at school by Lee.'

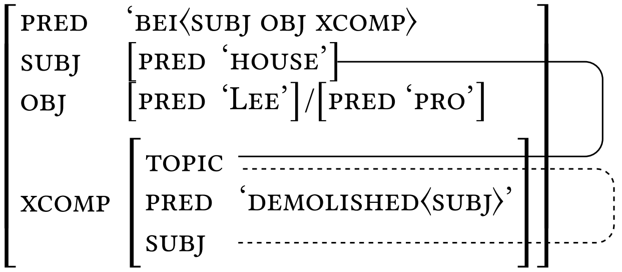
(32) Mandarin
yi zhi laoshu bei zai jiujing zhong jinpao-le yi nian.
one CLF mouse BEI at alcohol inside soak-PFV one year
'A mouse has been soaked in alcohol for a year.'

The analysis proposed by Her (2009) has *bei* as a three-place predicate requiring three theta roles, which are mapped to SUBJ, OBJ, and XCOMP, with a meaning that approximates (33). The lexical entry, including its lexical category, lexical form, and the control relations, is shown in (34). Note that the operation that links theta roles with GFs is γ; thus $\gamma(\hat{\theta})$ in (34) refers to the GF linked to the logical subject. (↑ OBJ) = (↑ XCOMP $\gamma(\hat{\theta})$) thus means that OBJ controls the GF in XCOMP that is linked to the $\hat{\theta}$. The f-structure of a typical *bei* sentence is illustrated in (35).

(33) *bei* ⟨*x y z*⟩: *x* is (adversely) affected by *y* in a way that *z* describes

(34) *bei* V (↑ PRED) = 'BEI⟨SUBJ OBJ XCOMP⟩'
(↑ SUBJ) = (↑ XCOMP TOPIC)
(↑ OBJ) = (↑ XCOMP $\gamma(\hat{\theta})$)
¬(↑ OBJ) ⇒ (↑ OBJ PRED) = 'PRO'

(35) Mandarin
na jian fangzi bei (Lisi) chai-le.
that CLF house BEI Lee demolish-PFV
'That house got demolished (by Lee).'

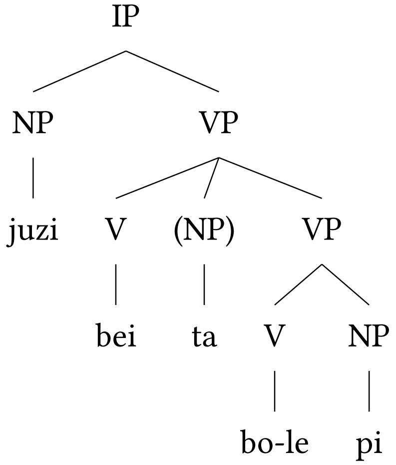


In (35), (↑ OBJ), which is either an overt agent *Lee* or a covert pronoun, is responsible for adversely affecting (↑ SUBJ), the house, in a way described by

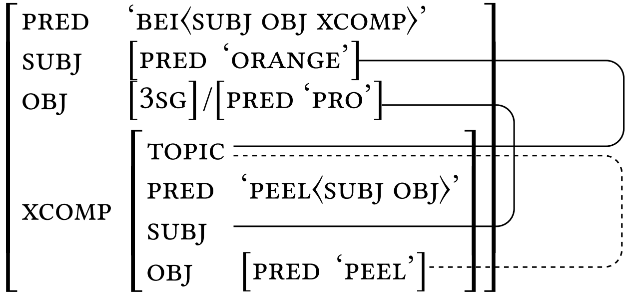
(↑ xcomp), i.e., the house is demolished. Note that (↑ subj) controls the topic in xcomp, which is anaphorically linked to subj, indicated by the dotted line. The matrix subj, the house, is also the subj of the embedded clause, which is passive in nature. A non-canonical example is given in (36), with both c-structure and f-structure illustrated.

(36) Mandarin
juzi bei (ta) bo-le pi.
orange bei 3sg peel-pfv peel
'The orange has its peel peeled off (by him).

a. c-structure:



b. f-structure:



In (36), (↑ obj), which is again either overt or covert, is responsible for adversely affecting (↑ subj), the orange, in a way described by (↑ xcomp), i.e., the orange has its peel peeled off. Note that (↑ subj) controls the topic in xcomp, and (↑ obj) controls the subj in xcomp. Within the xcomp, topic is anaphorically linked to obj.

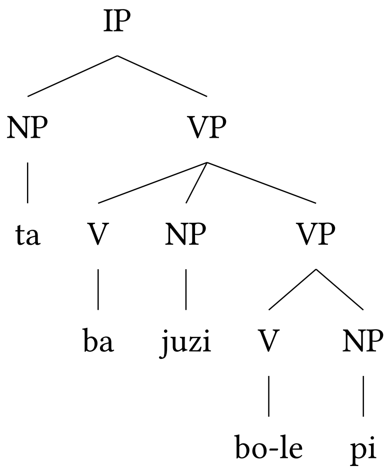
Based on this account, Her (2009) contends that the *bei* construction is the passive counterpart of the *ba* construction, not the canonical active sentence. Thus, *ba* is likewise a three-place predicate, as in (37), and its lexical entry is shown in (38). The example in (39) is therefore the active counterpart of the passive (36). See also Bender (2000) for an LFG analysis of the *ba* construction in Mandarin.

(37) *ba* ⟨*x y z*⟩: *x* affected *y* in a way that *z* describes

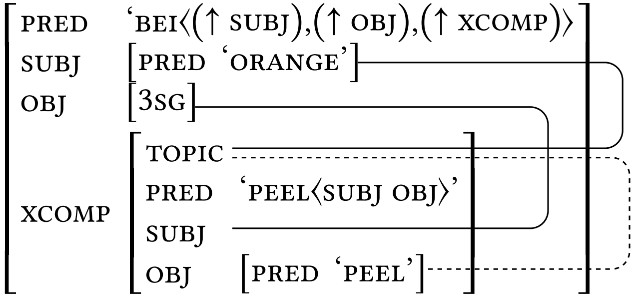
(38) *ba* V (↑ pred) = ‘ba⟨subj obj xcomp⟩’
(↑ obj) = (↑ xcomp topic)
(↑ subj) = (↑ xcomp $\gamma(\hat{\theta})$)

(39) Mandarin
ta ba juzi bo-le pi.
3sg ba orange peel-pfv peel
‘He peeled the peel off the orange.’

a. c-structure:



b. f-structure:



In (39), (↑ subj), *he*, is responsible for affecting (↑ obj), the orange, in a way described by (↑ xcomp), i.e., *he peeled the peel off the orange*. Note that (↑ subj) controls the subj in xcomp, and (↑ obj) controls the topic in xcomp, which is in turn anaphorically linked to obj.

In summary, *ba* and *bei* are both treated as three-place predicates. While the former involves a causer as subj, an affectee as obj, and an active proposition describing the caused event as xcomp, the latter involves an affectee as subj, a causer as obj, and a passive proposition describing the caused event as xcomp. Thus, in this sense the *bei* construction is the passive counterpart of the *ba* constructive.

See also Yang (2020) for a discussion of the impersonal BEI-passive in Mandarin.

4.2 Cantonese

A discussion on aspects of the passive structure in Cantonese is offered in Chow (2019). While Cantonese shares a phonologically similar passive morpheme *bei* with Mandarin, the two counterparts differing only in tones, one clear morphosyntactic difference is that the NP following *bei* in Mandarin is optional (40a), while that in Cantonese is obligatory (40b). In other words, the 'short' passive discussed in the previous section is not allowed in Cantonese. Even in agentless passives, the NP *jan* 'person' must follow *bei.*

(40) a. Mandarin
Zhangsan bei (Lisi) daa-le.
Zhangsan bei Lisi hit-pfv
'Zhangsan has been hit (by Lisi).'

b. Cantonese
Siuming bei *(jan) daa.
Siuming pass people hit
'Siu Ming was beaten up.'

Based on this, Chow (2019) argues that passivization in Cantonese involves the subject being linked to an oblique object, a non-core argument (Bresnan 1982c; Chow 2019: 232). It is also shown that, unlike Kit's (1998) and Her's (2009) analyses for the Mandarin *bei*, the Cantonese *bei* is a 'non-argument taking and a non-predicative' coverb (Chow 2019: 186), which contributes a (↑ voice)=pass feature to f-structure.

Similar to Her (2009), Chow (2019) acknowledges that the matrix subject in a passive structure is linked to the topic role. Indeed, the same propositional content may be expressed by an active, a 'direct' or canonical passive (41a), or a 'indirect' passive (42b) structure, depending on the information structure to be expressed. In an canonical passive structure, the entire theme-NP is topical

– it is expressed as the subject. In an ‘indirect’ passive structure, however, it is the possessor of the theme-NP which is topical – the possessor is linked to the subject.

(41) Cantonese

a. The ‘direct’ or canonical passive
[Can saang gaa ce] bei tungsi zong-laan zo.
Mr. Chan CLF car PASS colleague crash-broken PFV
‘Mr. Chan’s car has been crashed by his colleague.’

b. The ‘indirect’ passive
[Can saang] bei tungsi zong-laan zo [gaa ce].
Mr. Chan PASS colleague crash-broken PFV CLF car
‘Mr. Chan had his car crashed by his colleague.’

Semantically, the subject must be adversely affected in order for an indirect passive to be acceptable. Chow (2018, 2019) proposes that, for the indirect passive structure [NP1 BEI2 NP2 V NP3] to be licensed, an additional malefactive role, which must be topical, is introduced into the structure. Due to the limits of space, we shall leave the discussion here and ask interested readers to refer to these studies.

5 Dative alternation

Dative alternations, as well as ditransitive constructions, have been extensively discussed in the Chinese linguistics literature. In addition to the word order variations and the introduction of an applied object common in other languages (e.g. Bresnan et al. 2007), the challenges in analyzing the Mandarin dative alternative involve the position and the grammatical status of the lexical form *gei* ‘give’ (e.g. Chao 1968, Zhu 1982). The discussion in this section focuses on Mandarin only, as the dative alternation is not attested in Cantonese (Lam 2008).

(42) Ditransitive constructions with *gei* in Mandarin (42a, 42c & 42d are from Huang & Ahrens 1999)

a. SUBJ *gei* IO V DO

b. SUBJ DO V (*gei)* IO

c. SUBJ V (*gei*) IO DO

d. SUBJ V DO *gei* IO

The pattern in (42d) will be treated as the semantically most transparent word order for *gei* 'give.to'. It should, however, be noted that it is not clear whether a clearly favoured canonical word order is available (Yao & Liu 2010). In a ditransitive construction, *gei* introduces the IO as the goal towards which a theme DO moves. In the literature, there are several different views regarding the grammatical status of *gei*: *gei* is (i) a verb, producing a serial verb construction with the other verb in the construction; (ii) a co-verb/preposition, marking the IO in the construction. The verb/preposition debate is familiar in the Chinese linguistics literature, and has been applied to several other lexical items with similar distributions. Either account is generally adequate in describing the patterns in (42a) and (42d). The patterns in (42b) and (42c), where *gei* is optional and the optionality depends on the V, has generated interesting debates specific to the ditransitive construction (e.g. Chao 1968, Li & Thompson 1981, Cheng & Huang 1988). Huang & Ahrens (1999) observe that verbs without an inherent meaning of transfer (e.g. *ti* 'to kick', *bian* 'to knit'), typically require the presence of *gei*, while *gei* in structures with verbs with an inherent meaning of transfer may be optional (e.g. *song* 'to give as a gift, to send', *zhu* 'to lend', *mai* 'to sell,' and *gei* 'to give'). This suggests that the *gei* immediately after the verb is a stem that introduces an applicative goal role to the argument structure of the verb. This account has been incorporated into Huang's (1993a) LMT of Mandarin. The compounding account has also been adopted by several Construction Grammar-based accounts (e.g. Ahrens 1995, Zhang 1999, Liu 2006). Huang (1993a) argues that the postverbal *gei* is a part of the complex predicate which involves a morpholexical rule introducing an additional goal role into the argument structure. The study also observes that there is a significant contrast between the English and Chinese dative constructions — the theme can become SUBJ in a passive construction in Mandarin, but not the goal.

(43) a. Mary gave John a book.
b. John was given a book by Mary.
c. A book was given to Mary by John.

(44) Mandarin (adapted from Huang (1993a: example 22))
a. Zhangsan ti-*(gei) Lisi yi ge qiu.
Zhangsan kick-GEI Lisi one CLF ball
'Zhangsan kicked a ball to Lisi.'
b. *Lisi (bei Zhangsan) ti-gei-le yi ge qiu.
Lisi BEI Zhangsan kick-GEI-PFV one CLF ball

c. nei ge qiu (bei Zhangsan) ti-gei-le Lisi.
that CLF ball BEI Zhangsan kick-GEI-PFV Lisi
'That ball was kicked to Lisi (by Zhangsan).'

In sum, this account of V-*gei* compounding, adding an applicative GOAL role, illustrates the lower accessibility of the goal role on the Thematic Hierarchy, and predicts that the goal role cannot be linked to SUBJ in a Mandarin passive structure.

See also Her (2006a) for an alternative analysis of the Mandarin dative alternation.

6 Compounds

Compounding is a productive morpholexical process in Chinese (Hsieh et al. 2022). Mandarin is known to have at least the following types of compounds that can introduce new predicate-argument structures: (i) subject-verb (SV) compounds; (ii) verb-object (VO) compounds; (iii) verb-resultative (VR) compounds; and, (iv) verb-verb (VV) compounds. In this section, the LFG treatments of resultative compounds and VO compounds are presented in Sections 6.1-6.2 and Section 6.3, respectively.

6.1 Early LFG studies on Mandarin compounds

Chao (1968) has observed that a number of distinctive grammatical features of Chinese are related to the prevalence of compounds: (i) V+N compounds tend not to take another object directly; (ii) the noun in the compound is often separable even though it is a sub-lexical unit (called 'ionization' in Chao 1968); (iii) separable compounds allow certain degrees of internal modification, and in some cases, an object may appear in non-canonical positions. The earliest published studies in the LFG literature on Mandarin, Huang (1985, 1986, 1988, 1990) for example, have aimed to account for these separable compounds and their non-canonical object positions.

Huang (1990) provides an account for VO compounds in Mandarin. One example that is of particular interest is the idiom chunk *chi cu* 'be jealous of', consisting of the lexical verb *chi* 'eat' and the noun *cu* 'vinegar'. The chunk is a non-compositional compound, as the overall meaning is only available if both the V and the N are found in the sentence. What is interesting, and yet challenging, is the fact that the V and the N in the compound can be separated, by *de* in the following example:

(45) Mandarin
Sanbai conglai bu chi Yunniang de cu.
Sanbai ever NEG eat Yunniang DE vinegar
'Sanbai is never jealous of Yunniang.'

Huang (1990) proposes an account for separable compounds in terms of lexical discontinuity – both the verb and the separable noun contribute information to the overall interpretation. The subscript marks the use of this form as a component of an idiom. Note that PRED is associated with the noun, and the constraining equation ensures that the non-compositional meaning will only be available if the form *chi* also occurs in the sentence.

(46) a. *chi*$_2$ V (↑ VMORF) = CHI
b. *cu*$_2$ N (↑ PRED)='BE.JEALOUS⟨SUBJ OBL⟩'
(↑ VMORF) $=_c$ CHI
(↑ CL) = DE

Huang (1990) further shows that this proposal successfully accounts for various constructions in which the compound occurs, including topicalization. This example illustrates how complex structures can be captured with simple lexical rules.

6.2 VO compounds in Cantonese

VO compounds are found in Cantonese, too. As discussed in the previous section and as observed in Bodomo et al. (2017), among others, the challenge with analyzing VO compounds is that they seem to be lexical in that their meanings are often non-compositional and depend on the co-occurrence of a V and some specific N; but, at the same time, they seem to be phrasal in that other constituents can clearly be inserted in between the V and the N:

(47) Cantonese
a. jau-seoi
swim-water
'swim'
b. ngo jau-zo zan seoi.
1SG swim-PFV for.a.while water
'I have swum for a while.' (Bodomo et al. 2017: 389, ex. 18)

Bodomo et al. (2017) treat *seoi* 'water' as a syntactic object, whose form is obligatorily required to give the target meaning (hence the FORM feature in OBJ below), but it is not subcategorized for by the PRED, as the VO compound *jau-seoi* 'swim' requires only an agent argument at a-structure and *seoi* 'water' is athematic in the compound (Bodomo et al. 2017: 389):

(48)
$$\left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{swim}\langle\textsc{subj obj}\rangle\text{'} \\ \textsc{subj} & \left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{pro}\text{'} \\ \textsc{num} & \textsc{sg} \\ \textsc{pers} & 1 \end{array}\right] \\ \textsc{asp} & \textsc{pfv} \\ \textsc{obj} & \left[\begin{array}{ll} \textsc{form} & \textsc{seoi} \end{array}\right] \\ \textsc{adj} & \left\{\left[\begin{array}{ll} \textsc{pred} & \text{`}\textsc{zan}\text{'} \end{array}\right]\right\} \end{array}\right]$$

Bodomo et al. (2017) apply this analysis to Mandarin VO compounds, too. Che & Bodomo (2018) discuss Mandarin VO compounds, as well as idioms, and adopt a complex predicate analysis for VO compounds.

A complex predicate approach has also been proposed to analyze serial verb constructions, which are common in Chinese. See Bodomo et al. (2003) for a syntactic and semantic account of Cantonese serial verb constructions involving the benefactive role.

6.3 Resultative compounds

Chinese resultative compounds involve the concatenation of two verbs, and the merge of their predicate argument structures. They are called resultative compounds (VR) because the first verb denotes an action, and the second verb typically refers to the result caused. Previous studies have found that both verbs contribute to the argument structure of the compound. Li (1990) proposes a structure-based account that allows most possible predicate-argument structures, but fails to select the correct reading among other possibilities. Huang & Lin (1992) assume that VV compounds in Mandarin represent composite event structures and the complex predicate formation can be resolved with morpholexical mapping based on prototypical argument templates. Li (1995) proposes another account based on the causative hierarchy. Her (2004, 2007) offers an LFG account by incorporating unified mapping principles of LMT.

Her's (2004, 2007) account focuses on cases where the first V has either one or two arguments, while the second V has only one argument. In addition, it is assumed that the VR compounds have two arguments. Hence, there are cases in which each verb contributes an argument, or the more complicated cases where the argument from the second verb can be merged with either the first or the second argument of a transitive verb, such as *niu* 'to wring' in (50). The two argument merging scenarios are given in (49).

(49) V-V Resultative Compounding

$$V_1\langle x\ y\rangle + V_2\langle z\rangle \rightarrow \begin{array}{l}\text{(i) } \langle x\ y\text{-}z\rangle \\ \text{(ii)} \langle x\text{-}z\ y\rangle\end{array}$$

Given that the resultative compound is transitive, thus a two-place predicate, the single role of V_2 must join one of the two roles of V_1 and form a composite role. Logically, two possibilities are obtained as shown in (49), but three patterns of argument-function linking are observed, as in (50)-(52). Note also that a causative reading is also obtained, except in (51).

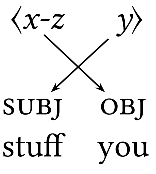
(50) Mandarin; causative
Lisi niu-gan-le maojin.
Lee wring-dry-PFV towel
'Lee wrung the towel dry.'

$$\begin{array}{cc} \langle x & y\text{-}z\rangle \\ \downarrow & \downarrow \\ \text{SUBJ} & \text{OBJ} \\ \text{Lee} & \text{towel} \end{array}$$

(51) Mandarin; non-causative
Zhangsan chi-yan-le zhe zhong dongxi.
John eat-tired.of-PFV this kind stuff
'John got tired of eating this kind of stuff.'

$$\begin{array}{cc} \langle x\text{-}z & y\rangle \\ \downarrow & \downarrow \\ \text{SUBJ} & \text{OBJ} \\ \text{John} & \text{stuff} \end{array}$$

(52) Mandarin; causative
zhe zhong dongxi hui chi-si ni.
this kind stuff will eat-dead 2SG
Eating this kind of stuff will make you dead.'



Her's (2007) resultative compound rules are given below in (53).

(53) V-V Resultative Compounding

$\mathrm{V}_{\mathrm{caus}}\langle x\ y\rangle + \mathrm{V}_{\mathrm{res}}\langle z\rangle \rightarrow \mathrm{V}_{\mathrm{caus}}\mathrm{V}_{\mathrm{res}}\langle \alpha\ \beta\rangle$, where $\langle \alpha\ \beta\rangle^{*}$ =

(i) $\langle x\ y\text{-}\cancel{z}\rangle$

(ii) $\langle x[\mathrm{caus}]\ \cancel{y}\text{-}z[\mathrm{af}]\rangle$

(iii) $\langle x\text{-}\cancel{z}\ y\rangle$

(iv) $\langle \cancel{x}\text{-}z[\mathrm{af}]\ y[\mathrm{caus}]\rangle$

*Unsuppressed *z* and the other unsuppressed role receive [af] and [caus], respectively

With these rules, and a modified version of LMT, all possible interpretations of resultative compounds with V⟨*x y*⟩ and V⟨*x*⟩ combinations can be accounted for. See Her (2007) for details.

7 Lexical Mapping Theory and locative inversion

LFG crucially observes radical lexicalism (Karttunen 1989), and views grammatical operations as the projection and unification of mentally represented lexical information (Bresnan 1982b). Word order variations and alternations are not accounted for by transformational rules, but by the projection and unification of the mental representation of information from conceptual structure to c-structure. See Belyaev 2023a [this volume] and Belyaev 2023b [this volume] for a discussion on the architecture of LFG.

The introduction of Lexical Mapping Theory (LMT) to LFG to derive lexicalized argument structures in terms of GFs is crucial in allowing the theory to account for concept-driven lexicalization. It also provides an elegant way to account for word order and other typological variations. LMT formulates rules to capture how conceptualized event structures are lexicalized as argument structures to mediate mapping to functional structures (Bresnan & Kanerva 1989, Alsina 1993). Huang (1993a) proposes an adapted LMT for Mandarin, adopting previous assumptions that the mapping is determined by the thematic hierarchy, and the theory of intrinsic and default classification of grammatical functions. The adaptations are proposed, taking into consideration both the theoretical concerns to incorporate Dowty's (1991) Proto-role properties, and the need to capture several atypical argument realization patterns in Mandarin. These patterns include the NP realization of extent/dimension (54a), and the use of time/location NPs instead of pleonastic pronouns in the subject position in presentative constructions (54b).

(54) Mandarin

a. Ta ti-le wo yi jiao.
3sg kick-pfv 1sg one foot
'S/he kicked me once'

b. Qiangshang gua-le ji fu hua.
wall.top hang-pfv several clf painting
'There are several paintings on the wall.'

Huang also provides evidence to show that the GOAL role is below the THEME role on the thematic hierarchy in lexicalized compounds, idiom chunks and ditransitive verbs. The thematic hierarchy for Mandarin is thus revised, as shown in (55). The intrinsic and default classification of grammatical functions (57a) are slightly modified to simplify feature assignments, and to accommodate the locative inversion construction in Mandarin.

(55) Thematic hierarchy for Mandarin Chinese (Huang 1993a)
ag > ben/mal > instr > th/pat > exp/goal > loc/dom

Huang & Her (1998) and Her (2010) propose a simplified LMT. This proposal keeps the universal thematic hierarchy, with the assumption that morpholexical operations can replace the Subject Condition. Note that the two proposals take different approaches to accommodate the Mandarin Chinese data. Huang (1993a) has revised the thematic hierarchy, but has kept intrinsic and default classification of grammatical functions, while Her (2010) has kept the thematic hierarchy (56), but has adjusted the criteria for the ±*r*(estricted) and ±*o*(bjective) specifications. The different proposals aim to account for several important generalizations in Chinese, some of which will be discussed below.

(56) Thematic Hierarchy for Mandarin Chinese (Her 2010)
ag > ben > go/exp > inst > pt/th > loc

In terms of the classifications, the [−] values, considered less marked than the [+] values, are thus given a higher position on the hierarchy. Her (2010) also assumes that [−*r*] (unrestricted) is less marked than [−*o*] (non-object-like), given that [−*r*] gfs are not restricted to specific argument roles, Huang (1993a) does not make the same assumption.

(57) Markedness Hierarchy of Grammatical Functions:

a. subj ([−*r*, −*o*]) > obj ([−*r*, +*o*]) / obl$_\theta$ ([+*r*, −*o*]) > obj$_\theta$ ([+*r*, +*o*]) (Huang 1993b)

b. subj ([−*r*, −*o*]) > obj ([−*r*, +*o*]) > obl$_\theta$ ([+*r*, −*o*]) > obj$_\theta$ ([+*r*, +*o*])
(Her 2010)

See also Fu (1993) and Pan (1997) for introductions to LMT published in Chinese journals.

Locative inversion is heavily influenced by considerations at information structure (Bresnan 1989; Dalrymple 2001: 209). It is also known as the presentative or existential construction. Gu (1992, 1997) assumes that most verbs which may participate in the locative inversion in Mandarin are derived from transitive verbs. Pan (1996, 1997) argues that it is necessary to distinguish two types of locative inversion, based on the presence of the aspectual markers *-le* pfv or *-zhe* dur on the verb. Huang et al. (1999) shows that the range of different meanings associated with the locative inversion and the presentative sentences can be accounted for by considering the interaction of constructional and lexical meanings. Cui & Yuan (2020) suggest that existential sentences exhibit features of ergativity.

The challenge that the locative inversion presents to LFG, especially to LMT, is how it is possible to map the locative role, ranked low on the thematic hierarchy, to the most prominent grammatical function subj. Bresnan & Kanerva (1989), based on data from Chicheŵa, propose a special default rule for the presentational focus construction. The rule assumes that the locative phrase bears the focus feature and ensures that a locative [−*r*] argument appears. Bresnan (1994) extends the account to English. Huang & Her (1998), however, shows that the proposal cannot account for the locative inversion in Mandarin, especially in constructions involving three-place predicates, such as *fang* ‘put’:

(58) Mandarin

a. Lisi fang-qian zai zhuo-shang.
Lisi place-money at table-top
‘Lisi placed some money on the table.’

b. qian (Lisi) fang zai zhuo-shang.
money Lisi placed at table-top
‘Money was placed on the table by Lisi.’

c. zhuo-shang (Lisi) fang-le qian.
table-top Lisi place-pfv money
‘On the table was placed some money.’

Crucially, both (58b) and (58c) are treated as locative inversion structures. There is, however, evidence suggesting that (58b), in fact, involves topicalization, but not locative inversion. First, *qian* 'money' is not a locative phrase. Second, the verb in (58b) does not require the presence of the aspectual markers -*zhe* DUR or -*le* PRF, unlike the verb in well-accepted Mandarin locative inversion structures. The preposed NP in (58b) can therefore be treated as a regular topicalized phrase, without further stipulations. See also Lui (2020) for a discussion of the locative inversion in Cantonese.

8 Classifiers and measure words

Mandarin is a textbook example of a numeral classifier language. As a lexical category, numeral classifiers have two subcategories, namely sortal classifiers (C), *aka* classifiers; and mensural classifiers (M), *aka* measure words (Huang & Shi 2016). See (59) and (60) for examples of Cs and Ms, respectively (Her 2012b).

(59) Mandarin

a. san gen xiangjiao
3 CLF banana
'3 bananas'

b. yibai ben shu
100 CLF book
'100 books'

c. shi pi ma
10 CLF horse
'10 horses'

(60) Mandarin

a. san da xiangjiao
3 M-dozen banana
'3 dozens of bananas'

b. yibai xiang shu
100 M-box book
'100 boxes of books'

c. shi qun ma
10 M-herd horse
'ten herds of horses'

C and M consistently appear after a numeral (Num) and before a noun (N) and are mutually exclusive in this position, as only one C/M can be used. It is a near consensus in the Chinese linguistics literature to assign the same phrasal structure to them. The syntactic position is typically called the classifier position. See Jiang et al. (2022) for a summary of syntactic approaches, and Chen et al. (2022) for a summary of semantic approaches to the Chinese classifier system.

Cs and Ms, however, do exhibit some differences (Chao 1968, Her 2017; see also Huang 2015 for an ontological account). In terms of modification, the adjective, whether it is found before or after a C, modifies the head N. (61a) and (61b) therefore have the same meaning. An adjective in a nominal structure with an M, however, modifies the immediately following element. Thus, in (62a), *da* 'big' modifies *xiang* 'box', yielding the meaning 'one big box of apples', while in (62b), *da* 'big' modifies *pingguo,* yielding the meaning 'one box of big apples' (Her 2012b):

(61) Mandarin sortal classifiers
 a. yi da ke pingguo
  1 big CLF apple
 b. yi ke da pingguo
  1 CLF big apple
  'one big apple'

(62) Mandarin mensural classifiers
 a. yi da xiang pingguo
  1 big M-box apple
  'one big box of apples'
 b. yi xiang da pingguo
  1 M-box big apple
  'one box of big apples'

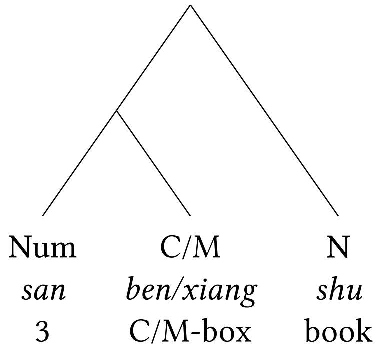
Another difference between Cs and Ms is that the former has the fixed numeral value of precisely *1*, while Ms can be of any value, numerical or non-numerical, except *1*, as shown in (63). In (63), K is a C or M, and k is the mathematical value of K.

(63) C/M distinction in mathematical values
 $[\text{Num}\ \underline{\text{K}}\ \text{N}] = [\text{NUM}\times k\text{N}]$, where K=C *iff* $k = 1$, otherwise K=M.

The LFG account offered in Her (2012b) assigns a left-branching c-structure to C/M, as in (64), consistent with the traditional approach but contra the dominant right-branching structure preferred in recent derivational syntax. See Her

(2017) and Her & Tsai (2020) for arguments from typological as well as Mandarin-internal perspectives. Sample lexical entries of N, Num, C, and M are given in (65).

(64) Unified left-branching c-structure of the classifier construction



(65) Sample lexical entries

a.	*shu*	N	(↑ PRED)=‘BOOK’ (↑ PROFILABLE)={BEN本,CE冊}
b.	*san*	Num	(↑ CARD)=3
c.	*ben*	C/M	(↑ PROFILED)=BEN本
d.	*xiang*	C/M	(↑ PRED)=‘BOX’

Cs and Ms are two subcategories of a single lexical category C/M. Their differences are located in f-structure. CLF in (65c) has no PRED, but M in (65d) does; C, however, has a feature PROFILED, whose value is the essential property each CLF serves to profile, or highlight. A noun can only have one or more of its essential features profiled and may thus co-occur with more than one C, though one at a time as a formal requirement. In (65a), for example, *shu* ‘book’ normally takes the CLF *ben*, but *ce* is also an option, accounted for by the feature PROFILABLE, which takes a set, {BEN, CE}, as its value. The relevant annotated phrase structure rules are given in (66).

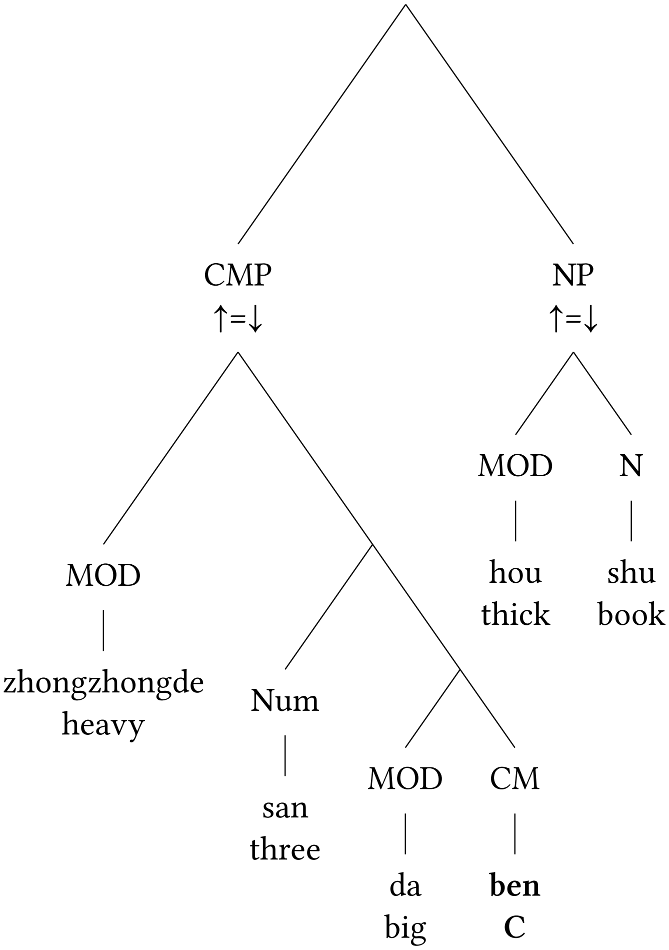
(66) Annotated phrase structure rules for the classifier construction

a. NP ⟶ … C/MP … N
(↓ PRED) ⇒ (↑ QUANTIFIER)=↓ ↑=↓
¬(↓ PRED) ⇒ {↑=↓, (↓ PROFILED) $\in_c$ (↑ PROFILABLE)}

b. C/MP ⟶ … Num … C/M
↑=↓ ↑=↓
((↑ CARD)=1)

The notation ‘A⇒B’ in (66) means ‘if A, then B’. Thus, in a C/MP, if it has PRED, indicating it is an M, then the information goes in a QUANTIFIER function; if it does not have PRED, indicating it is a C, then it serves as a co-head with N and its PROFILED value must be a member of N’s PROFILABLE set of values. The c-structure and f-structure of two nominal phrases with a CLF and an M are given in (67) and (68), respectively.

(67) Mandarin
zhongzhong-de san da ben hou shu
heavy-DE 3 big CLF thick book
‘three heavy big thick books’

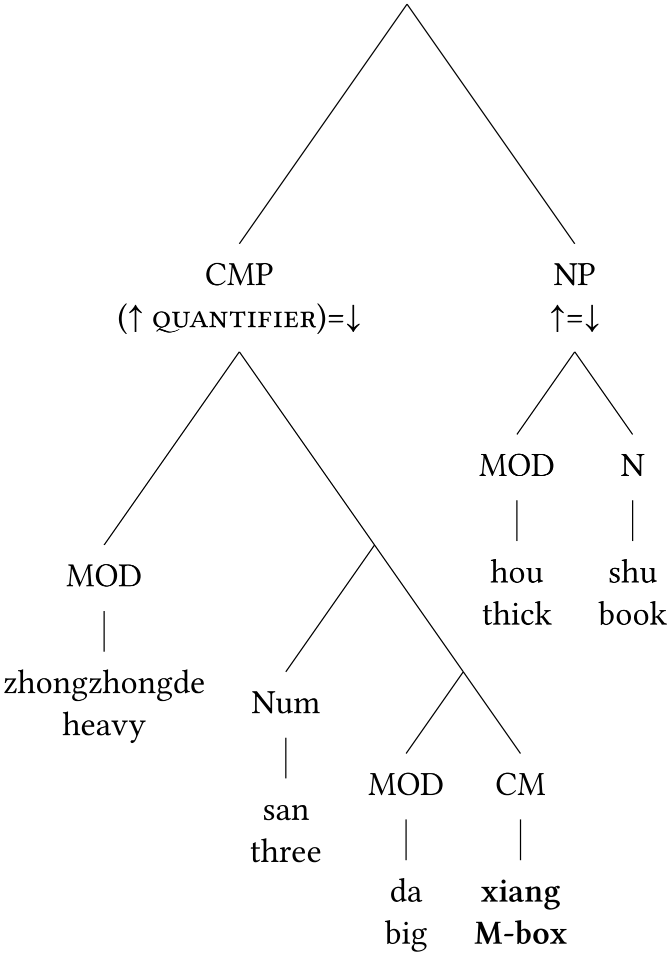


$$\left[\begin{array}{ll} \text{PRED} & \text{BOOK} \\ \textbf{PROFILED} & \textbf{BEN 本} \\ \text{PROFILABLE} & \{\text{BEN 本, CE 冊}\} \\ \text{CARD} & 3 \\ \text{ADJUNCTS} & \left\{\begin{array}{l} [\text{“HEAVY”}] \\ [\text{“BIG”}] \\ [\text{“THICK”}] \end{array}\right\} \end{array}\right]$$

(68) Mandarin

zhongzhong-de	san	da	xiang	hou	shu
heavy-DE	3	big	M-box	thick	book

‘three heavy big boxes of thick books’



$$\begin{bmatrix} \text{PRED} & \text{BOOK} \\ \text{ADJUNCTS} & \left\{\left[\text{“THICK”}\right]\right\} \\ \text{PROFILABLE} & \left\{\text{BEN 本, CE 冊}\right\} \\ \text{CARD} & 3 \\ \text{QUANTIFIER} & \begin{bmatrix} \text{PRED} & \text{‘BOX’} \\ \text{CARD} & 3 \\ \text{ADJUNCTS} & \left\{\begin{matrix} \left[\text{“HEAVY”}\right] \\ \left[\text{“BIG”}\right] \end{matrix}\right\} \end{bmatrix} \end{bmatrix}$$

The parallel architecture of c-structure and f-structure allows Cs and Ms to belong to one syntactic category and (67) and (68) thus share the same c-structure, while their differences are captured in the f-structure, where a CLF serves as a co-head of the nominal construction and an M serves as the head of a quantifier phrase.

See Börjars et al. (2018) for a different proposal for the c- and f-structures of Mandarin noun phrases containing classifiers and measure words, and Huang & Ahrens (2000) for a discussion on kind and event classifiers in Mandarin.

9 Other properties and phenomena

A number of other properties and phenomena are prominent in Chinese as well, and studies of these are available in the very large body of LFG literature on the analysis of Chinese. However, due to constraints of space and scope, we cannot discuss all of these in detail in this chapter. This section will hopefully serve as a pointer to some of these works. The syntax of Mandarin questions has been investigated in Shiu & Huang (1989) and Huang (1993b). Relativization and topicalization phenomena in Mandarin have been studied in Huang (1992), where the author proposes a functional uncertainty analysis (Kaplan & Zaenen 1989). Huang (1988) analyses ‘possessive subjects’ in Mandarin, while Huang (1990) offers an LFG account of possessive-object constructions in Mandarin, showing how these display lexical discontinuity. Chief (1996) explores an LFG account of Mandarin reflexive verbs. Dong (2016) provides an LFG analysis of pronominal binding in Mandarin. Lam (2020) investigates anaphoric and functional control in Mandarin. Che (2014) is a study of particles in Mandarin.

10 NLP applications of LFG in Chinese

LFG has played an important role in the development of Chinese NLP. Joan Bresnan, Ronald Kaplan, Lauri Karttunen and Annie Zaenen visited Taiwan at the dawn of Chinese computational linguistics in 1989 and made lasting impact (Bresnan 1989). One of the immediate outcomes was the Information-based Case Grammar (ICG, Chen & Huang 1990), the first comprehensive grammar of Chinese that incorporated features of both LFG and HPSG. Her et al. (1991) and Her (1995) describe a rule-based commercial machine translation system for English-Chinese, where parsing, transfer and generation are all based on LFG. This system was later acquired by Apptek (https://www.apptek.com/) and expanded to include multiple language pairs and many other NLP applications. Kit (1992, 1993a,b) and Kit & Webster (1992) are also among the earliest studies applying LFG assumptions to parse Chinese. Webster & Kit (1995) describe the use of a 'Chinese-Lexical Functional Grammar (C-LFG)' parser to analyze simple sentences from texts. Sun (2001) outlines the computational implementation of LFG in Chinese. Fang & King (2007) provide an LFG grammar of Mandarin for machine use. Guo et al. (2008) describes LFG-based generation for Chinese, while Burke et al. (2004) and Guo (2009) describe LFG-based Chinese treebanks. Chief et al. (2000) present a corpus-based approach to the analysis of synonyms in Chinese. Jiang et al. (2018) annotate Chinese light verb constructions according to the paradigm of PARSEME, a platform built based on LFG and other theoretical frameworks.

11 Conclusion: LFG and Chinese Linguistics

The assumptions of LFG have been applied to the research on a number of grammatical phenomena in Chinese languages since Huang (1985). A number of LFG-based studies on Chinese have made a significant impact to Chinese linguistics. Huang & Mangione (1985), one of the earliest LFG papers on Chinese, has inspired Huang's (1988) treatment of, and a long debate on, the status of V1 and V2 in the Mandarin resultative verb construction. Interestingly, the V2-as-matrix-verb analysis, initially proposed by Huang & Mangione (1985), is gradually emerging as a possible consensus. Similarly, the functional uncertainty of LFG allows a transparent account of Mandarin long-distance dependencies without abstract levels and movements (Huang 1992). Huang (1993a) first introduced the concept of applicatives to Mandarin, and initiated many interesting discussions in Chinese linguistics in the past 20 years. LFG studies (Huang 1989a, Tan 1991, Her 1991) on the TOPIC and SUBJ functions in Chinese have contributed to the ongoing topic/subject debate in Chinese. LFG studies have also provided crucial insights to the understanding of the *ba* and *bei* constructions in Chinese (e.g. Her 1989, Bender 2000, Her 2009), especially in terms of treating *ba* and *bei* as the main predicate. The seeming dilemma of Chinese compounds displaying lexical non-compositionality and phrasal compositionality (e.g. the separable compounds) can be straight-forwardly dealt with by adopting the assumptions of LFG. This is perhaps one of the topics receiving the most attention in the LFG literature on Chinese, including but not limited to Huang (1990), Huang & Lin (1992), Her (1996, 1997), and Bodomo et al. (2017).

Accounts of Chinese languages have contributed to the development of the LFG framework, too. Shiu & Huang (1989) was one of the first LFG accounts on sentential clitics (e.g. Mandarin question particles). Huang (1992, 1993b) applies the concept of functional uncertainty to account for Mandarin data. Her (2006b) introduces the concepts of interaction and optimality to LMT. Her (2012a,b) provides a full account of the classifier system. Finally, Bodomo (2001) and colleagues' work on Cantonese and Zhuang have added to the typological diversity of LFG research.

Acknowledgments

We thank our reviewers for their constructive comments, which have helped improve the chapter in many ways. All remaining errors are our own.

Abbreviations

Besides the abbreviations from the Leipzig Glossing Conventions, this chapter uses the following abbreviations.

EXP	experiential	PRT	particle
M	measure word	ZAI	marker meaning 'now' or 'at the moment'

Chapter 36

LFG and Slavic languages

Bozhil Hristov
University of Sofia

This chapter provides a survey of LFG work on Slavic languages. It briefly introduces some of the Slavic family's most salient grammatical properties, before outlining how they have been handled in the framework of LFG. The topics include lexical categories and their grammatical features, the morphology-syntax interface, agreement and government, clause structure and information packaging, passivisation, subjectless and impersonal constructions, copular clauses, clitics, negation, distance distributivity, anaphoric control, and coordination. LFG analyses are placed in a wider context, highlighting how they have enhanced our understanding of Slavic, as well as how Slavic has contributed to modifying the formalism of LFG.

To the memory of my grandfather, Metodi Alexandrov,
named after one of the first teachers of the Slavs

1 Introduction and background

1.1 The Slavic languages

Today, the Slavic (or Slavonic) languages are spoken in their heartland of central and eastern Europe, as well as in vast swathes of Asia and various immigrant communities around the world. They all evolved from a common ancestor, Proto-Slav(on)ic/Common Slav(on)ic, itself a variety descended from Proto-Indo-European which can be reconstructed based on the evidence from the attested daughter languages, as well as data obtained from wider comparison across Indo-European (see Comrie & Corbett 1993, Schenker 1993, 1995, Sussex & Cubberley 2006, Berger et al. 2009). The Slavic languages are conventionally divided into

Bozhil Hristov. 2023. LFG and Slavic languages. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 1753–1804. Berlin: Language Science Press. DOI: 10.5281/zenodo.10186030

three main branches according to the splits that occurred after the breakup of the original Slavic speech community in the first millennium AD:

East: Russian, B(y)elorussian (Belarusian), Ukrainian;

West: Czech, Slovak(ian), Polish, Kashubian (Cassubian), †Polabian, Upper and Lower Sorbian;

South: †Old Church Slavonic (Old Bulgarian), attested between the 9th and 11th centuries AD and in many respects close to the common Slavic progenitor, Bulgarian, Macedonian, Bosnian/Croatian/Serbian, formerly also known as Serbo-Croat(ian), Slovene (Slovenian).

In their authoritative description of the family, Comrie & Corbett (1993: 5) note that "in many ways the Slavonic languages form a homogeneous group within Indo-European. They are therefore an ideal area for comparative and typological work." Most LFG work has been done on Russian, Polish, Bulgarian and Bosnian/Croatian/Serbian. Below, I first survey some of the salient grammatical properties of the members of the Slavic family, before exploring how they can be captured and elucidated in the framework of Lexical Functional Grammar.

1.2 Salient grammatical properties of Slavic languages

Some of the major issues which are still at the forefront of contemporary Slavic linguistics, including LFG research, received a pioneering treatment in the foundational volumes on Slavic studies, most notably Miklosich (1862–1875) and Vondrák (1906–1908). Such topics include case, number and gender inflections and their usage, constituent order and information packaging, pro-drop, as well as clitic placement.

1.2.1 Case, number and gender inflections

Slavic languages have a very rich morphology, boasting an elaborate inflectional system, which makes them a conservative group within the larger Indo-European family. The morphosyntactic categories found in Slavic are those typically found in Indo-European. They are primarily encoded by fusional affixes, i.e. with one morpheme marking several grammatical categories, e.g. case, number and gender (see Comrie & Corbett 1993: 6, 14–17, Sussex & Cubberley 2006: Chapters 5 and 6, Berger et al. 2009). As is typical of Indo-European, verbs and nouns are grouped into conjugational and declensional classes.

The Common Slavonic case values inherited from Proto-Indo-European include: nominative (for subjects and predicative subject complements/PREDLINK), accusative (characteristically for direct objects, but also for objects of prepositions, temporal adjuncts, etc.), genitive (for possession and various other relations, also taking over the functions of the IE ablative), dative (typically for indirect objects), instrumental (for means or accompaniment, including with prepositions), locative (for location in space or time, now required by diverse prepositions), and vocative (for direct address). The majority of cases have been preserved more or less intact in the modern Slavic varieties, with the exception of Bulgarian and Macedonian, where case has been almost completely abandoned.[1]

The original three-number contrast between singular, dual, and plural has usually been reduced to a binary opposition between singular and plural, with vestiges of the dual found in all the Slavic languages, though only Slovene and Sorbian retain the dual as a distinct category. The standard Late Indo-European genders of masculine, feminine and neuter find continuation in Slavic, which additionally saw the development and spread of a (masculine) personal subgender, sometimes later extended as animate vs. inanimate (see Browne 1993: 319, 363–364, Rothstein 1993: 696–698, Schenker 1993: 108, Timberlake 1993: 836ff, Kibort 2006: Section 2, Berger et al. 2009). Since gender is a grammatical category, there can be disparities between the grammatical gender of a noun and its semantics – for instance, words denoting humans (e.g. ‘child’, ‘boy’ or ‘girl’) can be grammatically neuter, while face cards can be treated as animate.

The morphosyntactic categories listed above participate in extensive agreement, including subject-verb agreement (normally in person and number, except for some tenses consisting solely of historically participial forms which agree in gender and number, as in (8) below; cf. (24), with person, number and gender agreement in Polish; see further Sussex & Cubberley 2006: 279–280). There is agreement in number, gender, and case (in the languages that have it) between

---

[1] Przepiórkowski & Patejuk (2011, 2012a,b, 2015), Patejuk (2015) and Patejuk & Przepiórkowski (2014a,b, 2018) offer explicitly formalised outlines of case in Polish, addressing various specificities, including the so-called instrumental of predication (cf. Dalrymple et al. 2004: 192 for instrumental predicative complements in Russian). For an LFG take on case in contemporary Russian, consult Neidle (1988), King (1995: Chapter 8), and Bresnan et al. (2016: 422–425). In addition to their main uses, individual cases can possess more idiosyncratic meanings/functions – for instance, direct objects in negated clauses can appear in the genitive rather than the accusative. The fact that essentially the same phenomenon may exist in more than one Slavic language does not guarantee that it operates in the same way across the board: the “genitive of negation” facts in Modern Russian, for example, differ considerably from those in Polish and even from those in earlier Russian, while this characteristic quirk of Slavic grammar is by now virtually extinct in Czech.

dependents inside the NP and the head noun. In an LFG setting, Dalrymple (2001: 146–148) and Dalrymple et al. (2019: 223–225) discuss agreement in gender and number between Russian relative pronouns and their antecedents, while Neidle (1982, 1988) and Bresnan et al. (2016: 402) examine the behaviour of so-called second predicates in Russian, alongside other agreement phenomena. The interaction of inflectional patterns and morphosyntactic features with syntax and semantics sometimes leads to feature clashes and complex resolution rules which have attracted a great deal of descriptive/typological and theoretical interest, including from scholars working within constraint-based frameworks such as LFG and HPSG (see Section 2.2–Section 2.3, as well as Corbett 1983, Huntley 1993: 134–136, Rothstein 1993: 732–734, Timberlake 1993: 865–866).

1.2.2 Constituent order and information packaging

In Modern English, word order encodes syntactic functions like subject (which comes before the verb) or object (characteristically after the verb). Changing the order of constituents either changes the meaning (*Mary kissed John* ≠ *John kissed Mary*, both SVO), or results in ungrammaticality (**Mary John kissed*, SOV). By contrast, all the permutations of S, V and O are permissible in Slavic, even in a language which has lost noun case marking, like Bulgarian:[2]

(1) Bulgarian (personal knowledge)

a. Marija celuna Ivan [SVO]
Marija kissed.3sg Ivan
‘Marija kissed Ivan.’ (neutral)

b. Ivan (go) celuna Marija [OVS]
Ivan (him) kissed.3sg Marija
‘(As for Ivan,) Ivan was kissed by Marija.’/‘It was Marija that kissed Ivan.’/‘It was Ivan that Marija kissed.’ (with the exact interpretation depending on context, stress/intonation and the presence/absence of the optional clitic pronoun *go* ‘him’)

c. Marija Ivan celuna [SOV]
Marija Ivan kissed.3sg
‘It was Ivan that Marija kissed (not somebody else).’ (one possible interpretation)

---

[2] See Rudin (1985: Chapter 2). “Freer” word order is typical of early Indo-European languages and can be attributed to PIE, which might have had SOV as its basic pattern, at the same time allowing various alternative arrangements. Sussex & Cubberley (2006: Chapter 7) and some of the chapters in Berger et al. (2009) provide an overview of Slavic sentence structure, including specific phenomena like passives. While Bulgarian word order is free, major constituents such as NPs have a stricter internal structure and cannot be broken up.

d. Ivan Marija (go) celuna [OSV]
Ivan Marija (him) kissed.3sg
'It was Marija that kissed Ivan.' (one possible interpretation)

e. Celuna (go) Marija Ivan [VSO]
kissed.3sg (him) Marija Ivan
'Marija did kiss Ivan.'

f. Celuna (go) Ivan Marija [VOS]
kissed.3sg (him) Ivan Marija
'Marija did kiss Ivan.'

Note that most of these will be ambiguous out of context without a reduplicated/resumptive object clitic pronoun and/or appropriate intonation. In the absence of evidence to the contrary, preference might be given to SVO interpretations as the most neutral. Case will serve to disambiguate the meaning in the languages that retain case inflections on nouns, such as Russian, Czech, Polish or Bosnian/Croatian/Serbian, barring syncretism in some declensions. While Bulgarian and Macedonian have lost the original Slavic case declensions for nouns, they preserve vestigial case distinctions on pronouns, not unlike English or Romance. Sometimes the ambiguity can be resolved by subject-verb agreement, for instance where the subject and object are not identical in number and/or person (or gender for some participial forms).

Crucially, the sentences in (1a)–(1f) do not differ in terms of the subject and agent (*Marija* in all of them) and the syntactic object/semantic patient (*Ivan*). Thus, unlike in English, word order in Slavic does not encode grammatical relations. Instead, word order serves information-packaging purposes, namely the arrangement of given and new information or the topic and the focus of the message (Comrie & Corbett 1993: 7, 12–14, King 1995).[3] These insights became prominent due to work done by linguists from the Prague School on information packaging in Czech, variously labelled functional sentence perspective, communicative dynamism or topic-comment/theme-rheme structure (see Mathesius 1939, 1947, Hajičová et al. 1998, as well as other representatives of the Prague School listed in Dalrymple et al. 2019: 369–370). Given information, which is shared by the speaker and the addressee, tends to be placed towards the beginning of the

---

[3] Compare Browne (1993: 343–344) for Bosnian/Croatian/Serbian, Huntley (1993: 164–165) for Old Church Slavonic, Rothstein (1993: 723, 726–727) for Polish, Scatton (1993: 222, 234–235), Timberlake (1993: 858–860), Bresnan et al. (2016: 199–207, with references) for Russian, Bulgarian and Macedonian.

sentence, while important new information, i.e. the focus, tends to be placed towards the end of the sentence; this is especially notable in (1b) in the presence of the object clitic, which assumes that *Ivan* is old and familiar information on which the rest of the message can be "pegged" (something like 'As for Ivan, he was kissed by Marija'). Therefore, Comrie & Corbett (1993: 13) conclude that "in a sense the basic word order in most Slavonic languages can be said to be Topic-X-Focus, where X represents material other than the topic and focus (non-focus comment material)." The sentence-initial slot can alternatively be associated with a focused constituent, as in some of the examples/interpretations above, including (1b) in the sense 'It was Ivan that Marija kissed', this time without the object clitic and with stress on *Ivan* (see Section 2.4 for a more precise formalisation). It can thus be generalised that Topic-X-Focus order is the default for statements in written Slavonic, but in spoken varieties clause-initial stress may function as a marker of focus.

This means that it is hard to fit individual Slavic languages into types such as SVO, SOV, etc. SVO is the most frequent and therefore arguably the most basic default (surface) word order across the family, though King (1995) proposes that Russian, and perhaps the rest of Slavic, is underlyingly VSO.[4] The frequency of subject-initial clauses might have to do with the frequency of subjects acting as typical topics (cf. Jaeger & Gerassimova 2002: 210).

1.2.3 Passives and passive-like constructions

Related to organising the informational content of a message are passive constructions, which Slavic builds with a passive participle combined with the auxiliary 'be' (alongside alternative auxiliaries in some varieties). There also exist reflexive constructions with a reflexive marker (clitic or affix) derived from Proto-Slavic **sę* (<IE **s(w)e-*), which sometimes indicate "middle" or passive meanings, as in (2) (see Section 2.5 below; cf. Browne 1993: 333 for Bosnian/Croatian/Serbian, Rothstein 1993: 712–714 and Kibort 2006: Section 3, for Polish).

(2) Bulgarian (personal knowledge)

a. Ivan otvori vratata
   Ivan opened the.door
   'Ivan opened the door.'

---

[4] Suggestions that Bulgarian may have a flat/exocentric S structure, discussed in Section 2.4.2 and Section 3.3, or be a VSO language, can be found in King (1995: 120 fn. 21, 127); cf. Rudin (1985).

b. Vratata se otvori
the.door REFL opened
'The door opened.'/'The door was/got opened.'

Sussex & Cubberley (2006: 369) note that passives are less common in Slavic than in English: while one of the major roles of the passive in a syntactically more rigid language like English is to enable the rearrangement of old/new information in the clause, a natural way to achieve that in Slavic is to use OV(S) word order instead (cf. (1b) and its passive English translation).

1.2.4 Pro-drop and impersonal clauses

Since finite verbs express the number and person of their subjects, unstressed and unemphatic subject pronouns are often omitted, although the individual languages vary in terms of the extent to which they favour so-called pro-drop or zero anaphora (Comrie & Corbett 1993: 7).[5] Subject pronouns may be inserted for special stress and emphasis.

Slavic additionally has genuinely subjectless/impersonal clauses which neutralise the categories of verbal person and number (as well as gender), utilising the default third person singular (neuter) in the absence of a subject (even an implied one), as in (3)–(4), with accusative or dative experiencers (see Scatton 1993: 222, 227, Schenker 1993: 107–108, King 1995: 134–135).

(3) Russian (from King 1995: 18)
Ann-u tošni-l-o.
Anna-ACC be.sick-PST-N.SG
'Anna was [feeling] sick.'

(4) Russian (ibid.)
Mne budet xolodn-o.
me.DAT be.FUT.3SG cold-N.SG
'I will be cold.'

In an LFG context, Dalrymple (2001: 19) adduces syntactic evidence that Russian, unlike English, has bona fide subjectless sentences. Further discussion, also highlighting disputed matters and controversies, can be found in Section 2.6.

---

[5] Cf. Browne (1993: 365–366), Huntley (1993: 175), Rothstein (1993: 742), Scatton (1993: 234), Timberlake (1993: 871–872), King (1995: 17, 21–22, 69), Sussex & Cubberley (2006: 402).

1.2.5 Clitics

Three classes of clitics, inherently stressless words which are unable to stand on their own, can be distinguished in Slavic: proclitics, enclitics and variable clitics, which can be either pro- or enclitics depending on the environment. Proclitics are placed in front of their host (the word/phrase they need to "lean on"), while enclitics follow their host. The position of clitics with respect to other words is fixed and sometimes regulated by complex rules, which (unsurprisingly) differ across the individual members of the family, even when it comes to the distributional restrictions imposed on otherwise cognate items (see further Section 2.8).

Examples of clitics from the material above include the so-called "short" personal pronoun *go* 'him' (3SG.M.ACC) in (1b) (as opposed to the longer/full non-clitic *nego* 'him'), or the reflexive *se* in (2b). Bulgarian *go*, for instance, belongs in the group of variable clitics: it acts as an enclitic on a stressed verb form when the verb form is sentence-initial, (1e); otherwise, *go* is a proclitic which precedes its verbal host, (1d). By contrast, clitics in the closely related Bosnian/Croatian/Serbian are consistently enclitic, forming an accentual unit with the word that precedes them (see Browne 1993: 345–346, Dimitrova-Vulchanova 1999, Bresnan et al. 2016: 427–429, Diesing & Zec 2016, Zec & Filipović Đurđević 2016, for more detail and refinement).

1.2.6 Other phenomena

Apart from the most salient grammatical phenomena of Slavic languages outlined above, the discussion below will feature some additional phenomena that have generated debate in the LFG literature. One such phenomenon is something approximating negative concord/agreement, as in (5), where the negative particle *ne* on the verb appears with other negative forms (see Section 2.9):

(5) Bosnian/Croatian/Serbian (from Browne 1993: 362)
Ni(t)ko nigd(j)e ne vidi nikoga.
nobody nowhere NEG sees nobody
'Nobody sees anybody anywhere.'

Another peculiarity, typical of Russian, is the regular omission of the copula 'be' in the present tense, which will receive more attention in Section 2.7 (see also Timberlake 1993: 861–864, 869, 874). Finally, very little work has been done in LFG on Slavic aspect, a conspicuous feature of verbs across the family. Slavic aspect for the most part has to do with semantics (e.g. completion/incompletion), morphology and syntax, all of which are self-contained modules in LFG, so existing analyses can be imported "wholesale", as noted by an anonymous reviewer, though spelling out the Glue details or the morphology-syntax interface would still be an intriguing and non-trivial task. This work would be unlike transformational work, where aspectual derivation is commonly done in the syntax.

Revisiting the main points from this introduction, Section 2 examines LFG treatments of the major grammatical phenomena in Slavic, beginning with the unit of the word, more specifically lexical categories/parts of speech (Section 2.1) and the morphosyntactic features associated with them (Section 2.2). Section 2.3 then zooms in on agreement and government processes, whereas Section 2.4 outlines how LFG models the structure of the clause. This is followed by brief accounts of specific constructions like passive (Section 2.5), subjectless, impersonal (Section 2.6), and copular (Section 2.7) clauses, clitics and clitic placement (Section 2.8), as well as negation and negative concord (Section 2.9). The final sub-sections are dedicated to distance distributivity (Section 2.10), coordination (Section 2.11), and anaphora (Section 2.12). Section 3 places the relevant LFG research in the context of other frameworks, while Section 4 sums up how LFG has contributed to our understanding and adequate description of the grammar of Slavic languages.

2 LFG analyses of major grammatical phenomena

2.1 Lexical categories and the morphology-syntax interface

This section gives a taste of the rich Slavic inflectional system outlined in the opening of the chapter, highlighting how relevant morphological information can be captured in LFG terms and interfaced with the syntax, especially in cases of discrepancy between them. Having assembled at least partial morphological entries of word forms in this and the following two sections, I then illustrate how they are plugged into the syntax, a topic discussed at greater length in Section 2.4.

Building on typological work by Baerman et al. (2015) and Spencer (2013: 122–123), Dalrymple et al. (2019: 451–453) provide an LFG-based account of mixed lexical categories like Russian *stolovaja* 'dining room, canteen', a lexeme which shares properties of adjectives and nouns. Historically, it derives from an adjective but synchronically it behaves like a noun with a set of adjectival inflections, as illustrated in Table 1, where the paradigm of the deadjectival noun *stolovaja* 'dining room' is laid out side by side with those of the regular adjective *bol'š-oj* 'big' (with a feminine in *-aja*), and the regular feminine noun *lampa* 'lamp'.

Table 1: Nominal and adjectival declensions in Modern Russian (Spencer 2013: 123).

	Noun ‘dining room’	Adjective ‘big’	Noun ‘lamp’
NOM	stolov-aja	bol’š-aja	lamp-a
ACC	stolov-uju	bol’š-uju	lamp-u
GEN	stolov-oj	bol’š-oj	lamp-y
DAT	stolov-oj	bol’š-oj	lamp-e
INS	stolov-oj	bol’š-oj	lamp-oj
PREPOSITIONAL/LOC	stolov-oj	bol’š-oj	lamp-e

In the notation of LFG, a regular adjectival form like *bol’šaja* will be assigned to the M-CAT:ADJ, M-CLASS:REGULAR, with an M-CASE value NOM. These are some of its important morphological properties. The feminine noun *lampa* will accordingly be of the M-CAT:NOUN, M-CLASS:REGULAR, with M-CASE:NOM. Crucially, the mixed lexical category *stolovaja* will have an entry to acknowledge its intermediate status between an adjective and a noun: M-CAT:ADJ (i.e. a word which patterns morphologically as an adjective), M-CLASS:MIXED-A-N (i.e. a mixed category with the syntactic behaviour of a noun), M-CASE:NOM. These so-called m(orphological)-entries are then fed into a mapping rule, which will assign the mixed-category word *stolovaja* with the m-feature M-CLASS:MIXED-A-N to the c(onstituent)-structure category of N(oun) – this is the word-class membership relevant to the syntax. The mapping rule will essentially map the M-CAT:ADJ to the c-structure category N in the presence of the m-feature M-CLASS:MIXED-A-N, or to the c-structure category of A(djective) if the m-feature is specified as M-CLASS:REGULAR. Depending on the mapping, the word forms thus interfaced can in turn be plugged into c-structure trees as N or A terminal nodes, as discussed in more detail in Section 2.4. There have been similar discussions in the specialist literature whether to treat participles as verbal forms or as adjectives, or whether deverbal nouns are actually nouns or verbal forms.

2.2 Concord and index features and mismatched nouns

As noted in Section 1.2.1, Slavic preserves a great deal of its Indo-European morphological heritage, including elaborate declensional patterns. This has prompted a lot of important typological work to do with case, number and gender agreement, most notably by Corbett (1983, 1986, 2006), among others. Material from

Slavic has additionally revolutionised the way agreement is thought of in non-transformational theories like HPSG and LFG. Starting with analyses of Bosnian/Croatian/Serbian cast in the HPSG framework, Wechsler & Zlatić (2000, 2003) propose that there exist two bundles of syntactic agreement features, labelled concord and index, in addition to purely semantic features. Earlier HPSG work likewise recognises AGR/INDEX features, participating in morphosyntactic vs. index agreement (see Czuba & Przepiórkowski 1995, with references, dealing with agreement and case assignment in Polish; consult also Haug 2023 [this volume]).

In Wechsler & Zlatić's model, concord and index both belong to syntax, the former more closely related to morphological declension and the latter more closely reflecting semantics, while semantic properties form a separate category. All the values reside in the lexical entries of individual nouns and generally match, but not always. The motivation behind postulating three separate sets of attributes comes from Bosnian/Croatian/Serbian nouns like *deca* 'children' and *braća* 'brothers', which are said to control feminine singular attributive targets (concord agreement), neuter plural verbs/participles and pronouns (index agreement) and, potentially, masculine plural pronouns (semantic/pragmatic agreement), as in (6), where I illustrate concord agreement within the subject NP and index agreement in the predicate.[6]

(6) Bosnian/Croatian/Serbian (from Wechsler & Zlatić (2003: 51))

Ta	dobr-a	deca	su	doš-l-a.
that.F.SG	good-F.SG	children	AUX.3PL	come-PTCP-N.PL

'Those good children came.'

Figure 1 provides an LFG representation of the features involved in (6), complete with lexical entries which supply the feature values and/or the requirements of individual word forms, alongside a f(unctional)-structure matrix, expressing the functional syntactic relations between the various elements.

---

[6] Being closer to declension, the concord bundle is comprised of case, number and gender, whereas the index bundle, being closer to semantics, includes person, number and gender – note that subject-verb agreement in person and number, visible on finite *su* 'are', must therefore operate with the index bundle (cf. Dalrymple et al. 2019: 69–71). Here, I focus on gender and number. The analysis of the participle ending in *-a* as neuter plural rather than feminine singular is justified in Wechsler & Zlatić (2003, 2012), Dalrymple & Hristov (2010), Hristov (2012, 2013a). Although this is not shown in (6), anaphora between clauses can involve masculine plural pronouns, e.g. *deca…oni* 'they'/*koji* 'who', though *deca* can control feminine singular agreement in the relative pronoun, especially when it appears in cases other than the nominative.

ta ‘that’: (*s* concord gend) = f
(*s* concord num) = sg
dobra ‘good’: (*s* concord gend) = f
(*s* concord num) = sg
deca ‘children’: (*s* concord gend) = f
(*s* concord num) = sg
(*s* index gend) = n
(*s* index num) = pl
došla ‘come’: (*f* subj index gend) = n
(*f* subj index num) = pl

$$f\left[\begin{array}{ll} \textsc{pred} & \text{‘}\textsc{come}\langle\textsc{subj}\rangle\text{’} \\ \textsc{subj} & s\left[\begin{array}{ll} \textsc{pred} & \text{‘}\textsc{children}\text{’} \\ \textsc{spec} & \text{‘}\textsc{that}\text{’} \\ \textsc{adj} & \left\{\left[\begin{array}{ll}\textsc{pred} & \text{‘}\textsc{good}\text{’}\end{array}\right]\right\} \\ \textsc{concord} & \left[\begin{array}{ll}\textsc{gend} & \textsc{f}\\ \textsc{num} & \textsc{sg}\end{array}\right] \\ \textsc{index} & \left[\begin{array}{ll}\textsc{gend} & \textsc{n}\\ \textsc{num} & \textsc{pl}\end{array}\right]\end{array}\right]\end{array}\right]$$

Figure 1: Lexical entries and f-structure for a clause with a mismatched BCS noun (adapted from Dalrymple & Hristov 2010: 189)

Hristov (2012, 2013a) advocates the usefulness of these distinctions in the description of the closely related Bulgarian, which has lost its declensions but nevertheless still exhibits analogous gender mismatches in certain nouns. This feature geometry has been further developed in LFG/HPSG and applied to additional Slavic material by Dalrymple & Kaplan (2000), Przepiórkowski et al. (2002), King & Dalrymple (2004), Dalrymple & Hristov (2010), Hristov (2012, 2013a), and Belyaev et al. (2015). Those publications sketch out a formalised typology of agreement configurations in conjoined and non-conjoined environments, as well as factors which might influence the choice of one pattern over another. Such agreement mismatches have been instrumental in formulating hypotheses about the (non-)distributivity of features in conjoined contexts (i.e. does a requirement hold of every single conjunct), feature resolution (i.e. computing the value(s) of a conjoined phrase based on the values of its constituents), or what acts as the default value.

In sum, this tripartite split into concord, index and semantics has been widely adopted by researchers in the LFG and HPSG community and has generally proved fruitful, though it is still a matter of debate, with some disagreement over whether the bifurcation into two syntactic features, concord and index, is really justified (see Alsina & Arsenijević 2012a,b,c, Wechsler & Zlatić 2012, Hristov 2013a). It remains an outstanding issue for more conclusive future research to determine which features tend to be distributive, resolving or both, as well as their domain(s) of operation. Wechsler (2011), for instance, proposes that predicative adjectives in Bosnian/Croatian/Serbian can exhibit concord, rather than just index, agreement (cf. (6)). The predicative adjective in (7) shows plural (concord) agreement even when the second person plural subject pronoun is used formally for a single addressee.

(7) Bosnian/Croatian/Serbian (Wechsler 2011, quoted in Dalrymple et al. 2019: 79)

Vi	ste	duhovit-i
you.PL	be.PRS.2PL	funny-M.PL

'You (one formal addressee/multiple addressees) are funny.'

In Bulgarian, on the other hand, some predicative participles may oscillate between singular and plural, while predicative adjectives will normally be singular with single-addressee *Vie* 'you.PL' (cf. Sussex & Cubberley 2006: 567 for variation across Slavic).

2.3 Agreement and case assignment in a constraint-based setting

As became apparent in the previous section, agreement is modelled in LFG by relying on the lexical entries of individual word forms, which project information that is then propagated to the f(unctional)-structure – the locus of agreement phenomena in LFG (see Figure 1, as well as Haug 2023 [this volume]). Unlike transformational approaches, where agreement is handled by copying feature values from one node in the syntactic tree to another or by moving items in order for features to be checked, non-derivational constraint-based frameworks like LFG and HPSG tend to assume that two elements which participate in an agreement relation supply partial information about a single linguistic object – a view which amounts to seeing agreement as multiple specifications of compatible feature values by a controller and its target(s) (see Pollard & Sag 1988: 237, Pollard & Sag 1994: Chapter 2, Bresnan 2001: Chapter 8, Dalrymple 2001: Chapter 5, Corbett 2006: 115, Wechsler & Zlatić 2003, Dalrymple & Hristov 2010: 186, Hristov 2012: 24ff, and Haug 2023 [this volume]).

This works very well for Slavic data, especially when it comes to mismatched or underspecified targets and controllers. It is likewise eminently suitable for pro-drop in null-subject languages like Slavic, where the subject controller is often not present, so it would be mysterious where the agreement information on the verbal target was "copied" from (unless one posits "disembodied" features or invisible/underlying elements which are then deleted). These considerations have led LFG and HPSG scholars to reject formalisations of agreement as directional feature copying, favouring instead a view of feature co-specification (with transformational feature checking more in this spirit; see the entry in (16), Section 2.4.2, as well as Section 2.6).

Similarly, case assignment is modelled in LFG via the interaction of the inflectional entries of lexemes, c(onstituent)-structure configurations and the flow of compatible features between c- and f-structure, as in Figure 2 below (cf. Butt 2023 [this volume]). In the spirit of constraint-based grammatical architectures, case specification can be further governed by language-specific constraints, illustrated for Russian in Section 2.4.3. Analysis and LFG notational conventions for case assignment in Polish can be found in Patejuk (2015), Patejuk & Przepiórkowski (2014b), and Patejuk & Przepiórkowski (2017: 337–339), where the authors rely on, inter alia, disjunctive rules to account for the variation between accusative and genitive objects depending on the presence/absence of negation. Przepiórkowski (1999, 2000), Przepiórkowski & Patejuk (2011, 2012a,b), Patejuk (2015) and Patejuk & Przepiórkowski (2014b, 2017, 2018) deal with agreement, structural case assignment and control phenomena in Polish, especially in conjoined and gapped contexts. Case in Slavic is an important and interesting topic, and LFG provides many novel ideas and accounts in this area, for which the reader is referred to the relevant works cited above, as well as early work by Neidle (1982, 1988), or Dalrymple et al. (2009) on indeterminacy (to be revisited in (32) below).

2.4 Constituent structure, the encoding of grammatical functions and information structure

2.4.1 Russian

A contrast was drawn in Section 1.2.2 between languages like English, where word order encodes syntactic functions, and Slavic, where word order serves information-packaging purposes. These divergent typological preferences find a natural reflection in LFG's parallel architecture, which relies on separate modules to represent constituency and word order (c-structure), syntactic functions (f-structure), and discourse functions (i(nformation)-structure). Although separate, all of these modules are appropriately interfaced to constrain each other, so that

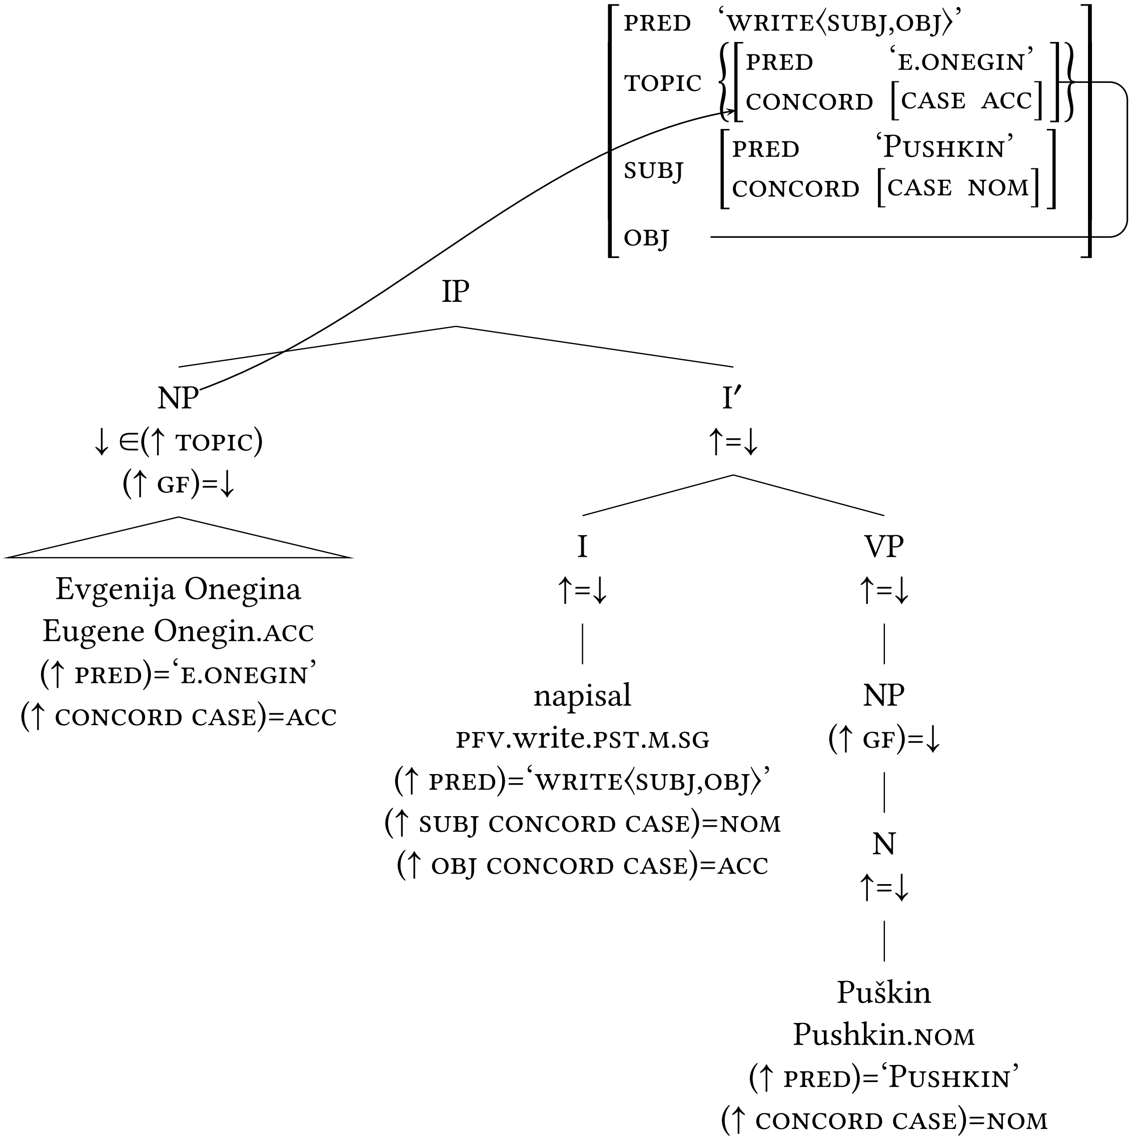

Figure 2: C- and f-structure for a Russian sentence with a topicalised object

accurate description of typologically diverse linguistic systems can be achieved (see Belyaev 2023b,a [this volume]).

English is traditionally assumed to associate the specifier of IP at c-structure with the SUBJ function at f-structure, in line with the generalisation that word order in English encodes syntactic functions. By contrast, King (1995) demonstrates that the specifier of IP in Russian is associated with the discourse functions of topic or focus, in line with the generalisation that word order in Slavic encodes discourse functions, rather than syntactic ones. Formalised in Figure 2, (8) is an example from King (1995: 206) (also cited in Dalrymple 2001: 72 and Bresnan et al. 2016: 203, where the VP is replaced with S, discussed further below).

(8) Russian
‘Evgenija Onegina’ napisal Puškin.
Eugene Onegin wrote Pushkin
‘Pushkin wrote ‘Eugene Onegin’.’ [in answer to the question ‘Who wrote ‘Eugene Onegin’?’]

In Figure 2, the topic value is modelled as a set (indicated with curly brackets), since there can be more than one topic, and the topic is further associated with a grammatical function within the clause, since the topic is simultaneously a constituent which bears a certain syntactic function. In addition, the topic is housed within the f-structure, whereas other authors might prefer to accord it a separate interfaced level (i-structure; cf. King 1995: 216–218, 250–251, King 1997, Dalrymple 2001: 182–183, Patejuk 2015: 22, Bresnan et al. 2016: 98–99, 106, Dalrymple et al. 2019: 121ff., 366–367, 374–394, Zaenen 2023 [this volume]).[7]

Furthermore, note that in Russian and many other languages, all finite verbs appear in I, while in English this phrase-structure position is reserved for tensed auxiliaries, excluding tensed lexical verbs. Only non-finite verbs appear within the VP in Russian, hence finite verbs are of category I and non-finite verbs of category V (King 1994, 1995, Dalrymple 2001: 53–54, 61–62, Bresnan et al. 2016: 102, 104, 109, 147–150, 199–209, Dalrymple et al. 2019: 99–100, 108ff., 119).[8]

The topic in (8) happens to be a noun phrase, but it could have been a different type of constituent. To indicate that pretty much any type of phrase can appear

---

[7] Based on Russian data, King (1997) provides detailed argumentation why a separation between f- and i-structure is necessary. In (8), the focused constituent *Puškin* appears clause-finally – in more emotive and intonationally and/or pragmatically marked contexts, it can be clause-initial, preceding the topic (see further King 1995: 91–92, 153, 207ff.). On the relationship between prosody and constituent structure in Russian and more generally, see King (1995: 128ff.), Dalrymple (2001: 50), Dalrymple et al. (2019: 94–95, 400ff.); for Serbian/Croatian, cf. O’Connor (2006), as well as Bögel 2023 [this volume].

[8] King (1994), King (1995: esp. Chapter 3), Dalrymple (2001: 62–63), Bresnan et al. (2016: 201–203) and Dalrymple et al. (2019: 110) provide empirical evidence for distinct IP and VP constituents in Russian, including coordination and negation, where the negative proclitic *ne* attaches to finite verbs in I, and not to infinitives in V:

(i) Ja [ne bud-u [pisa-t’ pisem]$_{\mathrm{VP}}$ i [čita-t’ knig]$_{\mathrm{VP}}$]$_{\mathrm{I'}}$
I NEG will-1SG write-INF letters.GEN and read-INF books.GEN
‘I will not write letters and read books.’ [negation scopes over both conjoined VPs and unproblematically licenses the “genitive of negation” on both objects]

in the specifier of CP or IP in Russian, King (1995: 171, 197–198) uses the metacategory XP in the following phrase-structure rules (cf. Dalrymple 2001: 94, 96–97, Dalrymple et al. 2019: 141–142, 144–145, including formal statements to the effect that specifiers appear before heads and complements after heads):

(9) Phrase-structure rules for Russian:
CP ⟶ XP, C′
C′ ⟶ C, IP
IP ⟶ XP, I′

XP is in turn spelled out as follows:

(10) XP ≡ {NP | PP | VP | AP | AdvP}

In Figure 2, the topic happens to be the object, but topics in general can be identified with any grammatical function. The functional uncertainty of the grammatical function assigned to the topic constituent can be represented by defining an abbreviatory symbol GF as a disjunction of all grammatical functions (Dalrymple 2001: 139–140, Dalrymple et al. 2019: 205–206):

(11) GF ≡ {SUBJ | OBJ | OBJ$_{\theta}$| COMP | XCOMP | OBL | ADJ | XADJ}

Thus, King (1995: 204) proposes the following annotated phrase-structure rule for an IP in Russian, which can be seen as an instruction on how to build a c-structure tree and assign functions to the constituents:[9]

(ii) *Ja [ne pisa-l-a pisem]$_{\text{I}'}$ i [čita-l-a knig]$_{\text{I}'}$
I NEG write-PST-F.SG letters.GEN and read-PST-F.SG books.GEN
'I did not write letters and read books.' [negation cannot scope over both I's; each I' needs to be negated separately; from King (1995: 42–43, 184ff.)]

It is worth stressing that erstwhile *l*-participles like *(na)pisal(a)* 'wrote' have been reanalysed as finite tensed forms after the loss of the copular auxiliary in what used to be a periphrastic/analytic present perfect construction – now a synthetic preterite in Modern Russian. Analogous IP/VP contrasts exist in Bosnian/Croatian/Serbian and elsewhere in the family (see King 1995: 41, fn. 31).

[9] Note that the rule has GF (rather than GF+ or GF*), which means that the TOPIC has to bear some grammatical function in the same clause, and not an embedded clause (see Dalrymple et al. 2019: 126); cf. Kaplan 2023 [this volume], since many constructions with functional uncertainty allow for long-distance uncertainty (GF*), and not just local uncertainty (GF); see also the discussion of embedding in Bulgarian below, as well as Dalrymple et al. (2019: 223–225) for embedding in Russian relative clauses.

(12) $$\text{IP} \longrightarrow \begin{pmatrix} \text{XP} \\ \downarrow \in (\uparrow \textsc{topic}) \\ (\uparrow \textsc{gf}) = \downarrow \end{pmatrix} \begin{pmatrix} \text{I}' \\ \uparrow = \downarrow \end{pmatrix}$$

King (1994, 1995), Bresnan et al. (2016: 70–71, 204–210) and Dalrymple et al. (2019: 113–114) discuss how further topics can be adjoined in Russian (and Bulgarian), as well as the complexities of scrambling, extraction and the domain of the operation of the principles of function assignment. Having thus presented the basics of Russian phrase structure, in the next section I outline the phrase structure of Bulgarian, which has a great deal in common with Russian, but there are some important typological differences too.

2.4.2 Bulgarian

Similarly to Figure 2 above, since they are focused and hence discourse-prominent elements, *wh*-phrases in Bulgarian will also appear in the specifier of IP (Rudin 1985, Izvorski 1993, Dalrymple 2001: 73).[10] In this respect, Russian and Bulgarian (unlike English) are both discourse-configurational and have in common the fact that the specifier of IP is reserved for arguments with certain (grammaticised) discourse functions (topic and/or focus), irrespective of the syntactic roles those arguments may perform (subject, object, etc.). (13) illustrates a *wh*-question with a sentence-initial topic, formalised in Figure 3.

(13) Bulgarian (from Dalrymple 2001: 73, Dalrymple et al. 2019: 124)
Ivan kakvo pravi?
Ivan what does
‘What is Ivan doing?’

Unlike Russian, which seems to require strict locality of topic extraction according to the rule in (12), the discourse functions in Bulgarian can be related to arguments in an embedded subordinate clause, as shown in (14) and the accompanying Figure 4:

(14) Bulgarian (from Dalrymple et al. 2019: 125)
Ivan kakvo kaza, če pravi?
Ivan what say.PST.2SG COMP does
‘What did you say that Ivan is doing?’

---

[10] On the availability of multiple specifiers with multiple *wh*-constituents in Bulgarian and Russian, consult Rudin (1985: 94ff.), Dalrymple (2001: 57), Jaeger & Gerassimova (2002: 209–210), Dalrymple et al. (2019: 98, 677–678, 694–696), which also feature discussion of long-distance dependencies.

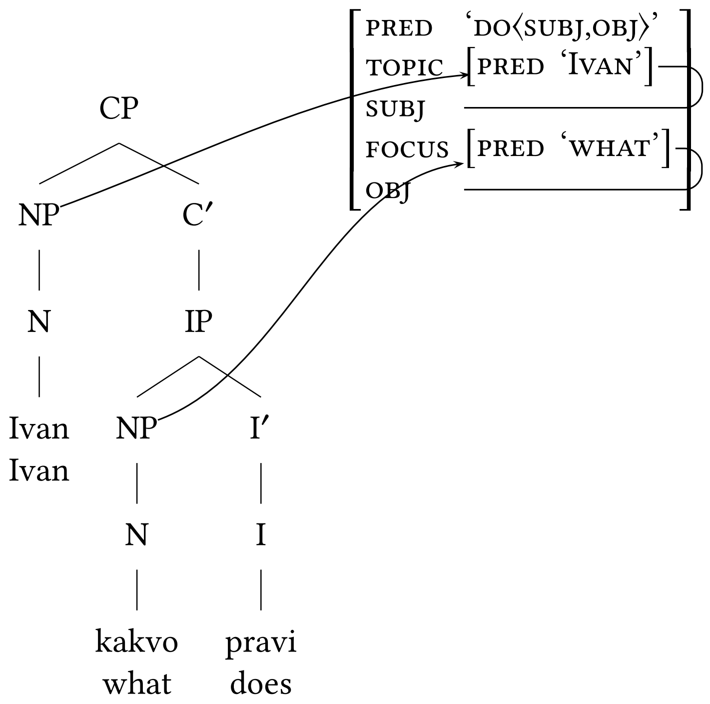

Figure 3: C- and f-structure for a Bulgarian sentence with topic and focus

Despite the immediately apparent family resemblance between Bulgarian and Russian, reflected in the structure of their clauses, there are some subtle differences which are worth noting. Figure 3 and Figure 4 demonstrate that the specifier position of CP is associated with the topic function in Bulgarian and focused *wh*-words appear in the Spec of IP, while in both English and Russian *wh*-phrases are found in the specifier of CP (with Spec of IP reserved for the Russian topic in Figure 2).[11] Thus, although word order in Russian and Bulgarian is reasonably free, scholars have arrived at different conclusions as to the way the constituent structure in each of those two related languages is organised and interfaced with

---

[11] See Rudin (1985: esp. 18ff.), King (1995: esp. Chapters 3, 5 and 10), Dalrymple (2001: 64, 73), Jaeger & Gerassimova (2002: 205ff.), Dalrymple et al. (2019: 124–125), for evidence and argumentation; cf. (1c)–(1d) above, which fit this template of Topic-Focus-Verb very well too. According to other sources, however, either C or Spec of CP does serve as the “landing site” for (certain) question words in Bulgarian (see Rudin 1985: 83ff. and King 1995: esp. 56–60, 120ff., 247–248 for a panoply of proposals, also featuring some discussion of other Slavic varieties). It likewise remains an open question how one should best represent sentences in colloquial Russian which contain non-initial *wh*-words, e.g. *Ivan čto skazal?* ‘What did Ivan say?’, which matches the surface order of the Bulgarian interrogative in (13) (cf. the comments about additional topic adjunction in the previous section).

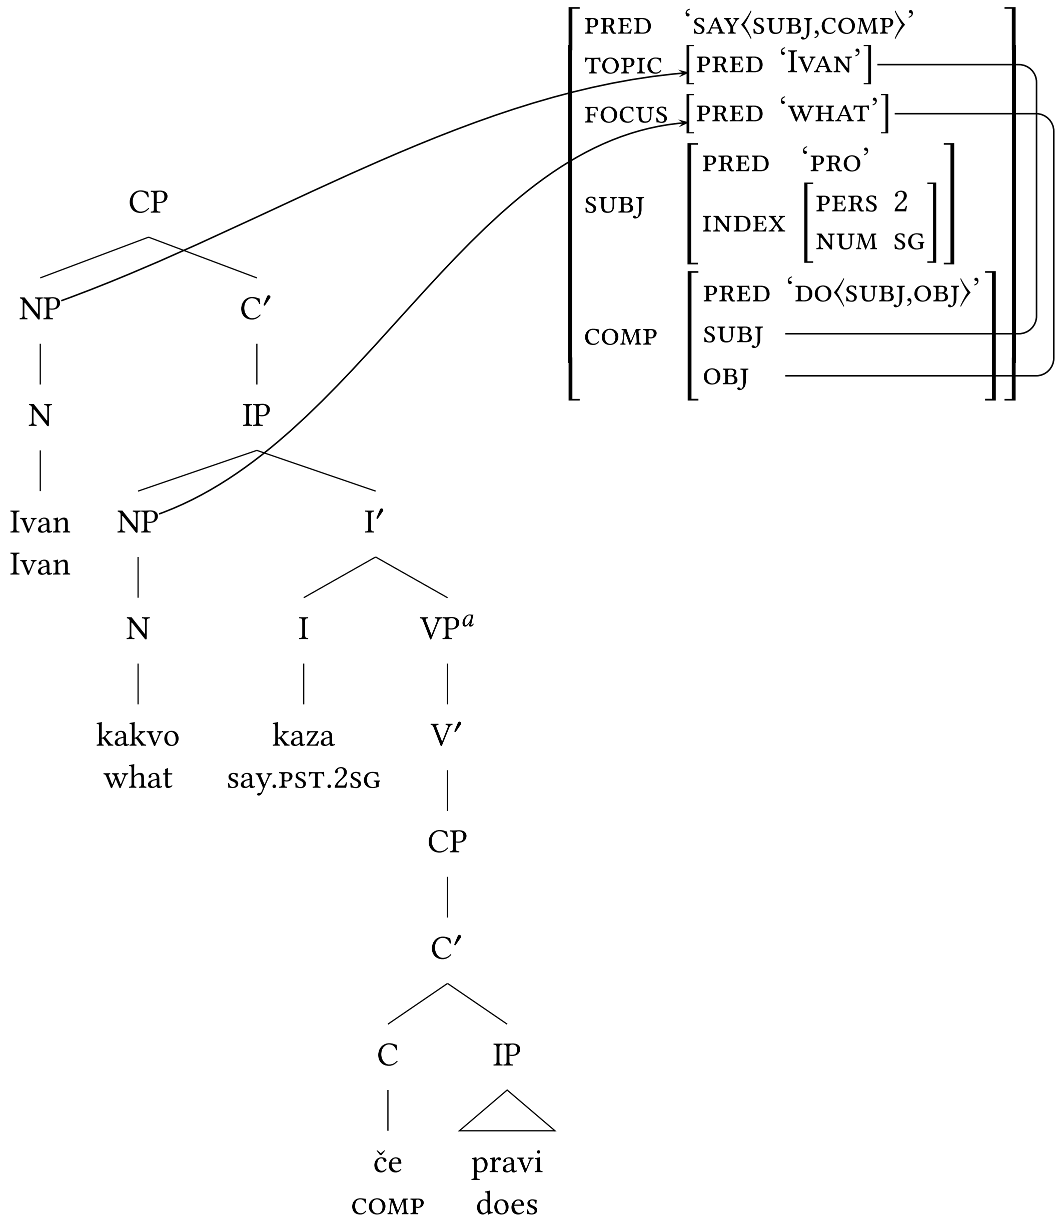

Figure 4: C- and f-structure for a Bulgarian sentence with embedding

---

[a] The VP and V’ might host the non-finite form in a periphrastic construction like the viable Bulgarian perfect *si kazal* ‘have said’ (see footnote 8 for finiteness and *l*-participles). The VP and V’ nodes have been copied along with their labels from the original source, but the reader should additionally consult the phrase-structure rules and the discussion of (reasonably innocuous) inconsistency below.

the other levels of representation, most notably the structure of discourse. It remains for future work to subject these conclusions to further empirical and theoretical scrutiny and to extend them to the rest of the family.[12]

Another important point specific to LFG is the optionality of c-structure constituents, including heads. For example, the VP in Figure 2 does not dominate a head V node, since the finite verb in Russian appears in I, and Figure 3 is missing the head of CP, since the sentence contains no complementiser. Specifiers are also optional in LFG, so if there are no appropriate topicalised or focused constituents, those slots too will remain unoccupied (see King 1995: 171–172, Dalrymple 2001: 60, 63, Dalrymple et al. 2019: 107–108).

As pointed out in Section 1.2.2, Bulgarian is cross-linguistically unusual in that it allows free word order even though it has lost its nominal case inflections, with only vestigial case forms of pronouns. In this way, Bulgarian and Macedonian stand out typologically among the members of the Slavic family and beyond. Quite frequently, the syntactic functions of subject and object can be identified by relying on subject-verb agreement and/or clitic doubling. There are situations, however, where there are no morphosyntactic clues as to the functions the arguments in a clause will perform – then a phrase may be assigned any of the grammatical functions selected by the predicate, depending on context and/or world knowledge (Rudin 1985, Dalrymple 2001: 133–135, Dalrymple et al. 2019: 184–189).

I will now proceed to first outline some general phrase-structure rules for Bulgarian, followed by a sample entry of a verb, which forms the core of the clause and assigns roles to its arguments. I will then illustrate three possibilities for clauses with or without morphosyntactic clues as to the assignment of syntactic roles. Finally, I will compare the Bulgarian system to those of members of the family which retain case declensions.

In line with the assumption that the specifier of IP is associated with the discourse function of focus in Bulgarian, Dalrymple (2001: 134) proposes the following phrase-structure rules. The NP daughter of IP is assigned the focus discourse function and in addition will bear a grammatical function at f-structure too (GF). As in Russian, there is no requirement as to what this grammatical function will be (cf. the discussion of GF vs. GF*, which might be needed in the context of embedding; see further Rudin 1985: esp. Chapter 7, as well as the slightly updated notation in Dalrymple et al. 2019: 185).

---

[12] See Patejuk (2015) and Patejuk & Przepiórkowski (2017: 329–330, 340–341) for similar proposals regarding the clause structure of Polish, notably with a suggested flat IP.

(15) Annotated phrase-structure rules for Bulgarian

$$\begin{array}{lll}
\mathrm{IP} & \longrightarrow & \left(\begin{array}{c}\mathrm{NP}\\ (\uparrow \textsc{focus}){=}\downarrow\\ (\uparrow \textsc{gf}){=}\downarrow\end{array}\right) \left(\begin{array}{c}\mathrm{I}'\\ \uparrow{=}\downarrow\end{array}\right)\\
\mathrm{I}' & \longrightarrow & \left(\begin{array}{c}\mathrm{I}\\ \uparrow{=}\downarrow\end{array}\right) \left(\begin{array}{c}\mathrm{S}\\ \uparrow{=}\downarrow\end{array}\right)\\
\mathrm{I} & \longrightarrow & \left(\begin{array}{c}\mathrm{Cl}\\ (\uparrow \textsc{obj}){=}\downarrow\end{array}\right) \left(\begin{array}{c}\mathrm{I}\\ \uparrow{=}\downarrow\end{array}\right)\\
\mathrm{S} & \longrightarrow & \left\{\begin{array}{c|c}\mathrm{NP} & \mathrm{V}\\ (\uparrow \textsc{gf}){=}\downarrow & \uparrow{=}\downarrow\end{array}\right\}^{*}
\end{array}$$

In essence, these annotated rules are similar to those operative in other languages which allow relatively free word order, such as Warlpiri or Latin (cf. Nordlinger 2023 [this volume]). Naturally, these phrase-structure rules are only a fragment of a fuller grammar and will need to be elaborated and fine-tuned in order to attain more comprehensive coverage of Bulgarian syntax. The diagrams and the phrase-structure annotations in this section demonstrate that there is still some inconsistency within and between the various LFG publications, so more uniformity would be desirable in future work (cf. the VP in Figure 4 to the S here, among other small details, e.g. finite verbs labelled as V rather than I in some of the sources). Nevertheless, this is a good starting point illustrating what the skeleton of a Bulgarian clause looks like. According to the rules in (15), the desired freedom with which the constituents are arranged is achieved with the help of the exocentric S node, which here supersedes the VP from the earlier diagrams and can contain NPs with any grammatical function preceding or following the verb (cf. Dalrymple 2001: 64–67, 77–78, Dalrymple et al. 2019: 112–114).[13]

---

[13] The S rule licenses any number of NPs or Vs in any order, but having more than one lexical/main/full verb will lead to a clash at f-structure (two different semantic PREDs in the same clause contributed by each of the two verbs; cf. Section 3.1). So the phrase-structure rule will give too many possibilities (in particular, it will allow any number of verbs), but these will be filtered out by f-structure constraints (assuming that all lexical verbs contribute a semantic PRED– this rule will allow two verbs, as long as one of them is auxiliary-like and contributes only grammatical features, while the other contributes the semantic PRED) (M. Dalrymple, p.c.). Similarly, the NPs will have to be subcategorised for by the verb, which prevents the proliferation of NPs at will. As noted above, other LFG work offers alternative treatments. Jaeger & Gerassimova (2002: 201–202), for instance, postulate the following flat unordered VP phrase-structure rule for Bulgarian (see further Section 3.3):

(i) $$\mathrm{VP} \longrightarrow \left(\begin{array}{c}\mathrm{XP}\\ (\uparrow \textsc{gf}){=}\downarrow\end{array}\right), \left(\begin{array}{c}\mathrm{PP}\\ (\uparrow \textsc{obj2}){=}\downarrow\end{array}\right), \begin{array}{c}\mathrm{V}'\\ \uparrow{=}\downarrow\end{array}$$

Moving on to the syntactic core of the clause, the following is the lexical entry for the finite verb form *celuna* '(he/she) kissed', appearing as an I terminal node in tree diagrams:

(16) Lexical entry for a Bulgarian verb

celuna I (↑ PRED) = 'KISS<SUBJ,OBJ>'
((↑ SUBJ PRED) = 'PRO')
(↑ SUBJ INDEX PERS) = 3
(↑ SUBJ INDEX NUM) = SG
(↑ SUBJ CONCORD CASE) = NOM
(↑ OBJ CONCORD CASE) = ACC

In addition to stating the subject's person, number and case properties, this entry contains an *optional* equation which specifies a pronominal value ('PRO') for the semantic PRED of the verb's subject. This is LFG's way of capturing pro-drop – this equation kicks in only if there is no overt subject and the information about it comes solely from the features marked on the verb (cf. Section 2.6; Bresnan et al. 2016: 59, 358, 440; Toivonen 2023 [this volume]). However, for a transitive verb like *celuna* '(he/she) kissed', either an overt object phrase or an object clitic pronoun must obligatorily appear, because no PRED value is specified for the object of the verb.

This lexical entry and the phrase-structure rules can now be combined to generate a clause. In (17), the personal names *Ivan* and *Marija* are not marked for case, so both of them are compatible with either nominative or accusative specifications. As before, the metavariable GF in Figure 5 represents any grammatical function – this metavariable is arbitrarily instantiated to SUBJ for *Marija* and OBJ for *Ivan* based on the context or extra-linguistic knowledge (see Rudin 1985: esp. 15–16, Dalrymple 2001: 134, 136). For a sentence like this, language users cannot appeal to phrase-structure position, case marking or agreement to disambiguate the syntactic roles of the two arguments, though SVO might be strongly preferred out of context (cf. (22) and Section 1.2.2).

(17) Bulgarian
Ivan celuna Marija
Ivan kiss.PST.3SG Marija
'It was Ivan that Marija kissed.'

Things are different in (18), which furnishes morphosyntactic clues to the assignment of grammatical functions. Here, the clause-initial FOCUS NP is plural,

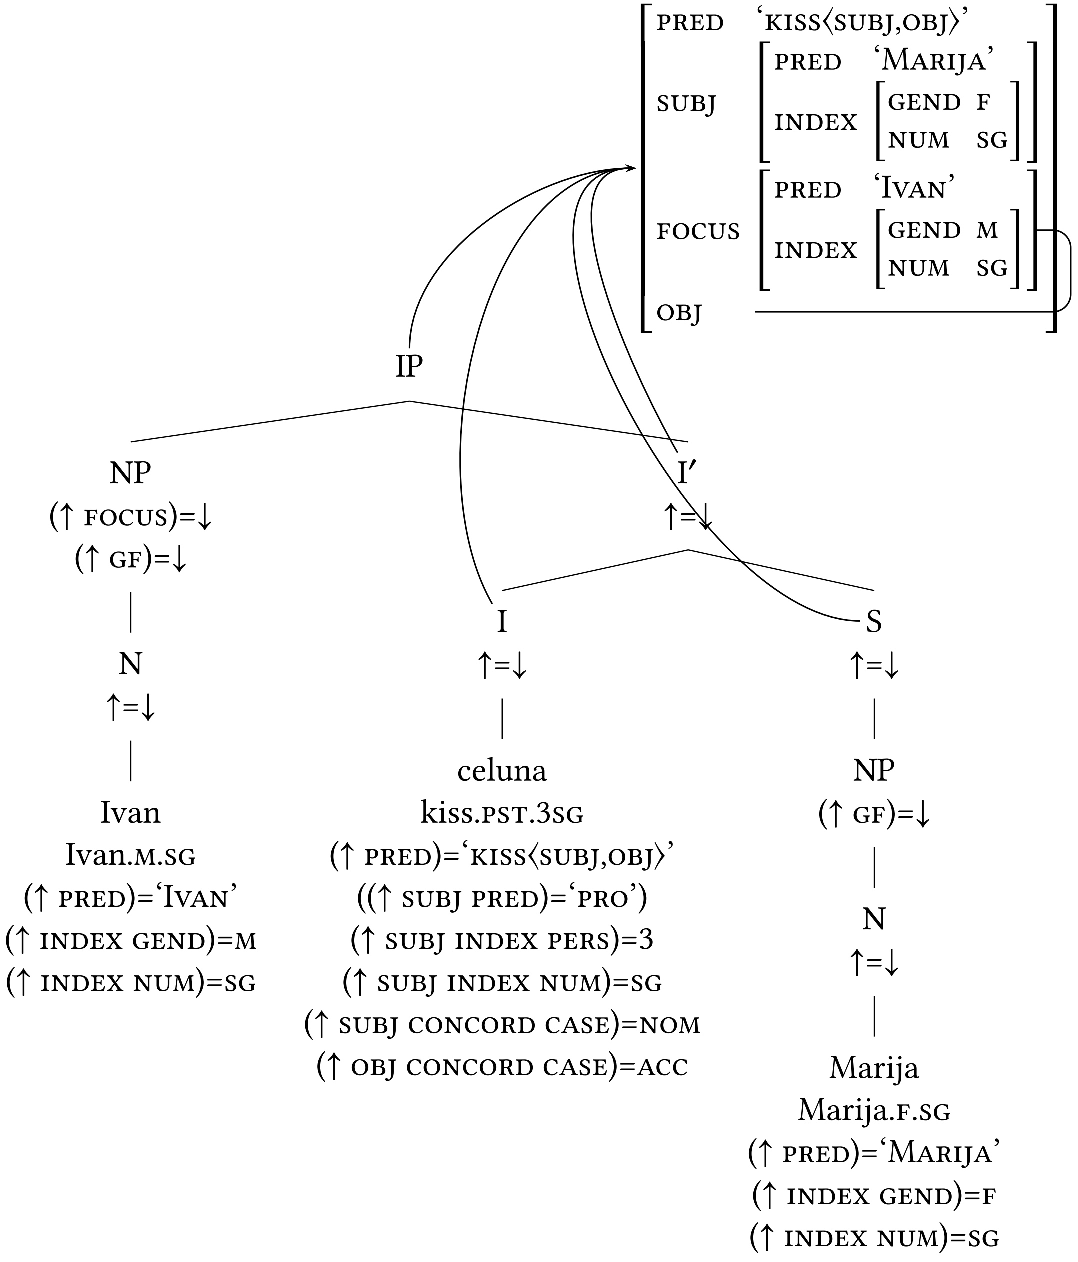

Figure 5: C- and f-structure for an ambiguous sentence in Bulgarian

so the subject must be *Marija* because the verb shows unambiguous third person singular agreement with its subject (consult Rudin 1985: 15, Dalrymple 2001: 137).

(18) Bulgarian
Deca-ta celuna Marija
children.PL-DEF kiss.PST.3SG Marija
'It was the children that Marija kissed.'

Apart from subject-verb agreement, disambiguation can also be achieved by doubled/reduplicated object clitics, as in (20), which relies on the following lexical entry for the clitic pronoun *go* 'him':[14]

(19) Lexical entry for a Bulgarian object clitic pronoun

go ((↑ PRED) = 'PRO')
(↑ INDEX PERS) = 3
(↑ INDEX GEND) = M
(↑ INDEX NUM) = SG
(↑ CONCORD CASE) = ACC

If no full object NP is available, the semantic PRED value for the object function will be contributed by the object clitic. Since the PRED of this clitic is optional (enclosed in parentheses), *go* can unproblematically appear even when the object function is filled by a masculine NP like *Ivan*, but not a feminine NP like *Marija*, which would be incompatible in terms of gender (see Dalrymple 2001: 135, 138; cf. Section 2.8 and Alsina 2023 [this volume]).

(20) Bulgarian
Marija go celuna Ivan
Marija him.OBJ.CLITIC kiss.PST.3SG Ivan
'Marija kissed Ivan.'/'It was Marija that kissed Ivan.' (with the exact emphasis depending on context and prosody, so Marija could be a focused element or play another role at information-structure)

Note that the overtly marked case of *go* 'him' appears in the f-structure for the non-case-marked *Ivan* because the two c-structure nodes (the clitic *go* and the N *Ivan*) correspond to the same f-structure, with the information from each node in the tree diagram fed into the f-structure that they share (cf. Dalrymple 2001: 74–75, Bresnan et al. 2016: 48). Without providing a separate semantic PRED value (which would go against LFG's Consistency Principle), the clitic in Figure 6 effectively supplies a case value for the caseless noun it agrees with.

---

[14] See Rudin (1985: 17), as well as Jaeger & Gerassimova (2002), on the interaction between word order, information structure and (topic-marking) object clitics.

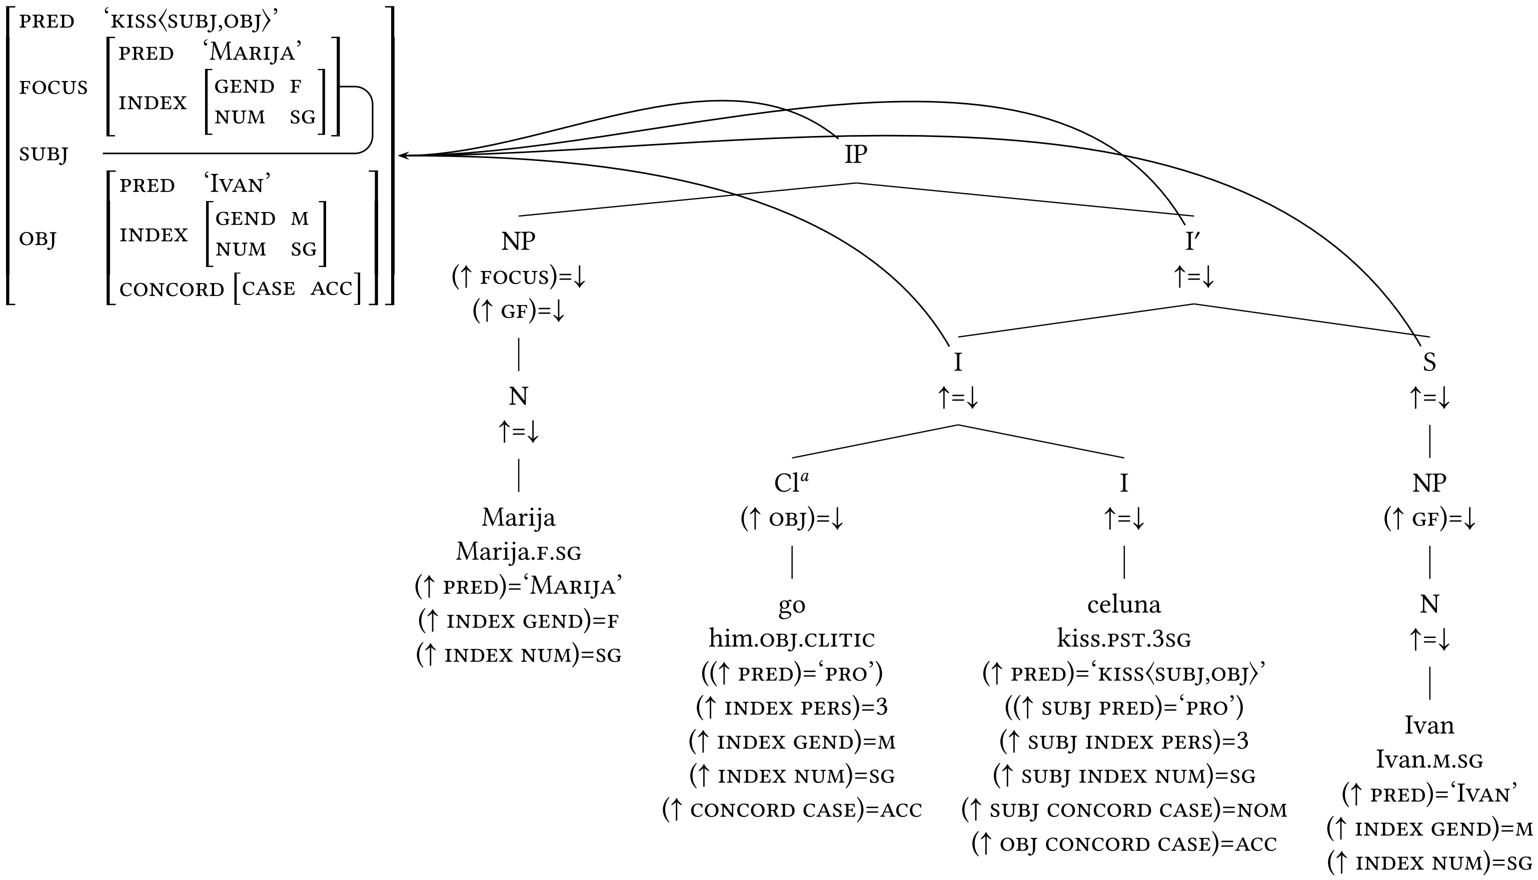

Figure 6: Disambiguation with clitics in Bulgarian

---

[a] Alternatively, the object clitic could be represented as a non-projecting noun – see Dalrymple et al. (2019: 188) and Section 2.8.

2.4.3 Slavic in general

The situation in the Slavic languages with healthy case-marking on nouns, such as Russian, Ukrainian, Czech, Polish or Bosnian/Croatian/Serbian, will be very similar to that in Bulgarian. What Bulgarian and Macedonian achieve with clitics is achieved with case inflections in the rest of the family.[15] The unambiguous case values normally contributed by each nominal argument serve to uniquely identify that argument's syntactic function, much like a clitic in Bulgarian/Macedonian (cf. Figure 2 and Figure 6). The case principles of function specification in Russian can be formulated as follows:

(21) Case principles of function specification in Russian (from Bresnan et al. 2016: 70–71, 203–205)
(↓ CASE)=NOM ⇒ (↑ SUBJ)=↓
(↓ CASE)=ACC ⇒ (↑ OBJ)=↓

These annotations state that if the case of a node is nominative, it will serve as the subject of the construction that contains it. Conversely, if the case of a node is accusative, it will serve as the object of the matrix construction. Naturally, similar statements will be needed for the additional functions/meanings of cases. These are morphological means of function specification which are independent of c-structure position (the latter would be needed for function specification in a configurational language like English).[16]

In circumstances of syncretism, where case distinctions collapse, the assignment of syntactic functions will of necessity proceed randomly or depending on the wider context, world knowledge and/or subject-verb agreement, much as in Bulgarian/Macedonian. In (22), neither noun distinguishes nominative from accusative.

(22) Russian (from Comrie & Corbett 1993: 14)
Mat' ljubit doč'
mother.NOM/ACC loves daughter.NOM/ACC
'The mother loves the daughter.'

---

[15] An important difference is that clitics are arguably head-marking on the verb, while case is dependent-marking on the nominal arguments of the verb – see Jaeger & Gerassimova (2002), Bresnan et al. (2016: 113–115, 205–207).

[16] Consult Neidle (1988), King (1995: esp. Chapter 8), and Bloom (1999), for the syntactic distribution of Russian cases from a general LFG perspective, including different methods of case assignment (configurational, grammatical/functional, lexical, and semantic). Przepiórkowski & Patejuk (2011, 2012a,b) and Patejuk (2015) offer discussion of Polish. For English, see Hristov (2012, 2013b).

Although (22) is syntactically ambiguous in the same way as (17), an SVO interpretation might be preferred as the most neutral out of context (see Jakobson 1936, Comrie & Corbett 1993: 14, King 1995: 2 fn. 2, Sussex & Cubberley 2006: 319, 406–407). In spoken language, intonation will normally dispel the ambiguity, as noted in seminal monographs by Yanko (2001, 2008). LFG's parallel architecture is perfectly suited for handling such phenomena where the interplay between syntax, morphology and prosody is not a trivial one-to-one correspondence.

2.5 Passives and related constructions

Instead of being considered a syntactic transformation, the passive is seen in LFG as a lexical operation/alternation in the argument structure of a verb. Argument structure itself is a separate module in the LFG architecture which maps onto the morphology and the syntax – there is an association between thematic/semantic roles, argument slots and syntactic functions, as in (23) (cf. Section 2.1; Kibort 2007; Bresnan et al. 2016: Chapter 3, 76–79; Dalrymple et al. 2019: 340–345; Findlay et al. 2023 [this volume]).

(23) Argument structure of a Polish transitive verb

SUBJ OBJ
| |
wyłał ‘spilled < __ , __ >’
| |
AGENT THEME

In the passive and some related constructions, the thematically highest argument, which is otherwise aligned with the syntactic function of subject, is suppressed or demoted in the argument structure, and hence unavailable for linking to the subject function in the syntax. Therefore, the next highest argument compatible with such a function is mapped/promoted to SUBJ, which ties in well with the general descriptive intuition about what passivisation accomplishes.

Apart from passives proper, Kibort (2001, 2004, 2006, 2007, 2012) discusses similar alternations which exhibit divergent mappings between the argument structure and the syntactic component, as in the following pair of sentences (cf. Section 1.2.3):

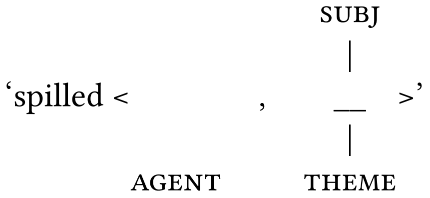
(24) Polish (from Kibort 2012: ex. 14, also cited in Dalrymple et al. 2019: 343)

a. Tomek wylał zup-ę
Tomek(M)[NOM.SG] spilled[3SG.M] soup(F)-ACC.SG
‘Tomek spilled the soup.’

b. Zup-a wylał-a się
soup(F)-NOM.SG spilled-3SG.F REFL
'The soup spilled.'

Kibort (2001, 2007, 2012) asserts that the transitive and reflexive versions of 'spill' have two distinct lexical entries, based on different argument structures, though of course both thematically entail a spiller agent and a spillee patient/theme. The transitive one has an agent (Tomek) assigned to the subject role and a patient/theme (the soup) which is realised as the object, as in (23) above. The reflexive 'spill', by contrast, has no core argument position with which the agent can be associated (since it expresses the event affecting the patient/theme without specifying the cause), so the sole patient/theme argument is mapped to the subject role:

(25) Anticausative in Polish (based on Kibort 2001: ex. 43: Kibort 2012: ex. 16)



If the agent is mentioned, it will appear as a secondary/oblique object (a non-volitional human participant or perhaps a maleficiary) or as an optional adjunct – the former scenario entails demotion, while the latter entails suppression of the agent argument. Although they come up with a somewhat dissimilar formal proposal, Patejuk & Przepiórkowski (2015) likewise note that reflexive *się*, rather than being a legitimate reflexive pronoun, here just indicates that the verb has been detransitivised (cf. Schenker 1985; a similar point is made in pioneering generative papers on Bulgarian, Walter 1963a,b, for which see Venkova 2017, as well as in traditional/transformational descriptions, e.g. Bojadžiev et al. (1999: 604). Kibort (2012) labels such "anticausative" operations as lexical detransitivisers which, according to her, delete the first core argument from the valency frame (though they do not obliterate the corresponding semantic participant).

Kibort (2007, 2012) claims that the passive proper is different from such reflexive anticausative constructions in that it does not suppress/erase the agent argument (thereby relegating it merely to a potential adjunct role in the syntax), but only changes the agent's argument-structure specifications, so that it is linked to a non-subject syntactic function, such as an oblique argument (though it then ought to be stipulated that such arguments are optional).

Unlike in English, even intransitive verbs can be passivised in Polish and elsewhere in Slavic, resulting in an impersonal construction (see Kibort 2001, 2012).

Essentially the same account is available for such intransitive impersonals, whereby the agent subject in the active is altered in terms of its argument specifications so that it is forced to map onto an oblique in the passive (if it appears at all). As a result, the sole (optional) argument of a passivised intransitive verb like *palić* in (26) is not realised as SUBJ and the clause is truly subjectless – which takes us to the topic of the next section.[17]

(26) Polish (from Kibort 2006: ex. 55; also cited in Dalrymple et al. 2019: 344)
Wchodzi-sz i czuje-sz, że był-o palon-e.
come.in-2SG and smell-2SG that was-3SG.N smoke.PTCP-N.SG
'You come in and you can smell that there has been smoking (here).'

Kibort's demarcation of fine distinctions between various possible interfaces amounts to suggesting that meaning-preserving/morphosyntactic operations like the passive interfere only with the argument-to-function mapping, whereas other, morpholexical and morphosemantic, meaning-altering processes (e.g. the anticausative) additionally affect the lexical and/or semantic tiers of representation of the predicate. These intriguing predictions arising from LFG's modularity have a bearing on describing in greater depth the nature of Slavic argument alternations, more of which are discussed in Kibort's work.

2.6 Pro-drop, subjectless and impersonal constructions

Many linguistic theories include a stipulation that all predicates must have subjects. This is dubbed the Subject Condition in LFG, the Final 1 Law in Relational Grammar and the Extended Projection Principle in Chomsky's (1981) generative framework (see Bresnan 2001: 311, Kibort 2001, Dalrymple et al. 2019: 21). In clauses with pro-drop, the subject has simply been omitted but it can be recovered based on the agreement morphology of the verb. Pro-drop is a widespread phenomenon in Slavic, as noted in Section 1.2.4. In theories where syntactic functions are defined positionally and equated with phrase-structure configurations, pro-drop is usually regarded as a phrase-structure operation – either the transformational deletion of a pronoun or the licensing of a phonologically null con-

---

[17] Alternatively, the agent might be said to potentially surface as an adjunct rather than an oblique argument, if one adopts a suppression as opposed to a demotion account of passivisation. The exact status of these agents remains unsettled, as does the subtle distinction between suppression and demotion. For more detail, including the overarching principles of LFG's Lexical Mapping Theory and the notational technicalities, consult Kibort (2001, 2007) and Findlay et al. 2023 [this volume]. Passivisation is discussed in relation to raising by Kibort (2012) and Patejuk & Przepiórkowski (2014a), who see the auxiliary as a raising main predicate taking the passive/resultative participle of the lexical verb as its complement.

stituent which represents the pronominal argument in the tree diagram. By contrast, in the grammatical design of LFG pro-drop involves the *functional* specification of a pronominal argument by a head – in our case, the verbal head of the clause specifies a pronominal value for its subject argument, as in (16), which entails the (potential) absence of an overt subject pronoun from the phrasal structure (see Kibort 2006, Bresnan et al. 2016: 154 fn. 4, Toivonen 2023 [this volume]). Still, sentences with pro-drop have a (covert) subject, which is represented in LFG's more abstract f-structure, as in Figure 4. Therefore pro-drop does not violate the Subject Condition.[18]

While the Subject Condition holds in English and numerous other languages, it has been argued that certain languages do admit genuinely subjectless sentences. Kibort (2006, 2012) discusses Polish constructions she claims to be truly subjectless. They comprise a small class of inherently impersonal predicates, as in (27) below, or intransitive predicates which have undergone passivisation, as in (26) above (cf. Dalrymple et al. 2019: 22).

(27) Polish (from Kibort 2006; also cited in Dalrymple et al. 2019: 22)

Słychać	ją	/ jakieś	mruczenie
hear	her.ACC	some.N.ACC	murmuring.N.ACC

'One can hear her/some murmuring.'

Formally, the verb in (27) is identical with the infinitive, so there is no agreement morphology on this non-finite form which could be said to introduce subject features (as in pro-drop). It has long been recognised in traditional descriptive grammars of Slavic that no subject can be reconstructed for such clauses. As noted by Kibort (2006: §4.1), those defective verbs do not have even a "covert" subject which could participate in syntactic control or reflexive binding. The impersonal clauses from Section 1.2.4, with default third person singular (neuter) agreement on the predicate, are also traditionally regarded as truly subjectless, i.e. clauses which cannot have an overt subject, so the Subject Condition might not be universal in the face of this Slavic data.[19]

---

[18] King (1997) also shows how lexical entries for verbs specifying a PRO value for their subjects can be further annotated with the TOPIC discourse status typical of such elided elements.

[19] However, Kibort (2006) treats Polish weather constructions and impersonals involving adversity or physical/psychological states as special instances of subject ellipsis/pro-drop, contrary to the traditional view whereby they lack a subject. The reader can find a more elaborate classification of types of subjectlessness in Kibort (2006). In another strand of research, verbs with non-nominative arguments like Russian *menja tošnit* 'I feel sick' have sometimes been analysed as having "non-canonical subjects", though this too remains a matter of debate. The same goes for the status of "genitive subjects" in negative constructions (see Timberlake 1993: 868ff., with references).

2.7 Copular constructions

English and many other languages, including members of the Slavic family, require the presence of a copular/link verb in copular clauses. Russian, on the other hand, famously has copular constructions with no overt copula, as pointed out in Section 1.2.6 and illustrated in (28). The c-structure of a Russian verbless clause can be represented as in Figure 7, with a headless IP (Dalrymple et al. 2019: 191; cf. Section 2.4.2 and Section 3.1 for headlessness in LFG).

(28) Russian (from Dalrymple et al. 2004: 192)
On student
He student
'He is a student.'

In a construction like this, it is not immediately obvious what contributes the main semantic PRED of the clause, which is required for the f-structure to be complete and coherent (see Section 3.1 below; cf. a similar issue arising from pro-drop). According to one analysis, the main clausal PRED is contributed by the predicative nominal; according to another, the main clausal PRED is contributed by a special phrase-structure rule or the phrase-structure configuration. Such competing analyses have been put forward for both verbless clauses and constructions with an overt link verb (Dalrymple et al. 2004, Nordlinger & Sadler 2007: 141–142, Dalrymple et al. 2019: 189ff.).[20]

Especially in the absence of a verb, it could be argued that the main clausal PRED value is contributed by the predicative nominal element, which will then select arguments in the same way an ordinary verb would. On this so-called single-tier view, the predicative nominal is the syntactic head of the clause; its f-structure will therefore be identified with the f-structure of the clause and it will contribute the clausal PRED value, as in Figure 8. Consequently, there must exist a lexical entry for the noun *student* which contributes the main clausal PRED value and selects a subject, i.e. (↑PRED) = 'STUDENT<SUBJ>', alongside a "normal" lexical entry for the same nominal form which does not require a subject (for clauses such as 'He met a student', where the subject requirements are imposed by the verb).

Under the so-called double-tier approach, by contrast, both non-verbal elements are arguments (a subject and a predicative complement/PREDLINK). The main PRED selecting these arguments can be supplied by an overt copula or by

---

[20] In the case of overt copulas, the debate surrounding the construction revolves around whether the copula supplies a semantic PRED value or just the tense, aspect, mood, number and person features. Patejuk & Przepiórkowski (2014a) highlight similar issues in the analysis of *be* in Polish passive constructions.

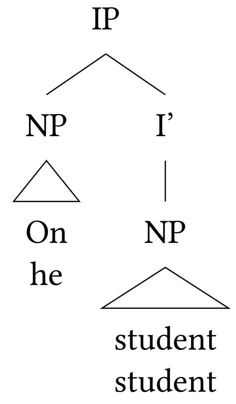


Figure 7: A verbless copular clause in Russian

$$\begin{bmatrix} \text{PRED} & \text{‘STUDENT}\langle\text{SUBJ}\rangle\text{’} \\ \text{SUBJ} & \begin{bmatrix} \text{PRED} & \text{‘PRO’} \\ \text{INDEX} & \begin{bmatrix} \text{PERS} & 3 \\ \text{GEND} & \text{M} \\ \text{NUM} & \text{SG} \end{bmatrix} \end{bmatrix} \end{bmatrix}$$

Figure 8: Single-tier analysis of *On student* (based on Dalrymple et al. 2004: 192, Nordlinger & Sadler 2007: 141–142, and Dalrymple et al. 2019: 194)

the phrase structure (in the case of verbless clauses). This type of analysis might rely on empty-node rules or the constructional properties of the configuration to license the requisite PRED value. Importantly, LFG’s rule annotations can introduce a PRED value in the f-structure, but they will not customarily produce any empty nodes in the constituent structure (as might be done in other theories). One possible f-structure resulting from this approach is presented in Figure 9.

$$\begin{bmatrix} \text{PRED} & \text{‘BE}\langle\text{SUBJ,PREDLINK}\rangle\text{’} \\ \text{SUBJ} & \begin{bmatrix} \text{PRED} & \text{‘PRO’} \\ \text{INDEX} & \begin{bmatrix} \text{PERS} & 3 \\ \text{GEND} & \text{M} \\ \text{NUM} & \text{SG} \end{bmatrix} \end{bmatrix} \\ \text{PREDLINK} & \begin{bmatrix} \text{PRED} & \text{‘STUDENT’} \end{bmatrix} \end{bmatrix}$$

Figure 9: Double-tier analysis of *On student* (based on Dalrymple et al. 2004: 193, Nordlinger & Sadler 2007: 141–142, and Dalrymple et al. 2019: 194–195)

In the spirit of LFG, there have been claims that the presence or absence of a copula is just a matter of superficial c-structure variation, and the “underlying” f-structure for both types of construction should be identical, especially in the light of the fact that both constructions can coexist in the same language, with the appearance or omission of the copula correlating with tense, among other factors.[21] The double-tier approach appears to have gained wider currency in the LFG literature, though the debate as to whether a unified solution should be sought, and if so, which one, is ongoing.

2.8 Clitics and clitic placement

In the more recent LFG literature, clitics are seen as non-projecting words which do not project their own phrases according to the X-bar schema (see Jaeger & Gerassimova 2002, Bresnan et al. 2016: 116–117; cf. Figure 6). This treatment recognises their intermediate status between independent words and bound affixes and primarily concerns the behaviour of clitics at c-structure, which is additionally regulated by language-specific phrase-structure rules of the type we saw for Bulgarian in (15). Other phenomena are modelled via the interface of lexical entries and f-structure.

One important process involving clitics is clitic doubling/reduplication. Some Slavic languages allow it, while others do not. Bosnian/Croatian/Serbian, for one, does not – a clitic pronoun and a full pronoun cannot be used in the same sentence in this South Slavic variety. In the constraint-based lexicalist framework of LFG, the ungrammaticality of clitic doubling is accounted for by giving both types of pronoun, clitic and full, a semantic form of the following shape (as part of the lexical entry):

(29) (↑ PRED)=‘PRO’

If both a full pronoun and a coreferential clitic were to appear in the same clause, there would be a clash because of the multiple specifications of semantic forms for the same f-structure object, resulting in an ill-formed, inconsistent f-structure (cf. Section 3.1).

By contrast, it became apparent in the earlier sections that clitic doubling is found in other Slavic languages spoken in the Balkans, including Bulgarian and Macedonian, both central members of the Balkan Sprachbund/Linguistic Area

---

[21] In Russian, the copula is null in the present tense but it has to be overt in the past and the future (Dalrymple et al. 2004: 191–192). Traditionally, this is used as an argument in favour of a zero copula in the present, but an argument can be made that there is a structural difference between copular and copula-less sentences. Ukrainian admits either null or overt copulas in the present tense. See Section 1.2.6, as well as Patejuk & Przepiórkowski (2014a, 2018), who discuss certain copular constructions in Polish, another Slavic language with optional copulas; cf. Dalrymple et al. (2019: 195–197).

(see Jaeger & Gerassimova 2002; cf. Alsina 2023 [this volume] for Spanish). LFG models this typological parameter by making the PRED value of the clitic optional in a language which admits clitic doubling. A clitic will then contribute a semantic value only if it is the sole object; if it reduplicates a full NP, including a non-clitic pronoun, the clitic will not contribute its own semantic value due to its optionality and no clash will ensue (see entry in (19) and Figure 6 above, as well as Franks & King 2000, Dalrymple 2001: 105–106, Bresnan et al. 2016: 357–358, 440, Dalrymple et al. 2019: 130–131, 152–153).[22]

When more than one clitic occurs in a clause, they group in what is known as a clitic cluster. The rules regulating the internal order inside this clitic cluster, as well as where the clitic cluster can go in the clause, can also be very strict and complex (see Franks & King 2000: 234ff, Jaeger & Gerassimova 2002: 201, Bögel et al. 2010; cf. Section 1.2.5).

2.9 Negation and negative concord

The Russian negator *ne* was described as a proclitic in Section 2.4.1, though this status has been contested for some of its cognates elsewhere in Slavic, as well as for Russian itself. There have been arguments in the LFG literature that, as in Czech, the Polish equivalent negator is actually a prefix, rather than a clitic, though the negator is written as a separate word in Polish, while Czech orthography has long recognised its bound status (see Patejuk & Przepiórkowski 2014a, Przepiórkowski & Patejuk 2015; cf. King 1995 for similar ideas regarding Russian). Irrespective of its status as clitic or prefix, the negative item in Slavic can license morphosyntactic phenomena like the genitive of negation as well as negative concord, both of them already encountered in the preceding exposition (Section 1.2.1, Section 1.2.6, Section 2.3, Section 2.4.1).[23]

---

[22] In varieties with clitic doubling, the clitic pronouns appear to be undergoing reanalysis as agreement markers which match the morphosyntactic features of the constituent they reduplicate. See Bresnan et al. (2016: Chapter 8) and Toivonen 2023 [this volume] for further discussion, including the diachronic developments from one stage to the next, e.g. bleaching from obligatory semantic PRED > optional semantic PRED > no semantic PRED (as for an agreement affix), as well as links to pro-drop, pronoun incorporation and the grammaticalisation of agreement affixes.

[23] The affixal status of the negative marker in Czech and Sorbian is acknowledged in the World Atlas of Language Structures (Dryer 2013), but a similar status is denied there to Polish *nie* (cf. Przepiórkowski & Patejuk 2015: 329, fn. 10). Importantly, the claim that the Polish marker is also an affix is made regarding verbal negation only. When the same form *nie* negates a distinguished clausal constituent, it is not a bound morpheme, as it may be separated from the constituent it negates and it may scope over coordination, among other characteristic features. Furthermore, Polish constituent negation does not trigger the genitive of negation, nor does it license other negative words in negative concord.

As dictated by negative concord, negative words with negative meaning need to appear in the presence of verbal negation. Indeed, there are words in Slavic which are allowed to occur only where negation is available in the relevant domain. Such words are referred to as *n*-words or negative polarity items and include Polish *nikt* 'nobody' in (30), as well as those from Bosnian/Croatian/Serbian in (5), among many others (see Patejuk & Przepiórkowski 2014a: §4.3.1). This sets Slavic apart from Standard Modern English, where such multiple negation is prescriptively outlawed (though it is still common in dialects).

(30) Polish (from Patejuk & Przepiórkowski 2014a: ex. 22)
Nikt *(nie) odszedł głodny.
nobody.NOM NEG left hungry
'Nobody left hungry.'

Although *n*-words are grammatically negative in themselves and certainly carry negative meaning (e.g. the word for 'nobody' can give a negative answer to a question even when uttered on its own), they do not contribute additional negation when they fall within the scope of sentential negation. This is basically the nature of what is referred to as negative concord, a phenomenon akin to agreement where features need to match for purely syntactic reasons.[24]

Both the genitive of negation and negative concord can operate in contexts of clause embedding too (e.g. with so-called open/infinitival complement clauses missing a separate subject), though embedded items are sometimes not obligatorily affected and certain types of embedding can prevent negation-sensitive phenomena (e.g. finite full/closed/sentential complements with their own subject which are insensitive to negation in the matrix clause). This is where LFG's distinction between XCOMP for the former (infinitival) complements and COMP for the latter (finite) clausal complements comes in very useful in differentiating between those natural classes (see Przepiórkowski 2000 and Patejuk & Przepiórkowski 2014b). As is usual for LFG and related theories, the interaction between polarity and polarity-sensitive phenomena such as the genitive of negation and negative concord is modelled via constraints (see Bond 2023 [this volume]). The restrictions also find natural expression in the setting of f-structure. Further issues concerning negation in Polish are discussed by Przepiórkowski & Patejuk (2015), who propose different f-structure representations for the two major types

---

[24] Note that this is a different use of the term *concord*, distinct from the concord bundle of features discussed in Section 2.2, though both these concepts have to do with the more general idea of agreement.

of negation: constituent negation and eventuality negation (a.k.a. predicate/sentential negation). In the attribute-value matrices, negation can be introduced as an adjunct feature or as a binary NEG or polarity feature. Adjunction makes it easy to represent multiple negation via multiple negative elements in the adjunct set.

2.10 Distance distributivity

Distance distributivity is observed in English sentences like *I gave the boys two apples each* – *each* attaches to the NP denoting the distributed quantity (the apples) and looks elsewhere in the sentence, here for a set of boys, to distribute over. In Slavic, distance distributivity is discussed with regard to Polish by Przepiórkowski (2013, 2014, 2015), as well as Przepiórkowski & Patejuk (2013). Przepiórkowski & Patejuk (2013) contend that Polish has a number of function words expressing distance distributivity which share their form and semantic contribution but differ in their syntactic behaviour, namely different lexical items instantiated as *po* 'each'. While *po* may at first glance appear to be a single item, it can in fact be classified as a preposition (governing the strictly prepositional locative case), or as an adnumeral operator compatible with a variety of cases and hence transparent to case requirements. In order to account for this discordant behaviour, Przepiórkowski & Patejuk harness the LFG mechanisms of templates (a complex template of sub-entries within one main entry) and restriction, as well as the notion of weak head borrowed from HPSG.[25] The issue is further explored in Przepiórkowski's (2013, 2014, 2015) work, where he additionally deploys Glue semantics (see Asudeh 2023 [this volume]).[26]

2.11 Coordination

The interaction of coordination with concord and index features was already discussed in Section 2.2, so the current section will be dedicated to other problematic areas in the analysis of conjoined structures (cf. Patejuk 2023 [this volume] for a fuller account). Przepiórkowski & Patejuk (2012a), Patejuk & Przepiórkowski (2012, 2014b, 2017: 338–339) and Patejuk (2015) discuss the coordination of unlike categories in Polish, here an NP and a clause, both serving as arguments

---

[25] Weak heads inherit morphosyntactic properties from their complements, for instance whenever *po* appears to be transparent to case requirements and the case value of the phrase it heads is determined by the complement.

[26] See Franks (1995: §5.2.1) for a comparison of distributive *po* across Slavic couched in generative linguistics; cf. Berger et al. (2009: Chapter 32), as well as Sussex & Cubberley (2006: 467–468), who suggest that *po* might even be a prefix.

(one an obj, the other a comp) of the same predicate, with the same semantic interpretation:

(31) Polish (from Patejuk & Przepiórkowski 2017: 338)

Lisa	chciała	książkę	i	żeby	ktoś	ją	przytulił.
Lisa.nom	wanted	book.acc	and	that	somebody.nom	she.acc	hug

‘Lisa wanted a book and someone to hug her.’

Other unlike coordination strategies might involve a governing predicate (or even different heads) taking conjoined nominal arguments in different cases and/ or with different grammatical functions. The possibility of all of these is ensured by specifying, say, the verb for ‘want’ in (31) as requiring either a case-bearing accusative NP object or a *that*-clause. Probably the biggest challenges in such cases are to ensure that the different alternatives can be realised simultaneously in the same sentence (rather than only on different occasions), as well as to decide how to label the function of the conjoined phrase as a whole.[27]

The inverse scenario entails having two coordinated heads which impose different restrictions on a shared dependent. Those requirements can be met by a single constituent in cases of syncretism, as in (32).

(32) Polish (from Dyła 1984: ex. 2)

Kogo	Janek	lubi	a	Jerzy	nienawidzi?
who.acc/gen	Janek	likes	and	Jerzy	hates

‘Who does Janek like and Jerzy hate?’

The verb form *lubi* requires its object to bear accusative case, while *nienawidzi* takes an object marked for the genitive – *kogo* is syncretic/indeterminate between the two and can simultaneously satisfy both requirements. Dalrymple & Kaplan (2000) therefore propose a set-valued case attribute for this syncretic form, as in (33), while Patejuk & Przepiórkowski (2014b) and Patejuk (2015: 41ff.) refine the original proposal.

(33) Partial lexical entry for Polish *kogo*

kogo Pron (↑ pred)=‘who’
(↑ case) = {acc,gen}

---

[27] See further Patejuk & Przepiórkowski (2012), Przepiórkowski & Patejuk (2012a), Dalrymple et al. (2019: 225–230, 617ff., 650–651), where mention is made of the existence of similar constructions in Russian and Croatian. Patejuk (2015: 54–55, 68ff.) discusses both the issues of simultaneous realisation and labelling, in addition to the issue of embedding.

2.12 Anaphoric control

In obligatory anaphoric control constructions, there should be coreference between an argument of a main/matrix clause and a so-called controlled argument in a subordinate complement clause (see Dalrymple et al. 2019: 561ff.). The coreference of the two arguments is represented in LFG by coindexing them at f-structure (see Rákosi 2023 [this volume], Kaplan 2023 [this volume], Vincent 2023 [this volume]). Early work on obligatory anaphoric control in Serbian/Croatian was carried out by Zec (1987), while Neidle (1982) covers control in Russian (cf. Bojadžiev et al. 1999: 607–610 for Bulgarian, relying on different types of empty "pro"). Control in Polish is discussed by Patejuk & Przepiórkowski (2018). In (34), the dative experiencer acts as the controller of the unexpressed subject of the bracketed infinitival clause: the author is taken to be both the person experiencing difficulty and the person receiving the details.[28]

(34) Polish (from Patejuk & Przepiórkowski 2018: 316)
Oczywiście autorowi najtrudniej był-o [uzyskać
obviously author.dat difficult.adv.superl was-3sg.n get.inf
szczegóły].
details.acc
'Obviously, to get the details was the most difficult [thing] for the author.'

3 LFG analyses in the context of other frameworks

The preceding sections have provided a survey through the lens of LFG of a wide range of grammatical phenomena illustrated from several Slavic languages, which are not always typologically identical. Bresnan et al. (2016: xi) describe LFG as "a theory of grammar which has a powerful, flexible, and mathematically well-defined grammar formalism designed for typologically diverse languages". In the LFG view of grammar, the surface form and organisation of clauses differs from language to language. This is reflected in c-structure, which entails no claims to universality. The categories and the types of constituents, as well as their surface arrangement, all have to be justified on a language-by-language basis (cf. the argumentation in Section 2.4.1). However, the underlying functional

---

[28] Cf. the discussion of raising in the context of the Polish passive in Section 2.5, with raising seen as "functional" (as opposed to anaphoric) control in LFG. As noted by an anonymous reviewer, there are no uncontroversial examples of functional control/raising in Slavic, with the exception of the analysis of the passive mentioned above, and also possibly verbs like 'begin', although this has not been discussed in LFG.

makeup of clauses is regarded as cross-linguistically more uniform, as expressed in LFG's more abstract f-structure (cf. the closing remarks in Section 2.7). Even close relatives like Bulgarian and Russian were shown to have typologically divergent clause structures, despite both organising their clauses according to the packaging of information in discourse (Section 2.4).

In addition, LFG operates with a constraint-based, parallel correspondence architecture. Unlike transformational theories, no use is made of serial derivations, and the framework postulates no "deep" structures as inputs to syntactic operations. LFG shares these principles with theories like HPSG (see Przepiórkowski 2023 [this volume]; cf. the relevant chapters in Berger et al. 2009). Indeed, there has been a great deal of common ground and cross-pollination, with numerous ideas borrowed from HPSG, most notably Wechsler & Zlatić's HPSG-based proposal about agreement features in Bosnian/Croatian/Serbian (Section 2.2), or Przepiórkowski's and Patejuk's generalisations about Polish originally inspired by HPSG or cast in HPSG terms and cited on numerous occasions above. It is likewise worth singling out Borsley & Przepiórkowski's (1999) edited volume on Slavic in HPSG, which promoted some seminal ideas, or HPSG work on individual languages, e.g. Osenova's (2001), Venkova's (2006) and Osenova & Simov's (2007) analyses of Bulgarian, among many others. While HPSG and LFG analyses are highly compatible and often easily convertible from one formalism to the other, LFG has some design features which make it stand out from other theories, especially dominant transformational ones. These are briefly outlined below in the light of the Slavic data presented in this chapter.

3.1 Optionality of c-structure heads and no movement or other transformations

The optionality of c-structure heads is a distinctive property of LFG (see Lovestrand & Lowe 2017, Lowe & Lovestrand 2020), along with the absence of movement operations, which LFG shares with other non-transformational approaches to grammar. It emerged in the discussion of the phrase structure of Slavic languages (Section 2.4) that finite/tensed verbs in Russian and in other members of the family appear in the I slot, and the VP may contain no V head. In the theory of LFG, such examples need no special treatment and the verb is not believed to have "moved" to the c-structure position in which it appears (cf. Sells 2023 [this volume]). Due to its finite morphology, a tensed verb is simply assumed to be of category I in LFG, whereas in transformational frameworks it needs to travel from V to I in order to receive or check these morphological features.

The possibility and well-formedness of this non-transformational configuration is predicted by the overarching principles of LFG. Firstly, Russian finite verbs are assigned to the phrase-structure category of I, so they appear in I rather than within the VP. Having two main/full/lexical verbs, one in I and the other in the VP, is ruled out because each verb would contribute a PRED value to the f-structure, and LFG's Consistency Principle does not allow f-structures having a PRED feature with two different semantic forms as its value (cf. the analysis of clitic doubling in Section 2.8). Secondly, the theory rules out sentences with no verbs whatsoever, because then the main f-structure would be without a PRED, violating the Coherence Principle (though compare the discussion of verbless clauses). Therefore, exactly one verb must appear and it must be housed in the c-structure position appropriate for its constituent structure category.[29]

Compared to prevalent transformational approaches, the non-transformational LFG view is empirically more attractive and intuitive in handling typological diversity. A non-transformational theory avoids the biased assumption that languages with a word order and phrase structure very much unlike that of English, including the Slavic family, actually start out with a deep/underlying structure suspiciously reminiscent of that of English, but then undergo various transformations to achieve the desired "scrambling" effects (see Bresnan et al. 2016: 6ff.; cf. Rudin 1985, who assumes a "non-configurational base" in her transformational treatment of Bulgarian word order).

Modern transformational accounts by now operate with highly abstract underlying structures which, although historically derived from English patterns, even in English itself require a lot of derivation to produce the surface form of the sentence. However, what remains English-influenced is the general idea that (a) constituent structure is the main level of syntactic representation where most grammatical phenomena can be modelled; (b) constituent structure positions are strictly associated with specific grammatical functions. LFG, by contrast, works much better for Slavic because its modularity gives more prominence to relational syntax (f-structure), case morphology, etc.[30] LFG can still capture constituent structure phenomena equally neatly, including "binding" phenomena, as exemplified by Russian *svoj* 'one's own', or VP-internal asymmetries in Russian (cf. Bailyn 2011: 140–151).

---

[29] See King (1995: Chapter 10), who additionally provides an account of Russian questions without resorting to movement, as well as Dalrymple (2001: 79, 104–106), Dalrymple et al. (2019: 129–130); consult Rudin (1985) for a transformational treatment of word order, complementation and *wh*-constructions in Bulgarian.

[30] This was brought to my attention by an anonymous referee, who adds that it is not an accident that the notion of constituent structure did not really exist in the Slavic local linguistic traditions (e.g. in Russia, or in Prague School structuralism) before Chomsky: a kind of informal dependency grammar was traditionally used, and in the structuralist era, various dependency-based frameworks (Tesnière's approach or Mel'čuk's Meaning-Text Theory).

3.2 Modularity (parallel architecture)

It emerged in Section 2 that LFG's modular parallel architecture was well placed to deal with various grammatical phenomena in Slavic, not least the interdependence between flexible word order and the flow of information in discourse. Appealing to the interaction between c-, f- and i-structure, as well as semantics, proved more satisfactory than relying exclusively on the syntax, which would be inadequate on its own to capture all the relevant generalisations. The independence of grammatical and discourse functions from constituent structure, coupled with the constrained interface between the different modules, is designed to provide a good fit for languages which do not encode grammatical functions positionally, like the Slavic family.

In the light of these insights, the assignment of nominative and accusative case in Polish and Russian discussed in Section 2 was tied to grammatical function, independently of the phrase-structure position of the argument bearing this function. However, in a theory like GB or Minimalism, functions are defined positionally, so "structural" case can only be dispensed in certain c-structure configurations, with the relevant constituents then rearranged to obtain the desired "surface" word order. Such theory-motivated complications do not arise in LFG. Another area where LFG's interfaced modularity made rather interesting empirical predictions was argument alternations, some of which might affect the correspondence between argument structure and syntactic functions, while others might additionally interfere with the semantic representation of events (Section 2.5).

Moreover, as mentioned by an anonymous reviewer, LFG is different not only from transformational grammar but also from structuralist approaches which view language as a hierarchy of multiple levels (this view is also implicit in a lot of general/descriptive linguistic work). In LFG, the levels are parallel, which allows for a much more natural view of the interaction between them.

3.3 Exocentric S

Finally, using the exocentric S node (or equivalents), essentially a string which does not comply with X-bar schemata, also proved expedient in capturing the flexibility of Slavic syntax, similarly to the way it has ensured improved description of other non-configurational languages (see the rest of this volume, as well as Bresnan et al. 2016: 112–116). It was mentioned in Section 2.4 that there were actually several competing but underlyingly similar proposals – either S, a flat VP or a flat IP have been proposed for Slavic languages, including Russian, Bulgarian and Polish. LFG admits all of those as it does not constrain the rules of syntactic structure by demanding strict binary branching or X-bar theoretic templates at any cost (though see Bresnan et al. 2016: Chapter 6, Lovestrand & Lowe 2017). Whichever of those solutions a researcher adopts will bring the desirable consequence of more accurate modelling – allowing the requisite surface freedom of constituent arrangement, without scrambling transformations from deep structures which may be empirically hard to justify.

4 Conclusion

It has been my aim throughout this chapter to highlight the contribution of LFG to understanding and describing Slavic languages in a theoretically illuminating way, at the same time pointing out how Slavic material has in turn contributed to adjusting and updating the formal apparatus of LFG, for instance augmenting the sets of agreement attributes. The chapter has demonstrated that the typological pliability of LFG is well suited to Slavic data and enhances our understanding of it, especially the interplay between "free" word order and information structure, agreement, case assignment and negation phenomena, alternations in the argument structure of verbs or pro-drop and verbless clauses, among other processes. On the other hand, Slavic data has posed some challenges to the design and principles of LFG, notably the existence of genuinely subjectless sentences, which might call for revising or abandoning the Subject Condition. Many of the debates continue and are likely to shed more light on the actual linguistic material as well as the best theoretical tools to explore it with. Needless to say, a great deal more remains to be done in order to attain fuller coverage of Slavic grammar.

Acknowledgements

For words of encouragement, help and feedback on this chapter, I would like to thank Mary Dalrymple, Jan Fellerer, Steven Kaye, Mira Kovatcheva, Catherine Mary MacRobert, Adam Przepiórkowski, Andrew Spencer, Christo Stamenov, Tzvetomira Venkova, as well as three anonymous reviewers.

Part VII

Comparing LFG with other linguistic theories

Chapter 37

LFG and Cognitive and Constructional Theories

Yo Matsumoto
National Institute for Japanese Language and Linguistics

Goldberg's (Cognitive) Construction Grammar and Langacker's Cognitive Grammar are compared with LFG. The comparison to be made involves differences in the notions coded in the representations recognized in these theories. It is shown that information factored out in different structures in LFG is often coded in a single structure in the two theories examined. Once such differences are recognized, a fruitful comparison of analysis is possible, in spite of apparent differences in the areas of interest in language and the conceptualization of grammar.

1 Introduction

In this chapter, I will compare LFG with cognitive and constructional theories of grammar. I will specifically discuss the (Cognitive) Construction Grammar (CxG) of Adele Goldberg, and Cognitive Grammar (CogG) of Ronald Langacker. These two theories have several commonalities, including the nonderivational, parallel-structure architecture of grammar, the central role of form-meaning pairs, the embodiment of the usage-based view of grammar, and the cognitive-linguistic conceptualization of language. These pose interesting similarities and differences in their comparison with LFG.

Yo Matsumoto. 2023. LFG and Cognitive and Constructional Theories. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 1807–1828. Berlin: Language Science Press. DOI: 10.5281/zenodo.10186034

2 Construction Grammar

2.1 What is Construction Grammar?

2.1.1 The characteristics of Construction Grammar

Construction Grammar (CxG) originates in the work of Charles Fillmore in the 1980s, when he began to work on the noncompositional properties of syntactic units larger than the word (e.g. Fillmore 1988, Fillmore et al. 1988; see Fillmore 2020). His thinking was further developed by Adele Goldberg's work on Argument Structure Constructions (Goldberg 1995, 2003, 2006, 2019). Over the years, various versions of Construction Grammar have emerged, including Radical Construction Grammar (Croft 2001), Embodied Construction Grammar (Bergen & Chang 2005), Sign-based Construction Grammar (Boas & Sag 2012), and Fluid Construction Grammar (Steels 2011). (I will not attempt a comparison of these theories; see Hoffmann & Trousdale 2013 for a survey). Culicover & Jackendoff's (2005) Simpler Syntax is also a version of construction grammar (see Varaschin 2023 [this volume]). Langacker's Cognitive Grammar, which will be discussed later in Section 3, also incorporates the notion of construction (Langacker 2003, 2005). The idea of construction has also been applied to the area of morphology in the work of Riehemann (1998) and the Construction Morphology of Booij (2010, 2018).

The constructional view cuts across the distinction between formalist and cognitivist theories of grammar. One of the more formal versions of Construction Grammar is Sign-based Construction Grammar, which is a variant of HPSG (Pollard & Sag 1994; see also Sag 2010 and Müller 2021). In this chapter, I will mainly consider Goldberg's, which is often called Cognitive Construction Grammar (Goldberg 2006: 214) due to the influence of the ideas of Lakoff (1987) as seen in the role of metaphor and prototype (see Section 2.1.2 for the role of metaphor). I will briefly touch on other theories encompassing the notion of construction.

CxG takes the notion of construction as central. Constructions are conventionalized clusters of syntactic, phonological, semantic, and pragmatic properties. According to Fillmore and Goldberg, construction manifests at all levels of linguistic structures: sentence, phrase, word, and morpheme, etc. This view is encapsulated in the slogan "it's constructions all the way down" (Goldberg 2006: 18).

One example of a sentence-level grammatical construction is given in (1).

(1) Comparative correlative construction (Covariational conditional construction):
The higher you go, the cooler it becomes.

The comparative correlative construction in (1) has a number of formal and semantic properties unpredictable from the forms/meanings of its parts and the normal rules of their combinations (see Goldberg 2006: 6; see also Culicover & Jackendoff 2005; Hoffmann 2019). The concatenation of two clauses without a conjunction is unusual in English, and so is the parallel structure involving the preposing of *the* plus comparative. The meaning of correlation cannot be reduced to any of its parts (i.e. there is no overt lexical item indicating correlation, such as the conjunction *as*), although the sense of correlation is implicit in the formal parallelism of the two clauses. It is argued that properties of sentences like (1) must be stated with the pairing of form and meaning at a unit larger than the word, suggesting that the notion of the sign can be extended to nonlexical units, with consequences on the status of compositionality in grammar. One can thus say that CxG focuses on the subregularities found in grammatical combinations, unlike theories like LFG that pay attention to regularities and broad generalizations.

Goldberg's CxG incorporates the usage-based view of grammar and language acquisition: the representation of grammar is shaped by language use (see Langacker 1988, Barlow & Kemmer 2000, Bybee 2006, Diessel 2015, 2019). This is reflected in the view that "item-specific knowledge co-exists alongside generalizations" (Goldberg 2006: 12), which is implemented in the hierarchy of constructions in CxG (see Section 2.1.2). It also means that knowledge of grammatical constructions includes the frequency with which the forms are used (Goldberg 2006, Diessel 2015, Perek 2015), and language acquisition is seen as the process of making generalizations over the specific constructions (Goldberg 2006, Goldberg et al. 2004, Tomasello 2003). Such a usage-based view of grammar is largely shared by the probabilistic and exemplar-based LFG (Bresnan & Hay 2008, Bresnan & Ford 2010), though perhaps not by all practitioners of LFG.

What is regarded as a construction has changed somewhat over the years. In Goldberg (1995: 4), a construction is defined as a form-meaning pair in which "some aspect of form or function is not strictly predictable from its component parts." In Goldberg (2006: 5), the range of constructions was widened to include fully predictable patterns "as long as they occur with sufficient frequency." More recently Goldberg states that one needs to keep track of all uses in order to know whether a form-meaning pair occurs with sufficient frequency, and therefore speakers have representations of form-meaning pairs regardless of their frequency. She now defines constructions as "emergent clusters of lossy [i.e. not specified in full detail] memory traces that are aligned within our […] conceptual space on the basis of shared form, function, and contextual dimensions" (Goldberg 2019: 8).[1]

2.1.2 Argument Structure Constructions

Some constructions such as Ditransitive, Caused motion, Resultative constructions, relate to argument structure, and are thus called Argument Structure Constructions (Goldberg 1995, 2003, 2006, 2019, Boas 2003, Barðdal 2008). Take the example of the Caused motion construction exemplified in (2).

(2) Caused motion construction:
Susan sneezed the napkin off the table.

What motivates the constructional status of Caused motion is that verbs which normally do not subcategorize for an object and an oblique, such as *sneeze*, can appear with them in this construction. Goldberg argues that the argument structure and the semantics of caused motion in (2) come from the construction, and not from the verb. Goldberg represents the form and meaning of this construction as in (3).

(3) Caused motion construction, Goldberg (2006: 73):

Form	Meaning
[Subj V Obj $\text{Obl}_{\text{path/loc}}$]	[X causes Y to move $\text{Z}_{\text{path/loc}}$]

In Goldberg's view, the roles that a verb has and those that a construction has are different, and are called *participant roles* and *argument roles*, respectively. The participant roles of the verb (e.g. sneezer of the verb *sneeze*) is linked to the argument roles of the construction in the way represented in Figure 1. Participant roles are based on the semantic frame of a verb (cf. Fillmore 1982), and bear names specific to the event described (e.g. sneezer) rather than thematic role names. The *Coherence Principle* (Goldberg 1995) ensures that only those participant roles compatible with argument roles can be "fused" or linked.

---

[1] I would like to add a brief comment on Construction Morphology (CxM; Booij 2008, 2010, 2018; see also Chen & Matsumoto 2018). CxM is influenced by Goldberg's CxG. CxM is a theory of morphology in which complex words are analyzed in terms of constructions (pairs of form and meaning), which are represented in the form of constructional schemas (e.g. $[[x]_A\text{-ness}]_N \leftrightarrow$'the property/state of A'). In this theory the lexicon lists both constructional schemas and words that instantiate them, which are organized in a hierarchical network, as in Goldberg's CxG.

One significant similarity of CxM and LFG lies in the "full-entry" view of lexical items (Jackendoff 1997, Jackendoff & Audring 2019). This means that in CxM, words including inflected forms are fully formed and listed in the lexicon, as in LFG. In this respect, CxM is highly compatible with LFG.

Sem	CAUSE-MOVE	⟨	cause	goal	theme	⟩
	| R		|	⋮	|	
R: means	SNEEZE	⟨	sneezer			⟩
	↓		↓	↓	↓	
Syn	V		SUBJ	OBL	OBJ	

Figure 1: Composite structure of Caused motion + *sneeze* (Goldberg 1995: 54)

An important notion in CxG is the notion of a *constructional network* (Goldberg 1995, 2006). A network of constructions is built through *inheritance links*, through which many of the properties of particular constructions are motivated by more general or larger constructions. There are several types of inheritance links. One is *metaphorical extension links*, which are posited when two constructions are related by metaphorical mapping in the sense of Lakoff & Johnson (1980). Goldberg states that the Resultative construction is metaphorically inherited from the Caused motion construction (Goldberg 1995), as shown in Figure 2.[2]

Instance links are posited when a specific construction is a special case of a more general construction. Broad generalizations are captured at the level of general constructions which are inherited by more specific constructions. Subregularities are captured by positing constructions that are at lower levels of the network. An ultimate case of specific construction is fully instantiated sentences specified with lexical items. Goldberg (2006: 55) argues that even general constructions are stored in the mental lexicon together with specific examples that are highly conventional and frequent (e.g. *Give me a break* as an instance of the Ditransitive construction). In such a case, she argues, it is clear that both generalizations and instances are stored. CxG allows for such redundancy because specific constructions (including specific examples) are often associated with idiosyncratic meanings and special pragmatic functions. Moreover, speakers have knowledge of the frequencies of specific instances, providing evidence for the inclusion of such instances in grammar for even highly compositional constructions.

It is also important to note that expressions inherit from several constructions due to *multiple inheritance* (Goldberg 1995, 2003). For example, (4) inherits not just from the Caused motion construction but also from the Subject-auxiliary inversion and Passive constructions.

---

[2] In contrast, Jackendoff (1990) treats the two constructions as parallel instantiations of the same thematic structure, with different semantic field features (see Goldberg & Jackendoff 2004: note 13).

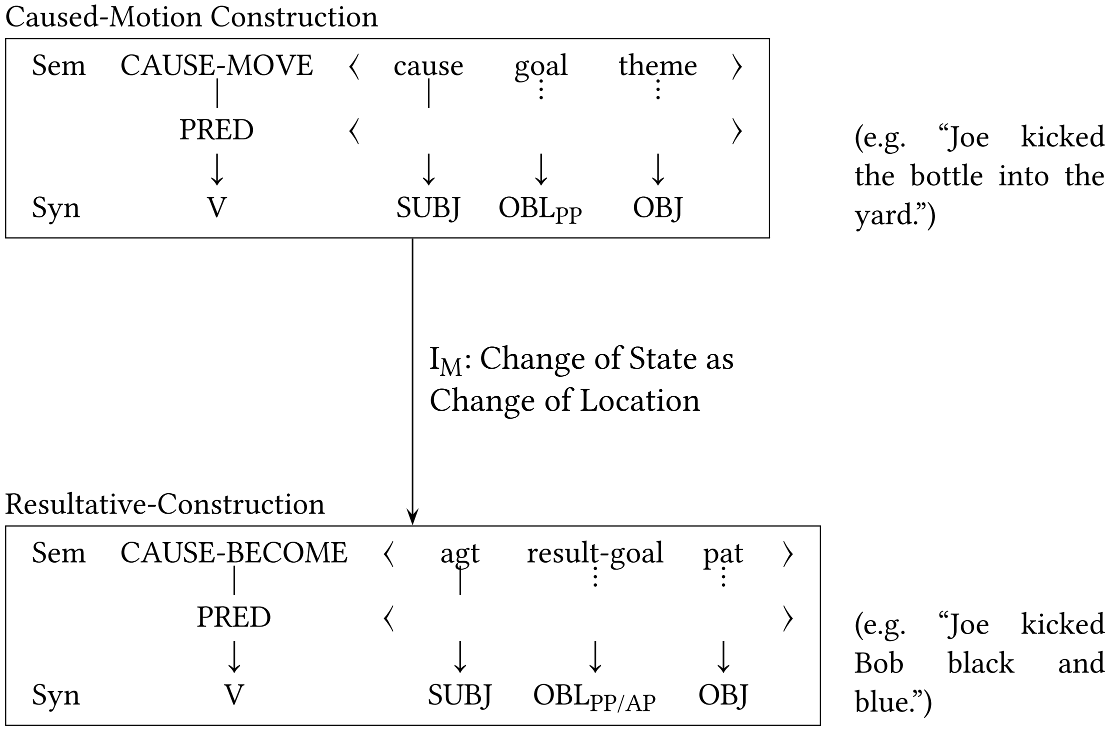

Figure 2: Caused motion construction and Resultative construction (Goldberg 1995: 88)

(4) *Was the ball thrown into the net?*

Goldberg’s (1995) theory of argument structure constructions was criticized within the CxG community for the generality of constructions posited and the underestimation of the role of verb meanings; see Boas (2003) and Iwata (2008, 2020) for models in which verb meanings play greater roles.

2.2 CxG and LFG

2.2.1 Factorization of grammar in CxG and LFG

CxG is, like LFG, a nonderivational theory of grammar, in which two representations (form and meaning) are not derivationally (i.e. transformationally) related but exist in a parallel way. In comparing LFG and CxG, it is worthwhile to consider what sort of factorization of grammar is achieved in different representations in the two theories. LFG recognizes c- and f-structures as grammatical structures, in which different grammatical information is coded (Kaplan & Bresnan 1982), and p-structure, a-structure, s-structure and i-structure in addition, in order to represent other information (see Dalrymple et al. 2019). In contrast, Goldberg's CxG recognizes two representations, form and meaning.

One issue to consider is which LFG grammatical structure the form in CxG corresponds to. In some cases, it appears to correspond to c-structure. The form of some constructions, such as lexically filled idioms (e.g. *give the devil his due*), includes the sound forms of words and linear order, which are c-structure information. In the formulation of the Caused motion construction in (3), however, the form contains linearly ordered grammatical functions, and thus contains parts of c-structure and f-structure information. The formalization of forms in CxG is eclectic.[3]

Goldberg's CxG contrasts with some other constructional theories, which have stricter separation of phonology and grammar. Jackendoff (1997), Jackendoff & Audring (2019) and Booij (2010), for example, adopt the tripartite Parallel Structure Architecture, involving phonological, syntactic, and semantic structures. In these theories, constructions are a set of these three structures.[4]

The way Goldberg uses the term *form* has been discussed by Langacker (2005) and Verhagen (2009). Langacker points out that the form in Goldberg's CxG (as well as Croft's Radical CxG) is in many cases not phonological and therefore is not truly the form. He argues that the form must not include grammatical information, which must reside in the relationship between the form and the meaning (see Section 3).

One may note that Goldberg's formulation of the formal properties of argument structure constructions shows some influence of LFG, as can be seen in the use of grammatical functions such as SUBJ, OBJ, and OBL (though Goldberg often uses the categorial term PP in place of OBL). Sometimes she has even used

---

[3] The following quote from Goldberg (2013) reveals her thinking over formalism in her construction grammar.

> I have avoided using all but the most minimal formalization in my own work because I believe the necessary use of features that formalism requires misleads researchers into believing that there might be a finite list of features or that many or most of the features are valid in cross-linguistic work. The facts belie this implication. The meanings or functions of words and constructions do not lend themselves to semantic decomposition [...] and often-suggested syntactic primitives such as noun, subject, agreement, or agent actually vary crosslinguistically as well [...] (Goldberg 2013: 30)

It is to be noted that there has not been much discussion on the phrase structures or phonology of sentences in CxG.

[4] Jackendoff recognizes tiers within a structure. One of them is the Grammatical Function Tier, which represents grammatical functions separately from phrase structure (Culicover & Jackendoff 2005: Chapter 6).

the LFG term XCOMP to refer to result phrases in the Resultative construction (e.g. Goldberg 1995:3), though not in her later writings (e.g. Goldberg 2006).

2.2.2 Construction, lexical integrity, and the lexicon

The most important difference between CxG and LFG lies in the role of the syntax-lexicon distinction. LFG treats the Principle of Lexical Integrity as central (Bresnan & Mchombo 1995, Bresnan 2001), by which syntax cannot operate into the internal structure of words. Bresnan (2001: 91) formulates this idea as: "Morphologically complete words are leaves of the c-structure tree and each leaf corresponds to one and only one c-structure." This principle suggests a clear division of syntax and the lexicon. LFG also assumes that all features of the whole are shared by those of its head, ensured by the up-equals-down functional annotation on the head. In contrast, all grammatical entities (e.g. phrases, words, and morphemes) are constructions in CxG, and in this sense there is no strict division between syntax and the lexicon. Syntactic and lexical constructions differ in their internal structure, but they are essentially the same pair of form and meaning (Goldberg 1995: 7). In addition, CxG acknowledges that the properties of a construction may differ from those of its head, as can be seen in the argument structure involved in the Caused motion construction in (2).

There have been attempts to treat constructional properties in LFG. Kaplan & Bresnan (1982) placed the special properties of an idiom *keep tabs on* in a lexical entry of *keep*, which calls for a specific object to be used in the meaning of 'observe'. Alsina (1996) and Butt (1995) went somewhat beyond what is normally expected from lexical integrity in LFG and recognized the case where two nonadjacent lexical items form one complex predicate (a single predicate in f-structure: see Andrews 2023 [this volume]). They argue that the mechanism of predicate composition creates a single predicate in such a case, and formulate how a complex a-structure maps onto a single predicate in f-structure (see Findlay et al. 2023 [this volume]).

Asudeh et al. (2013) argue for an analysis incorporating constructions that preserves lexical integrity. They distinguish between Phrase-structurally flagged constructions (such as the Swedish Directed Motion Construction; see Lødrup 2023 [this volume], and Lexically flagged constructions (such as the English *way*-construction; see Goldberg (1995: Chapter 9)). In the former case, a special construction-specific phrase structure rule is posited, which encodes the subcategorization frame of the construction and introduces a template containing information on the special properties of the construction. In the latter, such a template is introduced by the key lexical item in the construction. In this view, lexical integrity is preserved, but the subcategorization is now constructionally captured in terms of c-structure rules and the subcategorization specified in the lexicon is only a default one (see Asudeh et al. 2013: 27–29). It appears that this analysis can capture some properties of sentential constructions. It is not clear, however, whether Asudeh et al. (2013) would like to apply this sort of analysis to all cases of Goldberg's constructions, which would result in a large number of construction-specific phrase-structure rules. See Müller (2018) for discussions of Asudeh et al. (2013), and Findlay (2019) for a more recent treatment of multi-word constructions in LFG.

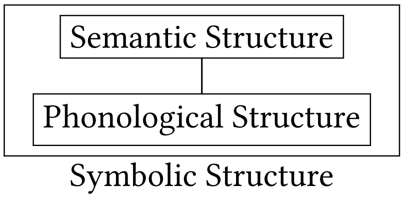
3 Cognitive Grammar

3.1 What is Cognitive Grammar?

Cognitive Grammar (CogG) is a theory developed by Ronald Langacker and his associates (Langacker 1987, 1990, 1991, 1999, 2008, 2009, Van Hoek 1995, Kumashiro & Langacker 2003: etc.). The theory grew out of Langacker's dissatisfaction with generative grammar, which he once adhered to. CogG abandons Chomsky's autonomy thesis (grammar is independent of semantics or matters of language use) and regards "language as an integral facet of cognition" and grammar as "inherently meaningful" (Langacker 1987: 509). For Langacker, the goal of linguistic investigation is to characterize language as a cognitive entity. In this respect CogG is part of the linguistic endeavor known as Cognitive Linguistics, along with works by Lakoff (1987) and others. While theories like LFG are interested in the the roles of different grammatical information, such as grammatical cateogories and functions, CogG is interested in the semantic import of grammatical notions.

CogG posits only semantic structure, phonological structure, and symbolic links between the two, based on the "symbolic" view of language, as shown in (5).

(5) Symbolic structure of Langacker:



Unlike CxG, Langacker posits the form part of the symbolic structure as purely phonological (Langacker 2005: 104). The lexicon, morphology and syntax in CogG reside in the way the phonological and semantic structures are linked, and there is no independent grammatical structure in CogG. In this respect CogG crucially differs from LFG.

Langacker (1987: 53) adopts the *content requirement* for entities used in his representations: only those elements that are part of the directly apprehended primary data or those that emerge from them by means of "basic psychological phenomena of schematization and categorization"[5] are permitted in grammar. This has led to the elimination of syntactic notions in CogG:

> Semantic structures, phonological structures, and symbolic links between them are the minimum needed for language to serve its communicative function. Cognitive Grammar is thus maximally austere in claiming that only these elements are necessary. (Langacker 2005: 106)

CogG, like Goldberg's CxG, embodies the usage-based view of language (see Langacker 1988, 2000). Langacker was the first to use the term *usage-based* (Langacker 1987: 46), and for him this meant that, unlike generative grammarians, grammar lists "the full range of linguistic conventions, regardless of whether these conventions can be subsumed under more general statements" (Langacker 1987: 494). Thus, grammar includes not just high-level broad generalizations but also low-level, limited-range generalizations that speakers can make out of the particular forms they are exposed to, a view which influenced Goldberg (see Section 2.1 above). Recent usage-based research has shifted to corpus-based frequency studies, but Langacker himself has not engaged in corpus-based frequency study.

3.2 CogG and LFG

3.2.1 Nature of representations

Langacker's CogG may appear to have little resemblance to LFG, and there has not been much interaction between the two theories. The adoption of image-schematic representation in CogG (see below) may strike LFG practitioners as quite alien, and the CogG abandonment of key grammatical notions used in LFG may lead one to think that any comparison is hopeless. Therefore an important purpose of this section is to try to find commonalities and areas of comparison.

---

[5] By schematization, Langacker means "the process of extracting commonality inherent in multiple experiences to arrive at a conception representing a higher level of abstraction," and by categorization, "the interpretation of experience with respect to previously existing structures" (Langacker 2008: 17).

There *are* some interesting similarities between the two theories, inviting meaningful comparison. Cognitive Grammar is a nonderivational theory in which different structures coexist without any derivational (i.e. transformational) relationship between them, as in LFG. CogG recognizes two structures, phonological structure and semantic structure, as noted above. It is beneficial to compare the phonological structure of CogG with LFG's c-structure and p-structure, and the semantic structure with f-structures and a-structure.

Phonological structure encodes surface formal groupings and linear order, and in this sense it encodes part of the information found in LFG c-structure. It also lacks empty categories, again similar to c-structure, in which they are avoided, used only as a last resort (see Kaplan & Zaenen 1989, Bresnan 1998, Bresnan et al. 2016: Chapter 9). Unlike c-structure, however, it does not contain category labels and *syntactic* phrase structure. The formal groupings that Langacker envisages are more phonological than syntactic. The phonological structure of the sentence (6a) is simply (6b), rather than (6c) (Langacker 2003: 79).

(6) a. *Bill said Joe believes Roger is angry.*
b. Bill said / Joe believes / Roger is angry.
c. [Bill said [Joe believes [Roger is angry]]]

Langacker argues that the grammatical constituency (embedding) often assigned for sentences like (6a) is in fact conceptual groupings, and does not exist in the phonological structure. Langacker's phonological structure is thus more similar to the p-structure in LFG proposed in Bögel et al. (2009), in which prosodic phrasing is encoded.

The most characteristic aspect of CogG is the adoption of the *image-schematic* representation in the semantic structure. The semantic structure is exemplified in Figure 3, which represents the semantic structure of *near the door*.

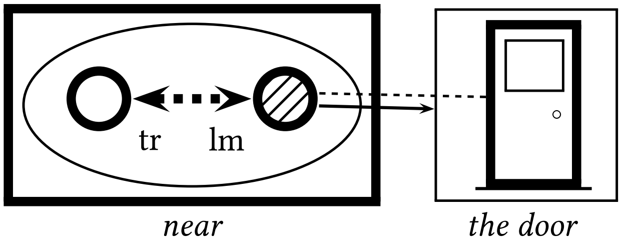


Figure 3: The semantic structure of *near the door* (Langacker 2008: 201)

The preposition *near* represents a relationship (represented by a bidirectional arrow) between two entities (represented by circles) within a vicinity (represented by an oblong area). The slashed entity is elaborated by the semantic structure of *the door*, with elaboration represented by a thin arrow), and the dotted line represents identity. (The abbreviations "lm" and "tr" refer to "landmark" and "trajector" respectively, which will be expounded later.)[6]

Note that the semantic structure includes not just what is foregrounded (*profile*) in the meaning of each expression but also what is in the background (*base*), such as the vicinity border. Profiles are indicated in thicker lines. The box for *near* is profiled since it is the head of the phrase *near the door*.

In the two structures seen above, we see an attempt to encode different information in a different kind of representation with its own geometry and categories, as is the case with LFG. Although the particular representations chosen are very different, we see in both theories attempt to find alternatives to phrase structure trees that have been used to represent all kinds of linguistic information. The two theories thus share the spirit of *liberating linguists from phrase structure trees* so familiar to linguists through Chomsky's generative grammar. In LFG, this is seen in the adoption of attribute-value matrices for f-structure, in which functional information is coded (Kaplan & Bresnan 1982). In CogG, it is seen in the adoption of image-schematic representation for the semantic structure seen above.

3.2.2 Phrase structure,grammatical categories and grammatical functions

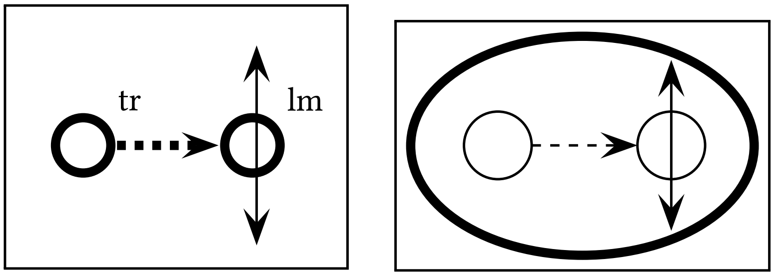
CogG clearly differs from LFG in terms of the (lack of) belief in the independent grammatical structure and grammatical notions. In CogG, there is no phrase structure, grammatical categories or grammatical functions *per se*. CogG's phonological structure does not code syntactic constituency, as noted above. According to Langacker, constituency is in fact conceptual groupings. There is no independent representation in which grammatical categories or grammatical functions are stated, either. What is represented is the *conceptual import* of these notions.

---

[6] Concerning the nature of semantic structures, Langacker (2008: 12) states the following:

> yet another [misconception] is that the schematic images they employ purport to be direct depictions of conceptual structure. The actual intent of these diagrams is rather more modest: to allow certain facets of conceptual organization to be represented in a format that is both user-friendly and explicit enough to serve as a basis for semantic and grammatical analysis.

CogG adopts a "notional approach" to grammatical categories (Rauh 2010). Grammatical categories are defined in terms of the nature of the profile in the semantic structure. Nouns designate Things; Verbs designate Processes; Adjectives, Adverbs, and Prepositions designate Atemporal Relationships. In this view, the verb *choose* can be represented in Figure 4a, and the noun *choice* (in the sense of the action of choice) in Figure 4b.



a. *choose* (V) b. *choice* (N)

Figure 4: Semantic structures for *choose* and *choice* (Langacker 2008: 100)

Here, a circle represents a Thing, and an arrow, a Process. While the verb *choose* profiles a Process involving two Things, for the noun *choice* (in the sense of the action of choosing) the whole Process is construed as a Thing (represented by a large oblong circle). The two refer to the same event, but they represent different *construals* of the event.

Grammatical functions are not recognized per se, either, in sharp contrast to LFG. Subject and Object in CogG are nominals which designate *prominent* participants in semantic structure. Among the participants of a relational expression like a verb and a preposition, the one given primary focal prominence is called a *Trajector* (tr), and the one given secondary focal prominence is called a *Landmark* (lm). In the case of a verb, the former is the subject of the verb, and the latter, the object. This is illustrated in Figure 5, which represents the semantic structure of a transitive verb in the Active, Passive, and Middle uses (e.g. *I opened the door*; *The door was opened*; *The door opens easily*). (The double arrows represent processes involving the transmission of force; single arrows represent changes; Δ indicates that a participant is left unspecified.)

The three are identical in terms of the *action-chain* represented (the energy source of which is agent, which acts on the patient, which undergoes a change). However, the three representations differ in the participant construed as a Trajector; it is agent in the case of Active, and patient in Passive and Middle. Note also that agent in the Middle verb (which is not an argument of the verb) is represented though not profiled. Langacker's semantic structure includes this sort

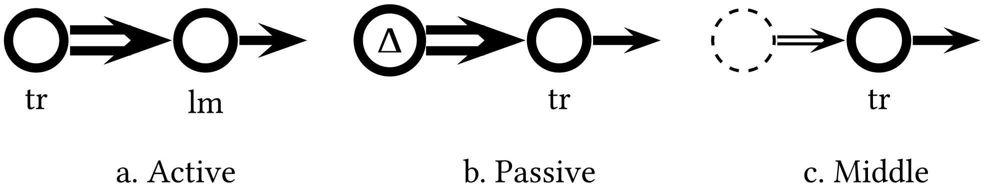


Figure 5: Image-schematic representation of Active, Passive and Middle (Langacker 2008: 396)

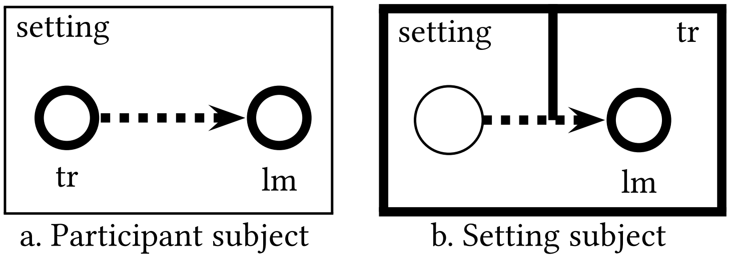
of entity existing in the background of the profiled process, unlike LFG's f- and a-structure.

The notion of Trajector is utilized to make generalizations that would involve SUBJ in LFG. As is well known, a subject is more likely to be the controller of verb agreement, the antecedent of reflexive pronouns, the controller of the embedded predicative complement, etc. According to Langacker, such phenomena are *symptoms* of the underlying cognitive salience of the Trajector (Langacker 1987: 235). Thus, Japanese subject honorification, which makes reference to SUBJ in f-structure in LFG analyses (Ishikawa 1985, Matsumoto 1996), is analyzed in CogG in reference to the Trajector of a predicate (participant subject; Kumashiro & Langacker 2003, Kumashiro 2016) (see the trajector in Figure 6a). CogG additionally recognizes the setting subject or the subject of a clause, utilized in sentences like *Friday saw a big event*, represented by the Trajector in Figure 6b. Kumashiro (2016) claims that Japanese reflexivization makes reference to the subject in this sense as an antecedent.



a. Participant subject b. Setting subject

Figure 6: Two notions of subject in CogG (Langacker 2008: 389)

Kumashiro (2016) argues that both are present in the double subject construction in Japanese. The participant subject corresponds to LFG's SUBJ in f-structure, while the setting subject may correspond to TOPIC in i-structure at least in some cases.

The correspondence of Trajector and Landmark to SUBJ and OBJ in LFG helps elucidate a CogG analysis of Subject-to-Object raising (Langacker 1995) in LFG terms. Langacker (1995) represents the semantic structure of the sentence *I expect Don to leave* as in Figure 7.

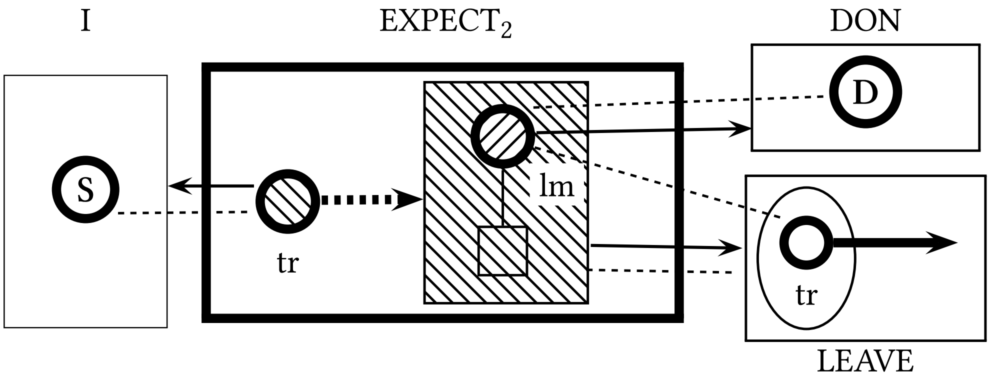


Figure 7: The semantic structure of *I expect Don to leave* (Langacker 1995: 34)

In this structure, the whole process of DON's leaving is the target of the process of the verb *expect*, represented by the dashed arrow pointed at the whole process of DON's leaving rather than the circle representing DON. (In contrast, an arrow representing the process of control verbs such as *persuade* would touch the circle representing DON.) On the other hand, it is DON that is given the Landmark status (indicated by a thick circle) with respect to the process of *expect*, which means that it is an object of the verb.

What is crucial in Subject-Object raising is that the main verb process takes something other than its semantic participant as its Landmark. This discrepancy is allowed since DON is the "reference point" for DON's leaving, which is its "active zone" (indicated by shading, as in Figure 7) with respect to the verb *expect*. An active zone of a reference point with respect to a process is an entity that in fact participates in the process, even though the metonymically related reference-point entity appears in (surface) forms.

One can establish a parallelism of this analysis with the LFG analysis of raising in Bresnan (1982a). The landmark status of DON in the semantic structure of EXPECT corresponds to the OBJ status of *Don,* and the Trajector status of DON in the semantic structure of LEAVE corresponds to its SUBJ status in the embedded structure (XCOMP). The lack of contact of the point of the dashed arrow and the Landmark represents the nonthematic status of the OBJ; the active zone with respect to the raising predicate EXPECT corresponds to an XCOMP (which allows the most salient entity inside it (i.e. SUBJ) to be related to an upper PRED); and the dotted line linking the Landmark of EXPECT and Trajector of LEAVE represents (the conceptual import of) functional control.[7]

---

[7] Note the following statement of Croft (1999: 108): "Although Langacker is at pains to demonstrate how radically opposed his theoretical framework is to the formalist research tradition (and to a great extent this is true), nevertheless even a committed formalist should be able to identify the essence of his analysis."

From LFG's point of view, CogG's semantic structure encodes information of different characters, which is factored out in different structures in LFG. From CogG's point of view, information coded in the semantic structures is all of the same sort, since they are conceptual imports of such grammatical notions as grammatical functions and categories.

4 Concluding remarks

In this chapter, I have compared (Cognitive) Construction Grammar and Cognitive Grammar with LFG. We have seen some general differences between LFG and those two theories: emphasis on subregularities (CxG) vs generalizations (LFG) and emphasis on grammatical categories (LFG) vs their semantic import (CogG). We have also seen that information factored out in different structures in LFG are often coded in a single structure in the two theories examined. In spite of such differences in the areas of interest in language and the conceptualization of grammar, I have hopefully shown that a comparison of these two theories with LFG is more fruitful than might have been thought, once the nature of information coded in the structures recognized in each theory is understood.

Acknowledgements

In writing this chapter, I acknowledge the help of Yi-Ting Chen, Keigo Ujiie, Akira Machida, and Mary Dalrymple. I would also like to thank four reviewers for their very helpful comments. All remaining errors are of course mine. This work is supported by the NINJAL project *Semantics and Grammar of Predicates.*

Chapter 38

LFG and Dependency Grammar

Dag Haug
University of Oslo

This chapter discusses Dependency Grammar from the perspective of LFG. I first introduce the key ideas behind Dependency Grammar and how they relate to LFG concepts. I then show how both LFGs and Dependency Grammars can be translated into Multiple Context-Free Grammars to study formal differences between the frameworks. Next I discuss two recent efforts to translate from LFG analyses to the version of Dependency Grammar adopted in Universal Dependencies. Finally I show how Glue semantics can be applied to dependency structures.

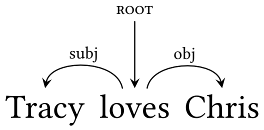
1 Introduction

Dependency Grammar (DG) is a tradition for syntactic analysis based on binary, asymmetric relations (called dependency relations or just *dependencies*) between words. These relations are typically labelled, giving rise to a set of labels that can be thought of as grammatical functions, which are of course also important in LFG. In fact, the correspondence between dependencies in DG and grammatical functions in LFG and their central role in both theories is the main similarity, formally and conceptually, between the two frameworks.

The primacy of dependencies is what holds together work in the DG tradition. As we will see, it is characteristic of almost all DG theories that they acknowledge a level of syntax that we will call the *core dependencies*. This is a set of dependencies restricted so as to form a tree over the words of a sentence, i.e. a structure where each word has exactly one head, except the root word, which has none (or equivalently, is attached to a synthetic root node). (1) shows a very simple example of this.

Dag Haug. 2023. LFG and Dependency Grammar. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 1829–1859. Berlin: Language Science Press. DOI: 10.5281/zenodo.10186040

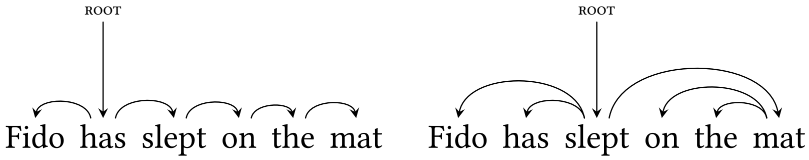
(1)



Most theoretical work and concrete analyses have seen the need to introduce additional mechanisms or levels of structure beyond core dependencies to give the theory more analytical bite; this goes all the way back to Tesnière (1959), the founding work of modern DG. However, there is typically little agreement about the additional mechanisms or levels of structure between individual scholars working in the DG tradition. So, while the core dependency representation is often acknowledged as theoretically inadequate, it has enjoyed considerable popularity as a simplified representation with practical applications in computational linguistics and natural language processing.

But even restricting attention to core dependencies, there are a number of choice points where different dependency frameworks make different decisions. For example, when the core dependencies model structures with a lexical word and one or more function words (for example, articles and nouns, auxiliaries and full verbs, or prepositions and their complements), we must take a stance on whether the lexical or the functional word is the head: the co-head option often used in LFG is not available. (2) shows what the (unlabelled) dependency structure of a simple sentence would look like if we take function words as heads (left) or lexical words as heads (right).

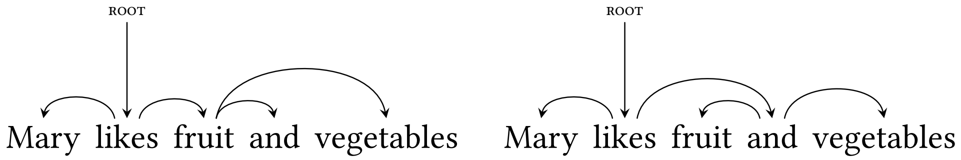
(2)



It is obviously not necessary to treat all function words the same, and so there are intermediate variants between these two extremes, taking for example prepositions and articles as heads, but not auxiliary verbs.

Another point at which dependency grammarians diverge is the treatment of coordination. Because coordination is normally thought of as symmetric, it is not easy to represent with directed dependencies. Here the most common competing analyses, shown in (3), involve taking the first conjunct as the head (left), which entails giving up on symmetry; or to make the conjunction the head (right) and maintain symmetry, but at the cost of dissociating the conjuncts from their normal head (e.g. the verb), which is the basis for most morphosyntactic and semantic constraints.

(3)



Faced with the choices illustrated in (2) and (3) many linguists in the DG tradition have felt that neither analysis is satisfactory, and they have therefore reacted by enriching the dependency formalism in various ways that result in data structures that have more in common with LFG. I discuss some key examples of this in Section 2. Even if much theoretical work in DG assumes such enriched data structures, most practical applications of DG rely on core dependencies, thereby forcing choices that, at least from an LFG perspective, are somewhat arbitrary.

One key difference between DG and LFG is that dependency grammarians typically do not formalize their work and in many cases do not provide (even informal) rules that generate the constructions they are interested in but content themselves with providing analyses of the whole structure. This goes back to the earliest dependency grammarians such as Tesnière, but has become even more prominent with the increasing use of dependency structures in data-driven parsing, where the goal is not to define a grammar that recognizes (or generates strings from) a formal language, but to parse strings into a single plausible structural representation. Nevertheless, it *is* possible to conceive of DGs as formal grammars. In Section 3 I discuss how this can be done using the framework of Multiple Context-Free Grammars. While this is not an approach that most dependency grammarians follow, it yields a useful framework for comparing DG and LFG. Another useful perspective on DG and LFG is offered by recent efforts to translate LFG resources into DG resources, which I discuss in Section 4. Section 5 explores the potential for combining dependency grammars with Glue semantics, the standard semantic framework in LFG.

2 The dependency grammar tradition and LFG

The idea of using binary, labelled, asymmetric relations to analyze syntax is found in the work of Pāṇini, Ancient Greek and Roman grammarians and the speculative grammarians of the Middle Ages (Covington 1984). On its own, this idea is too vague to define a theoretical framework and both Pāṇini and the speculative grammarians have also been seen as forerunners of generative grammar (Kiparsky 1993, Chomsky 1966). What defines the modern dependency grammar tradition, which started with Tesnière (1959), is the attempt to base syntax primarily, or even exclusively, on the concept of core dependencies, as opposed to the concept of constituency developed in American structuralism and the generative tradition. Although there have been a number of attempts to develop dependency grammar into a full-fledged grammatical theory (the most well-known ones being Functional Generative Description (Sgall et al. 1986); Meaning–Text Theory (MTT) (Mel'čuk 1988); and Word Grammar (Hudson 1984, 2010)), none of these are very widespread beyond the environments where they originated and hence there is no single, coherent version of DG as a formal framework. The focus of this section is therefore not to identify assumptions made in specific frameworks, but rather to compare ideas that are common in the dependency grammar tradition with LFG.

2.1 Dependency graphs and f-structures

There is an obvious similarity between dependencies, as found in DG, and the binary, labelled, asymmetric relations between the nodes of an LFG f-structure.[1] In both cases, the relations form a directed labelled graph over nodes corresponding to linguistic material. The similarity even extends to the set of labels used, which in both cases contain traditional grammatical functions such as subject and object. Formally, however, there are two important differences: First, the nodes of the f-structure are not words, but correspond to zero, one or several words/c-structure terminals. This is how LFG escapes the indeterminacy of direction of headedness in constructions which combine lexical and functional words that we saw in (2). Second, labelled dependencies are not necessarily functional, i.e. there may be two or more daughters bearing the same relation to the same head, in violation of LFG's uniqueness condition.[2]

In addition to these two formal differences, there are in practice many more differences, because DG analyses rarely use the full power of a directed graph and instead typically emphasize the core dependencies, which form a tree spanning the words of the sentence. To the extent that e.g. multiple heads are used, one of the heads is typically considered "primary". Even so, the formal similarities

---

[1] To emphasize the parallelism between f-structures and dependency graphs, we rely here on the graph-theoretic interpretation of attribute-value matrices, where feature structures and atomic values are nodes, and attributes are labelled edges between these nodes, and not the "official" interpretation of f-structures as functions (Kaplan 1995, Kaplan & Bresnan 1982). The graph-theoretic interpretation is standard in most other unification-based frameworks from Functional Unification Grammar (Kay 1979) onwards, and was, to my knowledge, first formalized by Moshier & Rounds (1987). It is used in HPSG (Richter 2021); see Przepiórkowski 2023: section 4 [this volume] for discussion of the differences between the two views.

[2] LFG can deal with several dependents bearing the same relation by using set-valued attributes e.g. for ADJUNCT; this introduces the concept of sets, which also has no counterpart in DG.

between dependencies and f-structures mean that similar theoretical questions can arise in both DG and LFG and even that one can think of LFG's f-structures as dependency graphs that take a particular view on certain foundational questions in DG.[3]

An overarching question in the DG tradition (see e.g. de Marneffe & Nivre 2019: 199f.) is whether dependency relations are sufficient for analyzing syntax. In one sense, the answer is obviously no. Like f-structures, dependency structures say nothing about word order. This is dealt with in the c-structure in LFG, and scholars within dependency grammar have also seen the need to enrich the theory with a mechanism for constraining word order. I return to this in Section 3. But more fundamentally, one might ask whether core dependencies, tree structures over words, are sufficient to capture functional aspects of syntax like f-structures do in LFG.

In fact, it is not too hard to see that core dependencies cannot fully represent the functional relations of a sentence. Consider for example, the subject in a raising construction.

(4) It seems to rain.

The expletive *it* bears a functional relation to the raising verb *seems* as witnessed by agreement; but the form of the expletive is licensed by the lexical verb *rain* (and would be different in e.g. *There seems to be a problem*), giving evidence for a second functional relation. If one insists on core dependencies, one of the two relations must be privileged.

The alternative is to increase the expressivity of the theory, and this is in fact what Tesnière did when he introduced two other kinds of relations beside dependencies that can hold between words, namely junction (*jonction*) and transfer (*translation*). Junction is the relation that holds between coordinated items that are either dependents of the same head or heads of the same dependent. Translation is the relation that holds between lexical words and functional words that license their appearing in various dependencies. For example, complementizers "translate" verbs so as to license their appearing in object position according to the analysis in Tesnière (1959: 24); similar analyses are given for determiners and adpositions.

Crucially, words that are linked by junction or transfer form a complex node (*nucleus dissocié*) in the dependency graph and jointly contract dependency relations. In this way, their dependents end up having more than one head; and they

---

[3] Furthermore, on the implementation side, Bröker (1998) shows how DGs can be encoded as LFGs and implemented in the XLE platform.

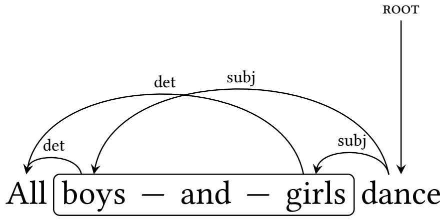
can collectively bear a single dependency relation to their head. In this respect, Tesnière's analyses are in fact quite close to standard LFG f-structures, where coordination is analyzed in terms of a set-valued attribute (5) and function words such as e.g. auxiliaries form a single f-struture node with their lexical verb (6).

(5) a. All boys and girls dance.

b.

$$\begin{bmatrix} \textsc{pred} & \text{‘}\textsc{dance}\langle\textsc{subj}\rangle\text{’} \\ \textsc{subj} & \left\{ \begin{matrix} \begin{bmatrix} \textsc{pred} & \text{‘}\textsc{boy}\text{’} \\ \textsc{spec} & \boxed{1}\begin{bmatrix} \textsc{pred} & \text{‘}\textsc{all}\text{’} \end{bmatrix} \end{bmatrix} \\ \\ \begin{bmatrix} \textsc{pred} & \text{‘}\textsc{girl}\text{’} \\ \textsc{spec} & \boxed{1} \end{bmatrix} \end{matrix} \right\} \end{bmatrix}$$

c.

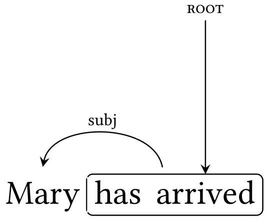


(6) a. Mary has arrived.

b.

$$\begin{bmatrix} \textsc{pred} & \text{‘}\textsc{arrive}\langle\textsc{subj}\rangle\text{’} \\ \textsc{tense} & \textsc{perfect} \\ \textsc{subj} & \begin{bmatrix} \textsc{pred} & \text{‘}\textsc{Mary}\text{’} \end{bmatrix} \end{bmatrix}$$

c.



In this respect, both Tesnière's theory and LFG's f-structure reject the idea that syntactic dependencies can be adequately captured in a tree structure over the words of a sentence. Nevertheless, LFG's approach is much more general than Tesnière's. Tesnière allows many-to-one relations between words and dependency nodes based on relations that are not dependencies, but he maintains the tree structure over dependency nodes. Therefore, the only way a word can have two heads is if those heads form a single node by junction or transfer, as in (5c) and (6c); but LFG also allows for a word to have two heads that do not form a group, as in the analysis of functional control verbs (7).

(7) a. Chris persuaded Mary to come

b. $$\begin{bmatrix} \textsc{pred} & \text{‘}\textsc{persuade}\langle\textsc{subj, obj, xcomp}\rangle\text{’} \\ \textsc{subj} & \begin{bmatrix} \textsc{pred} & \text{‘}\textsc{Chris}\text{’} \end{bmatrix} \\ \textsc{obj} & \boxed{1}\begin{bmatrix} \textsc{pred} & \text{‘}\textsc{Mary}\text{’} \end{bmatrix} \\ \textsc{xcomp} & \begin{bmatrix} \textsc{pred} & \text{‘}\textsc{come}\langle\textsc{subj}\rangle\text{’} \\ \textsc{subj} & \boxed{1} \end{bmatrix} \end{bmatrix}$$

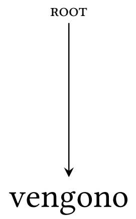
Such dependencies cannot be expressed in Tesnière’s formalism, because *persuade* and *come* share the dependent *Mary*, despite not forming a group. Moreover, *Mary* bears a different syntactic relation to each of them, which again is not possible in Tesnière’s formalism. More recent versions of dependency grammar have typically accounted for control and raising verbs by positing more levels of representation, see Section 2.2.

Finally, an important difference between Tesnière’s dependency graphs and f-structures is that f-structures may contain nodes that correpond to no overt word. A typical case is pro-drop, as in (8) from Italian.

(8) a. vengono
come-PRS.3PL

b. $$\begin{bmatrix} \textsc{pred} & \text{‘}\textsc{come}\langle\textsc{subj}\rangle\text{’} \\ \textsc{subj} & \begin{bmatrix} \textsc{pred} & \text{‘}\textsc{pro}\text{’} \end{bmatrix} \end{bmatrix}$$

c.



Again, Tesnière’s formalism cannot capture this: dependency nodes may correspond to one word, or more words if they form a group by junction or transfer, but not to zero. The strategy in later versions of DG has been the same as that used to address phenomena where LFG uses structure sharing, namely to introduce more levels of representation.

In sum, one can say from an LFG perspective that Tesnière’s dependency graphs, while certainly more expressive than core dependencies, are insufficiently general to deal with the complex functional relations that exist in natural language sentences.

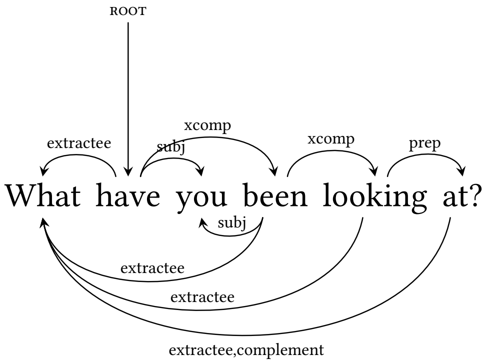
2.2 Other levels of syntactic representation

Tesnière's strategy was to enrich dependency graphs so as to be able to represent more functional relations than core dependencies can do. More recent versions of DG have instead opted to keep the core dependencies simple and instead go beyond a single level of grammatical description to accommodate more information. One prominent example is the so-called tectogrammatical layer found in Functional Generative Description (Sgall et al. 1986) and the associated Prague Treebanks (Hajič et al. 2020). This layer is annotated with an enriched dependency tree that will contain nodes that do not correspond to words (e.g. pro-dropped subjects) and secondary edges capturing multiple head-phenomena such as control.[4]

Melčuk's Meaning–Text Theory explicitly distinguishes a deep syntactic level between the semantic level and surface syntax. However, as pointed out by Kahane (2003), the deep syntactic level is the least defined level of MTT and it is not clear how much information it is supposed to contain. What is clear, however, is that grammatically imposed coreference relations are resolved in deep syntax, opening up a way to deal with, e.g., control.

In Word Grammar (Hudson 1984, 2010), too, control is treated by loosening the tree constraint on dependency structures. Example (9), from Hudson (2003: 521), illustrates how structure sharing is used to analyze raising (*you* shared by *have* and *been*)[5] and extraction (*what* shared by *have*, *been*, *looking* and *at*).

(9)



---

[4] The status of the tectogrammatical layer is not entirely clear: the Prague Dependency Treebank annotation guidelines (https://ufal.mff.cuni.cz/pdt2.0/doc/manuals/en/t-layer/html/ch02.html) say that it "represents the semantic structure of the sentence", but Hajič et al. (2020) describe it as "deep syntax". The difference may be merely terminological.

[5] Instead of Hudson's *sharer*, I have used the LFG relation XCOMP which Hudson explicitly mentions as an alternative name for the same concept. The diagram in Hudson (2003: 521) does not have a subject relation between *you* and *looking*, although *looking* is an XCOMP of *been*. It is unclear whether this is just an error.

The dependency graph in (9) is essentially identical to the standard LFG analysis (except that in extraction, LFG usually has structure sharing only between the gap and the filler position, without involving the intermediate f-structures). However, in Word Grammar, the edges above and below the words have different status:

> This diagram also illustrates the notion 'surface structure' […]. Each dependency is licensed by the grammar network, but when the result is structure-sharing just one of these dependencies is drawn above the words; the totality of dependencies drawn in this way constitutes the sentence's surface structure. In principle any of the competing dependencies could be chosen, but in general only one choice is compatible with the 'geometry' of a well-formed surface structure, which must be free of 'tangling' (crossing dependencies – i.e. discontinuous phrases) and 'dangling' (unintegrated words). There are no such constraints on the non-surface dependencies." (Hudson 2003: 521)

This illustrates the point that I made in the introduction: different varieties of dependency grammar may have different notions of "deep syntax", but they all share the idea that there is an interesting representation of syntactic dependencies that is a rooted tree over nodes that stand in a one-to-one correspondence with the words of the sentence. This is very different from LFG: all edges of an f-structure graph are equal. The subject edge that connects the subject of a control construction to the control verb has exactly the same status as the subject edge that connects the subject to the non-finite verb. Thus, there is no "privileged subgraph" of the f-structure that forms a rooted tree over the words. By contrast, Hudson's distinction between the surface structure and the non-surface dependencies gives rise to such a privileged subgraph, although it must be said that the distinction between surface and non-surface dependencies is not further developed in Word Grammar.

Dependency grammars also differ in their treatment of "null words", i.e. cases where LFG would have an f-structure node that does not correspond to any surface word, as in e.g. pro-drop. Most dependency analyses would simply leave out such subjects, as we saw in (8). But here too, many dependency grammars introduce the missing subjects in "deeper" projections, for example in the tectogrammatical layer of Functional Generative Description. In fact, Word Grammar is one of the few dependency grammar frameworks that acknowledge empty elements in the core syntactic graph. Creider & Hudson (2006) present an argument for this that runs along standard lines of LFG thinking. In Ancient Greek, predicate nouns and adjectives agree in case (and adjectives also in number and gender) with their subjects; and subjects of infinitives are in the accusative.

(10) Ancient Greek (Xenophon, Anabasis 1.3.6)
nomízo: gàr humâ:s emoì eînai kaì patrída kaì
think-1.PRS for you-ACC me-DAT be-INF and fatherland-ACC and
phílous
friends-ACC
'For I think you are to me both fatherland and friends'

But crucially, the predicative is accusative also when the accusative subject is absent (11), even in cases where there is a coreferential element in the higher clause (12).

(11) Ancient Greek (Isocrates 2.15)
philánthro:pon eînai deî
humane-ACC be-INF must
'one must be humane'

(12) Ancient Greek (Plato, Alcibiades 2, 141a7)
exarkései soi túrannon genésthai
suffice-FUT you-DAT king-ACC become-INF
'it will be enough for you to become king'

In (12), we observe that the predicate noun *turannon* does not agree directly with its logical subject *soi*, but rather with the unexpressed subject of the infinitive. Since case agreement is generally agreed to be syntactic (whereas agreement in number and gender could potentially be semantic), Creider & Hudson (2006) conclude that the unexpressed subject of the infinitive must nevertheless be present in the syntax. This is unsurprising from an LFG point of view, but does not seem to be generally accepted in DG. It is unclear, for example, how Functional Generative Description would deal with this kind of data, since null words are inserted only at the tectogrammatical layer, where there is no case feature.

3 Word order and generative power in DG and LFG

In most versions of dependency grammar, it is assumed that the nodes of a dependency structure are not linearly ordered in themselves: a dependency relation implies no particular linear order between a head and its dependents, but can be related to different surface linearizations. This view goes back to Tesnière (1959: chapter 7), who distinguishes sharply between structural order (dependencies) and linear order. The main exception to this is Functional Generative Description, which assumes a linear order on the nodes even in the tectogrammatical layer, to capture information structure.

But even if the nodes of the dependency structures are not linearly ordered, it is possible (and in fact necessary for most languages) to constrain the relation between dependency structure and linearization. One much-discussed constraint is *projectivity.*[6]

(13) A dependency graph is projective iff for every edge $n_h \rightarrow n_d$ it contains, n_h dominates all nodes that occur between n_h and n_d (where domination is the transitive closure of the edge/dependency relation)

An early result due to Gaifman (1965) is that projective dependency grammars are weakly equivalent to context-free grammars.[7] This result may in fact have led to a lack of interest in dependency grammar because it was widely believed in the sixties and seventies (and eventually proved in the eighties) that natural languages are *not* context-free. On the other hand, the recognition problem for a dependency grammar with no linearization constraints at all (thus allowing arbitrary discontinuities) is NP complete (Neuhaus & Bröker 1997).[8]

With the increasing popularity of dependency grammars in the 2000s, this led to the search for *intermediate* linearization constraints between strict projectivity and arbitrary non-projectivity. One important class of constraints is based on the notion of *block degree* (Holan et al. 1998). Intuitively, projectivity as defined in (13) ensures that the subgraph of n_h (i.e. n_h and the set of nodes it dominates) forms a single block of adjacent nodes. We can instead allow the subgraph to form *two* blocks of adjacent nodes, interrupted by a continuous set of words. We say that n_h has block degree 2; and the block degree of a dependency tree is the highest block degree of any of its nodes. Equivalently, we can speak of gap degree, which is block degree minus 1 (i.e., the number of allowed gaps). (14) illustrates this with an example from Latin.

---

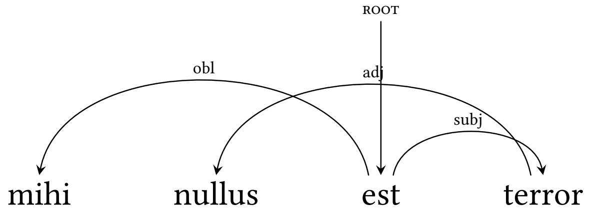
[6] It seems that this term originated with a technical report by P. Ihm and Y. Lecerf "Eléments pour une grammaire générale des langues projectives", Bruxelles 1960, but I have been unable to find this paper.

[7] See also Hays (1964).

[8] As we will see in Section 4, this is not an issue in data-driven parsing, which sidesteps the recognition problem and aims directly at providing a contextually plausible parse.

(14) a. Latin
Mihi nullus est terror
me.DAT none.NOM is fear.NOM
'I have no fear.'

b.



The gap degree of *est* is 0, since its subgraph is continuous; but the gap degree of *terror* is 1, since there is one gap in its subgraph – *est* intervenes between *terror* and *nullus*, but is not dominated by *terror*. As a result, the gap degree of the whole tree is 1.

To study the computational complexity of the dependency grammars that could generate structures like (14), and their relationship to LFG grammars, it is convenient to use phrase structure-based systems that allow discontinuities, so-called Linear Context-Free Rewriting Systems (LCFRS, Vijay-Shanker et al. 1987) or the notational variant Multiple Context-Free Grammars (MCFG, Seki et al. 1991). The MCFG formalism is a generalization of CFG which retains ordinary CFG productions for the expression of categorial structure, but uses explicit *yield functions* to compute the yield of the mother node from the yields of the daughters. In an ordinary CFG, yield computation is conflated with category formation: a rule such as DP → D NP says both that the category DP is formed of a D and an NP, and that the yield of the resulting DP is formed by concatenating the yields of D and NP. In effect, then, a CFG can be seen as an MCFG with concatenation as the only yield function.[9]

To allow for greater expressivity, MCFG allows yields to be *tuples* of strings. For example, we may want to say that the yield of DP is a pair (2-tuple) consisting of the yields of D and NP. This pair will then be the input to further yield functions that apply to productions with DP on the right-hand side. More generally, we may allow yields to be *n*-tuples of strings. The interesting point is that there is a close correspondence between yield components in an MCFG and blocks in a corresponding dependency structure. We can extract MCFG rules from dependency trees, as shown in Kuhlmann (2013), where a formal exposition is given. Here I just provide an intuitive understanding of how the tree in (14b) gives rise to the rules in Table 1.

---

[9] See Clark (2014) for an accessible introduction for linguists and Kallmeyer (2010: chapter 6) for a more formal introduction.

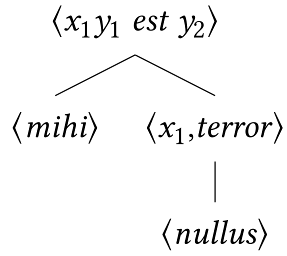
Table 1: Rules extracted from the tree in (14b)

rule	yield function	compact notation
ADJ → $g()$	$g = \langle nullus \rangle$	ADJ → $\langle nullus \rangle$
OBL → $h()$	$h = \langle mihi \rangle$	OBL → $\langle mihi \rangle$
SUBJ → $i($ADJ$)$	$i = \langle x_1, terror \rangle$	SUBJ → $\langle x_1, terror \rangle$ (ADJ)
ROOT → $j($OBL SUBJ$)$	$j = \langle x_1 y_1\ est\ y_2 \rangle$	ROOT → $\langle x_1 y_1\ est\ y_2 \rangle$(OBL SUBJ)

Looking at *nullus* in (14b), we see that it has no dependents, hence the right-hand side of the first rule is a constant function which fixes the yield to the string *nullus*, and similarly for *mihi*. For *terror*, things are more interesting. It takes one dependent, an ADJ, and hence its yield function i depends on the value of that argument. Concretely, the yield of the node *terror* is a tuple, consisting of the yield of the ADJ dependent which is represented as x_1,[10] and the string *terror*. Finally, the verb takes two arguments, SUBJ and OBL. The yield is constructed by concatenating the yield of the OBL (i.e. x_1), the first component of the SUBJ (i.e. y_1), the string *est*, and the second component of SUBJ (y_2).

With the rules in Table 1, we can construct the MCFG derivation tree in (15).

(15)



But notice that because the MCFG grammar is lexical, i.e. each rule introduces exactly one lexical item, the tree in (15) is isomorphic to the dependency tree in (14b). In other words, a lexicalized MCFG can simply be interpreted as a dependency grammar which simultaneously restricts word order.

This allows us to compare the generative capacity and the parsing complexity of dependency grammars with other formalisms. Under a reasonable constraint on discontinuities,[11] the expressivity of an MCFG depends only on the maximal

---

[10] The convention is that we use x for the yield of the first dependent and y for the yield of the second dependent, and subscript those variables with an index referring to blocks of the yield.

[11] Namely wellnestedness; a tree is wellnested if there are no disjoint subtrees that overlap linearly.

block degree of the grammar, giving rise to a hierarchy of *k*-MCFGs, where *k* is the block degree of the most complex yield function in the grammar. It turns out that 2-MCFGs (and hence dependency grammars that allow maximally one gap) are weakly equivalent to Tree Adjoining Grammars and 'classical' Combinatory Categorial Grammar, as was proven by Bodirsky et al. (2005).[12]

Even more interesting from an LFG perspective, there is also a result that a subclass of LFG grammars, so-called *finite copying LFGs*, can be translated into weakly equivalent MCFGs/LCFRSs (Seki et al. 1993). Finite copying LFGs are quite restricted in what functional annotations they allow, in particular they do not allow head annotations (↑=↓) or reentrancies, and also impose the crucial constraint that the grammar puts an upper bound on the number of c-structure nodes corresponding to a single f-structure. Wedekind & Kaplan (2020) show that we can impose this upper bound while still allowing head annotations and reentrancies, as long as they are nonconstructive. This allows most functional equations that are used in linguistic work, including functional control equations of the type (↑ F G)=(↑ H). Wedekind & Kaplan (2020) call these grammars *k*-bounded LFGs and prove that for any *k*-bounded LFG, a weakly equivalent *k*-MCFG can be constructed. Moreover, the MCFG rules can be annotated with functional descriptions that allow us to construct the f-structure that the corresponding *k*-bounded LFG assigns to the sentence, yielding a strongly equivalent MCFG.

These results allow us to compare dependency grammars and LFGs in a precise way. First of all, dependency grammars and *k*-bounded LFGs are weakly equivalent. Nevertheless, although strongly equivalent MCFGs can be constructed from both dependency grammars and *k*-LFGs, it is not the case that we can construct a strongly equivalent dependency grammar from an LFG. The interpretation of an MCFG as a dependency grammar relies on unique lexicalization: each rule contains a single lexical item interpreted as the head. The MCFGs that Wedekind & Kaplan (2020) construct from LFGs are not lexicalized in this way. They do contain functional descriptions that allow us to identify the head but, since LFG allows co-heads, the head is not guaranteed to be unique. Moreover, the functional descriptions in the MCFG constructed from an LFG may contain reentrancies, i.e. words having more than one head, which have no interpretation on the dependency grammar side, thus losing information. A final, minor point is that Kuhlmann's interpretation of MCFGs as dependency grammars say nothing about edge labels; it would be natural and straightforward to interpret LFG's ordinary function assignments as such labels.

---

[12] See also Kuhlmann (2007, 2010).

In sum, then, the formal analysis tells us that the difference between *k*-bounded LFGs and dependency grammars resides exactly in the availability of co-heads and reentrancies, which provide important information from a linguistic point of view. Finally, it should be noted that the restriction to *k*-bounded LFGs, while preserving coverage of many, perhaps most, linguistic phenomena, is nevertheless not trivial. Rambow (2014) argued that unbounded scrambling as found in German and other free word order languages falls outside the generative capacity of MCFGs (and mildly context sensitive grammar formalisms in general) and hence *k*-bounded LFGs.

The comparison of dependency grammars and LFGs through MCFGs is also interesting from other points of view. As Wedekind & Kaplan (2020) point out, the effect of converting an LFG to an MCFG is to precompute the interaction between f- and c-structure and construct a grammar that recognizes all and only the c-structures whose f-descriptions are satisfiable. From a practical point of view, this may be an advantage in parsing. But from the perspective of theoretical LFG, it can be argued that MCFGs and the dependency grammars they give rise to conflate c- and f-structure, making it harder to state linguistic generalizations. The advantage of LFG's projection architecture is precisely "to account for significant linguistic generalizations in a factored and modular way by means of related but appropriately dissimilar representations" (Kaplan 1989: 309). Seen from the dependency grammar side, the formal results offer a choice: Kuhlmann's translation to MCFGs makes it possible to enrich dependency grammars with an account of word order in a single component; but Wedekind & Kaplan's (2020) results show that MCFGs can be "modularized" into a word order component and a functional component (which is not surprising given that MCFGs generalize CFGs precisely by dissociating dominance and linearization) to give something very close to LFG. Either way, the formal analysis exposes similarities and differences between the frameworks. In principle, this paves the way for cross-fertilization on the theoretical side, but in practice such gains are limited by the fact that, as I pointed out in Section 1, dependency grammarians typically do not think in terms of (formal or informal) rules that generate the constructions they are interested in but content themselves with providing analyses of the whole structure.

4 DG and LFG in computational linguistics

4.1 Data-driven dependency parsing

On the computational side, there is a similar difference between DG on the one hand, and LFG and most other formal linguistic traditions on the other hand, in that there has generally been little interest in developing formal grammars that can generate or parse languages. There are some exceptions to this: in the framework of Constraint Dependency Grammar (Maruyama 1990), there is for example a broad-coverage parser of German (Foth et al. 2005); and Constraint Grammar (Karlsson et al. 1995) is a widely used system in which implemented grammars have been created for a wide variety of languages. Many of these grammars content themselves with assigning syntactic function labels to words, without building a full syntax tree, but even so, many have proven useful in practical tasks.

Nevertheless, the dominant use of DG in computational linguistics is closely associated with machine learning approaches where computers find patterns in human annotated data. For such approaches, it is sufficient that annotators provide case-by-case analyses of the corpus without actually abstracting the rules that would create these analyses. Consistency remains a goal, since it makes the patterns easier to learn, but it is not enforced in the way it would be in grammar-based annotation such as typical scenarios for creating LFG parsebanks, where annotators choose between alternative analyses provided by the underlying grammar.

As we have seen several times so far, the constraints on core dependency syntax, namely the unique mother and the one-to-one correspondence between nodes and tokens, mean that many theoretically relevant distinctions cannot be encoded. On the flip side, this makes the annotation task easier as the annotator does not have to be trained in drawing the distinctions. The result is also often more accessible to end users: while grammar-based treebanks contain much more information than dependency trees, this information is typically encoded in a specific theoretical framework and not always easily accessible to users without training in that framework. In short, core dependency trees offer a tradeoff between practical considerations and theoretical depth, which may be attractive for many applications where the deeper linguistic distinctions do not matter much.

On top of that, the simple target structure makes it possible to train very efficient statistical dependency parsers. This approach is fundamentally different from the formal grammar approach to DG developed by Kuhlmann (2013), which we saw in Section 3. Data-driven parsers learn from human annotation and try to provide the most plausible parse in context, without judging acceptability or enumerating possible parses. In this context, non-projective dependencies are not an issue and can be captured efficiently (McDonald et al. 2005). Nivre (2008) introduced algorithms that could produce projective dependency parses in time linear of the input and algorithms that allow non-projective parses and run in quadratic time. Such results led to a huge increase of interest in dependency parsing, which quickly became dominant in statistical approaches to computational linguistics.

Data-driven parsing requires annotated data and the last decade has seen a large increase in the number of dependency treebanks that are available, especially driven by the Universal Dependencies (UD) initiative.[13] UD developed out of the Stanford dependencies for English (de Marneffe & Manning 2008) (which means that there is a certain amount of LFG heritage) as an effort to create an annotation scheme that can be used across languages. Though it has been driven mainly by practical considerations in NLP research, it has in recent years also been used for linguistic research (e.g. Hahn et al. 2020, Berdicevskis & Piperski 2020).

As of release 2.9 (November 2021), UD contains 217 treebanks from 122 languages. A comparison with LFG's ParGram approach reveals the strengths and weaknesses of the approach.[14] Drawing on the long tradition of using DG to provide case-by-case analyses rather than abstracting grammars has made it possible to achieve an unprecedented breadth of coverage. On the other hand, the analyses are more shallow than those provided by LFG grammars and the lack of underlying grammars makes the UD project much more prone to inconsistencies both within and across treebanks.

4.2 Converting LFG parsebanks to dependency treebanks

The existence of annotated resources in both LFG and DG formats makes it possible to study differences between the two from a different perspective than the formal language approach we adopted in Section 3. In this section, we look at work on converting LFG-based resources to dependency structures to see how the two formats compare and to what extent information can be preserved when converting to the less expressive DG format.

For completeness, we mention that there has also been some work on enriching them to yield LFG-structures, e.g. by Forst (2003) and Haug (2012). However, both Forst and Haug started from relatively rich dependency annotations (with secondary edges), so that the conversion to f-structures was not difficult and

---

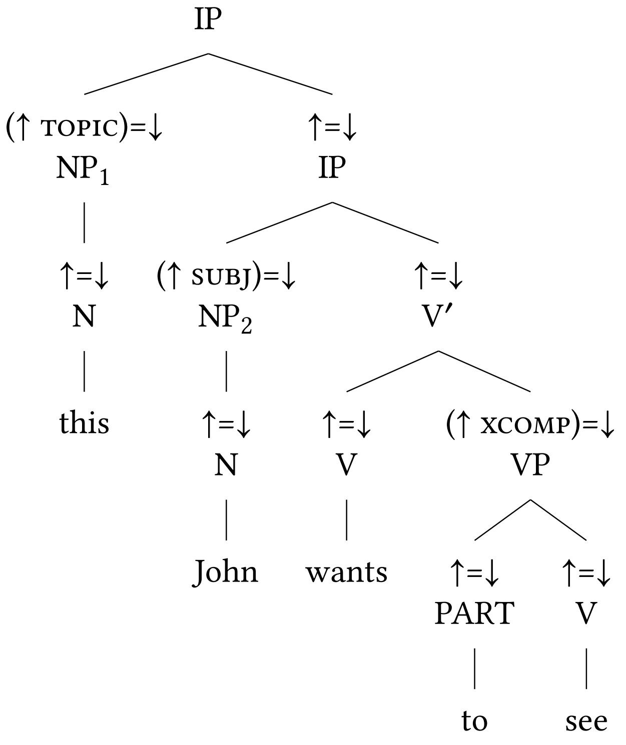
[13] See https://universaldependencies.org/ and de Marneffe et al. (2021).

[14] For more on ParGram, see Forst & King 2023 [this volume].

other issues were more important (e.g. the creation of c-structures from the dependency representations by Haug).

Several conversion algorithms have been developed to convert LFG structures to dependency structures. Here I discuss two recent approaches, by Meurer (2017) and Przepiórkowski & Patejuk (2020),[15] which contrast in interesting ways, since Meurer starts from the c-structure and Przepiórkowski and Patejuk from the f-structure. Both are natural starting points: the f-structure represents grammatical functions, just like the target dependency structure; but the c-structure has the advantage that its terminal nodes are in one-to-one correspondence with the words of the sentence, just like in the dependency structure. Both algorithms target the particular style of dependency annotation adopted in UD, but proceed in two steps, namely first the creation of a dependency structure, and second, the modification of that structure to comply with the exact representation chosen in UD. Here we focus on the first step. To illustrate how the two algorithms work, we consider the LFG structure in (16)–(17).

(16)



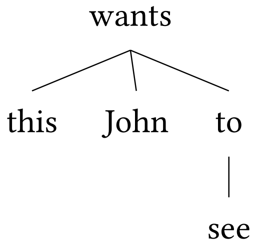
---

[15] Dione (2020) presents an approach that combines Meurer (2017) and Przepiórkowski & Patejuk (2020). For older work, see Øvrelid et al. (2009) and Çetinoğlu et al. (2010).

(17)
$$\begin{bmatrix} \textsc{pred} & \text{`}\textsc{want}\langle\textsc{subj, xcomp}\rangle\text{'} \\ \textsc{topic} & \boxed{1}\begin{bmatrix}\textsc{pred} & \text{`}\textsc{pro}\text{'}\end{bmatrix} \\ \textsc{subj} & \boxed{2}\begin{bmatrix}\textsc{pred} & \text{`}\textsc{John}\text{'}\end{bmatrix} \\ \textsc{xcomp} & \begin{bmatrix} \textsc{pred} & \text{`}\textsc{see}\langle\textsc{subj, obj}\rangle\text{'} \\ \textsc{subj} & \boxed{1} \\ \textsc{obj} & \boxed{2} \end{bmatrix} \end{bmatrix}$$

In Meurer's approach, the first step is to "lexicalize" the c-structure tree by recursively replacing each non-terminal node with its functional head node, as determined by the annotation $\uparrow=\downarrow$. This is straightforward for IP, NP$_1$ and NP$_2$ in (16): *wants*, *this* and *John* are uniquely linked to these nodes via an unbroken chain of $\uparrow=\downarrow$. But more generally, the challenge here is the same as in lexicalizing an MCFG that results from the Wedekind-Kaplan construction: co-heads and absence of heads mean there might be no unique daughter to lift. To find a unique head in such cases the algorithm proceeds as follows: 1) if no daughter of x is a functional head, attach all daughters to the mother of x and proceed as before; 2) if more than one daughter of x is a functional head, choose the one with the shortest embedding path; 3) if there is a tie, choose the leftmost node. For the VP in our example, case 3 applies and we choose *to* as the head; it is therefore lifted to the VP node, while *see* is only lifted to the V node. These lifting operations yield the tree in (18).

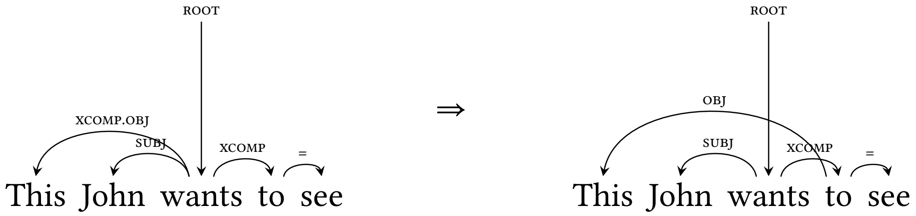
(18)



We then need to label the edges. Meurer's algorithm does that by labelling the edge between nodes x and their daughter y in the resulting tree with the f-structure path from $\phi(x)$ to $\phi(y)$. So, the edge from *John* to *wants* is labelled subj since that is the path from the f-structure of *wants* to the f-structure of *John*. But because of reentrancies in the f-strucure, the path between two f-structures is not always unique: for example, there is a path from the f-structure of *wants* to the f-structure of *this* that is labelled topic, but there is another path that is labelled xcomp obj. In such cases, Meurer chooses the shortest path that contains only grammatical functions (i.e. no discourse functions); in our case that yields the complex label xcomp.obj where the two elements of the f-structure path have been concatenated with a dot. Co-heads present another problem for the labelling approach: *to* and *see* share the same f-structure, so there is no path. In such cases a dummy relation = is used.

This algorithm produces a projective dependency graph with complex labels, as shown for our example in the lefthand side of (19). In the next step, the complex labels are resolved and nodes attached accordingly, potentially introducing non-projectivity. For our example, when the complex relation xcomp.obj is resolved, we obtain the non-projective tree on the right-hand side of (19).

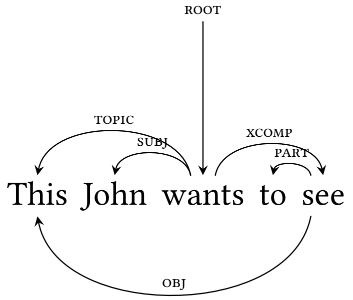
(19)



This then is the input to the final step, where the dependency tree is normalized according to the UD annotation standard.

Przepiórkowski & Patejuk (2020), by contrast, start from the f-structure, which already represents the syntactic dependencies. This means the challenge is different, namely to match the nodes of the f-structure to the words of the sentence, which are the nodes of the target dependency graph. F-structure nodes may correspond to zero, one or several words; they are given by the ϕ^{-1}, which is part of the source annotation. F-structures that correspond to no words (e.g. in pro-drop) may simply be ignored in the dependency structure; but for f-structures that correspond to more than one word, the “true” head that will take the f-structure’s place in the corresponding dependency structure must be identified, and the other words in ϕ^{-1} must be attached with appropriate relations. The basic algorithm is simple: if there is a verbal token in ϕ^{-1}, choose that as the true head; otherwise, choose a nominal or adjectival token; otherwise an explicit lexical conjunction. The other nodes are then attached to the true head with a relation labelled by their own preterminal category. This produces the structure in (20) from the f-structure in (17).

(20)



As we can see, the output from the algorithm of Przepiórkowski & Patejuk (2020) is not a tree, but a graph, where all f-structure relations are preserved, including two incoming edges to *this*. This is exploited to produce enhanced UD, which allows for this kind of graph structure; but the output is also trimmed to produce a basic UD structure.

(19)–(20) illustrate the output of the first steps in the conversions, where the target is to produce the desired data structure, namely a dependency tree or graph over words. As mentioned, the next step is to normalize this structure to the concrete requirements of the UD annotation standard. This is less interesting from our point of view, but it is worth looking at a few topics that display divergences between standard LFG solutions and choices that are made in the dependency grammar community as exemplified by UD.

First, UD subscribes to the primacy of content words. This means that content words are typically heads of function words, for example in structures consisting of auxiliary and verb, adposition and noun, and determiner and noun, as illustrated in the lower graph of (2) in Section 1. Also, there are no nested structures of function words, so e.g. in structures with multiple auxiliaries (*may have been understood*), all the auxiliaries attach directly to the lexical verb. While UD may be extreme among dependency grammar approaches in adopting this principle across the board, similar analyses are found for some of these structures in other frameworks. By contrast, such analyses are non-existing in the LFG literature, except for noun-determiner structures (where the determiner is often analyzed as a SPEC dependent of the noun): function words are typically either co-heads, or lone heads, taking a lexical word as their dependent. For example, there are analyses of auxiliaries as co-heads specifying features of the f-structure where the lexical verb contributes the PRED, and alternative analyses where auxiliary verbs take XCOMP dependents, potentially in a cascading sequence ending in the lexical verb.

In fact, the difference between the co-head analysis and the UD dependent analysis of function words is rather slight, as revealed by the conversion procedure of Przepiórkowski & Patejuk (2020). In f-structures that have functional co-heads, the lexical head will be chosen as the head during conversion, and hence the function words will end up as dependents. And in fact, given that UD uses a flat structure for multiple function words means that the two representations are more or less equivalent, a point made in the UD documentation too,[16] where it is said that function word relations are different from dependency relations between content words and in fact form Tesnière-style nuclei.

---

[16] https://universaldependencies.org/u/overview/syntax.html

This in turn opens the door to theoretical cross-fertilization. What are good criteria for choosing between the two analyses? The UD argument is that primacy of lexical words maximizes parallelism across languages, and the exact same argument has been raised in the LFG literature (Butt et al. 1996). On the other hand, Dyvik (1999) has countered that this leads to a stipulative, rather than empirical, notion of language universality and also that it can lead to analyses that are language-internally unmotivated. Recently, Osborne & Gerdes (2019) criticized the UD approach and argued that functional words should always be heads. They were apparently unaware of the LFG literature on the topic, perhaps because it is cast in terms of co-heads vs. XCOMPs. But as we have seen, the difference between a co-head analysis and a UD-style annotation is very slight, and so the arguments made in the LFG context are certainly relevant also for the DG community.

The other main divergence between initial dependencies, as resulting from the conversion algorithms, and the target UD structures concern coordination. Here LFG makes use of an additional data structure, sets, which have no equivalents in standard dependency grammar or in UD. (Although as we saw above, Tesnière's junction comes close.) There are many competing analyses of coordination in the dependency literature,[17] maybe suggesting that the basic data structure of dependency trees is ill-suited to model coordination, as Tesnière argued. The UD choice is to take the first conjunct as the head and attach the other conjuncts to it with a special dependency relation CONJ, whereas conjunctions and punctuation marks are attached to their following conjunct with CC and PUNCT. It is known that this annotation style cannot capture all important structural differences, such as the difference between a dependent of the first conjunct and a shared dependent of multiple conjuncts, or different style of nested coordinations. The conversion procedure exposes this lack of expressivity, but also makes it possible to quantify its effect. As observed by Przepiórkowski & Patejuk (2020), only twelve out of 21,732 utterances in the Polish LFG structure bank are effected.[18]

More generally, Przepiórkowski & Patejuk (2020) conclude that the information loss in converting from LFG to (enhanced) UD is in fact negligible, except in the case of pro-drop structures. As the UD effort continues to expand, there is therefore considerable potential for theoretical cross-fertilization.

---

[17] And also in (pre-UD) dependency treebanks, see Popel et al. (2013).

[18] See Przepiórkowski & Patejuk (2019) for a proposal as to how nested coordination could be captured in UD.

5 Semantics

Tesnière in general pays much less attention to meaning than to structure, but at various points he does talk about semantic dependencies. Several versions of dependency grammars (Functional Generative Description, Meaning–Text Theory) have taken this up and operate with a separate level of semantic structure. There are also various graph-based semantic representation languages such as Abstract Meaning Representation (AMR, Banarescu et al. 2013), which arguably are semantic dependency representations without an accompanying syntactic representation. All such semantic dependency graphs, whether they are coupled to syntax or not, differ considerably from standard logic-based formalizations of meaning as used in LFG and most other formal frameworks. They will not be further discussed here.

Robaldo's Dependency Tree Semantics (Robaldo 2006) is much closer to standard conceptions of formal semantics, as it aims to transform dependency trees into structures that can be interpreted model-theoretically. But for the purposes of comparison with LFG, it is more interesting to observe that Bröker (2003: 308), in his discussion of the formal foundations of dependency grammar, briefly suggested that the similarity between dependency trees and LFG's functional structure could make the application of Glue semantics (Dalrymple et al. 1993, Dalrymple 1999; see also Asudeh 2023 [this volume]) to dependency grammar a promising research area. Gotham & Haug (2018) flesh out this idea and show how to combine Universal Dependencies with Partial Compositional Discourse Representation Theory (Haug 2014).

On the formal side, there are few if any obstacles to such an application. The fundamental idea behind glue semantics is to have linear logic terms guide the composition of corresponding lambda terms. In the first order glue setting, the terms of the linear logic are the f-structures, atomic formulae are formed by applying predicates to the f-structures (in type-theoretic terms, these predicates act like unary type constructors) and complex formulae are formed with ⊸, which acts as a binary function type constructor. Consider (21), which gives the meanings, dependency structure and f-structure for *Everybody loves somebody.* We write e_1 for $e(1)$, i.e. the application of the type constructor/predicate e to the syntactic object/term with index 1.

(21)	a.	*everybody*	$\lambda P.\forall x.person(x) \rightarrow P(x)$	$(e_1 \multimap t_2) \multimap t_2$
		somebody	$\lambda P.\forall x.person(x) \wedge P(x)$	$(e_3 \multimap t_2) \multimap t_2$
		loves	$\lambda x.\lambda y.love(x,y)$	$e_1 \multimap e_3 \multimap t_2$

b. 
c. $$\begin{bmatrix} \textsc{pred} & \text{‘}\textsc{love}\langle\ \textsc{subj}\ \rangle\text{’} \\ \textsc{subj} & \begin{bmatrix}\textsc{pred} & \text{‘}\textsc{everybody}\end{bmatrix} \\ \textsc{obj} & \begin{bmatrix}\textsc{pred} & \text{‘}\textsc{somebody}\text{’}\end{bmatrix} \end{bmatrix}$$

Clearly, it makes no difference whether we interpret the glue types in (21a) over the dependency tree in (21b) or the f-structure in (21c): in both cases we just need the same mapping between the indices 1, 2, 3 and the corresponding f-structures or dependency nodes.

However, while the formal properties of the two theories are similar enough that Glue semantics can be used for both LFG and DG, a practical consideration is that dependency trees typically do not contain all the semantically relevant information that we find in the corresponding f-structure. Control structures are a case in point (22).

(22) 
The dependency tree in (22) lacks the information that *the dog* is the subject of *to bark*. However, the label xcomp does tell us that the missing subject of *to bark* is one of the dependents of *persuaded.* As a result, the best we can do is to introduce a discourse referent x_2 that is the subject of the infinitive clause and must be linked to one of the participants in the matrix event, though we do not know which one, unless we have access to the lexical information that *persuade* is an object control verb. We see that it is possible to compensate for some of the information loss in dependency trees, although the result only becomes useful if we have other, lexical information sources available: dependency trees on their own do not typically come with the rich semantic lexical entries that glue (and other formal semantic theories) require. We refer to Gotham & Haug (2018) for more details.

6 Summary

We have seen that the basic relations for analyzing functional syntax, dependencies in DG and grammatical functions in LFG, are very similar, both formally and conceptually. Nevertheless, the focus on core dependencies that is often seen in DG work leaves other levels of analysis less well-developed than in LFG. Word order, in particular, has not received much attention, but we have seen that it can be interestingly restricted through the use of lexicalized MCFGs, offering a point of comparison to LFGs, which can also be translated to MCFGs. Another point of comparison is offered by work on converting LFG parsebanks to dependency treebanks. Finally, we saw that the similarity between DG and LFG also means that they can use the same syntax-semantics interface in the form of Glue semantics.

All in all, the considerable similarities between the two theories suggest there is ample room for mutually benefiting discussion, especially if the increasing use of DG in computational linguistics triggers a corresponding interest in theoretical DG.

Acknowledgements

I thank the two anonymous reviewers, one non-anonymous reviewer (Adam Przepiórkowski) and the editor Mary Dalrymple for very helpful comments on a previous version of this chapter.

Chapter 39

LFG and HPSG

Adam Przepiórkowski
University of Warsaw, Polish Academy of Sciences & University of Oxford

This chapter presents and compares Lexical Functional Grammar and Head-driven Phrase Structure Grammar. It concentrates on their fundamental properties rather than on analyses of particular phenomena. After discussing representations assumed in each theory and the kinds of grammars that lead to such representations, the chapter devotes some attention to models explicitly or implicitly assumed in HPSG and LFG: it identifies some problems and suggests possible solutions.

1 Introduction

The aim of this chapter is to juxtapose two highly formalised grammatical theories: Lexical Functional Grammar (LFG; Kaplan & Bresnan 1982, Bresnan et al. 2016, Dalrymple et al. 2019) and Head-driven Phrase Structure Grammar (HPSG; Pollard & Sag 1987, 1994; Müller et al. 2021).[1] LFG was conceived in the late 1970s, HPSG – in the mid-1980s, so both theories have been around for decades. Within both theories, diverse phenomena have been analysed and then re-analysed, and many will undoubtedly receive new analyses in the future. For this reason, rather than compare particular analyses of some phenomena, this chapter focuses on more fundamental issues: on the general representational architecture of the two theories (in Section 2), on the kinds of grammars that lead to these representations (in Section 3), and on models assumed in both theories (in Section 4). Wechsler & Asudeh (2021) offers a comparison of the treatment of various phenomena in the two theories and, hence, complements the current chapter.

---

[1] This chapter does not presuppose substantial prior exposure to either LFG or HPSG.

Adam Przepiórkowski. 2023. LFG and HPSG. in Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 1861–1918. Berlin: Language Science Press. DOI: 10.5281/zenodo.10186042

2 Representations

Outside of their respective communities, both theories are best known as theories of syntax, although already at their conception both were envisaged as theories of multiple linguistic levels, including semantics. Current versions of both theories have well-developed approaches to semantics, as well as proposals for the representation of other linguistic levels: morphological and information-structural in the case of both theories, phonological in the case of HPSG, and prosodic in the case of LFG.

However, the two theories adopt rather different approaches to the representation of the various linguistic levels.

2.1 LFG

Let us have a look at possible representations of the simple sentence (1) in the two theories, starting with the LFG representation in Figure 1.

(1) She loves you.

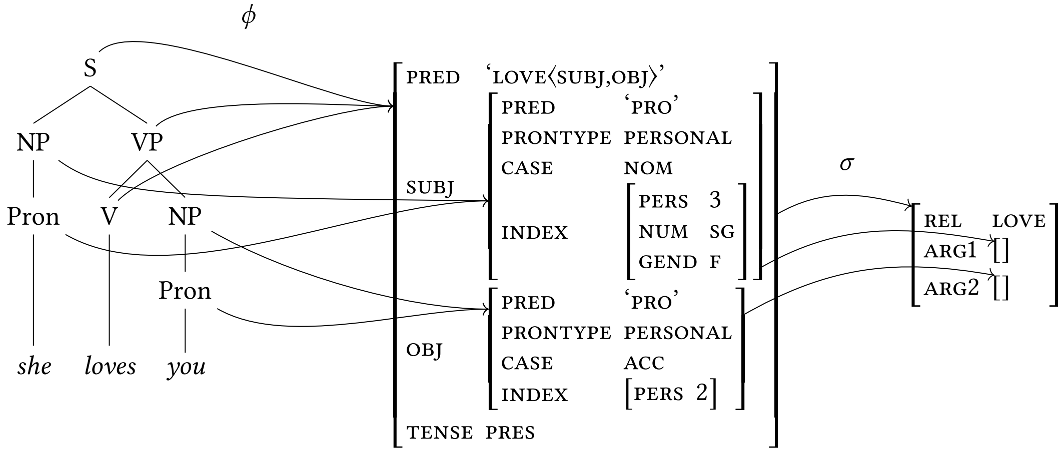

Figure 1: LFG representation of (1)

A prominent feature of LFG representations are the multiple levels. Figure 1 features three such levels: constituent structure (c-structure; the tree on the left), functional structure (f-structure; the attribute–value matrix, AVM for short, in the middle), and semantic structure (s-structure; the AVM on the right). The first two of these levels are syntactic in nature and they are the core of any LFG analysis. The repertoire and exact properties of other levels, including s-structure, is a matter of some debate. Among other prominent levels widely assumed in LFG are prosodic structure (for overviews see Dalrymple et al. 2019: Chapter 11 and Bögel 2023 [this volume]) and information structure (see Dalrymple et al. 2019: Chapter 10 and Zaenen 2023 [this volume]). Also argument structure used to be assumed as a separate level (see, e.g., Butt et al. 1997), but given an appropriately spelled-out approach to semantics, a separate a-structure does not seem to be needed (see, e.g., Asudeh & Giorgolo 2012 and Findlay 2016).

As shown in Figure 1, levels of representation are connected via mapping functions (rendered in the figure with arrows between levels). One such function, usually called ϕ, maps c-structures to f-structures, another, σ, maps f-structures to s-structures. These functions are not necessarily total. In particular, it is often assumed that ϕ maps to f-structures only non-terminal nodes of c-structures. For example, in Figure 1, the leftmost nodes NP and Pron, but not the terminal node *she* that they dominate, map to the f-structure representing the subject (the value of the SUBJ attribute), the rightmost nodes NP and Pron, but not the terminal *you*, map to the f-structure representing the object, etc. Similarly, the domain of σ consists of three f-structures (the ones containing the PRED attribute), with the exclusion of the f-structures which are the values of INDEX. These functions are also not surjective (not onto), for example the values of INDEX in the f-structure are not in the range of ϕ.

Let us take a brief look at particular levels. The c-structure in Figure 1 should be self-explanatory. Unlike derivational theories (see Sells 2023 [this volume]), but like Simpler Syntax (see Varaschin 2023 [this volume]) and HPSG, LFG assumes very simple constituency trees, usually without empty categories – but see Bresnan et al. (2016: Chapter 9) for exceptions – and without an abundance of functional nodes. Constituency structures are assumed to vary considerably between languages, even though their grammars are required to follow some – appropriately relaxed – version of the X′-theory.[2]

On the other hand, functional structures are cross-linguistically more uniform. While they contain morphosyntactic information, which is quite different for different languages, their main function is to represent grammatical functions such as subject and object, and the repertoire of grammatical functions is supposed to be universal.[3] F-structures also contain "semantic forms" – values of

---

[2] See, e.g., Bresnan et al. (2016: Chapter 6) and Dalrymple et al. (2019: Section 3.2). LFG versions of X′-theory are relaxed in various ways. While the standard X′-theory assumes at most binary branching, LFG does not make such an assumption. Also, standard derivational versions of X′-theory assume the presence of the head (perhaps subsequently moved to a different tree position or realised as a phonetically empty constituent to start with), while in LFG the head may be optional in a rule and completely absent from the resulting tree. In this sense, LFG versions of X′-theory may be construed as theories of descriptions rather than structures.

[3] See Patejuk & Przepiórkowski (2016) for a critical discussion of this assumption and Kaplan (2017) for a reply.

the PRED attribute – originally designed to encode in syntax the information that maps to semantic representations; as repeatedly noted in the literature, this information is largely redundant in contemporary LFG, given the existence of semantic structures.[4] In the case of Figure 1, the main f-structure represents a present-tense utterance with the semantic form 'LOVE⟨SUBJ,OBJ⟩'. Both the subject and the object of this utterance have the semantic form 'PRO', i.e., they are pronouns, specifically, personal pronouns. Their morphosyntactic information is represented within the values of CASE and INDEX.[5]

Finally, s-structures contain purely semantic information. In the case at hand, it is the information that the meaning of this utterance is modelled by the relation LOVE and that there are two arguments of this relation, corresponding to the subject and the object.

2.2 HPSG

Let us now have a look at the HPSG representation of (1) in Figure 2. HPSG representations are formally more uniform: there is just one contiguous data structure used for the representation of information from all linguistic levels, namely, an attribute–value matrix.[6] In particular, there are no separate levels of representation – all constituency, morphosyntactic, and semantic information is interspersed throughout the structure.

Clearly, the cost of the greater formal uniformity is the diminished perspicuity (or, for an unaccustomed eye, downright unreadability) of representations such as that in Figure 2. For this reason, it is common among HPSG practitioners to use all kinds of abbreviations and representational devices to make representations more readable. For example, the structure of that figure may be presented as in Figure 3, where the constituency structure becomes transparent.

Taking a closer look at the AVM in Figure 2 we may first note that, unlike f-structures (or s-structures) in LFG, feature structures in HPSG are typed. For example, the structure represented by the whole AVM is of type *hd-subj-ph* (i.e., *head-subject-phrase*), and the value of the attribute HD-DTR is of type *hd-comp-ph* (i.e., *head-complement-phrase*).

---

[4] See, e.g., Dalrymple et al. (1993: 13–14) and Kuhn (2001: Sections 1.3.3, 1.4.1).

[5] Analyses in both LFG and HPSG often follow Wechsler & Zlatić (2003) and distinguish between INDEX agreement and CONCORD agreement; here I retain INDEX as a separate bundle of features but do not explicitly represent the CONCORD bundle, just the CASE feature within it.

[6] Figure 2 also contains lists, indicated with angle brackets, but this is a shorthand notation for AVMs with attributes such as FIRST and REST (or HEAD and TAIL), whose values are the first element (head) of the list and the rest (tail) of the list.

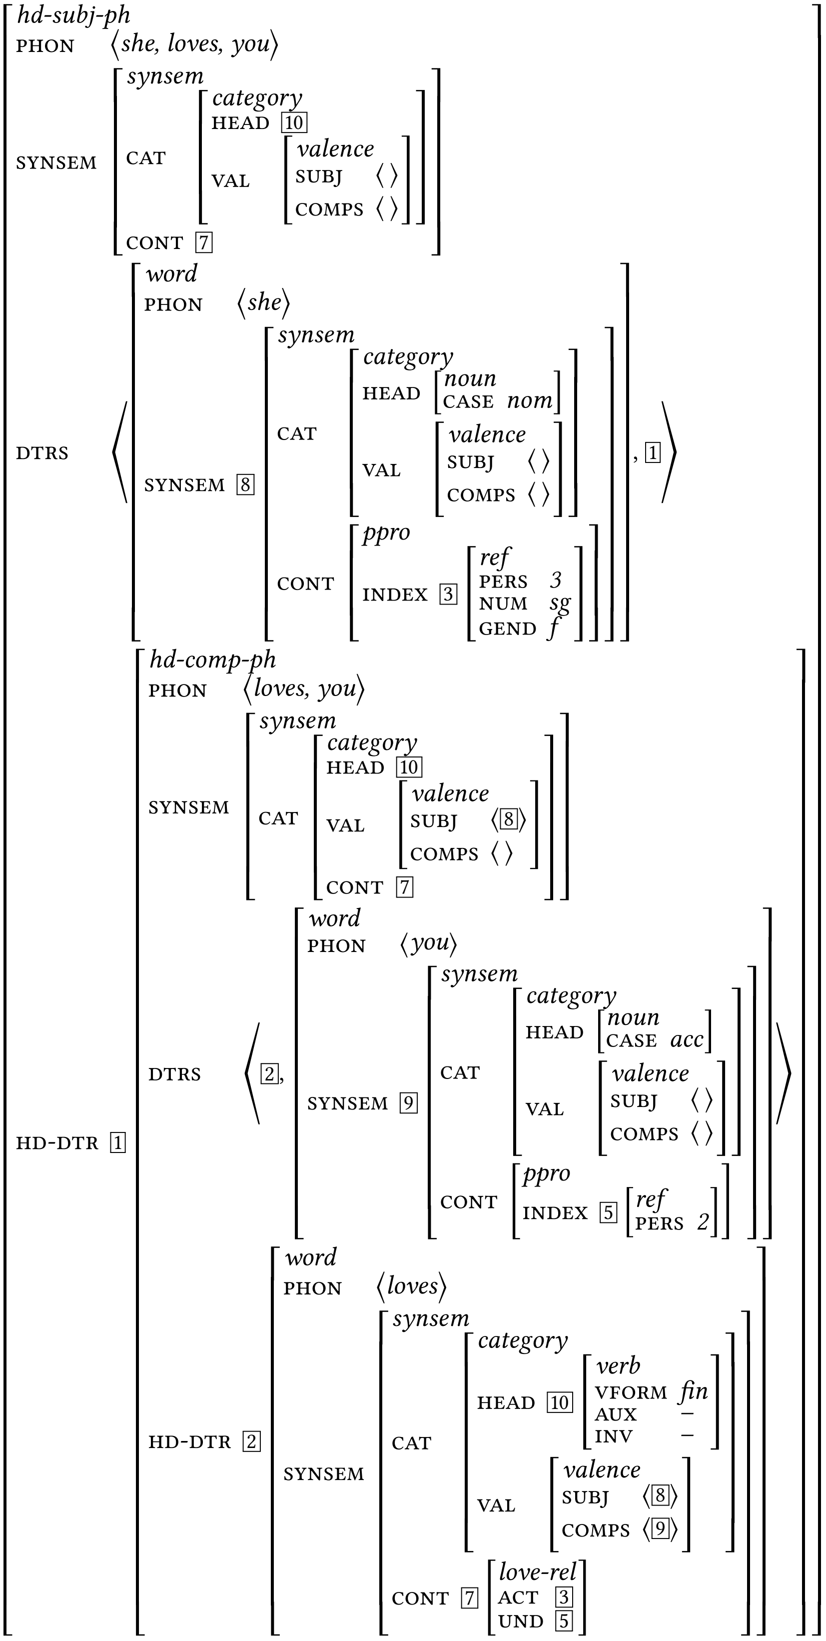

Figure 2: HPSG representation of (1)

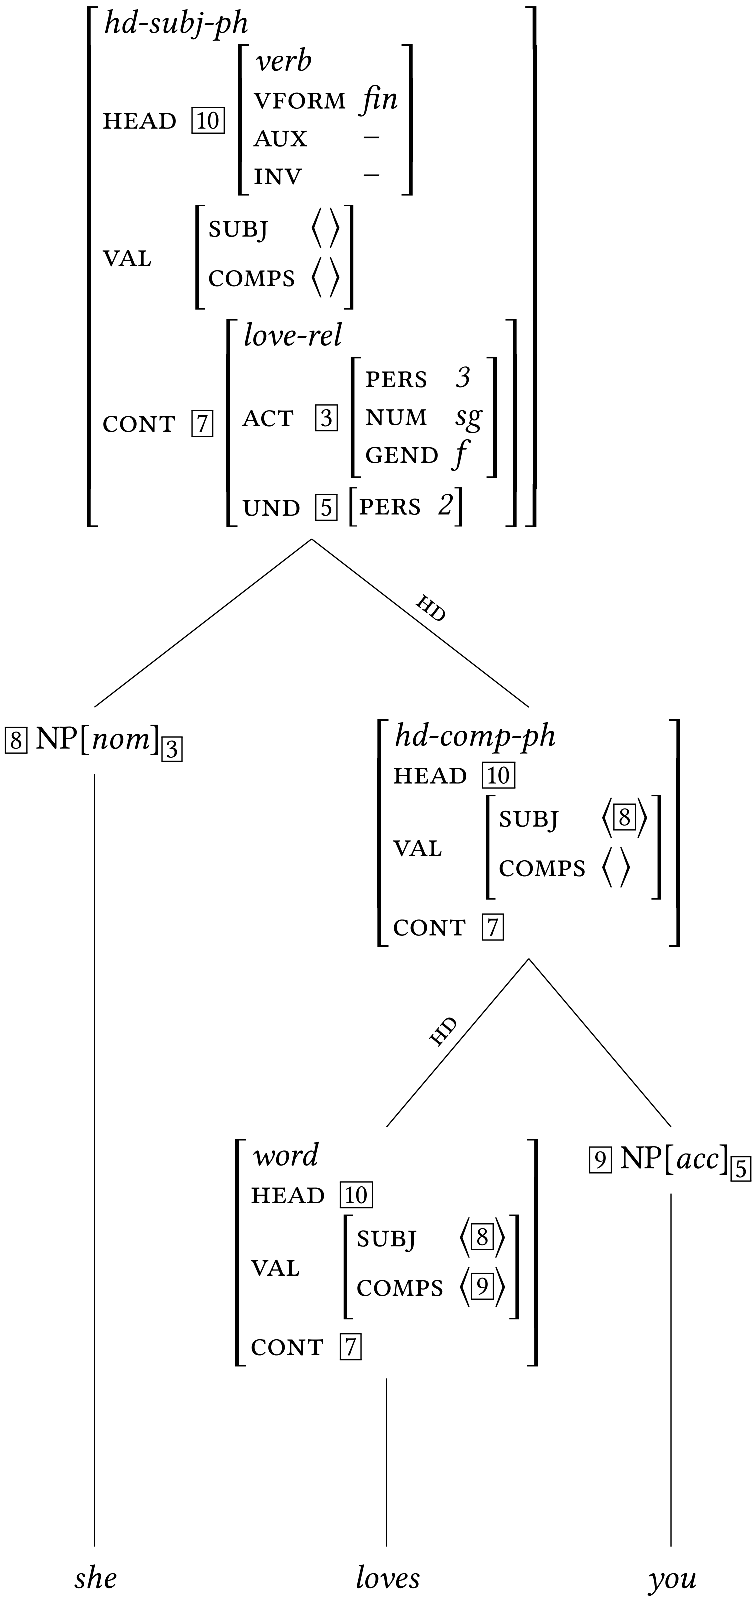

Figure 3: Shorthand HPSG representation of (1)

As discussed in more detail in Section 3.2 below, types determine what attributes may and must appear on the objects described by the AVM (not necessarily on the AVM itself, which may be a partial description of such objects; this point will be crucial below) and what their values may and must be.[7] Types are ordered in an inheritance hierarchy, where subtypes inherit conditions imposed by supertypes and may add more such conditions.[8] For example, both *hd-subj-ph* and *hd-comp-ph* are subtypes of *headed-phrase*, which is a subtype of *phrase*, which in turn – along with *word* – is a subtype of *sign*; see Figure 4.

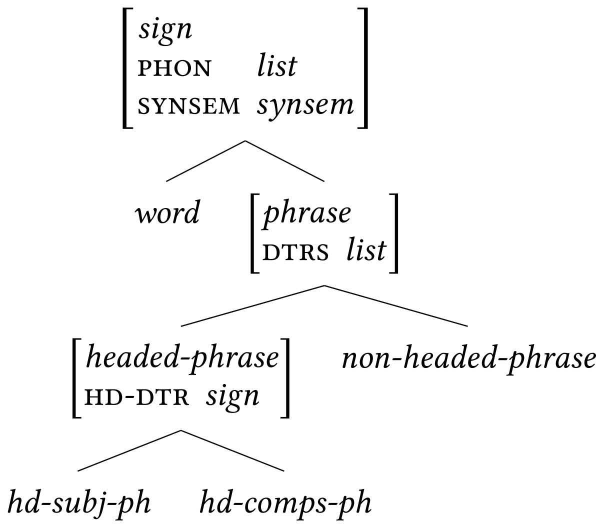

Figure 4: A small fragment of an HPSG type hierarchy

All objects of type *sign* must have two attributes: PHON and SYNSEM (I will explain their role shortly). The *word* subtype does not add any conditions, and all the three subsidiary AVMs of type *word* in Figure 2 have exactly these two attributes and no others. On the other hand, the *phrase* subtype of *sign* requires an additional attribute, namely, DTRS (i.e., DAUGHTERS), whose value is a list of immediate constituents. An important subtype of *phrase* is *headed-phrase*, where one of the immediate constituents is singled out as the syntactic head; this constituent

---

[7] In the HPSG lingo, this amounts to saying that feature structures are *totally well-typed* (Carpenter 1992: 94–95; Pollard & Sag 1994: 18).

[8] It is sometimes argued that LFG templates (which are, essentially, possibly parameterised macros, as in programming languages) "can play the same role in capturing linguistic generalizations as hierarchical type systems in theories like HPSG" (Dalrymple et al. 2004: 207); unfortunately, a discussion of similarities and differences between the two mechanisms – especially, the crucial ontological differences – is outside the scope of this fairly introductory chapter.

is the value of the additional HD-DTR (i.e., HEAD-DAUGHTER) attribute. Hence, any object of type *headed-phrase* must have four attributes: PHON, SYNSEM, DTRS, and HD-DTR. As *hd-subj-ph* and *hd-comp-ph* do not add any attributes, the two AVMs corresponding to the phrases *she loves you* and *loves you* have exactly these four attributes.

Let us take a closer look at the encoding of constituency structure via the attributes DTRS and HD-DTR. In the root AVM of Figure 2, the value of DTRS is a 2-element list, whose first element is a *word* structure of *she* and the second element is a *hd-comp-ph* structure of *loves you.* This second element is only marked as $\boxed{1}$ on the DTRS list, but it is fully presented as the value of the HD-DTR attribute; boxed numbers such as $\boxed{1}$ should be understood as bound variables signalling multiple occurrences of a structure in different places (here, in the DTRS list and in the value of HD-DTR). The structure $\boxed{1}$, being (a subtype of) a headed phrase, also has the attribute DTRS, whose value is a pair of structures of *loves* and *you*, and the HD-DTR attribute, which singles out the structure of *loves* as the head. This configuration of attributes DTRS and HD-DTR and their values encodes the syntactic tree of Figure 3.

The other two attributes of *phrase* structures, present also on *word* structures, are PHON and SYNSEM. In work which does not deal with phonology or phonetics the values of PHON are taken to be lists of words, as in Figure 2, but it is clear that in an exhaustive representation values of PHON must be highly structured.[9]

For our purposes, values of SYNSEM are more important – they represent all grammatical information other than constituency structure. Figure 2 presents slightly simplified values of SYNSEM: it omits those parts of *synsem* structures which are responsible for non-local information, i.e., for book keeping related to unbounded dependencies and relative clauses (see Borsley & Crysmann 2021, Arnold & Godard 2021, Chaves 2021, and references therein).[10] Local information is distributed between the attributes CAT(egory) and CONT(ent), as well as CONTEXT, not represented here either (see Pollard & Sag 1994: 332–337, as well as De Kuthy 2021 and references therein). CONT represents semantic information comparable to that distributed between LFG f-structures and s-structures. For example, the two personal pronouns (see the two CONT values of type *ppro*) contribute referential indices, referred to as $\boxed{3}$ and $\boxed{5}$, and the verb contributes the *love-rel*(ation) with the index $\boxed{3}$ of *she* as its ACT(or) and the index $\boxed{5}$ of *you* as

---

[9] See, e.g., Bird & Klein (1994) and Höhle (1999) for two very different proposals.

[10] Normally, *synsem* structures contain two attributes, LOCAL and NONLOCAL. Since NONLOCAL and its value is omitted here, also the attribute LOCAL is not mentioned in this chapter, and its values of type *local* are presented as SYNSEM values of type *synsem.*

its UND(ergoer). This verbal semantics is shared along the verbal spine, so the structures of *loves*, *loves you*, and *she loves you* all have the same CONT value $\boxed{7}$.

The other part of SYNSEM values, the *category* structure, models morphosyntactic and combinatorial properties. The former are the value of HEAD: *she* is a nominative (pro)noun, *you* is (here) an accusative (pro)noun, and *loves* is a finite verb (non-auxiliary, not inverted). The values of HEAD are shared between a mother and its head daughter – see the multiple occurrences of $\boxed{10}$. Finally, combinatorial properties are encoded in values of VAL(ence): the verb *loves* requires a subject ($\boxed{8}$ – the SYNSEM value of *she*) and a complement ($\boxed{9}$ – the SYNSEM value of *you*), *loves you* has no further complement expectations but still needs a subject, while *she loves you* is a fully saturated maximal projection – the values of its valency features are empty lists. Such maximal projections are often abbreviated the way illustrated in Figure 3: $\text{NP}[\textit{nom}]_{\boxed{3}}$ stands for (the SYNSEM value of) a structure with empty SUBJ and COMPS, with HEAD indicating a nominative noun, and with CONT|INDEX value $\boxed{3}$.[11]

2.3 Comparison

2.3.1 Levels of representation

The two structures in Figures 1 and 2 look somewhat similar in the sense that they both use complex AVMs, but also very different in the sense that the LFG representation distinguishes multiple levels, each with its own data structure and with a functional mapping between the levels, while the HPSG representation is a monolithic AVM. How important is this difference? My claim is that it is less important than usually assumed. For example, it is possible to define a bijection (a one-to-one correspondence) between LFG representations such as that in Figure 1 and corresponding HPSG-like monolithic AVM representations such as that in Figure 5. In this representation, the c-structure is encoded with the help of attributes LABEL, DTRS, and PHON, the mapping ϕ from the c-structure to the f-structure is achieved with the attribute SYNSEM, and the mapping σ from the f-structure to the s-structure – with the attribute CONT.[12]

Conversely, the HPSG representation of Figure 2 might be taken apart and LFG-ified as in Figure 6. The fact that non-terminal nodes in the c-structure are AVMs is not a problem in itself; in LFG it is often assumed that c-structure node labels

---

[11] While in LFG the attribute separator in paths is a space, e.g., “SUBJ CASE ”, in HPSG the vertical bar is used, e.g., “SYNSEM|CAT|HEAD|CASE”.

[12] In fact, this representation makes conspicuous the redundancy – mentioned in Section 2.1 – of PRED values with respect to s-structures (i.e., here, CONT values).

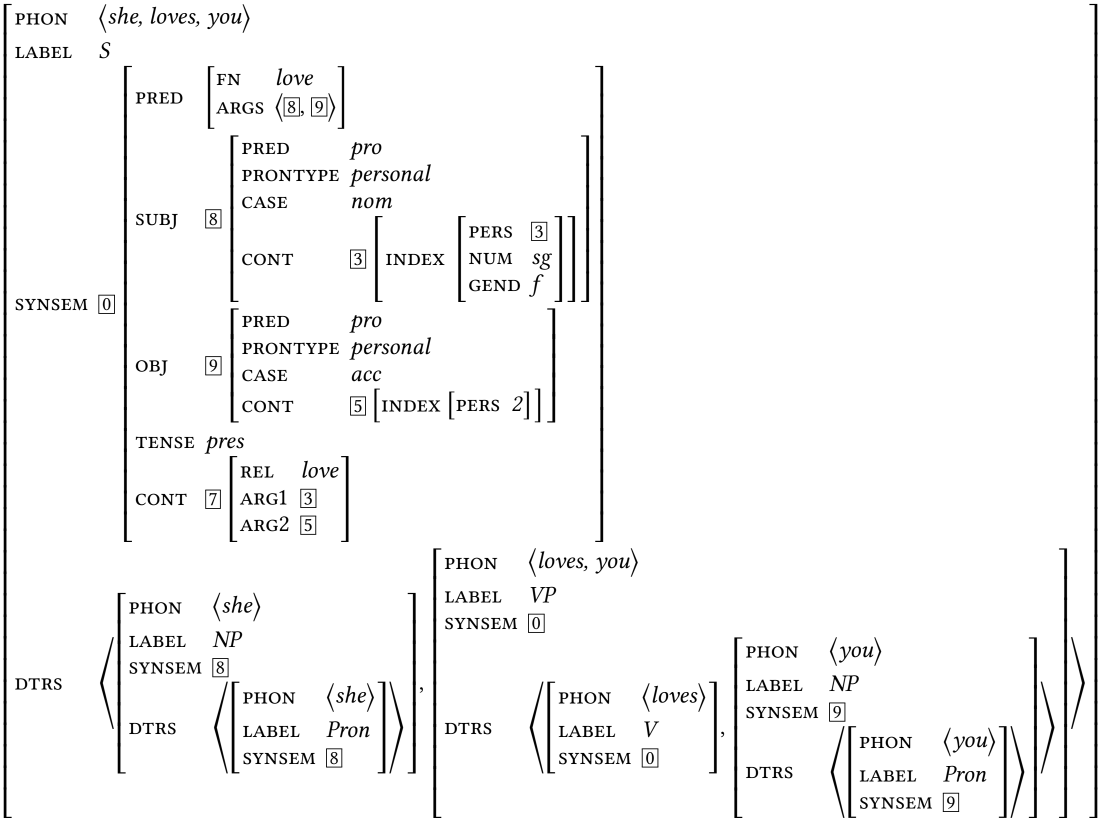

Figure 5: HPSG-like LFG representation of (1)

are really abbreviations of feature matrices (see, e.g., Kaplan 1995, Dalrymple 2017, and Lowe & Lovestrand 2020). What is somewhat unusual is that some of the attributes in these AVMs are list-valued and refer to other AVMs within the same c-structure (rather than to particular values within such AVMs as in, e.g., Lowe & Lovestrand 2020). However, this does not seem to violate any deep LFG principles.

What LFG grammars and the multi-level representations they lead to try to capture is the cognitive modularity and encapsulation of particular linguistic levels; constituency structures, functional structures, semantic structures, etc., each have their own sets of primitives and operations, and the interactions between them are only possible via the mapping functions ϕ, σ, etc. By contrast, no such encapsulation is attempted in HPSG, so it is easy to state constraints in this theory which may simultaneously refer to arbitrary parts of the structure of a sentence, e.g., the phonetic properties of a verb and the semantics of its subject; such a constraint would be much more cumbersome to state in LFG. On the other hand, actual LFG analyses sometimes make use of the converses of ϕ, σ, etc., i.e., refer to c-structures from the level of f-structures and to f-structures

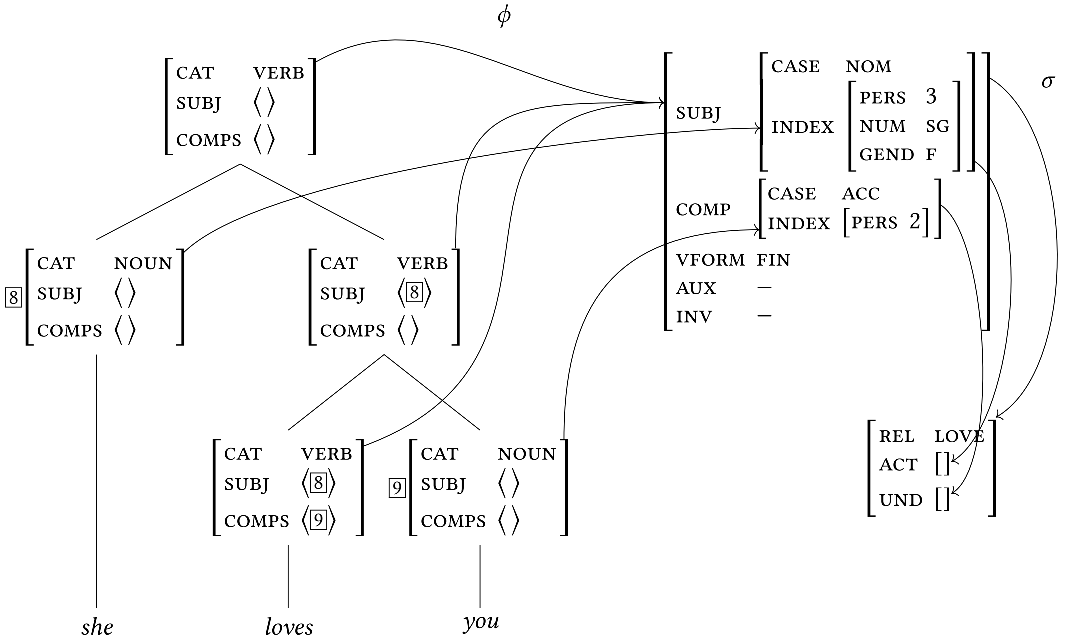

Figure 6: LFG-like HPSG representation of (1)

from the level of s-structures, so, in principle, any level may be referred to from any other level.[13] Hence, the difference between LFG and HPSG when it comes to encapsulation of linguistic levels is one of degree – and relative easiness of stating constraints across grammatical levels – rather than a categorical difference between the complete encapsulation and the total lack thereof.

In summary, while representations with separate linguistic levels such as those in Figures 1 and 6 are certainly more immediately readable than monolithic representations such as those in Figures 2 and 5, it is not clear that there are any fundamental differences in the kinds of linguistic analyses that LFG and HPSG presuppose.[14]

2.3.2 Grammatical functions

Perhaps a more important – and certainly linguistically more contentful – difference between HPSG and LFG regards grammatical functions. In LFG each

---

[13] However, as pointed out by Ash Asudeh (p.c.), correspondence functions in LFG are typically not injective (i.e., they are many-to-one), so their converses are proper relations rather than functions. For example, while ϕ maps particular c-structure nodes to particular f-structures, the converse of ϕ will map f-structures to *sets* of c-structure nodes, making it more difficult to refer to *particular* c-structure nodes from the level of f-structures. This "blurring" or "fuzziness" of converses of correspondence functions might be claimed to constitute a substantive hypothesis about encapsulation of grammatical levels.

[14] But see Section 3.3.3, on the expressiveness of formalisms underlying LFG and HPSG.

argument bears a different grammatical function drawn from a repertoire that includes SUBJ(ect) and OBJ(ect), as in Figure 1, but also OBL(ique), COMP(lement) – a closed sentential argument, XCOMP – an open verbal argument, etc. Moreover, at least OBJ and OBL are often indexed with thematic roles, grammatical cases, or particular prepositions. For example, in the case of sentence (2), the f-structure would contain another attribute apart from SUBJ (for *you*) and OBJ (for *me*), namely, $\text{OBJ}_{\text{THEME}}$ (for *your money*). Similarly, in the case of (3), the grammatical function of *to you* could be OBL_{GOAL}, etc. (see, e.g., Dalrymple et al. 2019: Section 10.3 and references therein).

(2) You never give me your money.

(3) But what I've got I'll give to you.

The HPSG approach to naming arguments is radically different: normally only the SUBJ(ect) is distinguished (see Pollard & Sag 1994: Chapter 9 and references therein), often for solely tree-configurational reasons, and all the other arguments are listed within the predicate's COMP(lement)s value. In the case of a 2-argument verb such as *love* this difference is not conspicuous, but in the case of, say, *give*, the two non-subject arguments would be elements of the COMPS list, whether they are realised as a direct object and a theme object, as in (2), or as a direct object and goal oblique, as in (3). Hence, the two attributes, SUBJ and COMPS, suffice for any configuration of arguments.[15]

Note that this is a difference between LFG and HPSG *qua* linguistic theories, not *qua* linguistic formalisms. Either approach can be simulated in the other formalism. For example, within LFG, Alsina (1996) proposes to constrain explicitly named grammatical functions to subject and object, and Patejuk & Przepiórkowski (2016) and Przepiórkowski (2016) further justify this approach and provide an LFG formalisation inspired by HPSG analyses of extended argument structure.[16]

---

[15] Also, the SUBJ/COMPS dichotomy is not assumed in some versions of HPSG (including the early versions of Pollard & Sag 1987 and Pollard & Sag 1994: Chapters 1–8, as well as the Sign-Based Construction Grammar of Sag 2012, sometimes perceived as a version of HPSG) and in HPSG grammars of some languages (e.g., German; Stefan Müller, p.c.).

[16] Two further – more formal – arguments for HPSG-like representations of grammatical functions in essentially LFG settings may be found in Johnson (1988: Chapter 4): first, they obviate the need for the LFG principles of completeness and coherence (cf. Section 3.3.4), which are encoded via formally problematic (cf. Section 4.3.3) constraining statements, and second, they lead to an analysis of Dutch infinitive constructions which, unlike the standard – at that time – LFG analysis, does not violate the offline parsability constraint (cf. Section 3.3.3). (Some problems with Johnson's (1988) own analysis of Dutch infinitive constructions are pointed out in Zaenen & Kaplan 1995.)

Conversely, explicit information about grammatical functions of particular arguments could be added to HPSG representations, as in Ackerman & Webelhuth (1998) or Hellan (2019).

2.3.3 Word forms

The final difference between the two representations in Figures 1 and 2 that I would like to point out concerns the place of the word string in these representations. Traditionally, in LFG the sequence of word forms – the form of the utterance – is the yield of the c-structure, i.e., the sequence of leaves. So finding an LFG representation of an utterance amounts to finding a grammatical representation in which the yield of the c-structure is that utterance.

On the other hand, in HPSG the sequence of words in an utterance is the value of that utterance's PHON attribute. This means that finding an HPSG representation of an utterance boils down to finding a grammatical structure in which the value of PHON is the list of words in that utterance. Normally this amounts to the same sequence of words as that read off the leaves of the constituency tree. For example, if – in a simple binary tree – the PHON of the first constituent is ⟨*come*⟩ and the PHON of the second is ⟨*together*⟩, then the PHON of the mother is ⟨*come*, *together*⟩ rather than ⟨*together*, *come*⟩ (or ⟨*drive*, *my*, *car*⟩, or whatever). This correspondence is explicitly present in the representation in Figure 2 and implicitly assumed in the shorthand representation in Figure 3, but there is a well-developed linearisation theory in HPSG which allows for controlled violations to this correspondence.

I will have more to say about the exact role of the string of word forms in both linguistic theories in Section 3.3.1.

2.4 Summary

Let us take stock of similarities and differences between the kinds of representations assumed in LFG and HPSG. The celebrated difference between the multi-level architecture of LFG and the monolithic structures assumed in HPSG is certainly important to many practitioners of both theories and has an impact on readability (of LFG representations) and the need to apply additional conventions and abbreviations (to render HPSG representations), but in my view it is of little substantial consequence. It is trivial to devise a lossless conversion of LFG representations to HPSG-like representations, and also HPSG structures may be converted to LFG-like representations which distinguish between constituency structures, structures representing other syntactic information, and semantic structures.

However, there are at least two more substantial differences conspicuous in the representations in Figures 1 and 2. One concerns grammatical functions: one function per argument in LFG and just one distinguished argument in HPSG. The other concerns the place of the sequence of words which make up an utterance: in LFG this sequence is commonly assumed to correspond to the sequence of leaves in the c-structure, while HPSG allows for dissociation between the string of words and the constituency structure.

3 Grammars

What kinds of grammars lead to representations such as those in Figures 1 and 2? I will first consider LFG, then HPSG, and then I will compare the two approaches.

3.1 LFG

Here is the relevant part of an LFG grammar that produces the structures in Figure 1.[17]

Grammar rules:

(4) $$\text{S} \longrightarrow \begin{array}{cc} \text{NP} & \text{VP} \\ (\uparrow \textsc{subj}) = \downarrow & \uparrow = \downarrow \\ (\downarrow \textsc{case}) = \textsc{nom} & (\downarrow \textsc{tense}) \end{array}$$

(5) $$\text{VP} \longrightarrow \begin{array}{cc} \text{V} & \text{NP} \\ \uparrow = \downarrow & (\uparrow \textsc{obj}) = \downarrow \\ & (\downarrow \textsc{case}) = \textsc{acc} \end{array}$$

(6) $$\text{NP} \longrightarrow \begin{array}{c} \text{Pron} \\ \uparrow = \downarrow \end{array}$$

Lexicon:

(7) *loves* V
$$\begin{array}{l} (\uparrow \textsc{pred}) = \text{‘}\textsc{love}\langle \textsc{subj},\textsc{obj} \rangle\text{’} \\ (\uparrow \textsc{subj index pers}) =_c 3 \\ (\uparrow \textsc{subj index num}) =_c \textsc{sg} \\ (\uparrow \textsc{tense}) = \textsc{prs} \\ (\uparrow_\sigma \textsc{rel}) = \textsc{love} \\ (\uparrow_\sigma \textsc{arg1}) = (\uparrow \textsc{subj})_\sigma \\ (\uparrow_\sigma \textsc{arg2}) = (\uparrow \textsc{obj})_\sigma \end{array}$$

---

[17] Only the core machinery is assumed here, mostly (apart from the σ-projected s-structures) present already in Kaplan & Bresnan (1982). See, e.g., Dalrymple et al. (2019: Chapter 6) for later additions such as functional uncertainty (including inside-out functional uncertainty), off-path constraints, the restriction operator, local names, templates, etc.

(8) *she* Pron (↑ PRED) = ‘PRO’
(↑ PRONTYPE) = PERSONAL
(↑ CASE) = NOM
(↑ INDEX PERS) = 3
(↑ INDEX NUM) = SG
(↑ INDEX GEND) = F

(9) *you* Pron (↑ PRED) = ‘PRO’
(↑ PRONTYPE) = PERSONAL
(↑ INDEX PERS) = 2

LFG grammars may be viewed as Context-Free Grammars (CFGs) with annotations; the purely CFG part of the grammar in (4)–(9) is this:

(4′) S ⟶ NP VP
(5′) VP ⟶ V NP
(6′) NP ⟶ Pron
(7′) V ⟶ *loves*
(8′) Pron ⟶ *she*
(9′) Pron ⟶ *you*

Within annotations, ↑ refers to the f-structure associated (via the ϕ function) with the mother node in the tree (i.e., with the preterminal node, in the case of lexical entries), and ↓ refers to the f-structure associated with the current node. For example, the functional equation (↑ SUBJ) = ↓ under the NP in rule (4) for S says that the f-structure associated with the S node has the SUBJ attribute whose value is the f-structure associated with the NP node. The other equation under the NP, (↓ CASE) = NOM, says that the f-structure for this NP has CASE with value NOM. The head equation ↑ = ↓ under the VP in the same rule says that S and VP are associated with the same f-structure.

These are so-called “defining equations” – they may be thought of as constructively building representations. The statement (↓ TENSE) under VP in rule (4) is a constraining condition requiring the presence of the TENSE attribute within the f-structure associated with the VP node. This constraining condition cannot be replaced with a defining equation such as (↓ TENSE) = PRS because infinitive verbs are assumed not to have the TENSE attribute at all, so the effect of such a defining equation would be to wrongly add the attribute TENSE (and its PRS value) to f-structures of such tenseless forms. Similarly, the constraining equation (↑ SUBJ INDEX PERS) $=_c$ 3 in the lexical entry (7) for *loves* requires that the f-structure associated with the subject of this verb have the attribute INDEX whose value has the attribute PERS whose value is 3, but the verb does not itself assign this value – some other part of the grammar (in this case, the lexical entry (8) for *she*) must take care of that. As we will see in Section 4.3.3, the existence of such constraining statements presents a difficulty for model-theoretic formalisations of LFG.

While the symbols ↑ and ↓ only implicitly refer to the function ϕ mapping c-structures to f-structures, the σ function mapping f-structures to s-structures is mentioned explicitly in some of the statements. For example, the statement $(\uparrow_\sigma$ ARG1$) = (\uparrow$ SUBJ$)_\sigma$ in the lexical entry (7) rather concisely says that there is an s-structure associated with the f-structure related to the preterminal V, this s-structure contains the attribute ARG1, and the value of this attribute is the s-structure associated with the f-structure which is the value of SUBJ within the f-structure related to this preterminal. It is easy to check that the representation in Figure 1 reflects this and all the other statements presented in this subsection.

3.2 HPSG

Theoretical HPSG grammars have a very different feel: they do not have a CFG backbone, but rather contain statements about various types of linguistic objects – not only phrases and words, but also valencies, contents, cases, etc.[18] HPSG grammars consist of two parts: a type hierarchy (already mentioned in Section 2.2, also called "sort hierarchy" and "signature") and a theory proper.

A small fragment of the type hierarchy assumed in the AVM of Figure 2 was given in Figure 4, and a much larger part is presented in Figure 7. This type hierarchy seems to mention all types occurring in Figure 2, but in fact it does not contain types for the word forms which appear within PHON values; on the simplest approach to values of PHON each word form is an atom of a type such as *she* or *loves*. (On a more comprehensive approach such as Höhle 1999, values of PHON are highly structured and contain various kinds of phonological information.) In a more realistic grammar, the type hierarchy would also contain more subtypes of *headed-phrase* (see Abeillé & Borsley 2021: Sections 5–6 and references therein), a much larger type subhierarchy below *content* (see, e.g., Richter & Sailer 1997, 1999 and Davis 2001 for two very different proposals targeting different aspects of semantic representations), a multiple inheritance hierarchy of subtypes of *head* (Malouf 1998), many more subtypes of *vform*, etc. As shown in Figure 7, type hierarchies are more than just plain taxonomies of types: they also

---

[18] However, some such statements, namely, Immediate Dominance Schemata (Pollard & Sag 1994: Section 1.5), directly encode some of the effects of phrase structure rules.

determine attributes that may occur in structures of particular types, as well as types of values of such attributes.

Theory proper is a set of statements – often called principles – which impose additional, more complex constraints. For example, the famous Head Feature Principle (HFP) says that, in a *headed-phrase*, the mother has the same value of the HEAD attribute as the head daughter. Formally, this principle may be stated as follows:

(10) Head Feature Principle:

$$\textit{headed-phrase} \Rightarrow \begin{bmatrix} \textsc{synsem}|\textsc{cat}|\textsc{head} & \boxed{1} \\ \textsc{hd-dtr}|\textsc{synsem}|\textsc{cat}|\textsc{head} & \boxed{1} \end{bmatrix}$$

Such principles are understood universally: every linguistic object must satisfy them. For this reason they are usually implicational, with the antecedent defining the scope of the principle. In the case of (10), either an object is of type *headed-phrase*, so the antecedent is true and, hence, the consequent must also be true, or the object is not of this type, in which case the antecedent is false and the whole implication is trivially true.

The AVM in Figure 2 describes a configuration of objects containing two objects of type *headed-phrase*, i.e., satisfying the antecedent of HFP: the root object of type *hd-subj-ph* and its HD-DTR value of type *hd-comp-ph*. Both satisfy HFP – see the three occurrences of $\boxed{10}$ in that figure. All other objects in this configuration satisfy HFP trivially, as they are not described by the antecedent of HFP; this holds for the *word* objects representing *she*, *loves*, and *you*, the *synsem* objects which are values of the SYNSEM attribute, the *list* objects which are values of various occurrences of PHON, SUBJ, COMPS, and DTRS, etc.

There are also constraints relating the values of VAL and DTRS. The role of valency attributes is similar to the role of slashes in Categorial Grammar (Ajdukiewicz 1935, Lambek 1958; see also Kubota 2021 and references therein) – they express information about the combinatory potential of an element. For example, the *word* structure for *loves* in Figure 2 specifies that this word expects a complement and a subject. Once it combines with the complement *you*, the mother phrase of type *hd-comp-ph* needs only a subject in order to be a fully saturated phrase (i.e., a sentence) – its COMPS list is empty ("⟨ ⟩" is a synonym of the *elist* type in Figure 7). Moreover, once this phrase combines with the subject *she*, both valency lists become empty. This behaviour is regulated by principles such as the following:

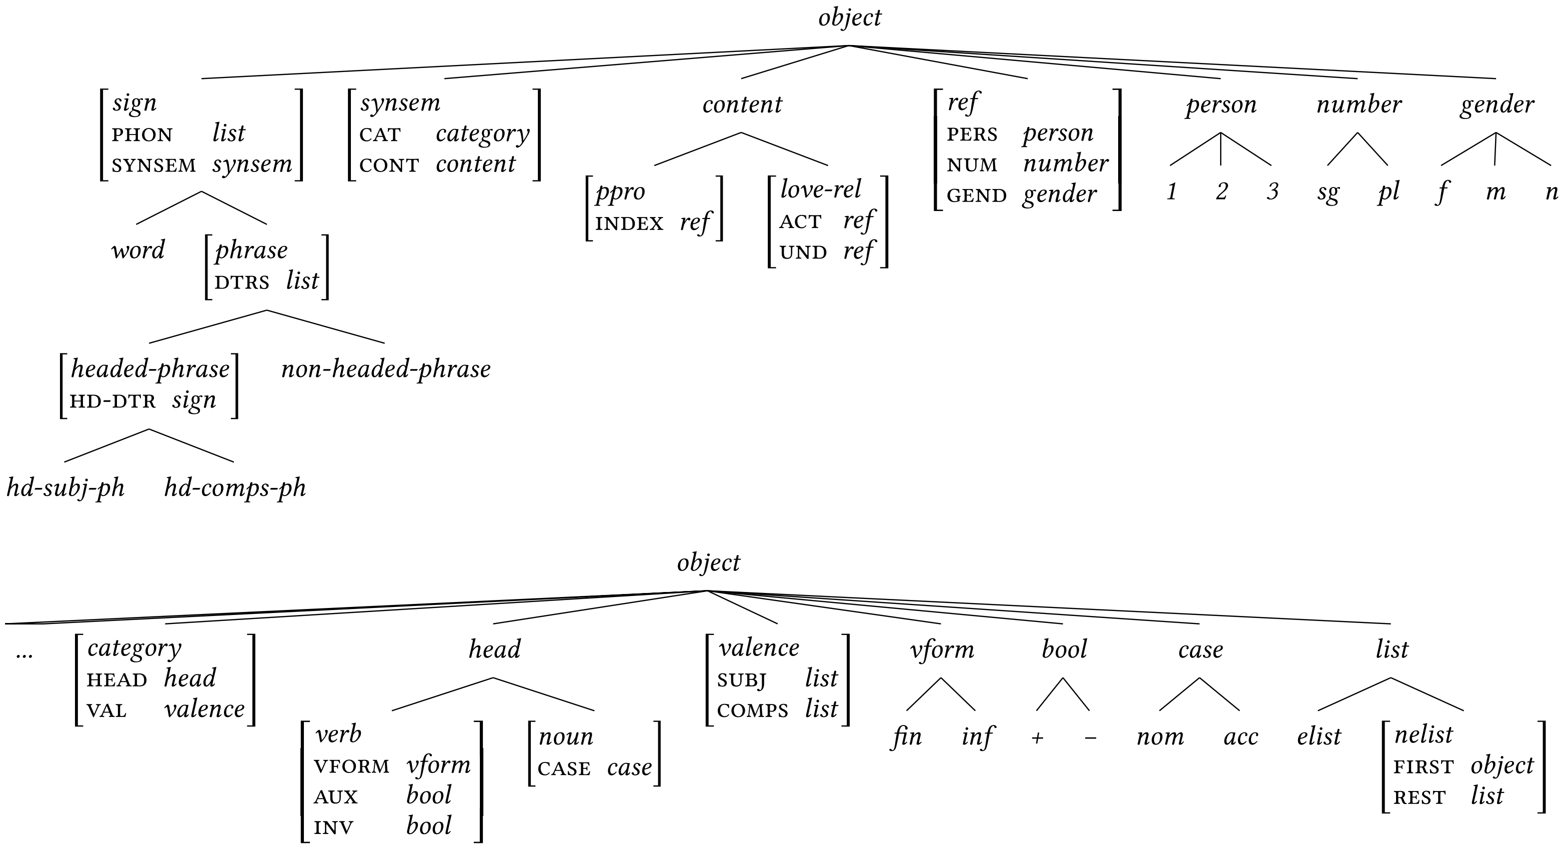

Figure 7: A larger part of an HPSG type hierarchy

(11) Valence Principles (modified and simplified):

a.
$$\textit{hd-subj-ph} \Rightarrow \begin{bmatrix} \text{\textsc{synsem}}|\text{\textsc{cat}}|\text{\textsc{val}} & \begin{bmatrix}\text{\textsc{subj}} & \langle\,\rangle \\ \text{\textsc{comps}} & \langle\,\rangle\end{bmatrix} \\ \text{\textsc{dtrs}} & \left\langle \left[\text{\textsc{synsem}}\ \boxed{2}\right], \boxed{1}\right\rangle \\ \text{\textsc{hd-dtr}} & \boxed{1} \begin{bmatrix}\text{\textsc{synsem}}|\text{\textsc{cat}}|\text{\textsc{val}} & \begin{bmatrix}\text{\textsc{subj}} & \langle\boxed{2}\rangle\\ \text{\textsc{comps}} & \langle\,\rangle\end{bmatrix}\end{bmatrix}\end{bmatrix}$$

b.
$$\textit{hd-comps-ph} \Rightarrow \begin{bmatrix} \text{\textsc{synsem}}|\text{\textsc{cat}}|\text{\textsc{val}} & \begin{bmatrix}\text{\textsc{subj}} & \boxed{0} \\ \text{\textsc{comps}} & \langle\,\rangle\end{bmatrix} \\ \text{\textsc{dtrs}} & \left\langle \boxed{1}, \left[\text{\textsc{synsem}}\ \boxed{2}\right]\right\rangle \\ \text{\textsc{hd-dtr}} & \boxed{1} \begin{bmatrix}\text{\textsc{synsem}}|\text{\textsc{cat}}|\text{\textsc{val}} & \begin{bmatrix}\text{\textsc{subj}} & \boxed{0}\\ \text{\textsc{comps}} & \langle\boxed{2}\rangle\end{bmatrix}\end{bmatrix}\end{bmatrix}$$

The constraint (11a) is saying that, in phrases of type *hd-subj-ph*, the head daughter ($\boxed{1}$) only requires a subject (its comps list is empty), this subject ($\boxed{2}$) is the (synsem value of the) first daughter of the phrase, while the second daughter ($\boxed{1}$) is the head daughter, and the phrase itself is fully saturated (both subj and comps are empty). Similarly, (11b) is saying that, in phrases of type *hd-comps-ph*, the single comps element of the head daughter is realised as its second daughter, the first daughter being the head, and the phrase does not expect a complement anymore. On the other hand, it still expects whatever subject (if any) is expected by the head daughter. The actual Valence Principle assumed in HPSG is more general; in particular, it allows for longer comps lists and the realisation of multiple arguments in a single local tree (see, e.g., Pollard & Sag 1994: 348).

Note that the values of valency attributes are lists of *synsem* structures (see $\boxed{2}$ in (11)), not whole phrases. This is an attempt to encode locality constraints on selection: a predicate may specify its arguments only by providing the kind of information that is encoded in synsem values, so it cannot select an argument on the basis of its phon value or with reference to the internal constituency structure of that argument (as it is encoded in the values of dtrs and hd-dtr).[19]

What about the lexicon? HPSG has full-fledged theories of the hierarchical lexicon, which make it possible to encode various generalisations across lexical items (see Davis & Koenig 2021 and references therein), but for the purpose of this comparison the simple principle in Figure 8 will do. What this principle is saying is that any *word* object must either satisfy the description in the first

---

[19] Note also that these principles do not say anything about values of phon. We will deal with phon values shortly, in Section 3.3.1.

$$
\textit{word} \Rightarrow \begin{bmatrix} \textsc{phon} & \langle \textit{she} \rangle \\ \textsc{synsem} & \begin{bmatrix} \textsc{cat} & \begin{bmatrix} \textsc{head} & \begin{bmatrix} \textit{noun} & \\ \textsc{case} & \textit{nom} \end{bmatrix} \\ \textsc{val} & \begin{bmatrix} \textit{valence} & \\ \textsc{subj} & \langle\,\rangle \\ \textsc{comps} & \langle\,\rangle \end{bmatrix} \end{bmatrix} \\ \textsc{cont} & \begin{bmatrix} \textit{ppro} & \\ \textsc{index} & \begin{bmatrix} \textit{ref} & \\ \textsc{pers} & \textit{3} \\ \textsc{num} & \textit{sg} \\ \textsc{gend} & \textit{f} \end{bmatrix} \end{bmatrix} \end{bmatrix} \end{bmatrix} \lor
$$

$$
\begin{bmatrix} \textsc{phon} & \langle \textit{you} \rangle \\ \textsc{synsem} & \begin{bmatrix} \textsc{cat} & \begin{bmatrix} \textsc{head} & \textit{noun} \\ \textsc{val} & \begin{bmatrix} \textit{valence} & \\ \textsc{subj} & \langle\,\rangle \\ \textsc{comps} & \langle\,\rangle \end{bmatrix} \end{bmatrix} \\ \textsc{cont} & \begin{bmatrix} \textit{ppro} & \\ \textsc{index} & \begin{bmatrix} \textit{ref} & \\ \textsc{pers} & \textit{2} \end{bmatrix} \end{bmatrix} \end{bmatrix} \end{bmatrix} \lor
$$

$$
\begin{bmatrix} \textsc{phon} & \langle \textit{loves} \rangle \\ \textsc{synsem} & \begin{bmatrix} \textsc{cat} & \begin{bmatrix} \textsc{head} & \begin{bmatrix} \textit{verb} & \\ \textsc{vform} & \textit{fin} \\ \textsc{aux} & - \\ \textsc{inv} & - \end{bmatrix} \\ \textsc{val} & \begin{bmatrix} \textsc{subj} & \left\langle \begin{bmatrix} \textsc{cat} & \begin{bmatrix} \textsc{head}|\textsc{case} & \textit{nom} \\ \textsc{val} & \begin{bmatrix} \textsc{subj} & \langle\,\rangle \\ \textsc{comps} & \langle\,\rangle \end{bmatrix} \end{bmatrix} \\ \textsc{cont}|\textsc{index} & \boxed{1} \begin{bmatrix} \textsc{pers} & \textit{3} \\ \textsc{num} & \textit{sg} \end{bmatrix} \end{bmatrix} \right\rangle \\ \textsc{comps} & \left\langle \begin{bmatrix} \textsc{cat} & \begin{bmatrix} \textsc{head}|\textsc{case} & \textit{acc} \\ \textsc{val} & \begin{bmatrix} \textsc{subj} & \langle\,\rangle \\ \textsc{comps} & \langle\,\rangle \end{bmatrix} \end{bmatrix} \\ \textsc{cont}|\textsc{index} & \boxed{2} \end{bmatrix} \right\rangle \end{bmatrix} \end{bmatrix} \\ \textsc{cont} & \begin{bmatrix} \textit{love-rel} & \\ \textsc{act} & \boxed{1} \\ \textsc{und} & \boxed{2} \end{bmatrix} \end{bmatrix} \end{bmatrix} \lor \ldots
$$

Figure 8: Word Principle

disjunct (which defines the word *she*), or the second disjunct (*you*), or the third disjunct (*loves*), etc. Again, it is easy to see that the structure described by the AVM in Figure 2 complies with this principle.

All the principles given or alluded to above constrain the shape of *sign*s – *word*s and *phrase*s – but principles may also refer to other types of objects. For example, the type hierarchy in Figure 7 only says that values of SUBJ and COMPS are lists, but the values of SUBJ cannot be of any length – their maximum length is one (a single predicate cannot have two subjects). This can be regulated with the constraint in (12) or – equivalently (given the type hierarchy in Figure 7) but more concisely – (13).

(12) $\textit{valence} \Rightarrow \left[\textsc{subj}\ \ \textit{elist}\right] \vee \left[\textsc{subj}|\textsc{rest}\ \ \textit{elist}\right]$

(13) $\textit{valence} \Rightarrow \neg\left[\textsc{subj}|\textsc{rest}\ \ \textit{nelist}\right]$

Moreover, values of SUBJ and COMPS cannot be just any lists – they must be lists of *synsem* objects. This may be achieved via constraint (14), whose antecedent is not just a type specification, with the predicate `list-of-synsems` defined as in (15).[20]

(14) $\begin{bmatrix}\textsc{subj} & \boxed{1}\\ \textsc{comps} & \boxed{2}\end{bmatrix} \Rightarrow \texttt{list-of-synsems(}\boxed{1}\texttt{)} \wedge \texttt{list-of-synsems(}\boxed{2}\texttt{)}$

(15) $\texttt{list-of-synsems(}\textit{elist}\texttt{).}$

$$\texttt{list-of-synsems(}\begin{bmatrix}\textit{nelist} & \\ \textsc{first} & \textit{synsem}\\ \textsc{rest} & \boxed{0}\end{bmatrix}\texttt{)} \overset{\forall}{\Longleftarrow} \texttt{list-of-synsems(}\boxed{0}\texttt{).}$$

This simple constraint illustrates an important aspect of contemporary HPSG, namely, the possibility to define and use in constraints any relation (Richter 1999, 2004). The notation for defining such relations is inspired by the programming language Prolog. The definition in (15) consists of two clauses jointly specifying what kinds of objects have the `list-of-synsems` property: the first clause says that the empty list is a list of synsems, and the second (recursive) clause says that a non-empty list whose FIRST element is a *synsem* object is a list of synsems if the REST of this list is a list of synsems. Nothing else is a list of synsems.

---

[20] I extend the notational conventions defined in Richter (2004: Section 3.2) in such a way that boxed variables appearing in the antecedents of implications are understood as bound by universal quantifiers scoping over the whole formula. So, the quantificational schema of (14) is: $\forall\boxed{1}\forall\boxed{2}\,(\phi(\boxed{1},\boxed{2}) \Rightarrow \psi(\boxed{1},\boxed{2}))$.

3.3 Comparison

3.3.1 Word order

One clear difference between the two frameworks stems from the fact that LFG grammars – but not HPSG grammars – are based on a CFG backbone. Traditionally (but see below) the sentence string is the yield of the c-structure, i.e., it is read off the leaves of the tree. In the case of free word order languages, this leads to trees in which functionally related constituents – for example, a noun and its adjectival modifier – are not always directly related configurationally.

Consider the Warlpiri sentence (16) from Simpson (1991: 257).

(16) Kurdu-jarra-rlu ka-pala maliki wajili-pi-nyi wita-jarra-rlu.
child-DU-ERG PRS-3.DU dog.ABS chase-NPST small-DU-ERG
'Two small children are chasing the dog.'
'Two children are chasing the dog and they are small.'

In this example, *wita-jarra-rlu* 'small' is a modifier of *kurdu-jarra-rlu* 'children', but on LFG analyses they do not form a constituent, as other constituents linearly intervene between these two words. For example, Austin & Bresnan (1996: 225) propose an analysis which results in the c-structure in Figure 9 (cf. Dalrymple et al. 2019: 112).

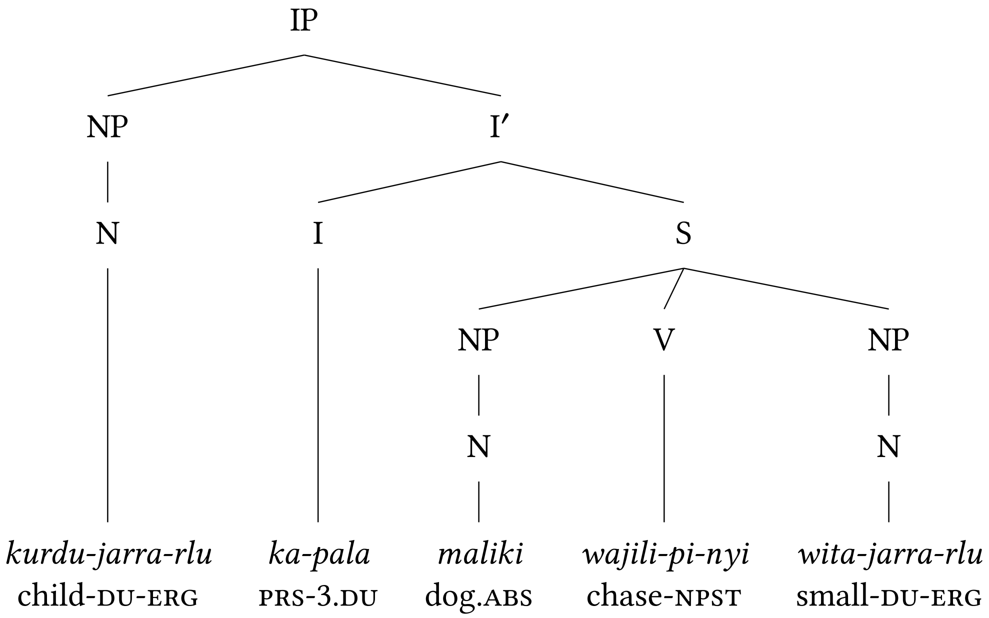

Figure 9: LFG c-structure of (16)

By contrast, it is possible to propose an HPSG analysis of Warlpiri word order on which *wita-jarra-rlu* ‘small’ and *kurdu-jarra-rlu* ‘children’ do form a constituent in (16) (in the sense in which the attribute DTRS represents immediate constituents). A shorthand and very schematic representation of the result of such an analysis is given in Figure 10 (after Donohue & Sag 1999: 13). Note that the order of words within the PHON value of the root of this tree is different from the order of PHON values of the leaves.

This analysis is possible because values of PHON are subject to the same constraints as any other structures. The usual tree behaviour, with PHON values of the mother being the concatenation of the PHON values of the daughters in the order in which they occur on the DTRS list, could be simulated with the constraint in (17), where $\mathsf{append\text{-}phons}(\boxed{2},\boxed{1})$ holds if $\boxed{1}$ is the concatenation of PHON values of the elements of $\boxed{2}$.[21]

(17) $$\begin{bmatrix} \textit{phrase} & \\ \textsc{phon} & \boxed{1} \\ \textsc{dtrs} & \boxed{2} \end{bmatrix} \Rightarrow \mathsf{append\text{-}phons}(\boxed{2},\boxed{1})$$

If the constraint in (17) were included in the grammar of Warlpiri, the representation in Figure 10 would be ill-formed.

However, other definitions are possible, which relax this usual approach. In fact, there is a long history of such linearisation accounts in HPSG, dating back to Reape (1992, 1996), Kathol & Pollard (1995), and Kathol (1995, 2000) (see also Müller 2021b and references therein); such a relaxed approach to word order is commonly assumed in HPSG analyses of ellipsis and coordination (see Nykiel & Kim 2021, Abeillé & Chaves 2021, and references therein). On such analyses, the two sentences in (18) (from Chaves 2008: 286) have exactly the same constituency structures but differ in PHON values.

(18) a. Tim gave a rose to Mary and a tulip to Sue.

b. Tim gave a rose to Mary and Tim gave a tulip to Sue.

---

[21] Formally, the relation $\mathsf{append\text{-}phons}$ is defined as in (i), and the relation append it relies on – as in (ii):

(i) $\mathsf{append\text{-}phons}(\textit{elist}, \textit{elist})$.

$$\mathsf{append\text{-}phons}\left(\begin{bmatrix} \textsc{first} & \begin{bmatrix} \textsc{phon} & \boxed{1} \end{bmatrix} \\ \textsc{rest} & \boxed{2} \end{bmatrix}, \boxed{3}\right) \overset{\forall}{\Longleftarrow} \begin{array}{c} \mathsf{append\text{-}phons}(\boxed{2},\boxed{4}) \wedge \\ \mathsf{append}(\boxed{1},\boxed{4},\boxed{3}). \end{array}$$

(ii) $\mathsf{append}(\textit{elist}, \boxed{1}\textit{list}, \boxed{1})$.

$$\mathsf{append}\left(\begin{bmatrix} \textsc{first} & \boxed{1} \\ \textsc{rest} & \boxed{2} \end{bmatrix}, \boxed{3}\textit{list}, \begin{bmatrix} \textsc{first} & \boxed{1} \\ \textsc{rest} & \boxed{4} \end{bmatrix}\right) \overset{\forall}{\Longleftarrow} \mathsf{append}(\boxed{2},\boxed{3},\boxed{4}).$$

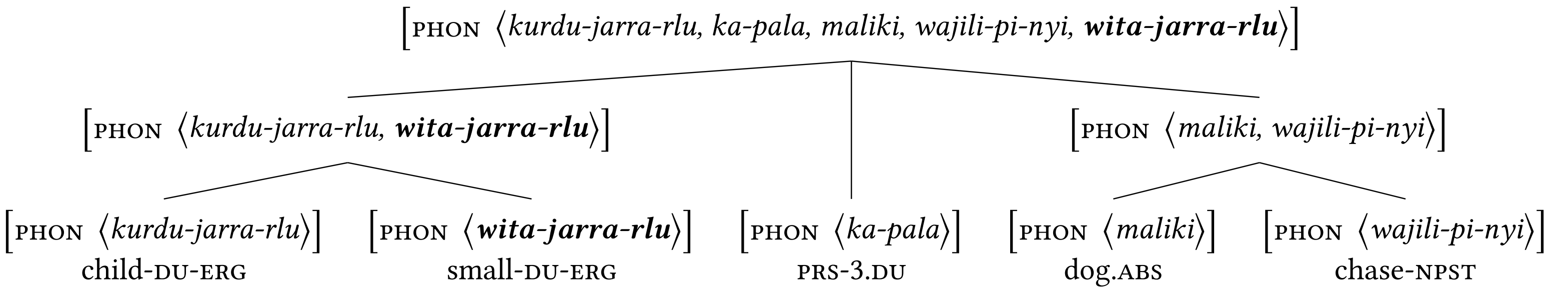

Figure 10: HPSG constituency structure of (16), with the form escaping the default word order constraints marked in bold

In LFG such a relaxed approach to word order is also in principle possible, on the assumption that there is a representation of the sentence string separate from c-structure. Such a separate string structure – sometimes called s-string (Dalrymple et al. 2019: Section 3.5) – is programmatically proposed in Kaplan (1987) and substantiated in Wescoat (2002), Asudeh (2009) and, especially, Dalrymple & Mycock (2011), among other works, but it is commonly assumed that the order of words in this additional string structure is the same as the order of leaves in c-structure. One exception to this common assumption are the analyses of cliticisation in Bögel et al. (2010) and in Lowe (2016), on which the position of clitics in the s-string may differ from their position in the tree.[22] However, to the best of my knowledge, there are no LFG analyses which would make a more substantial use of the possibility of relaxing the mapping between the s-string and the c-structure, analogous to those common in HPSG accounts of ellipsis.

3.3.2 Optionality of attributes

As has already been alluded to above and as will become fully clear in Section 4, grammars may be understood as theories describing certain linguistic objects. Figures such as 1 and 2 are representations of such objects. Both these figures represent all information that follows from all grammatical rules and principles of the respective grammars sketched in this section, but there is a sense in which the LFG representation in Figure 1 is complete while the HPSG representation in Figure 2 is only partial: it represents the effects of all constraints in the grammar proper, but it does not contain all information that follows from the type hierarchy.

Let us have a closer look at the INDEX values within structures corresponding to the word *you*. In both representations in Figures 1 and 2 this value is represented as an AVM with just one attribute, PERS, with a value indicating 2nd person. In the case of LFG, this is a complete description of the underlying feature structure; the linguistic object described by this subsidiary AVM has exactly one attribute: PERS. However, in the case of HPSG, the corresponding AVM is marked as representing a structure of type *ref*(erential index) and – according to the type hierarchy in Figure 7 (and the standard HPSG type system; see Pollard & Sag 1994: 399) – every *ref* object has exactly three attributes: PERS(on), NUM(ber), and GEND(er). Thus, the subsidiary AVM representing the value of INDEX for *you* is only a partial description of a complete linguistic object; any such object must also have specific values of NUM (*sg* or *pl*) and GEND (*m*, *f*, or *n*). That is, this

---

[22] Such a mechanism of prosodic inversion is also alluded to – but not provided an LFG formalisation – in Simpson (1991: 69), Kroeger (1993: 140), and Austin & Bresnan (1996: 226).

subsidiary AVM describes six different kinds of linguistic objects, differing in number and gender.

This technical difference between the two formalisms reflects a potentially important linguistic difference between the two theories: to what extent are the described linguistic objects allowed to be partial or indeterminate?[23] Such partial objects were the staple of the original HPSG of Pollard & Sag (1987), where the described objects were understood not as strictly linguistic objects but rather as informational objects – bits of information (including disjunctive and negative information) that competent speakers have about language.[24] But it seems that LFG sides with the latter-day HPSG in describing linguistic objects rather than informational objects. So the difference between the two representations of the INDEX value for *you* seems to be a linguistically contentful – and potentially verifiable – difference: on the LFG view the pronoun *you* is specified for person but *unspecified* or neutralised for number and gender, while on the HPSG view it is *ambiguous* between different values of number and gender.

Interestingly, it is easy to simulate the HPSG approach in LFG, but it is far from obvious how to simulate the LFG approach in HPSG. In LFG, the lexical entry of *you* could be extended from (9) to (19), with the last two statements requiring that NUM and GEND be present and have values within appropriate sets:

(19) *you* Pron (↑ PRED) = ‘PRO’
(↑ PRONTYPE) = PERSONAL
(↑ INDEX PERS) = 2
(↑ INDEX NUM) ∈ {SG, PL}
(↑ INDEX GEND) ∈ {M, F, N}

This leads to six different f-structure representations of the pronoun *you*, differing in the values of NUM and GEND.

Within HPSG, a more complex type subhierarchy could allow for different subtypes of *ref*, one of which would only be specified for the attribute PERS; let us call this subtype *ref-pers*. Then, the pronoun *you* could have the INDEX value of type *ref-pers*, with PERS equal to *2*. Another subtype, let us call it *ref-pers-num*, would be specified for PERS and NUM, and it would be appropriate for INDEX values of pronouns *I* (PERS *1*, NUM *sg*) and *we* (PERS *1*, NUM *pl*). This solution, however, is problematic in view of the following examples:

(20) Creatures, I give you yourselves… (C.S. Lewis, *The Magician’s Nephew*)

(21) Creature, I give you yourself…

---

[23] See also Kaplan (2019) for a discussion of this and related issues.

[24] See Richter (2004: Chapter 2) for a discussion of the differences between early and later HPSG.

The anaphoric pronouns *yourselves* and *yourself* are specified for person (2nd) and for number (plural and singular, respectively), but not for gender, so they should have INDEX values of type *ref-pers-num*. But, given the standard HPSG binding theory (cf. Section 4.3.2 below), these INDEX values should be equal to the INDEX values of the binder – the pronoun *you* in both examples above – so they should be of type *ref-pers*. The only way this is possible is that the two types, *ref-pers* and *ref-pers-num*, have a common subtype. But this common subtype would have to inherit the attribute NUM from *ref-pers-num*, so *ref-pers* would have a subtype with attribute NUM. Given that all objects in HPSG models – including all values of attributes – must bear maximally specific types (this will be made clear in Section 4.1 below), the pronoun *you* would be ambiguous: on one interpretation its INDEX would have a value (of this shared subtype) with NUM *sg*, on the other – with NUM *pl*. This would contradict the original motivation for the multiple subtypes of *ref*, namely, to make the pronoun *you* indeterminate with respect to number and gender, rather than ambiguous. It is not clear to me how to simulate within HPSG the behaviour of LFG – that is, how to make the pronoun *you* indeterminate with respect to number by default (i.e., apart from binding contexts such as (20)–(21)) – without complicating the standard HPSG binding theory.

In summary, while either approach may perhaps be simulated in the other theory, HPSG analyses naturally lead to a multiplicity of models differing in ways that linguists often do not care about, while LFG grammars naturally specify fewer linguistic objects, differing only in linguistically relevant aspects. We will return to this issue in Section 4.3.

3.3.3 Expressiveness

What is the relation of LFG and HPSG to the Chomsky–Schützenberger hierarchy of grammar formalisms (Chomsky 1956)? That is, what classes of languages do possible LFG and HPSG grammars describe? This question cannot be answered without making the notion of a "possible LFG/HPSG grammar" more precise. Given that both theories evolve and that at any particular point there are competing proposals about various aspects of the theories, this notion is not fully explicit and perhaps never will be.

Nevertheless, it is possible to ask about the complexity of the underlying formalisms, and it is clear that – without additional constraints – both are equivalent to Turing machines, i.e., they may describe any language that is algorithmically describable at all. There is no space here to formally prove this claim, but it is based on the well-known fact that attribute–value grammars may encode Turing machines (Johnson 1988: Section 3.4.2; see also Kaplan & Bresnan 1982: fn. 32). In particular, the unification grammar schema for simulating the effect of any Turing machine (i.e., for defining the same language as that recognised by that Turing machine) presented in Francez & Wintner (2012: Section 6.2) can be easily encoded in the formalisms underlying LFG and HPSG.[25]

Given this formal power of the underlying formalisms, the recognition problem (given a grammar and a sentence, is this sentence predicted by this grammar?) is undecidable – there is no general algorithm which could take an arbitrary grammar and sentence and always answer that question in finite time. In the case of LFG, this potential problem was recognised very early and a solution was proposed (Kaplan & Bresnan 1982: 266–267) in terms of what later became known as offline parsability (Pereira & Warren 1983: 142): a global condition on constituency structures, namely, that, first, they do not contain unary chains (subtrees with only unary branching) in which the same category appears twice and, second, that they do not use empty productions (i.e., that there are no empty leaves in the tree). The encoding of Turing machines in Francez & Wintner (2012: Section 6.2) violates both conditions (cf. fn. 25). A different way to make LFG grammars tractable is proposed – and references to other attempts are given – in Wedekind & Kaplan (2020).[26]

In the case of HPSG, the dominant underlying formalism (RSRL, Richter 1999, 2004; see Section 4.1) is known to be undecidable (Kepser 2004). A different formalisation, based on an extension of modal logic (namely, polyadic dynamic logic), is proposed and shown to have more desirable complexity properties in Søgaard & Lange (2009) but, to the best of my knowledge, it has remained largely unnoticed within the HPSG community.

Let me reiterate, however, that any less than desirable complexity results mentioned above pertain to formalisms underlying the linguistic theories, not to the

---

[25] In the case of LFG, the schemata ρ_1–ρ_8 of Francez & Wintner (2012: 230–232) can be directly translated into LFG phrase structure rules by taking CAT values to be node labels and by encoding all the other information present in the AVMs in ρ_1–ρ_8 via straightforward functional equations. In the case of HPSG, these schemata may be encoded as Immediate Dominance Schemata (Pollard & Sag 1994: Section 1.5), with an additional PHON attribute collecting the terminal symbols (dually to how they are collected in the values of the LEFT attribute in Francez & Wintner 2012). Schemata ρ_1–ρ_8 are essentially – appropriately annotated (which is the source of the additional complexity) – right-linear grammars with binary branching rules for reading the terminal symbols and with unary branching rules – including an empty production – for simulating a Turing machine. It is easy to modify this encoding to get rid of the empty production (the unary rules encoding transitions of a Turing machine could be used at the top of the tree instead of at the right-hand bottom), but the use of effectively unary rules with possible repetitions of non-terminal symbols along unary chains is non-negotiable.

[26] Simplifying, Wedekind & Kaplan (2020) require of grammars that there be an upper bound on the number of different c-structure nodes that may map to the same f-structure.

theories themselves. As has been repeatedly noted in both frameworks (see, e.g., Kaplan & Bresnan 1982: 271–272, Johnson 1988: 94–95, and Richter 2004: 242–243), it is very well possible that linguistic constraints sufficiently delimit the space of possible grammars to make the recognition problem decidable and efficient, and – conversely – it is also possible that human languages are in fact undecidable. That means that high complexity results for a formalism underlying a linguistic theory should not necessarily be held against that theory.

3.3.4 Generative-enumerative or model-theoretic?

Pullum & Scholz (2001) divide syntactic frameworks into "generative-enumerative" (GE) and "model-theoretic" (MT). GE frameworks have a derivational feel: at their centre are instructions for rewriting certain strings or structures into other strings or structures. Typical examples are formal grammars in the sense of the Chomsky hierarchy, for example, CFGs such as that in (4′)–(9′), where particular rules are such instructions. In the top-down mode, one starts with the string "S" and uses the rules to rewrite any non-terminal symbols – e.g., the rule (4′) to replace "S" with "NP VP" – until the resulting string contains only terminal symbols, e.g., "*she loves you*". In the bottom-up mode, one starts with a string of terminal symbols, e.g., "*she loves you*", and uses the rules in the other direction, until the resulting string "S", e.g.: "*she loves you*" → "*she loves* Pron" → "*she loves* NP" → "*she* V NP" → "*she* VP" → … → "S". The language defined by a grammar is the set of those strings of terminal symbols for which this procedure succeeds. Examples of GE systems are various transformational grammars, Categorial Grammars, Tree-Adjoining Grammars, etc. GE frameworks have an analogue in syntactic – proof-theoretic – aspects of logic.

By contrast, MT frameworks have an analogue in semantic – model-theoretic – aspects of logic. Grammars are sets of logical formulae which may be understood as defining models (namely, those models in which all the formulae are true). An early – historical – example is Arc-Pair Grammar, but currently HPSG seems to be the most clear case of an MT framework (Pullum 2019: 60). We will have a closer look at models of HPSG grammars shortly, in Section 4.1.

Some GE frameworks have a somewhat mixed character: they have a GE backbone but they also impose certain constraints on the resulting structures.[27] Two examples are the transformational grammar of the 1980s (GB; Chomsky 1981, 1986) and, to some extent, Generalized Phrase Structure Grammar (GPSG; Gazdar et al. 1985). It seems that, at least as originally conceived, LFG belongs in

---

[27] Thanks to Geoff Pullum for discussion and for the clarification that such "mixed" frameworks should still be classified as unambiguously GE.

the same category: there is a generative CFG backbone responsible for building c-structures (Kaplan & Bresnan 1982: 175), but also for generating functional statements which act as constraints on f-structures associated with particular c-structure nodes (Kaplan & Bresnan 1982: 181). The following quote makes this dual nature of the original LFG particularly clear:

> A string's constituent structure is generated by a context-free c-structure grammar. The grammar is augmented so that it also produces a finite collection of statements specifying various properties of the string's f-structure. (Kaplan & Bresnan 1982: 180–181)

If such statements – i.e., functional equations – cannot be satisfied, then the whole description for a given input fails, even if the c-structure rules produced an appropriate constituency tree for this input. The functional component thus acts as a filter on the output of the c-structure component (as explicitly stated in Kaplan & Bresnan 1982: 203–204).

Also some general LFG principles are formulated as constraints on possible f-structures (Kaplan & Bresnan 1982: 178–179, Dalrymple et al. 2019: Section 2.4.6): completeness and coherence jointly state that, simplifying a little, grammatical functions mentioned in PRED values must be exactly the grammatical functions occurring as attributes. The main f-structure in Figure 1 satisfies this constraint: PRED mentions SUBJ and OBJ and these are exactly the attributes which characterise grammatical functions in this f-structure. Similarly, f-structures which are values of SUBJ and OBJ satisfy this constraint: their PRED values do not mention any grammatical functions and none appears as an attribute in these f-structures.

Generative-enumerative frameworks may often be given model-theoretic reformulations. McCawley (1968) is usually credited with the observation that phrase structure rules may be understood as conditions on trees,[28] and fully-worked out MT equivalents of various GE formalisms were proposed by Rogers (1997, 1998). While there is no comprehensive MT formalisation of LFG, the description of the general architecture of LFG in Kaplan (1989: Section 2) is formulated in terms of conditions on particular structures, also on c-structures, and on correspondences between them,[29] and this view is prevalent in contemporary LFG.[30] For this rea-

---

[28] But cf. Pullum (2007: Section 1.7).

[29] The slightly modified version of Kaplan (1989) published a few years later explicitly invokes "model-based approach" as "of course, the hallmark of LFG" (Kaplan 1995: 11). An earlier model-theoretic formalisation of an LFG-like formalism (but without the distinction between defining and constraining statements) is Johnson (1988). See also Blackburn & Gardent (1995) for another attempt (also limited to defining statements; cf. Börjars & Payne 2013).

[30] For example: "In LFG, phrase structure rules are not rewrite rules, rather they are 'node admiss-

son, Pullum & Scholz (2001: 20) classify “recent LFG” as “perhaps” MT. I will have much more to say about model-theoretic aspects of LFG and HPSG in Section 4.

3.4 Summary

In this section we looked at two rather specific differences between LFG and HPSG grammars and two more general aspects. One specific difference concerns word order: in HPSG, but not in LFG, the string is often – especially, in analyses of ellipsis – assumed to be dissociated from the constituency structure. The other concerns determinacy: HPSG analyses often lead to multiple structures, i.e., to ambiguity, while LFG analyses more naturally lead to more compact indeterminate structures. Interestingly, despite the expressive power of the two theories, it is not always clear how to elegantly simulate in one theory the analysis commonly assumed in the other.

The two more general issues are expressivity and relation to the generative-enumerative vs. model-theoretic dichotomy postulated in Pullum & Scholz (2001). Underlying formalisms of both theories, unless additionally constrained, have the expressive power of Turing machines; such additional constraints were proposed in LFG right at the beginning and are the topic of ongoing work, while much less attention is devoted to the matter of complexity in HPSG. Finally, HPSG is a prototypical model-theoretic theory, while the place of LFG in this dichotomy is less clear, as no explicit model theory has ever been proposed for LFG. This is the issue to which I turn next.

4 Models

Grammars like those discussed in Section 3 are *descriptions* of collections of linguistic objects, pictures like those in Figures 1 and 2 of Section 2 are *representations* of particular configurations of such objects, but what exactly are these *objects* themselves? That is, what are the models of LFG and HPSG grammars? The two theories differ considerably in the extent to which answers to these question are provided: fully explicit model theories are proposed in HPSG, but only sketches and intuitive ideas may be found in LFG. For this reason, in this section I start with HPSG. First, however, a few words about models in general.

Take the following formulae of first-order logic:

(22) $\forall x.\, \mathit{black}(x) \leftrightarrow \neg \mathit{white}(x)$

---

ability conditions’ (McCawley, 1968); they are constraints rather than procedures.” (Snijders 2015: 61).

(23) $\forall x \forall y.\, bw(x, y) \rightarrow black(x) \wedge white(y)$

(24) $\forall x.\, black(x) \rightarrow \exists y.\, white(y) \wedge bw(x, y)$

(25) $\forall x.\, white(x) \rightarrow \exists y.\, black(y) \wedge bw(y, x)$

Together they are saying that everything is either *black* or *white* (see (22)) and that there is a relation, *bw*, which holds between *black* things and *white* things (see (23)) such that every *black* thing is in this relation with some (at least one) *white* thing (see (24)) and every *white* thing is related to some (at least one) *black* thing (see (25)). Informally speaking, the previous sentence is a description of possible models of formulae (22)–(25). One model is a two-element set such that one element is black, the other is white, and they are related. Another has two black elements and two white elements such that they are pairwise related, i.e., the relation *bw* denotes two pairs of elements. Another – one that also has two black elements and two white elements – is illustrated in Figure 11. The empty set is also a model, and there are infinitely many other models, both finite (of any cardinality apart from 1) and infinite (of any transfinite cardinality).

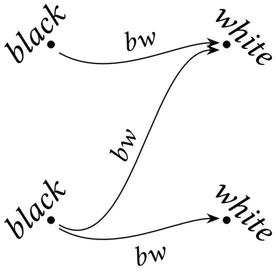

Figure 11: A model – one of many – of (22)–(25)

The meaning of the theory (22)–(25) may be equated with the collection of all models of that theory. However, we may want to exclude some models as not interesting or not really capturing what the formulae (22)–(25) are meant to capture. For example, perhaps we want models to be non-empty and – while possibly arbitrarily large – finite. The first condition may be stated by extending the theory with the formula $\exists x.\, x = x$.[31] However, the second condition, arbitrary finiteness, cannot be stated within first-order logic, so it must be stated meta-theoretically, as an additional constraint on permitted models.[32] As we will see below, both theories make use of such meta-theoretical conditions on models.

---

[31] Given the formulae (22)–(25), the same effect may be achieved, e.g., with $\exists x.\, black(x)$ or with $\exists x.\, white(x)$.

[32] Alternatively, a more expressive logic could be adopted.

4.1 HPSG

Of all linguistic theories, HPSG is perhaps unique in its concentrated attention to the issue of what grammars actually describe – what the models of HPSG theories are. There is no place here to summarise the different proposals found in the HPSG literature; some of them are critically discussed in Richter (2004: Section 2.2). Here, I will describe informally – and in terms which facilitate comparison with standard logical models and with potential LFG models – what I assume to be the standard HPSG approach, namely, the model theory of RSRL (Richter 1999, 2004).[33]

As in mathematical logic, RSRL models are sets of objects which may have various properties and relations defined on them. The properties correspond to the maximal types – called species – of type hierarchies: each object is assigned exactly one species.[34] For example, assuming the hierarchy of Figure 7, it is not enough for an object to have the property *list*; it must be either *elist* or *nelist*. Similarly, any *sign* object must actually be either a *word*, or a *hd-subj-ph*, or a *hd-comps-ph*, or a *non-headed-phrase*. In other words, species of HPSG type hierarchies partition sets of objects in HPSG models, just like the properties *black* and *white* partition sets of objects in models of the first-order theory (22)–(25).

Attributes correspond to relations. For example, still assuming the type hierarchy in Figure 7, the attribute REST is modelled as a relation between *nelist* objects and *list* (i.e., *elist* and *nelist*) objects. Similarly, SYNSEM relates *sign*s (i.e., objects of one of the species: *word*, *hd-subj-ph*, *hd-comps-ph*, and *non-headed-phrase*) to objects of type *synsem* (which is a species, according to this type hierarchy). This is similar to the possible interpretations of the relation *bw* as defined in (22)–(25): the domain of that relation is the set of black objects, and the co-domain – the set of white objects. However, the meanings of HPSG attributes are not just any relations; they are total functions on sets of appropriate species (*nelist*, in the case of REST) with values in the set of objects of appropriate species (*elist* and *nelist*, in the case of REST).

Additional constraints on objects and relations between them are provided by the theory proper, i.e., by principles such as the HFP in (10), repeated below as (26), and the principles in (11)–(14).

(26) Head Feature Principle:

$$\textit{headed-phrase} \Rightarrow \begin{bmatrix} \textsc{synsem}|\textsc{cat}|\textsc{head}\ \boxed{1} \\ \textsc{hd-dtr}|\textsc{synsem}|\textsc{cat}|\textsc{head}\ \boxed{1} \end{bmatrix}$$

---

[33] RSRL – Relational Speciate Re-entrant Language – adds relations and quantification to SRL – Speciate Re-entrant Language – of King 1989, 1999 (see also Pollard 1999). See Richter 2021 for an overview.

[34] That is, in the HPSG lingo, objects are *sort-resolved* (Pollard & Sag 1994: 18).

For example, HFP is saying that whenever there is an object of type *headed-phrase* – i.e., of species *hd-subj-ph* or *hd-comps-ph* – there must be other objects related via functions corresponding to HD-DTR, SYNSEM, CAT, and HEAD as illustrated in Figure 12. In this case, the value of the variable $\boxed{1}$ of (26) is the object number 7.

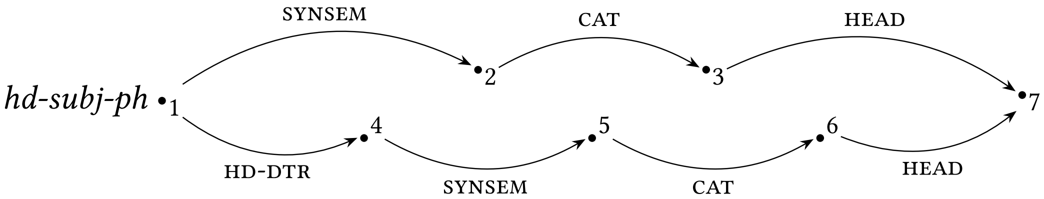

Figure 12: Configuration of objects satisfying the Head Feature Principle

Given the other principles and the type hierarchy, we know much more about this configuration of objects than is explicitly said in Figure 12. For example, the type hierarchy implies that the species of object 4 must be a maximal subtype of *sign*, the species of objects 2 and 5 must be *synsem*, etc. Additional constraints on configurations involving objects of type *hd-subj-ph* are imposed via one of the Valence Principles (namely, (11a)), etc.

Now, HPSG models are simply collections of objects such that each object satisfies all constraints following from the type hierarchy and the theory proper. For example, all seven objects in Figure 12 must satisfy HFP, not just object 1. And they all do, albeit – apart from object 1 – trivially: since objects 2–7 are not of type *headed-phrase*, the antecedent of HFP is false of them and the whole statement is true. But the configuration in this figure is not a complete model. For example, according to the type hierarchy in Figure 7, object 7, which is a value of HEAD, must be of type *head*, i.e., of species *verb* or *noun*. If it is a *verb*, there should be *vform* and *bool* objects in the model related to object 7 via attributes VFORM, AUX, and INV. If it is a *noun*, there should be an object related to object 7 via CASE. Similarly, according to the type hierarchy, object 1 should be related to two more objects via PHON and DTRS, and according to the Valence Principle (11a), the value of DTRS should be a two-element list, etc.

Since the late 1980s, all approaches to HPSG models agree with this general view of models, but they all impose additional – technical and sometimes philosophical – constraints on what counts as an interesting model. For example, the empty set is a model (all elements in this set satisfy all constraints), but a trivial one. Also a set consisting of just one object of species *elist* is a model, but it is not interesting. The common view is that HPSG models should be models of whole languages, that they should be exhaustive; in particular, a single exhaustive model contains configurations corresponding to all utterances licensed by the grammar. A little more technically but still very informally, exhaustive models simulate all other models: if there is a structure in some model, then this (or rather, an isomorphic) structure must also occur in an exhaustive model (King 1999). So, within a single exhaustive model, there are configurations of objects corresponding to the AVM in Figure 2,[35] other configurations corresponding to the utterance (2) (*You never give me your money*), and similarly for any other structures licensed by the grammar. This is a somewhat unusual approach to modelling; an analogous exhaustivity requirement in the case of the first-order theory (22)–(25) would mean that only infinite models are admitted, namely those which contain all possible correspondences of black and white objects.[36] We will return to this issue in Section 4.3.

The above considerations still leave open the question: What exactly are the objects in these models? For King (1999) they are bits of reality, actual linguistic tokens (e.g., every utterance of *She loves you* by anybody, ever), but also non-actual – potential – linguistic tokens, i.e., grammatical utterances which have the bad luck of never being actually uttered. This last notion is ontologically dubious, and also leads to proliferation of isomorphic structures within a single model, so it is not frequently subscribed to within the HPSG community.[37] Rather, it is often assumed that the objects in HPSG models are set-theoretic objects – or abstract feature structures – which only stand in conventional correspondence to actual or possible utterances (Pollard & Sag 1994, Pollard 1999). These abstract objects are designed in such a way that – simplifying again – any two isomorphic structures must actually be the same structure. Alternatively, the issue of what exactly these objects are is left unspecified, but an additional requirement is imposed that exhaustive models are minimal in the sense that they contain only one copy of any relevant configuration (Richter 2007).

4.2 LFG

While Kaplan (1995: 11) characterises LFG as “model-based”, no explicit and worked-out model theory has ever been proposed for LFG, as far as I know. Let us,

---

[35] Recall that the AVM in that figure is still an underspecified description, as it does not fix values of NUM and GEND within the *ref* object marked as $\boxed{5}$. It is also underspecified in other respects, to be discussed in Section 4.3.2.

[36] In fact, such models would be so large that they would not be sets anymore, but would rather be proper classes.

[37] Also, apart from the curious notion of non-actual tokens, it is not clear what counts as a single utterance token. For example, when John Lennon and Paul McCartney sing together *She loves you*, is this a single token, or two tokens (or perhaps none, because they are singing rather than speaking)? Does the answer depend on whether they sing in unison or in harmony? How many linguistic tokens are there when the song is broadcast on the radio, if any? Does that depend on the number of listeners at different locations?

nevertheless, try to construct a possible model corresponding to the representation in Figure 1, a model that is consistent with informal descriptions in Kaplan & Bresnan (1982) and Kaplan (1995).

First of all, the model must contain a collection of objects representing the nodes of the c-structure, as well as a collection of node labels (Kaplan 1995: 10). I assume that both grammatical categories (e.g., S or Pron) and orthographic forms (e.g., *she*) are labels. There are three relations defined on these objects: M (mother) is the partial function from nodes to nodes, defined on all nodes apart from the root; $<$ is the partial ordering relation on nodes, and λ is a function from nodes to labels. So a part of the model for the representation in Figure 1, one that corresponds to the c-structure, may look as in Figure 13 (with the linear relation $<$ not represented explicitly). There are 18 objects in this model: eight labels (S, VP, V, NP, Pron, *she*, *loves*, *you*) and ten nodes (objects whose exact nature is left unspecified). For an LFG grammar to lead to such models, it must be translated into appropriate formulae, appropriate tree axioms must be stated explicitly, and these axioms should be formulated in such a way that they apply to tree nodes and not to labels or objects corresponding to feature structures.

Kaplan & Bresnan (1982) and Kaplan (1995) are much more explicit about the kinds of objects that correspond to feature structures. There are three types of objects involved in models of feature structures: atoms (e.g., PRED, SUBJ, NOM, 3, etc.), semantic forms (to the first approximation, strings such as 'LOVE⟨SUBJ,OBJ⟩'), and sets. In particular, feature structures are modelled as finite functions – sets of pairs such that the first element of a pair is an atom and the second element is either an atom, or a semantic form, or a feature structure (i.e., a set again).[38] For example, the AVM in (27) is a representation of the set of pairs in (28), i.e. – given the commonly assumed Kuratowski's encoding of a pair $\langle a, b\rangle$ as the set $\{\{a\}, \{a, b\}\}$ (see, e.g., Enderton 1977: 36) – the set in (29).[39]

---

[38] Together with Kaplan & Bresnan (1982) and Kaplan (1995), I do not take into consideration sets other than those which model feature structures, i.e., I ignore here coordinate structures, values of the attribute ADJUNCT, etc.

[39] One potential problem with this standard LFG understanding of f-structures as sets is that, given the possibility of cyclic f-structures – naturally occurring in analyses of various types of modification, e.g., Johnson (1988: 19–20), Zweigenbaum (1988), and Haug & Nikitina (2012: 298), and in other contexts, e.g., Fang & Sells (2007: 209), Przepiórkowski & Patejuk (2012: Section 4.3.2), and Dalrymple et al. (2020) – sets that are used for modelling f-structures are not the well-founded sets of the standard (Zermelo–Fraenkel) set theory, but must rather rely on the non-standard notion of non-well-founded sets (see Aczel 1988: 103–112 on the history of this notion). To the best of my knowledge, this has not been noticed in the LFG literature so far.

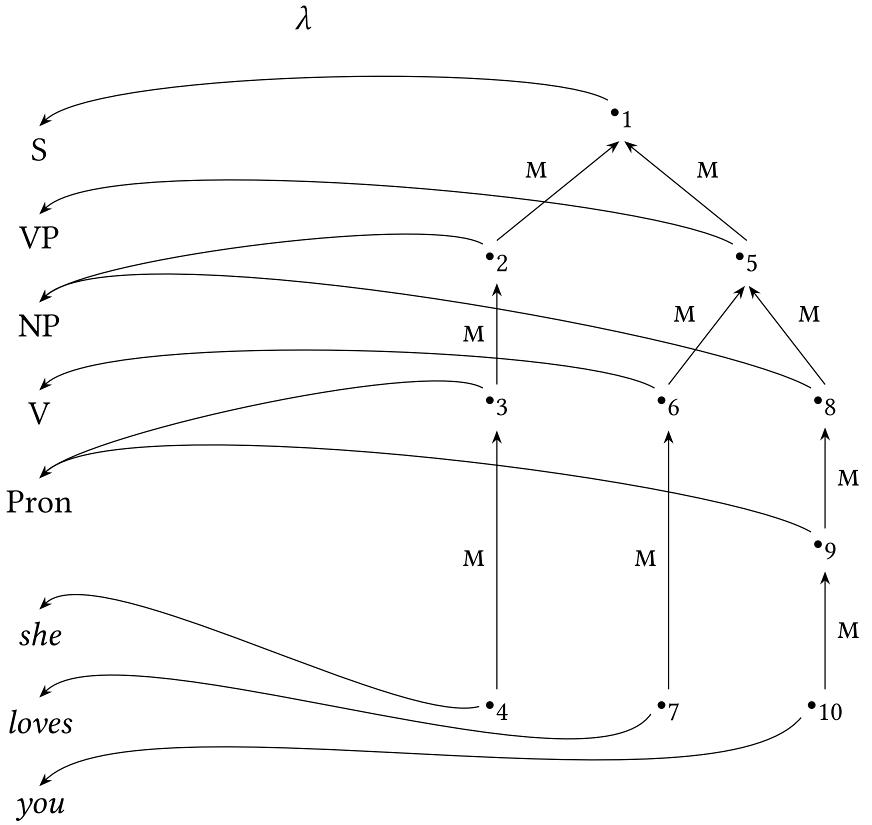

Figure 13: A possible LFG model of the c-structure of *She loves you* (without explicit representation of <)

(27) $\begin{bmatrix} \textsc{pers} & 3 \\ \textsc{num} & \textsc{sg} \\ \textsc{gend} & \textsc{f} \end{bmatrix}$

(28) $\{\langle \textsc{pers}, 3\rangle, \langle \textsc{num}, \textsc{sg}\rangle, \langle \textsc{gend}, \textsc{f}\rangle\}$

(29) $\{\ \{\{\textsc{pers}\}, \{\textsc{pers}, 3\}\},\ \{\{\textsc{num}\}, \{\textsc{num}, \textsc{sg}\}\},\ \{\{\textsc{gend}\}, \{\textsc{gend}, \textsc{f}\}\}\ \}$

Since some parts of f-structures (values of particular attributes, as well as attributes themselves) may be directly referred to in functional equations, they must all be direct elements of the model. That is, sets representing f-structures cannot be considered unanalysable elements of models; rather, the subsets and atoms within such sets must also be elements of LFG models, so they should be explicitly related by the (converse of the) membership relation $\in$. Hence, the set in (29) corresponding to the f-structure (27) translates into the configuration of model objects in Figure 14. There are 10 nodes in this configuration that encode particular sets (with node 1 representing the whole f-structure (27)) and six nodes are atoms.

The model in Figure 14 is rather complex, when compared to the simplicity of the AVM in (27). Why not assume the model in Figure 15 instead?[40] Unfortunately, as explained in more detail presently (in Section 4.3.1), this simpler model is incompatible with the LFG idea that attributes and atomic values are ontologically the same kinds of entities, namely, atoms. By contrast, according to the model in Figure 15, atomic values are atoms – objects of the universe of the model – but attributes are binary relations on such objects, i.e., ontologically very different entities. Hence, in the following I will assume the model in Figure 14 as most directly reflecting the LFG view that f-structures are finite functions.

Le me finish this section by noting that configurations in Figures 13 and 14 are fragments of a larger model corresponding to the representation of *She loves you* given in Figure 1. The complete model would also contain strings representing semantic forms, as well as more atoms, many more sets representing the full f-structure, sets representing the s-structure, and relations ϕ and σ.

4.3 Comparison

4.3.1 Modelling feature structures

It should be clear from the above discussion that AVM representations correspond to very different model configurations in the two theories. For example, while the HPSG model of the AVM in (30), shown in Figure 16, contains just four nodes corresponding directly to the whole index (object 1 of species *ref*), to 3rd person (object 2 of species *3*), to singular number (3 – *sg*), and to feminine gender (4 – *f*), the LFG model of the corresponding AVM in (27), shown in Figure 14, contains 16 nodes modelling not only the whole f-structure and the respective values of the three attributes, but also the attributes themselves and various intermediate sets.

(30)
$$\begin{bmatrix} \textit{ref} & \\ \textsc{pers} & \textit{3} \\ \textsc{num} & \textit{sg} \\ \textsc{gend} & \textit{f} \end{bmatrix}$$

This is not an incidental difference between the two theories. In HPSG, attributes such as PERS, NUM, and GEND and types such as *3*, *sg*, and *f* have very different interpretations: attributes denote relations (partial functions) between

---

[40] Compare the HPSG model of (30) in Figure 16 below. Such simpler models, in which feature structures are represented as objects and attributes as relations on objects, are also common in other theories working with AVMs (see, e.g., Blackburn & Spaan 1993: 132–133).

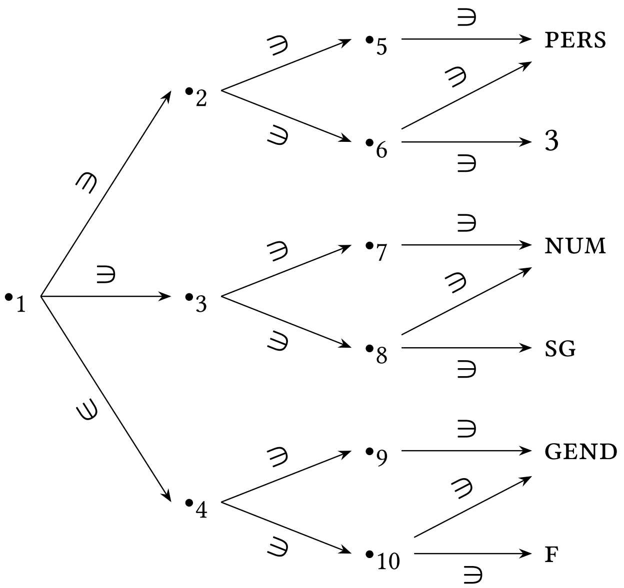

Figure 14: A possible LFG model of the f-structure in (27)

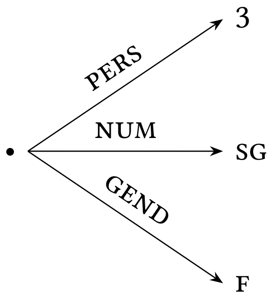

Figure 15: A hypothetical simpler model of the AVM in (27)

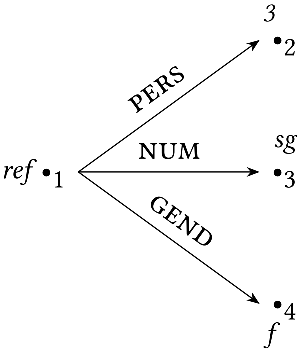

Figure 16: An HPSG model of the AVM in (30)

objects in the model, while types denote properties that objects may have. In particular, different objects may – and often do – have the same species, so there can be many objects of type *sg*, etc. This difference between attributes and types is rendered typographically by using small capitals for attributes and italics for types.

On the other hand, in LFG, attributes such as pers, num, and gend and their atomic values such as 3, sg, and f are the same kinds of objects, namely atoms, each of which may occur in the model just once (there is only one atom sg, etc.). Hence, there is also no typographic distinction between attributes and atomic values of attributes.

This ontological uniformity of attributes and atomic values is taken advantage of in some LFG analyses. For instance, according to the analysis of oblique arguments in Kaplan & Bresnan (1982: 196–201), a "case-marking" preposition which may introduce such an oblique argument defines the value of the attribute pcase to be the oblique function homonymous with this preposition, e.g.:

(31) *to* P (↑ pcase) = to

This feature and its value are also present in the f-structure corresponding to the resulting PP constituent. Verb forms like *handed*, as used in (32) from Kaplan & Bresnan (1982: 196), expect – apart from any subject and objects – an argument bearing this grammatical function, see (33).

(32) A girl handed a toy to the baby.

(33) *handed* V (↑ pred) = 'hand⟨subj,obj,to⟩'
(↑ tense) = pst

Finally, an appropriate VP rule – simplified here to (34) – contains the crucial equation (35) on the PP:

(34)
$$\begin{array}{llll} \text{VP} \longrightarrow & \text{V} & \text{NP} & \text{PP} \\ & \downarrow = \uparrow & (\uparrow \text{obj}) = \downarrow & (\uparrow (\downarrow \text{pcase})) = \downarrow \\ & & (\downarrow \text{case}) = \text{acc} & \end{array}$$

(35) (↑ (↓ pcase)) = ↓

Applied to the sentence (32), with the PP *to the baby*, (↓ pcase) in equation (35) evaluates to to, so the whole equation is equivalent to (↑ to) = ↓. Note that to, the atomic value of pcase of the preposition *to*, is used here as an attribute indicating an oblique grammatical function. While such double use of atoms as values and attributes is rare in actual LFG analyses, it is not unique to the account of obliques in Kaplan & Bresnan (1982); for example, it also occurs in the formalisation of information structure in Dalrymple & Nikolaeva (2011: Sections 4.3.3–4.3.5).

The above considerations do not imply that not distinguishing attributes from atomic values necessarily leads to such complex models as that partially illustrated in Figure 14. For example, Johnson (1988: Section 2.1.3) defines models of f-structures as consisting of a set of atoms, a set of objects directly modelling particular feature structures, and a 2-argument partial function δ whose first argument is an f-structure, second argument is an atom *qua* attribute, and the value is the value of this attribute in this f-structure. On this approach the AVM in (27) receives a model that may be represented pictorially as in Figure 17. Note, however, that on this view feature structures are no longer sets of ⟨attribute, value⟩ pairs, contrary to Kaplan & Bresnan (1982) and Kaplan (1995).

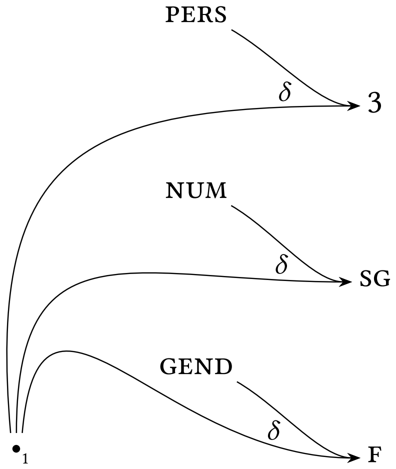

Figure 17: A model of the f-structure in (27) as in Johnson (1988)

4.3.2 Identity of indiscernibles?

Both theories have trouble with indiscernible structures. Let us illustrate this with sentence (36).

(36) She says she loves you.

Consider the LFG f-structure for this sentence in Figure 18. In the model configuration corresponding to this AVM there are single objects representing particular atoms: just one object NOM, one SG, one PRS, one TENSE, etc. Moreover, since feature structures are sets of ⟨attribute, value⟩ pairs, the two INDEX values – the substructures marked as $\boxed{2}$ and $\boxed{4}$ – are the same set (namely, the one in

(29)), so they should be modelled with the same single object in the model (or, more precisely, with a single configuration of objects shown in Figure 14, rooted in the same object 1). The problem is that nothing in our reconstruction of the intended LFG model theory guarantees this: two different models are possible, one in which $\boxed{2} = \boxed{4}$, and one in which $\boxed{2} \neq \boxed{4}$. Only the first of these models properly encodes the idea that feature structures are sets.[41] We will return to this issue below, when discussing HPSG models.

$$
\left[\begin{array}{ll}
\textsc{pred} & \text{‘}\textsc{say}\ \langle\textsc{subj},\textsc{comp}\rangle\text{’} \\
\textsc{subj} & \boxed{1}\left[\begin{array}{ll}
\textsc{pred} & \text{‘}\textsc{pro}\text{’} \\

\textsc{prontype} & \textsc{personal} \\
\textsc{case} & \textsc{acc} \\
\textsc{index} & \left[\textsc{pers}\ \ 2\right]
\end{array}\right] \\
\textsc{tense} & \textsc{pres}
\end{array}\right] \\
\textsc{tense} & \textsc{pres}
\end{array}\right]
$$

Figure 18: F-structure for (36)

The bigger problem is that, if f-structures are sets, the two f-structures representing *she*, i.e., $\boxed{1}$ and $\boxed{3}$ in Figure 18, are the same set-theoretical object. (In the modelling of f-structures suggested above they may be the same object, but – as discussed in the previous paragraph – they do not have to be.) But LFG requires that they be different objects – we do not want to say that the two ‘PRO’ values

---

[41] Interestingly, the XLE platform for implementing LFG grammars (Crouch et al. 2011), normally very faithful to the LFG theory, does not treat f-structures as (standard) sets: there, two indiscernible f-structures are assumed to be different objects, unless there is a statement in the grammar that explicitly requires their identity.

in these f-structures necessarily refer to the same person. The way LFG deals with this problem is to assume that PRED values – semantic forms – come with unique indices (normally not shown in AVMs), i.e., that whenever an equation like (↑ PRED) = ‘PRO’ is used, a new index is assigned to the semantic form. So the two references to the lexical entry for *she* in (8) that are made in the process of constructing the f-structure in Figure 18 result in two different equations, as if the following two statements were used:

(37) a. (↑ PRED) = ‘PRO’$_1$
 b. (↑ PRED) = ‘PRO’$_2$

Unfortunately, this mechanism, as it stands, seems to be inherently procedural: at the relevant step of the derivation it must be known which indices have already been used so that a new index can be assigned to a new semantic form. It is not immediately clear how to translate this mechanism to the model-theoretic view of LFG.[42]

Also HPSG has a problem with stating when exactly indiscernible structures should be treated as being the same structure.[43] In HPSG, not even atoms are guaranteed to be unique, so one of the models of sentence (36) (*She says she loves you*), whose partial AVM is given in Figure 19, might involve the configuration in Figure 20, with single objects of type *3* and *sg* and two different objects of type *f*. Given two different *ref* objects, there are eight possible configurations of this part of the model, and given also the possibility of two different *nom* objects, two different *she* objects (in PHON values), different *elist* objects, etc., there are billions of different models of sentence (36), all described by the AVM in Figure 19, differing in ways that linguists do not care about.[44] This contrasts with the efforts

---

[42] Given that PRED values are largely redundant (cf. Section 2.1 and fn. 12), this problem may be solved by removing PRED from f-structures altogether. Another – perhaps more conservative – possible solution, suggested by Ash Asudeh (p.c.), is to provide indices with sufficient inherent structure to guarantee their uniqueness. In the simple case of (36), it would suffice to take indices to be the relevant c-structure nodes, but a more complex solution is required to also apply to ‘PRO’ values of PRED in the case of pro-dropped constituents (especially in languages which allow pro-dropping of multiple arguments of a single predicate).

[43] The problem to be described presently is sometimes called “Höhle’s problem” (Pollard 2001, 2014: 113).

[44] Each word introduces three lists (values of PHON, VAL|SUBJ, and VAL|COMPS), and there are five words in this sentence, so there are 15 *elist* objects stemming from words alone. The number of different ways to partition a set of *n* elements into equivalence classes is given by Bell numbers B_n, and B_{15} = 1,382,958,545 (see https://oeis.org/A000110/list). This should be multiplied by the eight configurations of the two *ref* objects, etc. Richter (2007) proposes a constraint to the effect that all *elist* objects are the same object, but the problem of the other spurious ambiguities remains.

within HPSG (Pollard & Sag 1994, Pollard 1999, Richter 2007) to make models of various interpretations of utterances unique (at least up to isomorphism).

Now, it is possible to formulate within RSRL a constraint that makes sure that all indiscernible structures are in fact the same structure (Sailer 2003: Section 3.1.4), but such a constraint, if applied indeterminately, would be incompatible with various HPSG analyses – most importantly, with the standard HPSG binding theory (Pollard & Sag 1994: Chapter 6).[45] There is no space to present that theory here (see Müller 2021a for an overview), but suffice it to say that the traditional generative notion of coindexation is understood here literally: as identity of INDEX values. For example, the sentence (36) is assumed in HPSG to have two different structures corresponding to the following two indexations:

(38) a. She$_i$ says she$_i$ loves you.
b. She$_i$ says she$_j$ loves you. $(i \neq j)$

So while any model of (38a) should equate INDEX values within the two words *she* in this sentence, these INDEX values must be different objects in any model of (38b), even though they are indiscernible.

To the best of my knowledge, the problem of avoiding spuriously distinct models in a way that does not conflict with existing HPSG analyses (in particular, with the standard binding theory) remains unsolved.

4.3.3 Conditions on models

Both theories impose meta-theoretical conditions on what counts as an intended model. As mentioned in Section 4.1, the common constraint on HPSG models is that they be exhaustive, i.e., informally speaking, simulate all other models: they should contain all structures admitted by the grammar. The intuition behind this requirement is that a single model corresponds to the whole language described by the grammar.

LFG apparently assumes the more common view of models, where each model corresponds to a single utterance, and it is only the collection of all such models that corresponds to the whole language. However, meta-theoretical conditions on LFG models are in a way more complex than conditions imposed on HPSG models.

First of all, LFG models are required to be minimal. For example, functional equations in the lexical entry of *she* (see (8)) involving the attribute INDEX, i.e.

---

[45] Also the architecture for phonology proposed in Höhle (1999) crucially relies on not all indiscernible structures being the same structure. Sailer (2003) formulates the relevant constraint in such a way that it only applies to one type of structures.

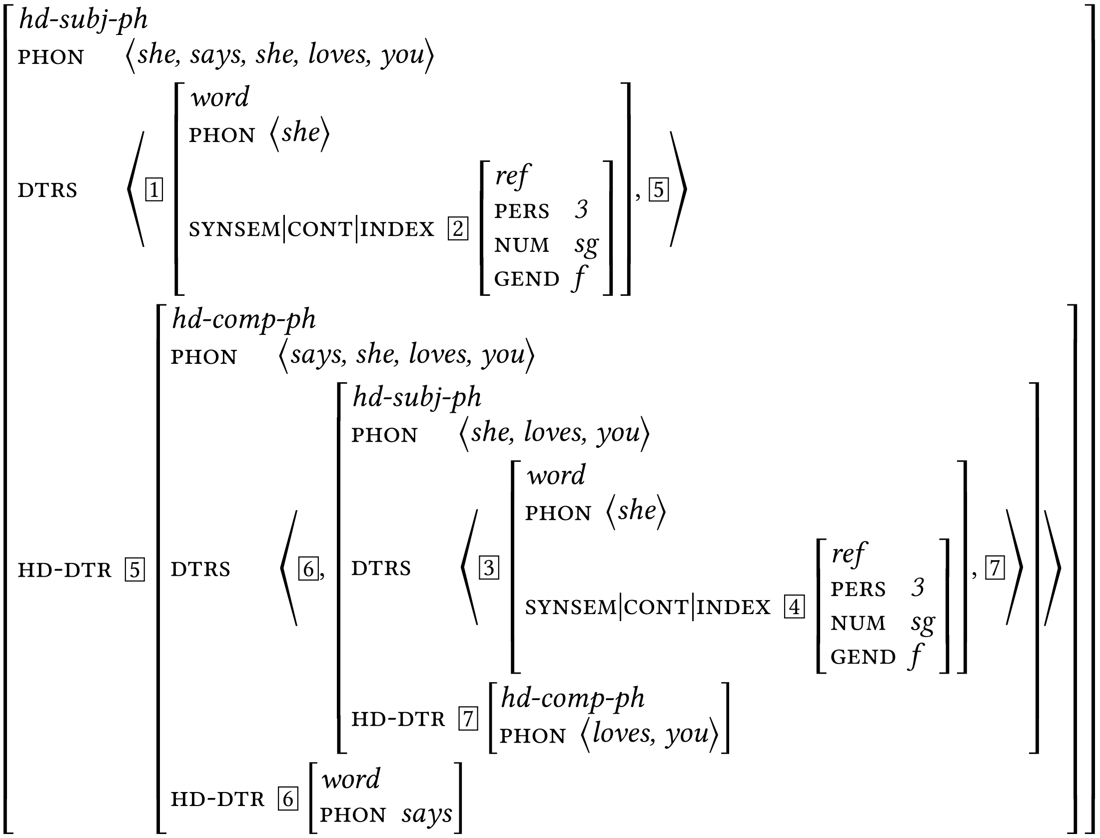

Figure 19: Partial HPSG representation of (36)

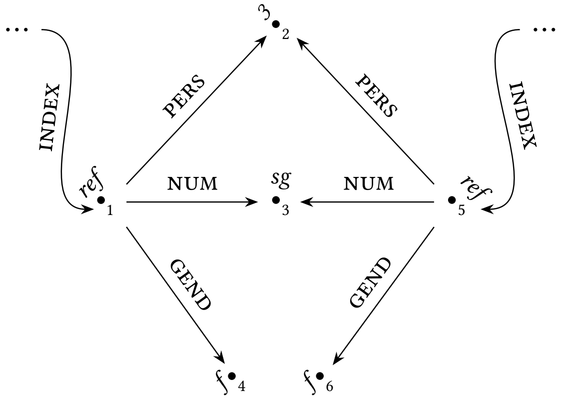

Figure 20: A fragment of a possible HPSG model of the AVM in Figure 19

equations repeated below in (39), describe as a possible value of INDEX not only the feature structure in (27), repeated below as (40), but also the one in (41) and infinitely many others, including infinite feature structures (both infinitely embedded and – on the assumption that the set of atoms may be infinite – with an infinite number of attributes).

(39) $(\uparrow \textsc{index pers}) = 3$
$(\uparrow \textsc{index num}) = \textsc{sg}$
$(\uparrow \textsc{index gend}) = \textsc{f}$

(40) $$\begin{bmatrix} \textsc{pers} & 3 \\ \textsc{num} & \textsc{sg} \\ \textsc{gend} & \textsc{f} \end{bmatrix}$$

(41) $$\begin{bmatrix} \textsc{pers} & 3 \\ \textsc{num} & \textsc{sg} \\ \textsc{gend} & \textsc{f} \\ \textsc{arbi} & \textsc{trary} \\ \textsc{non} & \begin{bmatrix} \textsc{sen} & \textsc{se} \end{bmatrix} \end{bmatrix}$$

Other constraints in the grammar do not preclude such values of INDEX, so a meta-theoretical constraint is needed to the effect that only minimal feature structures satisfying the grammar are admitted within models. Technically, this amounts to defining a partial order on models and admitting only the minimal elements of this order.

The second condition on models is more complex and concerns constraining statements such as (42a) (from the grammar rule (4)) and (42b) (from the lexical entry (7)).

(42) a. $(\downarrow \textsc{tense})$
b. $(\uparrow \textsc{subj index pers}) =_c 3$

Such statements are understood as additional filters on the minimal models of a grammar, or – more precisely – on the minimal models of the version of the grammar with all such constraining statements removed.

The precise model-theoretic nature of this mechanism has never, to the best of my knowledge, been specified. Constraining statements of this kind are not mentioned in the model-theoretic view of LFG of Kaplan (1995), and they are explicitly excluded in previous attempts to provide LFG (or LFG-like) formalisms with a model theory (see Johnson 1988: Section 4.2 and Blackburn & Gardent 1995: Section 6; see also Börjars & Payne 2013). But once meta-theoretical quantification over models and relations on models are permitted – and they are already inherent both in the HPSG notion of exhaustive models and the LFG notion of minimal models – it is possible to understand constraining statements in model-theoretic terms. One possibility is this:[46]

- Let θ be an LFG grammar, understood as a set of logical formulae. Some of the (sub)formulae are marked as constraining, the others are understood as defining.
- Let θ_{all} be the whole grammar θ without any division of (sub)formulae into defining and constraining, and θ_{def} – the same grammar with all constraining (sub)formulae removed.
- Let M_{all} be the collection of all models of θ_{all}, and M_{def} – the collection of all *minimal* models of θ_{def}.[47]
- Then $M \overset{\mathrm{df}}{\equiv} M_{def} \cap M_{all}$ is the collection of admitted models of θ.

The idea here is that M_{def} is the collection of all minimal models before the constraining filters are applied, and the intersection with M_{all}, i.e., with models in which all constraining statements are satisfied, removes from M_{def} those models which do not satisfy some constraining statements.

4.4 Summary

This section, aiming to present and compare model theories assumed in HPSG and LFG, is more speculative than the previous sections. The reason is that one object of comparison exists and the other does not, so it was necessary to reconstruct a possible model theory of LFG from informal and very partial suggestions.

Perhaps surprisingly, it turns out that the idea that f-structures are sets of ⟨attribute, value⟩ pairs does not translate into elegant models, but rather creates an overhead of the need to represent these sets as objects within models. Also, additional care needs to be taken to ensure that co-extensional sets are really the same model objects. Moreover, it is not immediately clear how to formally

---

[46] Given that statements may contain disjunctions, and that different constraining statements may occur in different disjuncts, the actual definition would have to be more complex: grammars would have to be converted to a disjunctive normal form and collections of models would have to be defined for each disjunct of this normal form. Then the final collection of models of the grammar would be the sum of all such collections.

[47] Formally, minimal models are the minimal elements of the subsumption relation defined on models as in Johnson (1988: Section 2.8).

and non-procedurally ensure unique indexation of semantic forms. Nevertheless, despite these difficulties, and despite the fact that constraining statements were excluded from previous attempts to construct a model theory for LFG, it is not difficult to imagine how to construct such a model theory, if only appropriately powerful meta-theoretical operations on candidate models are permitted (as – to some extent – they already are, given the minimality requirement).

Also somewhat surprisingly, while much attention has been devoted to model theory within HPSG, there are still unsolved problems there, concerning the multiplicity of different models admitted by typical HPSG grammars, differing in ways that linguists often do not suspect, and certainly do not care about.

Let the conclusion of this section be that, despite their age and stability, both theories would benefit from more work on their formal foundations.

5 Conclusion

So how similar are LFG and HPSG? I agree with Carl Pollard that in some ways they are more similar than sometimes perceived:

> I believe that the difference between LFG and so-called PSG [i.e., theories such as GPSG and HPSG; AP] is no greater than the differences among various theoretical proposals within PSG, or even within HPSG itself. As far as I am concerned, then, the separation between PSG and LFG exists more at a sociological level than at the level of scientific content – but I am aware that not everyone agrees about this. (Pollard 1997: 4)

In particular, the difference between the multi-level representations of LFG and the monolithic AVMs assumed in HPSG is – in my view – of little formal consequence, although it is certainly important for the compactness and readability of resulting structures.

In fact, LFG and HPSG converge in many respects. As emphasised above, both theories are highly formalised and – unlike derivational theories or Categorial Grammar – both are self-described as constraint-based or model-theoretic, although HPSG may boast of much more developed model theories. Importantly, both have well-developed computational platforms for implementing grammars: XLE (Crouch et al. 2011) in the case of LFG and LKB (Copestake 2002) and Trale (Carpenter et al. 2003) in the case of HPSG, with XLE allowing for very direct implementations of theoretical analyses.[48] In both cases, large-scale grammars of multiple languages have been developed.

Also, unlike some of the other highly formalised and implementable theories, both LFG and HPSG are empirically rich. A plethora of analyses of multiple phenomena in typologically varied languages have been offered within each theory, in a great many articles appearing in the best linguistic journals and in numerous monographs published by the most prominent publishers. Both have very well developed semantic components, and both make it possible to formulate precise analyses encompassing multiple linguistic levels. As emphasised in Wechsler & Asudeh (2021), many phenomena receive similar accounts in the two theories.

In summary, it is clear that LFG and HPSG are close neighbours in the linguistic theoretical landscape of the early 2020s, and it is my hope that this chapter encourages more neighbourly collaboration between the two theories.

Acknowledgements

Many thanks to the following people for comments on the first version of this chapter and – in some cases – for discussion: Doug Arnold, Ash Asudeh, Stefan Müller, Agnieszka Patejuk, Geoff Pullum, Frank Richter, Shuly Wintner, Annie Zaenen, and the anonymous reviewers. They should not be held responsible for any controversial opinions expressed here or for any remaining inadequacies; if some of their suggestions are less than fully addressed, it is only because this is just a chapter (and one that is too long already!), and not the monograph that a fuller presentation and comparison of LFG and HPSG deserves. And many thanks to Mary Dalrymple, the editor of this volume, for her infinite patience!

[48] More precisely, XLE makes it possible to faithfully implement syntactic and – with extensions described in Dalrymple et al. (2020) – semantic parts of LFG analyses. In the case of HPSG, Trale seems to be closer to its constraint-based nature, while LKB is more efficient and well-developed.

Chapter 40

LFG and Minimalism

Peter Sells
University of York

I compare and contrast LFG and the Minimalist Program (Chomsky 1995) with regard to different overall aspects of the frameworks: fundamental design properties, the representation of phrase structure, the representation of clausal grammatical information, the nature and role of syntactic features, and the analysis of agreement.

1 A framework for comparison

LFG and the Minimalist Program (MP; Chomsky 1995, 2000) are not straightforwardly comparable, as they are articulated in quite different ways. Going back to the 1980s, it could be said that LFG and Government-Binding Theory (Chomsky 1981) had a certain amount of commonality of approach, but as MP has developed from the earlier Government-Binding theory (GB), more and more emphasis has been placed in MP on derivation (see e.g. Hornstein et al. 2006, Hornstein 2018), rather than on information and representation, which are of course cornerstones of LFG.

As both LFG and GB were responses to theoretical concerns about "classical" transformational grammar, which was developed during the 1970s, it is useful to start with the legacy of the early transformational period, which I summarize in (1):

(1) a. the overt part of syntax is represented in a phrase structure tree
    b. all information in syntax is structured
    c. different parts of a syntactic representation may share information

Peter Sells. 2023. LFG and Minimalism. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 1919–1965. Berlin: Language Science Press. DOI: 10.5281/zenodo.10186044

As GB has developed into MP, it has been assumed that (1b-c) refer to the same structure as (1a): that only the structures of phrase structure represent syntactic information, and that relationships are expressed in that structure, being established by movement operations. For instance, topicalization of an object creates a relationship between a topic position and an object position, as a result of a derivational operation in the MP.

LFG is a framework which is also based on the principle that all syntactic information is structured, but importantly that not all syntactic information is structure in the sense of phrase structure, and so it embodies (1) by having (at least) three aspects to the overall representation of a sentence:

(2)
  a. overt phrase structure (c-structure)
  b. a clause-level representation of the information it conveys (f-structure)
  c. an argument-structure representation for predicate-argument structure (a-structure)

All syntactic frameworks have a means to represent argument structure, and for any given predicate, its argument structure is structured according to the Thematic Hierarchy (e.g. Jackendoff 1972) or something equivalent. This is a-structure in LFG (see Findlay et al. 2023 [this volume]). There is a mapping between this structure and the surface grammatical properties, f-structure, which is the representation of (2b). These properties include the GFs such as SUBJ and OBJ. The representation of clausal grammatical information (2b) is not part of the phrase structure representation (2a), but rather is the information that the overt structure conveys. This clausal representation is nevertheless structured in the sense that the information it contains is organized and grouped, according to principles of organization pertinent to this level.

This is different to the approach to clausal information in the MP, where information may start out quite distributed throughout the overall derivation, but can be aggregrated through successive movements, but also modified (e.g. a feature specification being used to drive one operation, then being deleted subsequent to the application of that operation; see Section 4.2). The core arguments of a predicate are merged first into a vP-VP structure (see Chomsky 1995: 315ff.) and this is the representation of argument structure; the internal argument(s) merge into VP and the external argument is the specifier of vP. Then further functional structure such as TP or CP is projected above vP. Functional or relational properties such as ‘subject’ and ‘object’ are characterized by the particular ‘Agree’ relations between v and Obj and between T and Subj.

Broadly speaking, the "subjecthood" properties identified by Keenan (1976) divide into those which properly refer to argument structure, and those which refer to clausal grammatical information (Manning 1996). Different syntactic phenomena may relate to either representation. For instance, anaphor binding is determined by the argument structure hierarchy in some languages (e.g. Schachter 1976 on Tagalog; Wechsler & Arka 1998 on Balinese). In other languages, the hierarchy of grammatical functions holding over f-structure is most relevant (see e.g. Bresnan 2001: 212–213; Bresnan et al. 2016: 217 on 'syntactic rank').

The representations of argument structure and of clausal information are largely language-invariant, though the mapping between them shows more variation, as do the ways in which different syntactic phenomena refer to them. The information that they represent is carried by the overt phrase structures, (2a), which are of course subject to the most variation, and therefore the least revealing about "deep" properties of language.

In this chapter I evaluate different aspects of the LFG and MP approaches to grammatical theory. In Section 2 I consider overall "design features" of the frameworks, and what motivates them. In particular I outline how LFG took a different direction from transformational grammar. In Section 3 I contrast the approaches of the frameworks to phrase structure, and how the balance of analysis between c-structure and f-structure falls in LFG. Finally in Section 4 I compare the role(s) that features play in LFG and in MP, and how featural specifications participate in agreement.

2 Design features of a grammatical framework

Kaplan (2019a) gives a personal statement of how the passage below from Chomsky (1965) inspired his research which became part of the foundation of LFG (see e.g. Kaplan & Bresnan 1982: 173–174):

> No doubt, a reasonable model of language use will incorporate, as a basic component, the generative grammar that expresses the speaker-hearer's knowledge of the language; but this generative grammar does not, in itself, prescribe the character or functioning of a perceptual model or a model of speech production. (Chomsky 1965: 9)

Kaplan also pursued the idea that linguistic complexity will be best modelled through (possibly complex) interactions of different (relatively simple) components, different representational dimensions, inspired by Simon (1962).

In this section I will consider how LFG addresses the core aims of a generative grammar, and how it has done so according to certain key foundational properties which set it apart from the procedural approach which has characterized the GB/MP approach led by Chomsky.

2.1 Levels of adequacy

One way to approach how a given framework takes up the agenda for Generative Grammar is to consider how the framework concerns itself with Chomsky's successive levels of adequacy:

> To summarize briefly, there are two respects in which one can speak of "justifying a generative grammar." On one level (that of descriptive adequacy), the grammar is justified to the extent that it correctly describes its object, namely the linguistic intuition – the tacit competence – of the native speaker. In this sense, the grammar is justified on external grounds, on grounds of correspondence to linguistic fact. On a much deeper and hence much more rarely attainable level (that of explanatory adequacy), a grammar is justified to the extent that it is a principled descriptively adequate system, in that the linguistic theory with which it is associated selects this grammar over others, given primary linguistic data with which all are compatible. In this sense, the grammar is justified on internal grounds, on grounds of its relation to a linguistic theory that constitutes an explanatory hypothesis about the form of language as such. The problem of internal justification – of explanatory adequacy – is essentially the problem of constructing a theory of language acquisition, an account of the specific innate abilities that make this achievement possible. (Chomsky 1965: 26–27)

Since the GB era, Chomsky has taken explanatory adequacy to be the focus of syntactic theorizing (Rizzi 2016; D'Alessandro 2019). Yet to do this presupposes that there is a core of facts and generalizations so that there is a stable set of grammars which satisfy descriptive adequacy. Hornstein (2018: 55) presents a list of structural properties that syntacticians might agree are the "mid-level generalizations" of grammar; see also D'Alessandro (2019: 8) for a summary. For instance, data as in (3)–(4), from Chomsky (1973: 261), lead to well-established generalizations to classify verbs as being raising or control predicates, and binding conditions on anaphors and pronouns:

(3) a. They appeared to John to like each other.
    b. * They appealed to John to like each other.

(4) a. * We appeared to John to like us.
b. We appealed to John to like us.

At the level of what facts and what kinds of facts are in the domain of syntax – such as those just given – frameworks such as GB/MP, LFG, and HPSG (Pollard & Sag 1987, 1994) are roughly commensurate, and so can be compared as to how they embody descriptive adequacy. Of course the formal details of a syntactic system which is intended to have a good "correspondence to linguistic fact" vary between each framework, but these are the easiest points of comparison. I take up this kind of comparison in Sections 3 and 4 below.

LFG is a framework which has been developed to address descriptive adequacy, and which can be part of broader cognitive or computational approaches to human language, following the first Chomsky quote above. In this sense, it perhaps could be argued that LFG committed 40 years ago to what has become known in the MP literature as Chomsky's "third factor" (Chomsky 2005: 6) for explaining the format of grammatical knowledge:

(5) "… we should, therefore, be seeking three factors that enter into the growth of language in the individual:

1. Genetic endowment, apparently nearly uniform for the species, which interprets part of the environment as linguistic experience, …
2. Experience, which leads to variation, within a fairly narrow range, …
3. Principles not specific to the faculty of language …
    - principles of data analysis that might be used in language acquisition
    - principles of structural architecture
    - principles of efficient computation"

The GB perspective on the language faculty put a great burden on an innate Universal Grammar which is essentially a parameterized blueprint for any individual grammar. This corresponds to Chomsky's first factor. Over the last 25 years, the trend in the development of the MP has been to reduce reliance on this purely innate component of grammar, in favor of the third factor. The reference in that factor to principles of data analysis and of structural architecture is quite salient as these are the principles at the basis of the considerations I raise in the next subsection, though of course this is not to imply that frameworks such as LFG deny that there are any ‘first factor’ properties or principles of our language capacity. However, as O’Grady (2012: 498) comments: “… the shift of focus to third-factor effects in generative grammar marks a milestone of sorts. Not because the idea is new, for it is not. Broadly speaking, the rest of the field has been committed to the primacy of third-factor explanations for decades.”

2.2 Foundational properties of syntactic systems

What kinds of property are fundamental to syntax, to be emergent from a theory which “constitutes an explanatory hypothesis about the form of language”, as in Chomsky’s notion of explanatory adequacy? From the Minimalist perspective, the key notion here is the binary merge of abstract syntactic elements – ‘External Merge’ for initial structure-building, and ‘Internal Merge’ for movement from an existing position to another one. The structure is built up incrementally, with steps in the derivation driven by categorial requirements of combination or by features (see Section 3.2 and Section 4.2 below); the terminal nodes of the structure are spelled out morphologically after the syntactic operations have taken place.

LFG has taken a different starting point as to what the key properties of syntax are; in the rest of this subsection I highlight the consequences of a few examples which determine the ‘lexicalist’ and ‘functional’ (that is, information-based) aspects of LFG.

2.2.1 Lexicalist

LFG is a lexicalist framework, built on the assumption that the terminals in the phrase structure are word-level entities, the X^0s of X′-theory. The roots of this approach are in the Lexicalist Hypothesis of Chomsky (1970). Chomsky argued that the shared properties of different words based on the same lexeme could be accounted for without recourse to transformation (a nominalization transformation for the specific examples considered in that paper), and he introduced X′-theory to account for structural similarities across categories. LFG, like other declarative frameworks, expands on this perspective, using other syntactic information not directly represented in the phrase structure (cf. (2)) to capture the appropriate similarities. An X^0 may be internally complex, carrying the same kinds of information as may be expressed by other elements or configurations in the syntax, but formed according to its constraints on morphology, not on syntax.

The following Swedish example from Müller & Wechsler (2014: 29) illustrates several properties which motivate the lexicalist analysis. It involves coordination of an active and a passive verb:

(6) Swedish
Golfklubben begärde och beviljade-s marklov för
golf.club.DEF requested and granted-PASS ground.permit for
banbygget efter en hel del förhandlingar och kompromisser
track.build.DEF after a whole part negotiations and compromises
med Länsstyrelsen och Naturvårdsverket.
with county.board.DEF and nature.protection.agency.DEF
'The golf club requested and was granted a ground permit for track construction after a lot of negotiations and compromises with the County Board and the Environmental Protection Agency.'

Müller and Wechsler argue that this example does not involve Right-Node Raising, but rather coordination of two finite verbs at the X^0-level (*begärde och beviljades*). Each verb is a syntactic word, marked for past tense (the *de* part of each), and the second one is marked for passive (the *s*). Hence the voice alternation active/passive is represented on single words, and does not involve spans of structure involving separate heads such as V, v, and Voice. Additionally, the second verb is a straightforward counterexample to the 'Mirror Principle' (Baker 1985), which is supposed to diagnose a close relationship between syntactic structure and word-internal morpheme structure. Swedish passive *-s* always appears external to other tense or aspectual suffixes on the word, even though in an expanded MP-style clausal structure the Voice head would be taken to be lower than and therefore closer to the lexeme stem with respect to Aspect or Tense heads.

The French example in (7) also motivates both the lexicalist approach, as well as the design feature that agreement is not directional.

(7) French
Je suis heureuse.
I am happy.F.SG
'I am happy.' (spoken by a female)

Neither the subject pronoun *je* nor the inflected verb *suis* are categorized or marked for gender – as in English and many other languages – yet the predicate adjective is marked as feminine (and singular). The non-formal linguistic intuition that the adjective agrees with its subject, or "agrees with a noun", has been the basis of many formalized linguistic analyses: the predicate adjective is a target and the subject should be its controller. Yet there is no plausible source in the lexical content of (7) for a feminine gender specification except for the adjective. It is certainly true of the *sentence* (7) that it expresses a meaning involving a feminine subject, but the morphosyntactic basis of that meaning could not be *je* or *suis*, under any plausible analysis of those words.

This example is very powerful. From it, it follows then that *heureuse* is a lexical item marked for feminine gender independently of the syntactic structure in which it appears, as there is no source for feminine in the rest of the structure. This entails the Lexicalist Hypothesis, as each X^0 in the syntactic structure has properties that do not refer to any other X^0 in the structure – usually referred to as 'Lexical Integrity' (e.g. Bresnan 2001: 92; Bresnan et al. 2016: 92).

2.2.2 Information-based clausal representation

Next, from the same example, it follows that "agreement" is the name we give to a situation in which two or more syntactic elements put constraints on a single informational unit, but that there is no priority of one element over the other(s). In (7), all three such elements (the words in this case) put constraints on what the subject is; and as the combination of those constraints is not contradictory, the example is well-formed. The f-structure contribution of each word is shown in (8). (9) shows the f-structure for the full example.

(8)

a. $\begin{bmatrix} \textsc{pred} & \text{`}\textsc{pro}\text{'} \\ \textsc{pers} & 1 \\ \textsc{num} & \textsc{sg} \end{bmatrix}$ = je

b. $\begin{bmatrix} \textsc{subj} & \begin{bmatrix} \textsc{pers} & 1 \\ \textsc{num} & \textsc{sg} \end{bmatrix} \\ \textsc{tense} & \textsc{pres} \\ \textsc{pred} & \text{`}\textsc{be}\langle(\uparrow \textsc{subj})(\uparrow \textsc{xcomp})\rangle\text{'} \\ \textsc{xcomp} & \begin{bmatrix} \textsc{subj} & [\ ] \end{bmatrix} \end{bmatrix}$ = suis

c. $\begin{bmatrix} \textsc{subj} & \begin{bmatrix} \textsc{gend} & \textsc{fem} \end{bmatrix} \\ \textsc{pred} & \text{`}\textsc{happy}\langle(\uparrow \textsc{subj})\rangle\text{'} \end{bmatrix}$ = heureuse

(9)
$$\begin{bmatrix} \textsc{subj} & \begin{bmatrix} \textsc{pred} & \text{‘}\textsc{pro}\text{’} \\ \textsc{pers} & 1 \\ \textsc{num} & \textsc{sg} \\ \textsc{gend} & \textsc{fem} \end{bmatrix} \\ \textsc{tense} & \textsc{pres} \\ \textsc{pred} & \text{‘}\textsc{be}\langle(\uparrow \textsc{subj})(\uparrow \textsc{xcomp})\rangle\text{’} \\ \textsc{xcomp} & \begin{bmatrix} \textsc{subj} & [\ ] \\ \textsc{pred} & \text{‘}\textsc{happy}\langle(\uparrow \textsc{subj})\rangle\text{’} \end{bmatrix} \end{bmatrix}$$

Local syntactic relationships indicated by the structure-sharing seen above are typically located in a predicate – these will involve what kind of arguments the predicate takes, possibly specifications of case, whether it is a raising or control predicate, agreement information, and so on. The apparent directionality of agreement seen in canonical examples has nothing to do with "agreement" itself – as a mechanism of agreement does not exist – but rather comes from the second property of *suis*, that it is effectively a raising predicate, and so whatever is true of its complement's subject is true of its subject. In (9) the information shown as the value of SUBJ is the minimal amount of which the constraints coming from each of the entries in (8) is true.

With regard to the implications for explanatory adequacy, this simple example shows that the format of grammars is only consistent with those that lack derivation and directionality – in other words, if the hypothesis space is restricted to declaratively stated grammars, we expect that languages will quite generally show examples like (7). In Section 4.3, I take up in more detail the key information-based properties of what we informally refer to as "agreement".

Other examples also show the importance of the information that an item carries over its phrase structure properties. (10) (originally from Hudson 1977; see also Gazdar et al. 1985: 64; Bresnan 2001: 19, Bresnan et al. 2016: 14) illustrates one of the "paradoxes of movement":

(10) a. * I aren't happy.
b. Aren't I happy?

An initial positioning of an internally-negated auxiliary is taken as evidence in movement analyses that the auxiliary has undergone several movements, combining with Neg and then with T[ense] before moving to C. However, from the notional analytic source *I am not happy* there is no pre-T-to-C version **I amn't happy*, as in (standard) English there is no form *amn't*, and (10a) is also ungrammatical. In this use, then, the form *aren't* is a word which can only appear in the C, or inverted-aux, position, but not in any other position. In terms familiar from the early days of transformational grammar, (10b) would have to be analyzed as a grammatical example derived from an ungrammatical source.

The contrast in (10) shows that the syntactic properties that an item has (being a tensed negated auxiliary in this case) are not inexorably associated with structural derivations which aggregate information. A movement-based account of (10) would have to assume that the syntactic features of *aren't* can be assembled on T, and from there moved to C, but that there is no lexical item which can spell out those features on T, but only on C. In other words, what actually matters is the surface position of the realization of a set of syntactic properties, not where (or where else) those properties came from. This is exactly what a declarative framework such as LFG provides, with the same implication for explanatory adequacy – if an element in a higher position must correspond to a derivationally related version of itself in a lower position, pairs like (10) should not exist. But they do exist, and they show that the format of grammars should recognize that words have bundles of features which are associated with (sets of) syntactic positions. Within the broader Miminalist approach, the realizational account of morphology in the Distributed Morphology framework (Halle & Marantz 1993; see Bobaljik 2017 for a recent overview) has the same sensitivity to syntactic position: for *aren't*, a rule of vocabulary insertion could be made sensitive to the collection of relevant syntactic features in the context of C, but not of T.

2.3 Rules and representations

As syntactic frameworks have developed since the 1980s, they have diverged as to whether the focus is on constraints stated on representations, or on steps in a procedural derivation. Government-Binding theory has a mix of properties: conditions on rule application and conditions on representations. For instance, the examples above in (3)–(4) involve *appear* as a raising predicate which requires an operation of the rule Move-α, while *appeal* is a control predicate which requires a representational check involving a PRO subject (see e.g. Haegeman 1994 for a summary of GB). More recently, the "movement theory of Control" (e.g. Hornstein & Polinsky 2010) eliminates the representational condition on the empty category subject in favor of a derivational analysis similar in the relevant ways to the one for the raising predicate.

The GB Binding Theory Principles A and B were originally each stated as a condition on a representation. For instance, Principle A looks for a specific relationship of coindexing between antecedent and anaphor within a certain domain; reinterpreted as a condition on rule application, the principle must involve an operation of movement up to (near) the antecedent, within a certain domain, following an idea first proposed in Lebeaux (1983).

In the development of the MP, Chomsky has taken the view that as some aspects of the grammar are procedural, and so require conditions on rule application, parsimony would dictate that all grammatical conditions are of that type, with no conditions on representation. Hence the levels of GB over which representational conditions were stated were eliminated. The MP is an attempt to deconstruct GB along purely procedural aspects (see e.g. Hornstein 2018: 54) – in the limit, there is no "stopping off" at any point to evaluate a representation. In fact, though, each step in a derivation must involve a local representation – but one within which or to which some further operation should take place. The proposed operation of 'Minimal Search' for the operation *Agree* (Chomsky 2007: 9) must inspect a structure to find something within it – here, an element W probing within a structure Z – and the outcome of that will constrain what (procedurally) can happen next: "Since W contains all information relevant to further computation involving Z, W is also necessarily the probe that selects a goal in any internal modification of Z. Minimal search conditions limit the goal of the probe to its complement, the smallest searchable domain."

The output of syntax is fed to the 'interfaces'. On the semantic side, the end of the syntactic derivation corresponds to the GB level of Logical Form (LF), which feeds to the 'conceptual-intentional' interface. On the phonetic side, the overt output of the derivation is spelled-out to Phonetic Form (PF), which feeds to the interface known as 'articulatory-perceptual' or 'sensorimotor' (see e.g. Chomsky 1995: 2, Chomsky 2007: 5). One leading idea of the Minimalist Programme is that LF and PF have no properties specific to them; rather, any apparent well-formedness conditions are due entirely to properties of the interfaces.

Within the core domain of syntax, there seem to be several phenomena which bear on the issue of rules vs. representations, and which appear to favor the latter – because their analysis seems irreducibly representational. I will mention two different instances and then go on to two others in more detail. First, as just noted, the MP operation of Agree has to access a representation, in order to establish a relation between Probe and Goal (see also Section 4.2). Second, the approach to case marking known as 'Dependent Case' (e.g. Baker 2015) calculates the case values of NPs by referring to larger structure – the underlying intuition being that in a clause containing two NPs, a subject c-commanding an object, the marked case value of Accusative for the object is the value assigned to an NP c-commanded by another, and in a typologically different system, the marked case value of Ergative for the subject is the value assigned to an NP which c-commands another. Hence the computation of case values must refer to a structural representation.

I now go in more depth into two instances which illustrate a different kind of representational condition – a negative condition. It is difficult to imagine how such conditions could successfully be captured procedurally. Returning to the binding conditions of GB, for Principle A, there have been different proposals to reinterpret it derivationally, for instance Lidz & Idsardi (1998), Hornstein (2001) and Boeckx et al. (2007), though others take a more traditional view, such as Safir (2008) and Charnavel & Sportiche (2016). While Principle A requires two elements to have a certain relationship, Principle B forbids two elements from having a certain relationship – it is a negative condition. A procedural reinterpretation does not seem directly possible for Principle B, as it requires disjointness (unless perhaps the system of recording contra-indexing of Chomsky 1980 is revived), though Reuland (2011) presents a revised Binding Theory which refers to properties of predicates and semantic constraints on the interpretation of their arguments.

Principles A and B as they apply to English are familiar. In some languages, with anaphoric systems more complex than that found in English, conditions on the various elements of the system may involve both positive and negative constraints – such as in Norwegian (Dalrymple 2001: 279–288, Bresnan et al. 2016: 259–261). Norwegian has four relevant anaphor/pronoun forms, shown in (11) with their LFG binding properties. The content of the binding properties is given in (12):

(11) Featural analysis of Norwegian pronouns:
  a. seg [+sbj, −ncl]
  b. ham [−ncl]
  c. seg selv [+sbj, +ncl]
  d. ham selv [−sbj, +ncl]

(12) a. [+sbj, −ncl] – The antecedent must be a subject in the minimal finite domain outside of the minimal nucleus containing the pronoun.
  b. [−ncl] – The antecedent must be outside of the minimal nucleus containing the pronoun.
  c. [+sbj, +ncl] – The antecedent must be a subject in the minimal nucleus containing the pronoun.
  d. [−sbj, +ncl] – The antecedent must be a nonsubject in the minimal nucleus containing the pronoun.

The negative conditions here seem to refer crucially to representations – to check that a relationship does not hold in a certain local domain, or to check that a relationship does hold, but not with a subject.

A different consideration about the role of representations comes from the distribution of the depictive *sisxoli* 'alone' in Tsez, a language of the Caucasus which has an ergative-absolutive case marking system. The depictive may be associated with a preceding NP, but may not itself precede its NP associate (Polinsky 2000). Hence the depictive has two possible associates in (13a), one in (13b), and none in (13c).

(13) Tzez

a. kid-bā ziya sisxoli bišer-si
girl-ERG cow.ABS alone feed-PST.EVID
'The girl$_i$ alone$_i$ fed the cow.'
'The girl fed the cow$_i$ alone$_i$.'

b. kid-bā sisxoli ziya bišer-si
girl-ERG alone cow.ABS feed-PST.EVID
'The girl$_i$ alone$_i$ fed the cow.'
*'The girl fed the cow$_i$ alone$_i$.'

c. * sisxoli kid-bā ziya bišer-si
alone girl-ERG cow.ABS feed-PST.EVID

The linear precedence condition is reinterpreted as one of c-command in later discussions of these same examples in Polinsky & Potsdam (2006) and Fukuda (2008) – the associate must c-command the depictive.

The distribution of the depictive becomes more interesting in the context of raising and control predicates. In Tsez the predicate *yoq-* 'begin' is ambiguous between control and raising, and in fact is a backward control predicate in its control use or a forward raising predicate in its raising use (Polinsky & Potsdam 2006). In LFG, the higher and lower SUBJ values of control or raising are structure-shared in f-structure, and as discussed in Sells (2006) that f-structure property is consistent with c-structure expression of the relevant argument in the matrix clause ('forward') or in the embedded clause ('backward'). (14a) is an interesting example regarding the syntax of the depictive, as it is grammatical even though the depictive apparently precedes its associate. Polinsky & Potsdam (2006) analyze this as a backward control structure: a null (absolutive) subject of 'begin', indicated by ∅ in (14b), controls the lower (ergative) subject of 'feed'. ∅ is used here as a notation to suggest the analysis of the example, but it has no actual correspondent in the c-structure, as is standard in the LFG analysis of control and raising. In this example, it is the null matrix argument indicated by ∅ which is the associate of the depictive, and both are constituents of the main clause (see the f-structure in (17) below):

(14) Tzez

a. sisxoli kid-bā ziya bišra yoq-si (backward control)
alone girl-ERG cow.ABS feed begin-PST.EVID
'The girl$_i$ alone$_i$ began to feed the cow.'
*'The girl began to feed the cow$_i$ alone$_i$.'

b. ∅$_i$ sisxoli [kid-bā$_i$ ziya bišra] yoq-si
alone [girl-ERG cow.ABS feed] begin-PST.EVID

The other use of *yoq-* is as a regular forward raising predicate. Its subject is in absolutive case as the predicate is not formally transitive, and the subject in the lower clause is the empty position, again indicated here by ∅. As seen in (15a), with the syntactic analysis in (15b), the same order of elements as in (14a) is ungrammatical in this instance, as the depictive does indeed precede its associate:

(15) Tzez

a. * sisxoli kid [ziya bišra] yoq-si (forward raising)
alone girl-ABS [cow.ABS feed] begin-PST.EVID

b. * sisxoli kid$_i$ [∅$_i$ ziya bišra] yoq-si
alone girl-ABS [cow.ABS feed] begin-PST.EVID

The LFG account of these data requires the concepts of f-command, which is like c-command but stated on f-structure, and of f-precedence (see Glossary for f-command and f-precedence). This latter concept makes reference to the c-structure expression(s) – if any – of f-structure elements. Crucially, an element such as a null argument which is present only in f-structure, but not in c-structure, has no (f-)precedence relations defined on it (Bresnan 2001: 195; Bresnan et al. 2016: 213). The LFG analysis of the Tsez depictive can be stated simply as in (16):

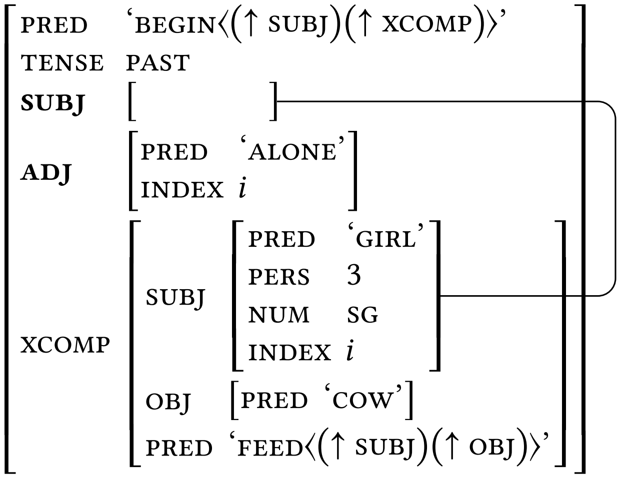
(16) a. The associate and the depictive f-command each other.

b. The depictive must not f-precede the associate.

(16a) is essentially a clause-mate condition, and (16b) is a negative condition. It does not require that the associate f-precede the depictive, but rather that the depictive does not f-precede the associate.

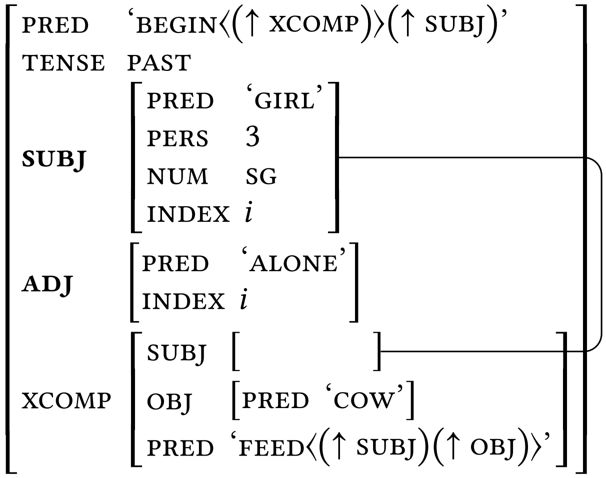
The f-structure of (14) is shown in (17), leaving out the case values of the arguments, which would formally conflict under straightforward structure-sharing (i.e. formal equality in LFG terms). The case values require a slightly nuanced analysis, whatever the framework (see Polinsky & Potsdam 2002, Sells 2006). For presentational purposes, I assume here that the formal relation between depictive and associate is that they share an INDEX value. Their GFs which f-command each other are indicated by the boldface GF names, in the matrix nucleus. The matrix SUBJ is structure-shared with the embedded SUBJ as the predicate is backward control. While there is a matrix SUBJ in f-structure, it has no c-structure expression (there is no '∅' in the c-structure); only the embedded subject is present in c-structure. Consequently, limited to the matrix f-structure in which the associate and depictive f-command each other, no precedence relation is defined on the boldface SUBJ, and so the condition in (16b) is also satisfied.

(17) F-structure of (14), ignoring the case values. **ADJ** does not f-precede **SUBJ**:



In contrast, for (15), involving a forward raising use of the predicate, the constraint in (16b) is not satisfied, because the SUBJ is overt in the matrix clause, and so f-precedes the depictive ADJ.

(18) F-structure of (15), ignoring the case conflict. **adj** f-precedes **subj**:



The Minimalist account in Polinsky & Potsdam (2006) (see also Fukuda 2008) is stated in terms of positive conditions, of which (19b) is the important one.

(19) a. The associate and the depictive are clause-mates.
b. The associate c-commands/binds (≡ precedes) the depictive.

What is interesting about (19b) is that it can only be successfully interpreted representationally. Suppose that at one point in the derivation, the associate (whether overt or covert) c-commands the depictive, and the relevant syntactic relationship is established, satisfying (19b). However, what is to prevent some later operation which scrambles the depictive higher, so that it c-commands its associate, in violation of (19b)? To prevent this possibility, (19b) must be interpreted as an output condition on the "final" representation, regardless of when during the derivation the relation between associate and depictive has been established. Hence even though (19b) is a positive condition, not a negative one, it is necessarily representational.

In the LFG analysis, (16b) is necessarily a negative condition, as the null subject in backward control is only represented in f-structure (14), and so could never be evaluated against a positive precedence condition like (19b). Evidence from other languages supports the position that null arguments are present in f-structure but absent from c-structure. Null pronouns in Malayalam are not sensitive to f-precedence conditions, unlike overt pronouns (Mohanan 1983: 664–665). Kameyama (1985) presents a similar argument for Japanese (summarized in Dalrymple 2001: 171ff. and 288ff.). For Malayalam, Mohanan observes that an overt pronoun may not precede its antecedent – compare (20) and (21a) with (21b) –

while a null pronoun (indicated for presentational purposes by *pro* in (21b)) may ‘precede’ its antecedent:

(20) Malayalam
  a. [kuṭṭiyute ammaye] awan n̲uḷḷi
    [child.GEN mother.ACC] he.NOM pinched
    ‘He$_i$ pinched the child$_i$’s mother.’
  b. * [awante ammaye] kuṭṭi n̲uḷḷi
    [he.GEN mother.ACC] child.NOM pinched
    ‘The child$_i$ pinched his$_i$ mother.’

(21) Malayalam
  a. [awan aanaye n̲uḷḷiyat̲inə s̄eeṣam] kuṭṭi$_i$ uraŋŋi
    [he.NOM elephant.ACC pinched.it after] child.NOM slept
    ‘The child$_i$ slept [after he$_{*i/j}$ pinched the elephant].’
  b. [*pro* aanaye n̲uḷḷiyat̲inə s̄eeṣam] kuṭṭi$_i$ uraŋŋi
    [elephant.ACC pinched.it after] child.NOM slept
    ‘The child$_i$ slept [after he$_{i,j}$ pinched the elephant].’

The overt pronoun ‘he’ in (21a) may not take ‘child’ as its antecedent, as the former precedes the latter, but this restriction is not there with the null pronoun in (21b). Why would overt and null pronouns have different precedence conditions on them? Mohanan (1983: 664) proposes that the correct analysis is that a pronoun cannot precede its antecedent, where precedence is defined on c-structure elements, such as overt pronouns, but is not defined for null pronouns, which are present only in f-structure.

Consider the c-structure relationships of the relevant parts of the examples, shown in (22a), with the f-structure of the example shown in (22b). The subscript numbers show the c-to-f-structure correspondences:

(22) a. C-structure:
    (pronoun$_1$) pinched$_2$ child$_3$
  b. F-structure:

$$\left[\begin{array}{ll} \text{SUBJ} & {}_3\left[\text{PRED}\ \text{‘CHILD’}\right] \\ \text{PRED} & \text{‘SLEEP}\langle(\uparrow \text{SUBJ})\rangle\text{’} \\ \text{TENSE} & \text{PAST} \\ \text{ADJ} & {}_2\left[\begin{array}{ll} \text{PRED} & \text{‘PINCH’} \\ \text{SUBJ} & {}_1\left[\text{PRED}\ \text{‘PRO’}\right] \\ \cdots & \cdots \end{array}\right] \end{array}\right]$$

In both examples in (21), the adjunct clause 2 f-precedes 3, ‘child’, because the c-structure correspondent(s) of 2 precede the correspondent(s) of 3. However with regard to 1 and 3, 1 f-precedes 3 only if 1 is present in c-structure, which is only the case in (21a). Hence the apparently different binding properties of pronouns reduce to their different properties in different parts of the syntactic analysis.

The implications of this analysis are far-reaching: if certain syntactic elements can have a range of grammatical properties without being represented in phrase structure – and the above is positive evidence that they are not represented in phrase structure – then every aspect of grammatical analysis which can or must refer to those properties must also be independent of any phrase structure representation, including phenomena such as subjecthood, agreement, binding, and so on.

Declarative frameworks have different dimensions of analysis – such as c-structure and f-structure as described below – but not different levels in the sense that GB had (e.g. D-structure, S-structure). As there are no rules or operations, there are no conditions on rules, and so all conditions are stated over representations, as constraints.

3 Phrase Structure

3.1 Heads and headed structures

LFG c-structures have some similarities with the S-structures of late GB. A canonical clause (for an SVO language) is structured around what I refer to as a ‘skeleton’ with a ‘spine’ (Sells 2001: 17). (24) below shows the skeleton, and the spine corresponds to all the non-argumental parts, V, I, C and their projections. These are separate categories which participate in the familiar clausal extended projection (Grimshaw 2000: 116ff. Bresnan 2001: 100), often now referred to as the ‘Hierarchy of Projections’ (Adger 2003).

The formal relation in the c-structure between V and I and C is usually developed from the idea of ‘extended projection’ of Grimshaw (2000); see also Bresnan (2001: 100–101), Bresnan et al. (2016: 103). The clausal categories are all projections of the category verb, which is specified by the traditional labels [+V, −N] (Chomsky 1970).

(23) Extended Projections

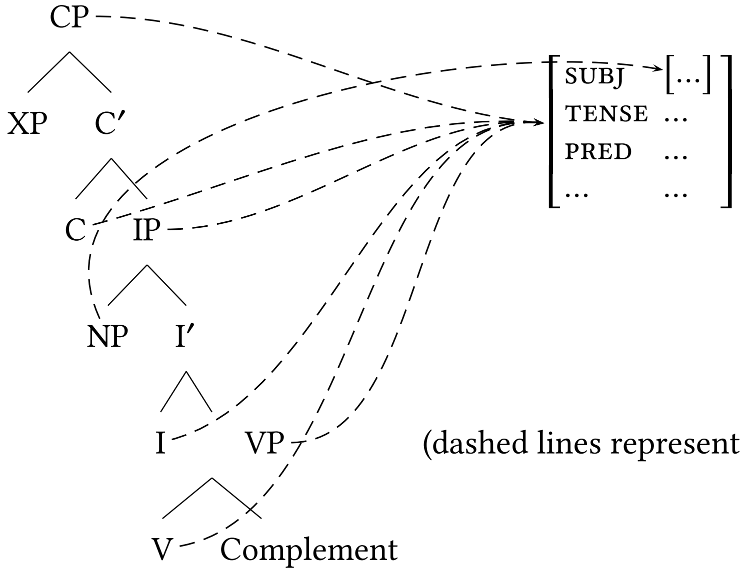
a. V = [+V, −N, P0] (the zeroth-level projection of V)

b. I = [+V, −N, P1] (the first-level projection of V)

c. C = [+V, −N, P2] (the second-level projection of V)

The outline clause structure has specifiers of CP and IP, and complement position(s) within VP, schematized here with the placeholder label Complement.

(24)



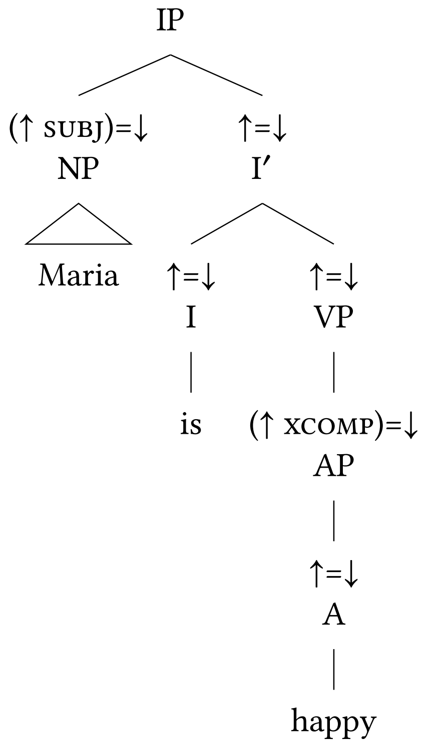
(dashed lines represent information flow)

Each node in the c-structure is annotated as to how it contributes to the f-structure. The formal annotations on nodes are not shown in (24), for simplicity, but the dashed lines represent the way that information flows from the c-structure to the f-structure.

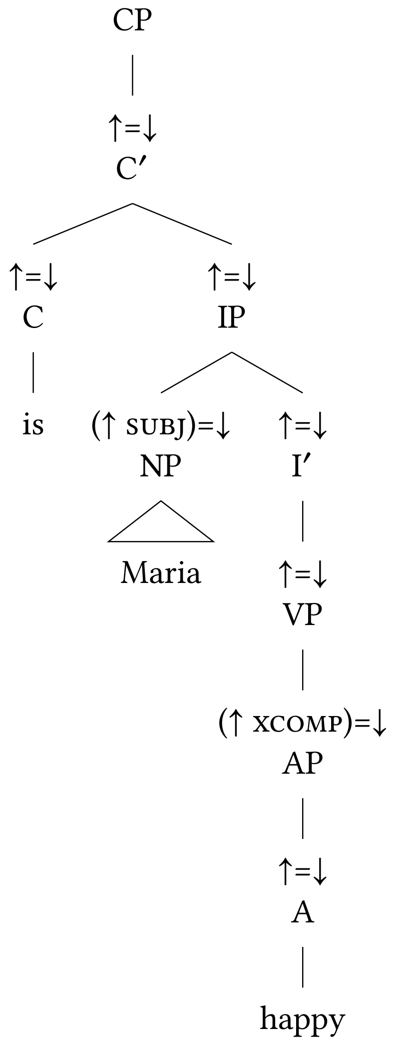
Every node in the clausal spine contributes its information to the main f-structure, as can be seen from the several lines converging on the outer f-structure, which represents the grammatical information of the clause (again for simplicity, I omit lines from the X′ nodes). The other nodes, XP, NP, and Complement, have different annotations on them, as they contribute to parts of the overall f-structure. For instance, the annotation on the node NP would indicate that its contribution is as the subject – in other words, NP as specifier of IP is the subject position. This is indicated by the dashed line going from NP in the c-structure to the value of SUBJ in the f-structure.

As far as clausal information is concerned, the verb itself contributes identically to the clause whether it is in V or in I or in C, a property usually referred to as 'head mobility' (see e.g. Bresnan 2001: 126ff. Bresnan et al. 2016: 129ff.). For instance, unless extra information is associated with the C node in (25b), both c-structures in (25) would determine the same f-structure:

(25) a.



b.



Head mobility can be illustrated with the c-structures above. On the assumption that the only VP can be the c-structure complement of I, then for the example *Maria is happy* in (25a) the VP lacks a c-structure head V, for the verb *is* is in I; and in (25b), for the string *Is Maria happy*, both IP and VP lack their X^0 heads. In these structures the finite form of *be* acts as an auxiliary verb, and so does not head a surface VP, but appears in a higher functional head position (in contrast *be* as a non-finite form would head VP, as in *Maria could [be happy]*).

Formally, the theory requires that every XP either has a c-structure head in the standard X′ sense, or that it maps to an f-structure shared with at least one YP which is headed in c-structure. Such a Y^0 is known as the 'extended head' of XP (the notion is originally due to Zaenen & Kaplan 1995: 221, revised to the formulation given here by Bresnan 2000: 353). So in (25a), I is the extended head of VP, and in (25b), C is the extended head of IP and of VP, leading to the illusion that the head is “moving”. Different verbal categories may be restricted, though, to particular c-structures positions: finite auxiliaries in English may only appear in I or C, not in V; finite non-auxiliaries must appear in V. Hence finite auxiliaries have the category [+V, −N, P>0] and finite verbs have the category [+V, −N, P0].

The discourse in the MP literature over the past 25 years as to whether head movement exists or whether it is part of ‘narrow syntax’ (see e.g. Roberts 2011; Harizanov & Gribanova 2019 for overviews) is quite puzzling from the perspective of declarative frameworks such as LFG or HPSG, as heads are central to the syntactic analysis. The issue arose in the development of the MP as position-occupying head movement does not obey the Extension Condition of Chomsky (1995), requiring that every operation of Merge extends the root node of the current tree. Head movement violates this condition, as it formally involves adjunction to a node lower than the root node (in contrast to XP adjunction, which does adjoin at the root). Consequently Chomsky raised the issue of the status of head movement (e.g. Chomsky 2000: 136–137; Chomsky 2001: 38) within the MP approach.

As the mapping from c-structure to f-structure in LFG suggests, the crucial fact about a clausal spine is that head positions share information, each being a functional co-head (see e.g. (25)). This is directly evidenced in various core cases of multiple expresssion of the same grammatical information in a single domain, as first described in LFG by Niño (1997). The same properties of clausal information are expressed on more than one head (see also Sells 2004, Lødrup 2014). The Finnish examples in (26) and (27) (Niño 1997: 135, 137) show the phenomenon:

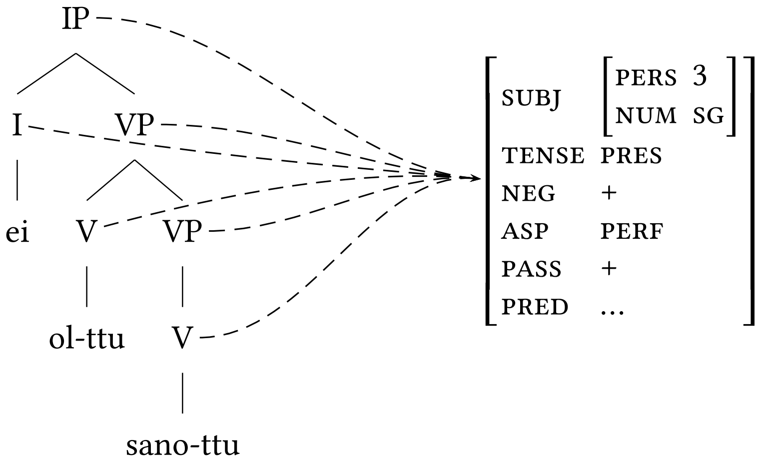
(26) Finnish
Äl-kää puhu-ko.
NEG.IMP-IMP.2.PL speak-IMP
‘Don’t (you pl.) speak!’

(27) Finnish
a. Ei ol-lut sano-ttu
NEG.3.SG PRF-PST.PTCP.SG say-PASS.PST.PTCP.SG
‘It has not been said.’
b. Ei ol-ttu sano-ttu
NEG.3.SG PRF-PASS.PST.PTCP.SG say-PASS.PST.PTCP.SG
‘It has not been said.’

(26) involves a special form of negation restricted to imperatives, as well as imperative marking on both the auxiliary and the main verb. In (27), singular

marking appears on all three words: the negative, which is a kind of auxiliary; another auxiliary; and the main verb. These examples also indicate that ‘passive’ is a feature in f-structure which can be accessed – see also Lødrup (2014) for evidence in Norwegian for the same conclusion. (27b) is a colloquial variant of (27a), in which the passive marking on the main verb also appears on the medial auxiliary. The c- and f-structure of (27b) are shown in (28). It can easily be seen that the constraints coming from each of the words in (27b) – using the glosses as a guide – are satisfied by this f-structure:

(28)



The co-head approach of LFG allows for different sources of the same constraint (e.g. that the value of NUM is SG) which will be true of just a single object (e.g. the subject). Hence feature exponence may be distributed or apparently multiplied. In the MP approach, each feature necessarily originates in only one position in the structure, and then must be copied or spread onto other positions, for data such as that above. In MP analyses, ‘imperative’ corresponds to a high position in the clause, so the IMP feature in (27) must spread downwards. However in (27b), the PASS feature would originate on the lowest verb, the only one marked in (27a), and so would have to spread upwards.

The distribution of morphological exponence is probably not related to direction of spreading, but rather concerns morphological constraints on each type of word as to what features it must express, might express, or cannot express. This can be seen clearly in the examples in (30) from Livonian (Niño 1997: 131), which obey the generalizations in (29):

(29) a. verbs are marked for number
  b. participles are not marked for person

(30) Livonian

a. ä-b u-m and-ên-∅
NEG-1 be-1.SG give-PST.PTCP-SG
'I have not given.'

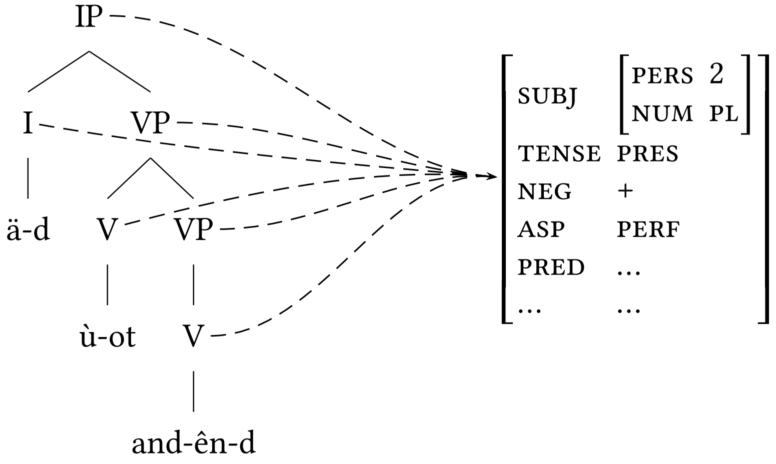
b. ä-b ù-om and-ên-d
NEG-1 be-1.PL give-PST.PTCP-PL
'We have not given.'

c. ä-d ù-od and-ên-∅
NEG-2 be-2.SG give-PST.PTCP-SG
'You have not given.'

d. ä-d ù-ot and-ên-d
NEG-2 be-2.PL give-PST.PTCP-PL
'You have not given.'

(31) shows the c- and f-structure of (30d). Again following the gloss, it can be seen that the PERS value of the subject is identically constrained by the first two words, while the NUM value is constrained by the last two words:

(31)



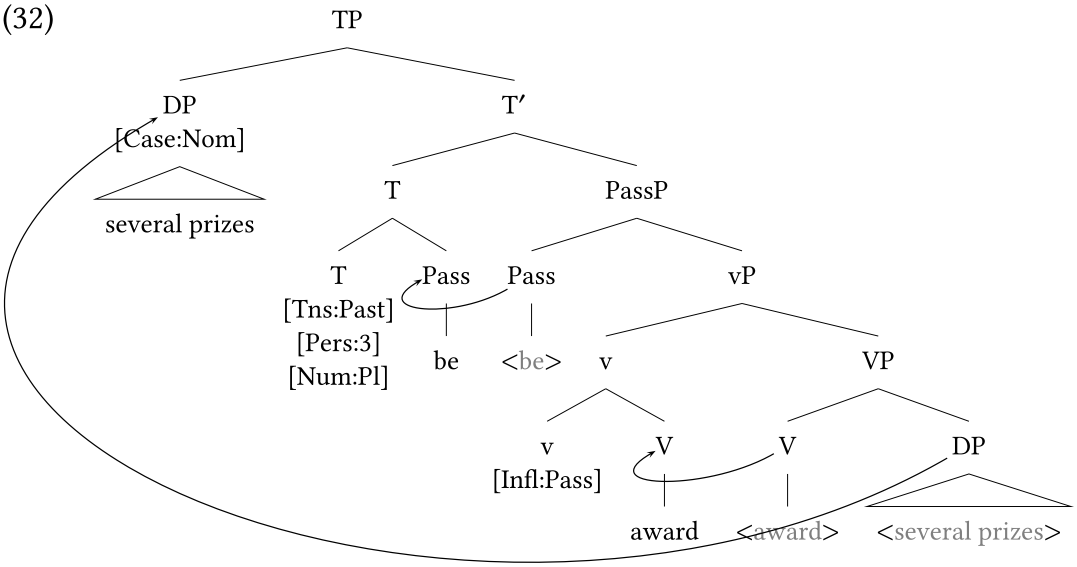
These patterns of multiple expresssion extend beyond simple clauses, into various kinds of complex predicate (see e.g. Sells 2004, Lødrup 2014), which might require a more nuanced syntactic analysis than simple embedding of f-structure nuclei – as argued for on the basis of entirely different data by Andrews & Manning (1999). The multiple expression data could profitably be analyzed in a realizational framework (as suggested in Sells 2004) – every informational element within a certain domain must have at least one rule of realization applying to it (this idea is formalized explicitly in Crysmann & Bonami 2016), but in certain circumstances one piece of information can be referred to more than once, as the generalizations in (29) suggest. Crucially, again, it is not that one piece of morphological exponence on a c-structure head is copied to another head, but rather that different (co-)heads are acting as exponents of the same grammatical information.

3.2 The MP approach to phrase structure: Merge

The legacy of the Government-Binding model of syntax into the MP is a procedural approach to structure and structure-building. Binary structures are built up by Merge of two elements, often known as External Merge or 'first merge'. The GB idea of movement is reinterpreted in the MP as Internal Merge – one element from within a given structure is (re-)merged near the top of the structure. As noted in Section 1, the argument structure of the predicate is represented in a vP-VP structure, above which there are further projections such as TP and CP. By the time the structure has built up at least to TP, this structure effectively codes clausal information.

Strictly speaking, the syntactic derivation is abstract, with syntactic relationships referring to the structural notion of c-command but not linear order, which comes in the mapping from syntax to Phonetic Form (PF). The relevant terminal nodes of the structure are spelled out as words via the principles of Distributed Morphology (for an overview of this framework, see Harley & Noyer 2003 or Embick & Noyer 2007). Consider the derivation in (32) of the example *several prizes were awarded*, which will also feature later on:

(32)



The internal argument of a transitive verb is merged with V (a kind of root) within VP, at the lower right of the structure. The structure builds from the bottom up via successive applications of Merge. The VP is immediately the complement of a "little v" vP, which introduces the external argument in a canonical transitive. The particular example here is a passive, with the external argument suppressed. The two components of the verb, V and v, are combined by head movement of V to v, as the structure shows. The notation <award> indicates the original position of V before movement.

The passive is indicated here by PassP, following the analysis of English auxiliaries in Adger (2003). The Pass head *be* merges with vP as its complement. Next, above that, a T′ is created with a formative for past tense in its T head. The auxiliary verb *be* also undergoes head movement, to combine with T. Finally, following X′-theory, T′ has a specifier which hosts the surface subject. In the case of a passive example, a DP is raised from a VP-internal position to fill the subject position.

The arrows in (32) indicate movement. Standardly in the Minimalist approach, movement leaves behind a "copy" of the moved constituent (Chomsky 1995), which the notation such as <award> etc. is intended to convey. Principles of realization at PF determine which copy is overt (pronounced) – usually the highest copy, as in the earlier versions of transformational grammar where moved constituents leave behind a trace, which is by definition unpronounced. The formalization of MP syntactic derivations due to Collins & Stabler (2016) captures the 'copy' idea by treating each operation of movement as creating a multidominance structure from a single terminal element; that formalization is extended to head movement by Bleaman (2021). However, for presentational purposes, I show the more familiar movement-with-copies structures here.

There are complex heads in T and v in (32), both formed via head movement. They also have a representation of the various features which are present or which are valued during the course of the derivation (see Section 4.2). These complex heads will realize their lexical and featural information as the words *were* and *awarded*.

Hence, the phrase structure derivation in the Minimalist approach represents all the clausal information, somewhat like LFG's f-structure, which is then spelled out as the overt form, which corresponds to some extent to LFG's c-structure.

3.3 Phrase structures are not isomorphic to clausal information

One difference between LFG and MP concerns how far the phrase structure is a direct representation of the clausal information. As just noted, the representation of clausal information in a Minimalist approach is encoded within the phrase structure (in its configuration and its derivation), while in LFG the relation between f-structure and c-structure is fundamentally more flexible. The Mandarin Verb Copy Construction (Li & Thompson 1981, Huang 1982) serves as a good example of how clausal information at f-structure can exist independently of any particular c-structure property. Postverbal arguments and adjuncts appear to be in competition within a single VP: in order to express an argument and an adjunct, the main verb must be duplicated to form a second VP, as in (33b).

(33) Mandarin

a. * Zhangsan tan gangqin de hen hao
Zhangsan play piano LNK very well
'Zhangsan plays piano very well'

b. Zhangsan tan gangqin tan de hen hao
Zhangsan play piano play LNK very well
'Zhangsan plays piano very well'

Huang (1982) proposed a phrase structure filter which essentially disallows arguments and adjuncts in the same VP. Fang & Sells (2007) note that both arguments of a ditransitive verb appear in the first VP (underlined in (34a)), and that an object may be displaced from within the first VP, otherwise preserving the phrase structure:

(34) Mandarin

a. wo song ta zhe jian liwu song de hen hao
I give him this CL gift give LNK very well
'I gave him this gift and it turned out to be a very good idea.'

b. zhe jian liwu wo song ta _ song de hen hao
this CL gift I give him _ give LNK very well
'This gift, I gave (it) him and (it turned out to be) very good.'

However, if an object is displaced from a monotransitive VP, verb "copying" is no longer an option (also see Huang 1982: 53):

(35) Mandarin

a. * gangqin Zhangsan tan _ tan de hen hao
piano Zhangsan play _ play LNK very well

b. gangqin Zhangsan tan _ de hen hao
piano Zhangsan play _ LNK very well
'The piano, Zhangsan played (it) very well.'

If we take (36) to be the basic f-structure of what should be expressed in one structure of (33), given the constraint that arguments and adjuncts cannot be in the same c-structure VP, it follows that (33b) is the only possible expression.

(36)
$$\begin{bmatrix} \textsc{pred} & \text{`}\textsc{play}\langle(\uparrow \textsc{subj})(\uparrow \textsc{obj})\rangle\text{'} \\ \textsc{subj} & [\textsc{pred}\ \text{`}\textsc{Zhangsan}\text{'}] \\ \textsc{obj} & [\textsc{pred}\ \text{`}\textsc{piano}\text{'}] \\ \textsc{adjunct} & [\textsc{pred}\ \text{`}\textsc{very well}\text{'}] \end{bmatrix}$$

On the other hand, if 'piano' appears as a structural TOPIC, in clause-initial position, only a single VP is required to express the in-situ material, which consists of the PRED and its ADJUNCT in (37), as in example (35b). The identification of TOPIC and OBJ takes place only at f-structure (Kaplan & Zaenen 1989).

(37)
$$\begin{bmatrix} \textsc{topic} & [\textsc{pred}\ \text{`}\textsc{piano}\text{'}] \\ \textsc{pred} & \text{`}\textsc{play}\langle(\uparrow \textsc{subj})(\uparrow \textsc{obj})\rangle\text{'} \\ \textsc{subj} & [\textsc{pred}\ \text{`}\textsc{Zhangsan}\text{'}] \\ \textsc{obj} & [\quad\quad] \\ \textsc{adjunct} & [\textsc{pred}\ \text{`}\textsc{very well}\text{'}] \end{bmatrix}$$

Examples such as (35b) show that the competition between arguments and adjuncts for the same VP is a phrase-structure phenomenon, and is not relevant for the level of clausal grammatical information: a verb in Mandarin can perfectly well have a full array of arguments and any adjuncts, but only some of those can be expressed within a single VP. Following a careful survey of the research on this topic, Bartos (2019) proposes an MP analysis which has to appeal to haplology of V to derive (35b) from (35a) (already suggested in Huang 1982: 99), but this is merely symptomatic of an underlying misanalysis, for the core relations between a predicate and its arguments and adjuncts are not isomorphically represented in phrase structure.

4 Features and agreement

4.1 Feature theory and LFG

LFG is built on the foundation that featural specifications in morpho-syntax are of the form [attribute value], and that well-formedness requires every attribute in a given representation to have an appropriate value. The attribute-value format is used in LFG to represent functional structure, which represents the relational and featural content of a clause, but not constituent structure. F-structure is deliberately designed to not look like a phrase structure, to signify that it represents a different kind of syntactic information, and also that the parts within it are unordered. (The concept of f-precedence in LFG (see Glossary) crucially makes reference to the c-structure realization of f-structure elements.)

Adger (2010) considers features and the format of features in MP. He also concludes that features should be represented as attribute-value pairs, but rejects the idea that feature names can have structured values, because that re-creates the hierarchical structure within the phrase structure (e.g. a structured value for SUBJ corresponds to a DP in the phrase structure with internal constituency). Of course, there is no claim in LFG that every attribute in f-structure is the name of a feature – ‘f’ stands for ‘functional’, not ‘feature’. Hence the closest comparison will be the atomically-valued attributes in f-structure, which will correspond most closely to features in MP, and which also accord with the general notion of morpho-syntactic features. More precisely, these will be the ‘syntactic’ features identified by Sadler & Spencer (2001) (see also Spencer 2013), which are the target of morpho-syntactic exponence (as in the discussion of Finnish and Livonian above in Section 3.1). In this subsection I compare the LFG and MP approaches to such features. An extended discussion of features in the MP in comparison to other frameworks can be found in Asudeh & Toivonen (2006: 409–420).

Featural information associated with each word introduces constraints on the well-formedness of the whole structure, within a ‘monotonic’ system: information cannot be selectively ignored, nor can it be changed. Hence declarative frameworks such as LFG necessarily have a property which has come to feature in MP discourse – the ‘No Tampering Condition’ (Chomsky 2007), which does not allow information on an item to be changed as it is merged in as part of the derivation (see also Section 5).

For instance, (38) is ungrammatical as not all the constraints coming from the lexical items can be satisfied simultaneously, and no part of the information can be ignored:

(38) * You am happy.

In this example, *you* will specify the value of PERSON of the subject as 2, but *am* will specify that same value as 1. There is no way to satisfy the requirements of these first two words in a single structure.

LFG introduces featural information either via lexical items or by the rules which license phrase structure. Every well-formed feature specification in f-structure is of the form [attribute value], by definition (see e.g. Kaplan & Bresnan 1982: 181–182). If any lexical item specifies a feature but without a value, that is an 'unvalued feature'; some other element in the structure must introduce the value for that feature, or else the overall structure will be ill-formed. Unvalued features play a significant role in MP analyses (because their function goes beyond that of simply representing information; see Section 4.2); they also find their place in declarative analyses, as described below, although valued features tend to be the norm.

The basic way for information to be specified is as a defining equation – for instance the information carried by the appropriate lexical entries to give the f-structures in (8). There is another kind of informational contribution, the constraining equation of LFG. Kaplan & Bresnan (1982: 207–209) motivate constraining equations with familiar facts such as those in (39), with their proposal for analysis in (40):

(39) A girl is handing (*is hands, *is handed) the baby a toy.

(40) *is*: (↑ XCOMP PARTICIPLE) $=_c$ PRESENT

The VP complement of *is* has the grammatical function XCOMP in the LFG analysis, and within that, the grammatical form *handing* would provide the value 'PRESENT' for the attribute PARTICIPLE. That fulfils the requirement in (40). The important move to a constraining equation over a defining one concerns the ungrammatical variants in (39). For instance, as a finite form, *hands* is not specified at all for the attribute PARTICIPLE, and so does not provide the information that (40) needs. However, if that information in (40) were specified as defining information, it would be unified in with the information from *hands*, and – at least on that count – the sequence **is hands* would not be ungrammatical, as nothing would be inconsistent. Kaplan and Bresnan note that in a unification-based system, constraining equations have the important consequence that negative-value specifications for otherwise unnecessary features can be avoided. (For more on features see Kaplan 2019b.)

Accounts involving a constraining-type analysis are common. This is the situation that is modelled in MP analyses with an 'uninterpretable' feature – two elements between which there is some dependency have the same feature specifications, but only one such specification is the 'real one'. An MP analysis of the English auxiliary system by Aelbrecht & Harwood (2015) involves the same idea as in (40), proposing that uninterpretable but valued features match between the governed verb and the higher auxiliary which governs it.

The use of a constraining equation can be further illustrated in the case of a strict Negative Polarity Item (NPI) – an item that must appear in the context of negation, but is not the expression of negation itself. Such an NPI constrains its syntactic environment to have the NEG feature with the value + (see e.g. Sells 2000); this information must be present, but supplied by some other element, namely overt negation. From the MP perspective, Zeijlstra (2015) discusses an analysis of NPIs in which they "carry some uninterpretable negative feature [uNEG] that must be checked against a higher, semantically negative element that carries an interpretable formal negative feature [iNEG]." Again, in the relevant sense, this is a valued feature which is contentful on one element, and is on another for the purpose only of establishing an abstract syntactic relation.

Returning to the case of an attribute introduced without a value, this is an existential constraint on f-structure (see Kaplan & Bresnan 1982: 210ff. and Dalrymple 2001: 112–114). For instance, the complementizer *that* in English introduces a clause which is tensed, but it places no restriction on the value of TENSE. Hence part of the functional information associated with *that* will be the existential constraint (↑ TENSE). This constrains the f-structure of the clause to have the attribute TENSE, and any well-formed f-structure must have a value for that attribute. The value is not supplied by *that*, so that information must come from elsewhere in the clause introduced by *that*.

In summary, the notions of 'unvalued' and 'uninterpretable' features which are important in MP analyses – see immediately below – have formalized equivalents in LFG, and in LFG, neither can by itself lead to a well-formed f-structure: an f-structure cannot contain an attribute without a value, and the contribution of a constraining equation must be matched by the contribution of a (valued) defining equation. In keeping with the character of the differences between the LFG and MP approaches, a clausal f-structure in LFG is never partial nor ill-formed, unlike stages in an MP derivation. Rather, each element in the c-structure in a given example contributes to a set of constraints which the overall f-structure must satisfy. If those constraints conflict, there is no f-structure which satisfies them, and the example is thereby ungrammatical.

4.2 Features in the MP

Features are put to at least three uses in MP analyses (see Adger 2010: 200–212). The first is to represent information, the second is to establish a relationship, and the third is to make something happen. The representational aspect usually involves valued features, and might involve unvalued ones. The second use involves the notion of interpretable and uninterpretable features, which is the mechanism for establishing a relationship known as 'Agree' between a Probe and a Goal (Chomsky 2000: 101).

For instance, Adger (2010: 189) gives the following illustrative example of a feature that is unvalued, and also uninterpretable. The idea that some features are uninterpretable was originally introduced by Chomsky (1995: 277–278). In (41), the first group of features are features of the subject DP, and the second group are features on the T head of TP.

(41) {D, definite, plural} … {T, past, *u*plural}

The DP is definite and plural, and T is past and also marked as plural, but the prefix notation *u* indicates that the plural feature, though present on T, is uninterpretable on it. Adger describes (41) as follows:

> The idea is that a feature like [plural] only has an interpretation when specified on a category which can be potentially interpreted as plural (e.g. on a noun), otherwise an instance of this feature will be uninterpretable: interpretability is detectable from a feature's syntactic/semantic context. The formal property of features (the *u* prefix) which enables them to enter into dependency relations is thus linked to the interpretation of features … (Adger 2010: 189)

The [plural] feature is not interpretable on T – the interpretation of tense never makes reference to singular/plural – but the matching occurence of [plural] on the subject DP establishes the Agree relation between these two groups of features. After it has been checked by a matching interpretable feature, [plural] is then eliminated on T.

From the perspective of LFG, the equivalent of [*u*plural] in (41) would be as in (42).

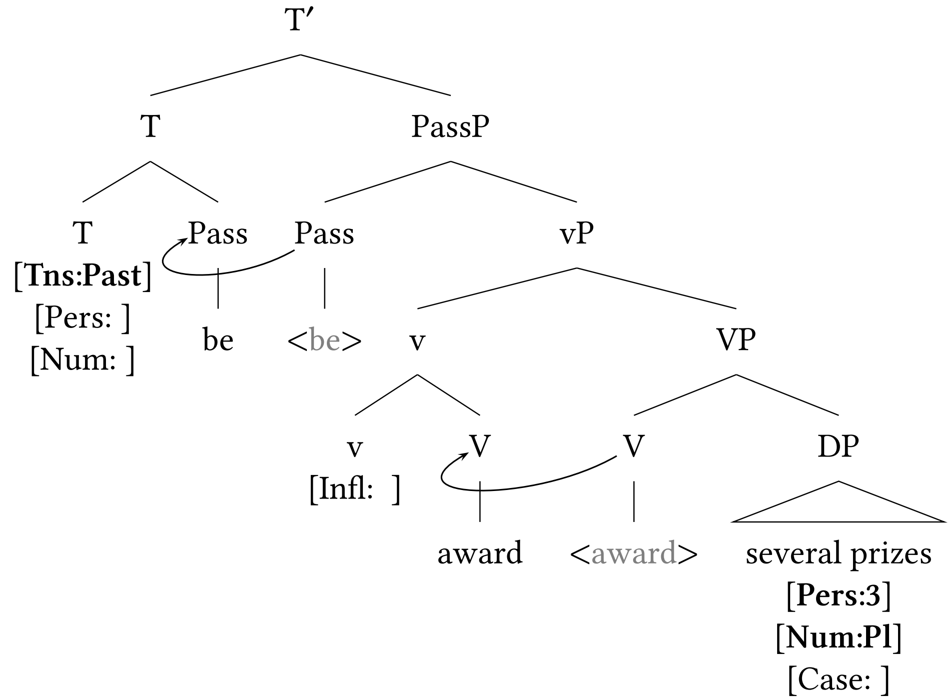
(42) $(\uparrow \textsc{subj num}) =_c \textsc{pl}$

Just as with (41), a structure described by (42) will only be well-formed if some other element (e.g. the subject) specifies the PL value for the feature, but it represents a different approach to the role of features. In (41), the feature on T is understood to convey "I am plural", which is uninterpretable; but the specification in (42) conveys "my subject's number is plural", which is actually straightforwardly interpretable.

The third use of features in the MP is to trigger an operation. Such features do not seem to overlap with the features considered above, and exist solely to make something happen. The canonical example is the 'EPP-feature' derived from GB, but used in different ways to force either XP movement or X^0 movement (head movement) in many MP analyses. This feature has been more recently cast as an 'Edge Feature' (e.g. Chomsky 2005). It is not clear formally what kind of feature this is – it must be satisfied, as an instruction for some structure to be built, and once satisfied, there are two options: either it becomes inactive, or it stays active, allowing for multiple specifiers (Chomsky 2007: 11).

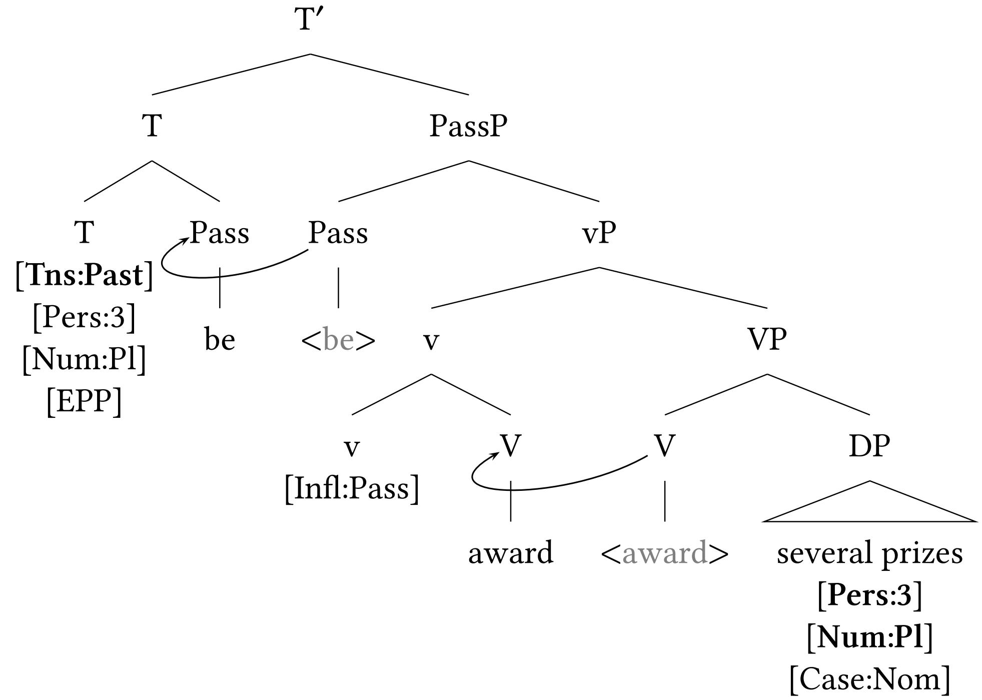
I now show in more detail how (un)valued and (un)interpretable features participate in an MP derivation. What is shown here is based on the presentation in Radford (2009: 284ff.), though using a slightly different representational format which is more internally consistent and which will also be more transparent in the context of the LFG approach to features described above. There is in fact a close relation between valued and interpretable features, as will be evident in the structures below. However, the two notions are formally distinct and can play different roles in an overall syntactic analysis (see e.g. Aelbrecht & Harwood 2015). The structure in (43) underlies the fragment *were awarded several prizes*, which is our illustrative example. The DP *several prizes* has interpretable features of person and number (it is 3rd person plural), and in the syntax it will have a value for case; but the case feature is initially unvalued, as the particular value of case will depend on the syntactic context of the DP. The v which ultimately hosts *award* has an Infl feature (sometimes referred to as VFORM in LFG), which will also be valued according to the syntactic context of the verb. Finally, the head T is specified as past tense, and it also hosts agreement features for person and number, which are unvalued at this initial stage. In the structure, the features shown in bold are those which are interpretable, and they also are the ones which are valued.

(43)



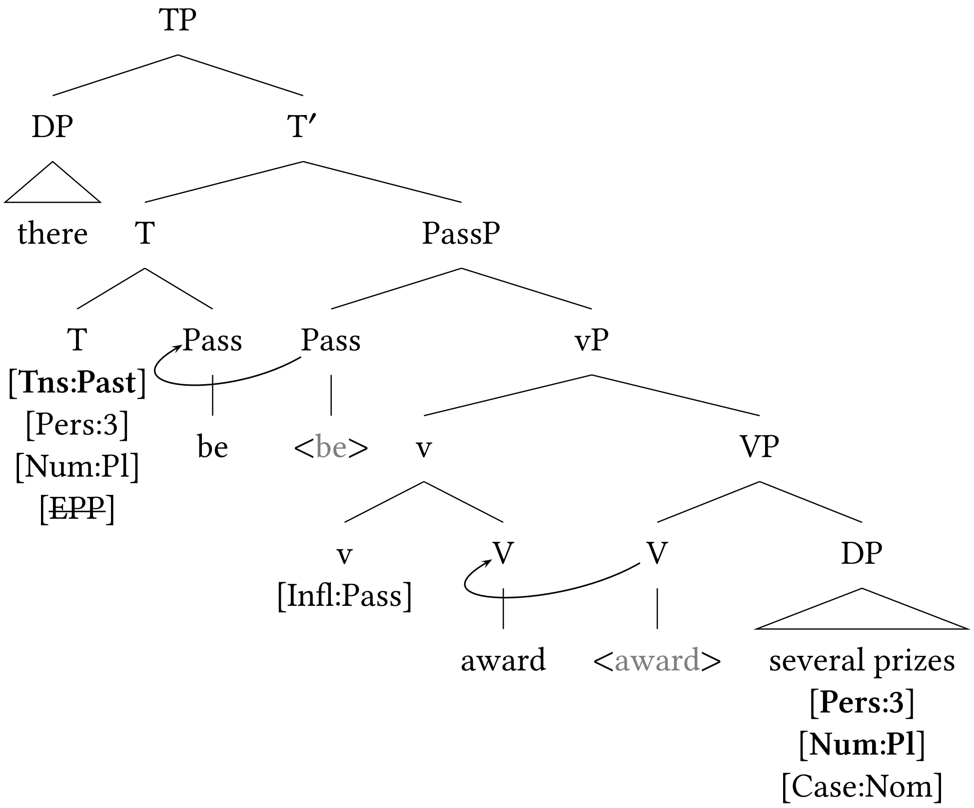
Formally, Agree establishes a relation between two nodes, a Probe and a Goal, one of which has an interpretable feature, with the other having a (matching) uninterpretable feature. In the simple example here, the uninterpretable features are the unvalued ones, and so they will become valued once Agree takes place. For instance, the Pass head *be* in (43) enters into an Agree relation with v and values the Infl feature as Pass(ive). The T head enters into an Agreement relation with the DP *several prizes*, valuing the Case on DP as Nom, and at the same time taking the values of person and number from that DP. Hence, after these Agree relations are established, all features are valued, as in (44), and these feature specifications will be relevant for morphological realization (e.g. the surface form of *be* will be *were*). Nevertheless, the non-bold (formerly unvalued) features are classed as uninterpretable, and must delete by the end of the syntactic derivation, Logical Form. Finally, (44) also shows one more feature on T, [EPP], which is discussed immediately below.

(44)



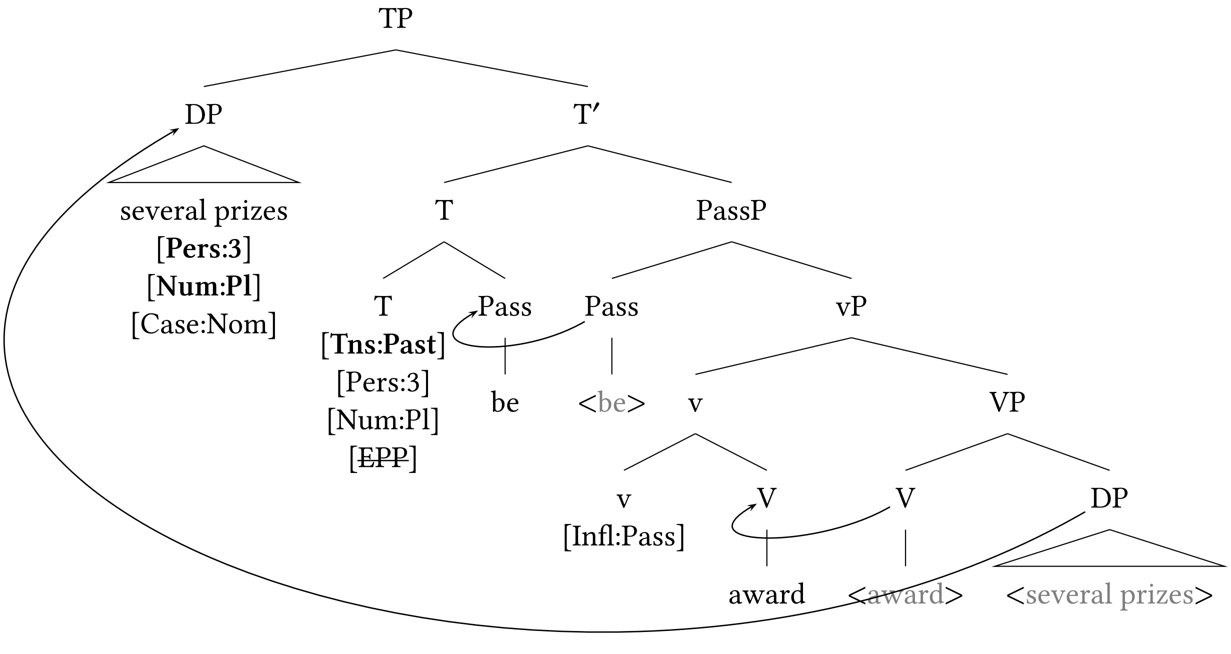
T in (44) has the [EPP] feature mentioned above, which has the effect that at the next step of the derivation a specifier must be created. This feature, then, does not represent a 'featural' property of the clause (unlike, say, 'past tense'), but represents a structural property. One option for satisfying this feature is to merge in an expletive placeholder, *there*:

(45)



Once the specifier is merged, the EPP feature is thereby satisfied, indicated in (45) by the strikethrough. Another way of satisfying this feature from the stage in (44) is to raise the object DP to the subject position, as a canonical passive:

(46)



4.3 Agreement and the direction of Agree

The second use of features in the MP noted above is that they participate in the process of Agree (Chomsky 2000), which is a prerequisite to establishing a relation in the syntax. The exemplar syntactic relation is that of agreement – say between a subject and a finite verb. As with canonical agreement (e.g. Corbett 2006), there is assumed to be a controller of agreement and a target for agreement, a directional or asymmetric relationship, formally instantiated as a Probe and a Goal in the MP. There is considerable debate in the MP literature as to the 'directionality' of Agree – is it upwards, or downwards? – as well as to whether feature valuation passes from the higher element to the lower one, or vice versa. For instance, Polinsky & Preminger (2019) make a linguistic argument about the direction of agreement (specifically, ϕ-feature agreement); they argue that agreement must be directional, looking downwards, but valuing features upwards. In contrast, Bjorkman & Zeijlstra (2019) argue for a more complex system in which a checking relation is first established, but only upwards, and then after that valuation can take place, in either direction. Some examples which bear on these issues are given below. These proposals are each 'substantive' proposals, motivated by empirical observations, as there is nothing formally about the MP system which requires a given directionality for Agree.

As noted above in Section 2.2.2, there is no sense in LFG in which agreement can be directional, as "agreement" is the informal notion we apply to a situation where more than one element provides featural information about some (other) element. The Archi examples below show that the distinction between Controller and Target, or between Probe and Goal, cannot be sustained anyway.

Polinsky & Preminger (2019) present examples such as (47) from Tsez, to support their claim that a Probe looks downwards to find a Goal – that the Probe c-commands the Goal – and the relevant feature values from the Goal are then valued upwards to the (previously incomplete) Probe. The key property of this example is that it involves long-distance agreement, in which the matrix verb does not agree with any local argument but rather agrees with the absolutive argument (object) of the embedded clause. Tsez has an ergative-absolutive case-marking system, and the verb agrees with an absolutive argument. The embedded absolutive in (47) is 'bread', class III, and both the local predicate 'eat' and the higher predicate 'know' agree with it in class, shown in boldface in the gloss:

(47) Tsez

eni-r	[už-ā	magalu	b-āc'-ru-łi]
mother-DAT	[boy-ERG	bread.**III**(ABS)	**III**-eat-PST.PTCP-NMLZ]

b-iy-xo
III-know-PRES
'The mother knows that as for the bread, the boy ate it.'

The particular argument that Polinsky and Preminger make is based on the observation that the opposite configuration appears to be unattested – we never find a structure in which a verb in a lower clause agrees with an argument in a higher clause. To rule out this logical possibility, they argue that syntactic theory should only allow downwards Agree/upwards valuation. The detail of their argument is not crucial here – what is relevant are the relative structural relations between the two elements in the agreement relationship. In (47), as the absolutive controls agreement on the higher predicate 'know', I will categorize this example as one in which the target must c-command the controller (hence, valuation is upwards).

The rest of the examples in this section are taken from Archi, another language with an ergative-absolutive system. Archi has a wide range of potential targets for agreement, but the controller is always the absolutive. (48) from Bond & Chumakina (2016: 67) shows various agreement targets (boldfaced in the gloss, each corresponding to the exponent *d-*):

(48) Archi
[d-ez χir] d-e⟨r⟩qˤa-r-ši d-i
[**II.SG**-1SG.DAT behind] **II.SG**-⟨IPFV⟩go-IPFV-CVB **II.SG**-be.PRES
'She follows me.' (male speaking)

Both the main verb and the auxiliary 'be' show agreement with the absolutive for gender and number. The gender system in Archi consists of four noun classes, and in this example, the gender agreement is for class II. The controller of agreement is not overt – it is the implicit subject of the intransitive predicate, formally in absolutive case. In addition, the first singular pronoun *d-ez* which is the object within the directional PP headed by 'behind' agrees with the absolutive of its clause, even though the pronoun is not a direct co-argument of the absolutive in this example. The pronoun is itself first person singular, but it also has an 'external agreement' slot for the clausal absolutive. Now that pronoun, inside the PP, cannot c-command anything outside that PP, and yet the intuition here is that it is the target of agreement: so for this example it must be the case that the controller (a null subject absolutive) c-commands the target. Valuation, if directional, should be downwards – exactly reversed from the Tsez example (47).

The LFG analysis of Archi agreement in Sadler (2016) codes each agreeing element for the relevant features of the notional agreement controller – the argument in absolutive case. As the GF of that argument could be subj or obj depending on the transitivity of the predicate, Sadler uses the designator piv, proposed by Falk (2006). Sadler (2016: 161) also uses the template approach (Dalrymple et al. 2004) to schematize over different agreement combinations. For the form in (49), @ii.sg associates the gender and number agreement values with the word, as in the second commentary enclosed in [ ]:

(49)

d-ez, Pronoun
(↑ pers) = 1
(↑ num) = sg [it is a first singular pronoun]
@ii.sg((gf ↑) piv) [its external agreement features are class ii singular]
…

For (48), (gf ↑) piv instantiates as (obl obj ↑) subj. The f-structure of the example is shown in (50), where the external agreement path for the first person pronoun – the inner [pred ‘pro’] – follows this instantiation and specifies values for gender and number, shown in boldface:

(50) F-structure of (48); agreement of the pronoun with the absolutive ((obl obj ↑) subj) must be: class ii, num sg

$$\left[\begin{array}{ll} \textbf{SUBJ} & \left[\begin{array}{ll} \text{PRED} & \text{‘PRO’} \\ \text{PERS} & 3 \\ \textbf{NUM} & \textbf{SG} \\ \textbf{CLASS} & \textbf{II} \\ \text{CASE} & \text{ABS} \end{array}\right] \\ \text{TENSE} & \text{PRES} \\ \text{PRED} & \text{‘GO}\langle(\uparrow \text{SUBJ})(\uparrow \text{OBL})\rangle\text{’} \\ \textbf{OBL} & \left[\begin{array}{ll} \text{PRED} & \text{‘BEHIND}\langle(\uparrow \text{OBJ})\rangle\text{’} \\ \textbf{OBJ} & \left[\begin{array}{ll} \text{PRED} & \text{‘PRO’} \\ \text{PERS} & 1 \\ \text{NUM} & \text{SG} \\ \text{CASE} & \text{DAT} \end{array}\right] \end{array}\right] \end{array}\right]$$

Note that the first person pronoun itself does not have any “agreement slot” within its own feature structure: it has no agreement feature specification which is supposed to match or be copied somewhere else in the (f-)structure.

The informal notions of controller and target have no embodied representation, which ultimately proves to be an important fact about the LFG analysis – because there are examples in which ‘controller’ and ‘target’ are the same single syntactic element. There are different types of example in Archi where an absolutive argument “agrees with itself” – a given syntactic element has an external agreement slot, to agree with the absolutive of its clause, but that element happens to be the absolutive itself. (See also Corbett 2006: 68–69, Borsley 2016: 137.) In these examples, the distinction between controller and target – as two distinct elements in an asymmetric relationship – is invalid, but on a co-description account of the kind illustrated by (49) the examples work out straightforwardly.

(51) is one such example. A reflexive pronoun in Archi has two slots for agreement – one for the features of its antecedent, as is familiar, and another one for the features of the absolutive of the clause. In (51) (from Bond & Chumakina 2016: 70) the subject is the pronoun ‘I’, in dative case, and the object is the reflexive, in absolutive case, and it is class II, signifying a female referent. The subject pronoun, main verb and auxiliary verb each agree in class with the absolutive, as does one of the slots in the reflexive – the whole form is 1SG, agreeing with the subject antecedent, and there is also an infixed class II agreement, again agreeing with the absolutive, which is the reflexive itself.

(51) Archi
d-ez zona⟨r⟩u d-ak:u-r-ši d-i
II.SG-1SG.DAT 1SG.REFL.ABS⟨**II.SG**⟩ **II.SG**-see-IPFV-CVB **II.SG**-be.PRS
daχon-n-a-š
mirror(IV)-SG.OBL-IN-EL
‘I am seeing myself in the mirror.’

So here, (GF ↑) PIV instantiates as (OBJ ↑) OBJ, one of the logical possibilities. The f-structure is shown in (52):

(52) F-structure of (51); agreement of the reflexive with the absolutive ((OBJ ↑) OBJ) must be: CLASS II, NUM sg

$$\left[\begin{array}{ll}
\text{SUBJ} & \left[\begin{array}{ll}\text{PRED} & \text{‘PRO’}\\ \text{PERS} & 1\\ \text{NUM} & \text{SG}\\ \text{CLASS} & \text{II}\\ \text{CASE} & \text{DAT}\end{array}\right]\\
\text{TENSE} & \text{PRES}\\
\text{PRED} & \text{‘SEE}\langle(\uparrow \text{SUBJ})(\uparrow \text{OBJ})\rangle\text{’}\\
\textbf{OBJ} & \left[\begin{array}{ll}\text{PRED} & \text{‘PRO’}\\ \text{REFL} & +\\ \text{PERS} & 1\\ \textbf{NUM} & \textbf{SG}\\ \textbf{CLASS} & \textbf{II}\\ \text{CASE} & \text{ABS}\end{array}\right]\\
\text{OBL} & \left[\text{“MIRROR”}\right]
\end{array}\right]$$

Like other aspects of the grammar, the correct account of "agreement" does not involve moving something – in this case, featural information – from one place to another, but rather is a partial specification of featural information in a larger structure.

5 Conclusion

LFG takes up the challenges of accounting for human language precisely as Chomsky first articulated them, yet continuing with a view quite different from his as to what the core non-negotiable properties of the syntactic system should be. It was developed as a systematic and coherent framework for the representation of grammatical information, based on certain key design features. While these design features give these frameworks a very different character from a procedural framework such as the MP, many of the components of analysis which MP has developed are already present in declarative frameworks (see Section 4), as is the convergence of interest in exploring 'third factor' considerations (see (5)).

As Chomsky has noted, the choice between grammatical frameworks can be understood in terms of the "extra burdens" that an over-exuberant approach will entail (Chomsky 2007: 10–11). From a declarative perspective, any procedural approach creates such burdens, as the necessary mechanisms are either too powerful or are not well-founded. If those mechanisms can change or even delete syntactic information or syntactic substance, it is necessary to constrain those destructive operations with the 'No Tampering Condition' – indeed, a very natural property of a grammatical system, but one that should be intrinsic to it.

The 'copy theory' of movement (Chomsky 1995) is a way of expressing the intuition that some information is shared. However, copies involve duplication of substance, which amounts to more than the sharing of information. The discussion of structure in Section 3 provides a perspective on two kinds of further burden that necessarily arise in a copy-based approach. First, with regard to head mobility, the LFG view is that the issue is one of alternative positions, rather than successive positions which exist to provide hosts for position-occupying movement. The head is indeed only "in" one head position, but it makes the same contribution that it would have made from any of its alternative possible positions, and so might appear as if it were contributing from each position. The evidence from multiple expression of clausal information supports this view. A recent MP account of the syntax of heads by Arregi & Pietraszko (2021) associates only the informational part of a given head with several head positions, effectively recapitulating the LFG analysis of head mobility through various operations to create the right representations. Second, the facts of Mandarin verb copying show that certain parts of the syntactic analysis indeed call for a duplication of substance (when there are both in-situ arguments and adjuncts in Mandarin), while other parts involve more abstract syntactic information (the notion of a verb *having* arguments and having adjuncts). If that abstract information is conflated with the phrase structure substance, the system generates too much, and then extra operations have to be invoked, pruning or conflating substance.

The formalization of the MP by Collins & Stabler (2016) is designed in part to address the No Tampering Condition, and the apparent duplication of substance. Instead of creating copies, in this formalization, successive movements of a given element create new multidominance relations from that single element, which therefore does not change during the derivation. Their formalization is extended to head movement by Bleaman (2021). This particular formalization might make MP derivations slightly closer in nature to f-structures, in that each object in the derivation is a single informational unit which may have multiple grammatical relations and phrase-structural relations (e.g. a topicalized object is both an object and a topic, but with just one overt realization, in topic position).

A different kind of burden of potential complexity falls on the feature system of the MP, as features are used to do more than represent information (see Section 4). It becomes necessary to posit "bad" feature specifications, such as uninterpretable features, which by design are not interpretable on their hosts, and which must be eliminated during the derivation. LFG has constraints of a different character for checking that certain grammatical relationships exist, and which do not involve recourse to local pockets of uninterpretability.

Acknowledgments

The content of this chapter has benefitted considerably from the comments of three anonymous reviewers, whose contributions I gratefully acknowledge; and thanks to Mary Dalrymple for her continued guidance.

Chapter 41

LFG and Role and Reference Grammar

Delia Bentley
The University of Manchester

Nigel Vincent
The University of Manchester

LFG and Role and Reference Grammar have in common the goals of developing a formal model for the grammars of natural languages that both accommodates typological diversity and avoids syntax-centred derivationality. That said, the two frameworks differ in their choice of conceptual primitives and in the way the different components interact. In the present chapter we explore those differences in particular with respect to core sentence structure, information structure, cross-linguistic patterns and variety, and diachrony.

1 Historical Context

Both LFG and RRG emerged in the 1970's and 1980's in the context of the general reconsideration of possible models of grammar that took place at that time. These developments were driven in part by a concern to rethink the best way to capture the interaction between syntax, semantics and pragmatics, in part by a desire to reflect the typological diversity of natural languages and avoid a bias towards the sorts of structure found in 'standard average European', and in part by considerations of psychological plausibility and computational tractability. At the same time, the two frameworks differ in the relative priority to be assigned to these different lines of argument and evidence.

In the case of RRG the two principal motivating questions were the following: (a) What would a linguistic theory look like if it were based on the analysis of Lakhota, Tagalog and Dyirbal, instead of English? (b) How can the interplay

Delia Bentley & Nigel Vincent. 2023. LFG and Role and Reference Grammar. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 1967–2027. Berlin: Language Science Press. DOI: 10.5281/zenodo.10186048

of syntax, semantics and pragmatics in different grammatical systems best be captured and explained? (Van Valin 2009: 704). Constraining the framework are, therefore, not only the classic Chomskyan criteria of descriptive and explanatory adequacy (on which see Rizzi 2016), but also those of typological and psychological adequacy, since in the words of Austin & Bresnan (1996: 263) 'theoretical economy and explanatory elegance are unreliable guides to truth'. Typological adequacy requires that the theory should grasp commonalities between different languages without attributing to a given language any features for which that language provides no evidence. Psychological adequacy, as formulated by Dik (1991: 248), states that a theory should be compatible with the results of psycholinguistic research on the acquisition, processing, production, interpretation and memorization of linguistic expressions. This is not to say that there are no postulated universal principles either in LFG or RRG, but rather that within neither framework is there the presumption of an innate, syntactically defined U(niversal) G(rammar).

This concern for psycholinguistic plausibility was shared with LFG, as discussed for example by Bresnan & Kaplan (1982), where it was linked to issues about the length and complexity of syntactic derivations within the transformational approach. Whereas at that time generative syntax was — and indeed still is — built on an exclusively categorial set of primitives, LFG and RRG in their different ways sought to explore in addition the use of relational concepts. Influential here had been, on the one hand, Relational Grammar with its definition of structures in terms of changing grammatical functions like subject and object, albeit while still retaining a derivational approach, and, on the other hand, Fillmorean Case Grammar with its set of semantically defined roles like agent and patient. For LFG this led to a much reduced, monostratal categorial component (c-structure) linked to but not derived from a set of grammatical relations (f-structure). RRG, by contrast, goes a step further and in addition sets aside notions like subject and object as also being in danger of biassing the system towards particular types and families of languages and opting instead for a core set of semantically defined relations. Despite these differences, RRG and LFG have in common the fact that, once the analytical burden is shared between categories and relations, grammatical structures are no longer required to respect the principles of endocentricity and binary branching which have become key parts of current Minimalist, cartographic and nanosyntactic approaches. A sentence can be represented simply as S rather than needing to be CP, TP or the like and if a language does not provide ready evidence of configurational structure, none needs to be imposed (Austin & Bresnan 1996; Van Valin & LaPolla 1997b: Chapter 2).

We move now to an overview of RRG (Section 2) before returning to a more detailed comparison of the two frameworks (Section 3) and consideration of the way they deal with issues involving language change, processing and acquisition (Sections 4, 5 and 6).

2 RRG: An overview

For RRG, grammar is a system in a traditional structuralist sense. However, RRG is not only interested in the syntagmatic and paradigmatic relations that characterize syntax, but also in the combinatorial relations between units of meaning within and out of context. This framework is, thus, like LFG, a parallel architecture theory (Jackendoff 2002: Chapter 5), which relies on three independent, albeit interacting, levels of analysis: discourse, lexical semantics and syntax.[1] Much of what other syntactic frameworks would explain in terms of syntactic derivation or movement is captured in RRG in terms of the mapping of these three dimensions. This reflects the assumption that grammatical structure can only be understood and explained with reference to the expressive and communicative functions of language.

Since it seeks explanation outside of the boundaries of syntax, RRG could thus be thought to lie on the functional side of the formalist-functional divide in theories of language (Butler 2005, 2006, Mairal Usón et al. 2012), and indeed Newmeyer (1998: 14-16) cites it as an example of what he calls ‘external functionalism’, adducing the description by Van Valin (1993: 1) of RRG as a ‘structuralist-functionalist theory of grammar’. However, a preference for the explanation of linguistic phenomena in terms of meaning and external context by no means implies an absence of a formal notation. And indeed within RRG each of the levels of analysis is conceived of in terms of an articulated formalism and there are explicit constraints on the interaction of the three levels. In addition, in the last ten to fifteen years, an increasing number of scholars have attempted to apply RRG to language processing, both in the computational and the neurolinguistic domain. Such attempts have resulted in the development of new formalisms, which use the RRG framework as their basis (see Section 5 below).

The basic architecture of RRG is illustrated in Figure 1. While the two arrows in the middle show the bidirectionality of the semantics-syntax linking, the position of discourse-pragmatics with respect to this mapping indicates that discourse

---

[1] A striking comparison in this connection is Sadock’s independent realisation that a language like Greenlandic calls for a parallel or ‘modular’ architecture (Sadock 1991: ix–xi), which in turn led to his own model of Autolexical Syntax.

can be relevant at every step in the linking (Bentley 2023 and Section 3.5 below). Specifically, discourse-related meaning (for example, the distinction between the information that has already been given and the new information that is provided with the utterance) is not only expressed syntactically, but also in prosody, morphology and even in lexical choices. In fact, the encoding of discourse-related meaning in syntax varies across languages in important ways and this variation has been the object of much research in RRG (see among others Van Valin 1999, Shimojo 1995, 2008, 2009, 2010, 2011, Bentley 2008).

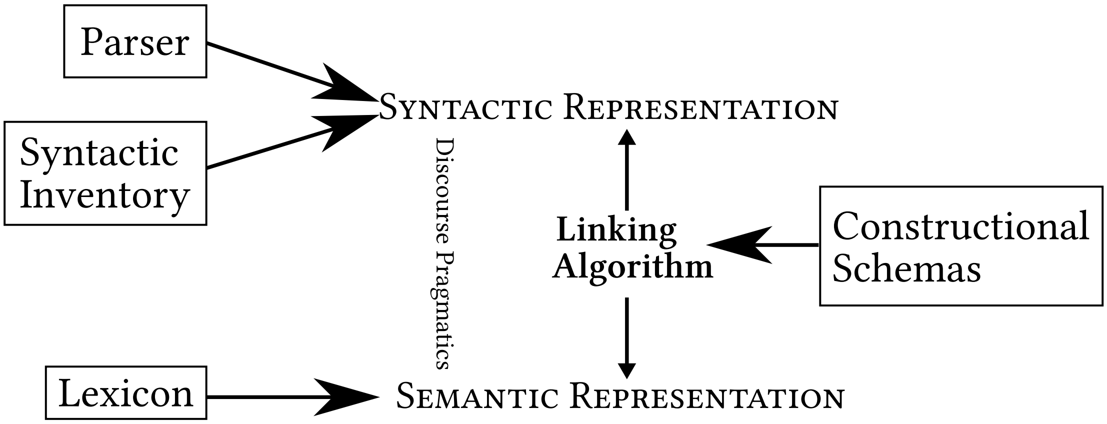

Figure 1: Organization of RRG (based on Van Valin 2005: 134)

We return to other properties of the linking at the end of Section 2.

2.1 The structure of the sentence and of reference phrases

There is a single syntactic representation for a sentence, which corresponds to the surface form of the sentence and appears in the Constituent Projection. As noted above, there is no requirement that the structure of the clause should be binary branching; the syntax of the sentence must be adequately represented in configurational and non-configurational, dependent-marking and head-marking languages alike. In clausal structure, a distinction is drawn between the semantically motivated positions, which are assumed to be universal, and other positions, which tend to be associated with particular pragmatic roles and are not universal. Together the two types of position form the Layered Structure of the Clause (see Figure 2).

There is no verb phrase in the Layered Structure of the Clause because not all languages offer evidence for it (for comparable considerations in LFG see Börjars et al. 2019: 5-6). The Nucleus hosts the predicate, while the arguments drawn from the semantic representation of the predicate, called core arguments, figure

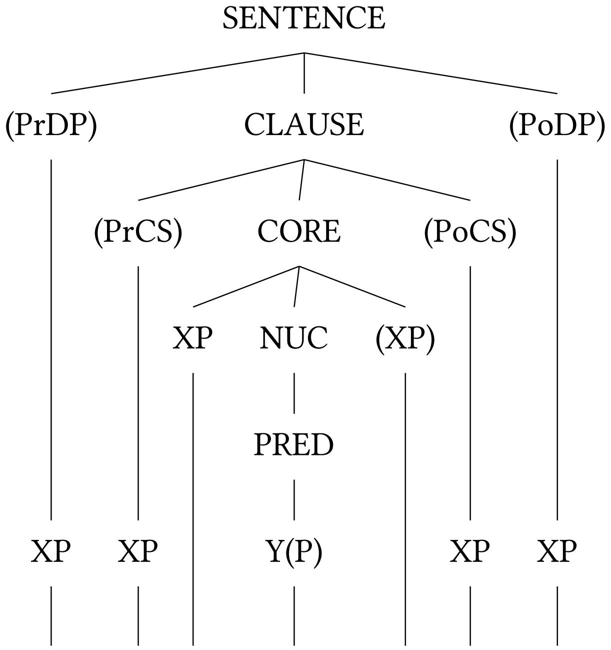

Figure 2: The Layered Structure of the Clause (from Van Valin 2023b)

within the Core and are labelled RPs (Reference Phrases).[2] No phonologically null elements are allowed in RRG syntax.[3] Neither the Nucleus nor the RP nodes are restricted to any particular lexical category, given that in some languages, such as Nootka and Tagalog, expressions that are verbs in categorial terms can have a referential function in the clause, in which case they behave as arguments, while nouns can have a predicative function (Van Valin 2008: 170).[4] In English too the predicate in the Nucleus can be an adjective, a noun phrase, or a prepositional phrase, although a verb is needed for the proper formation of the Nucleus of the clause. The Nucleus and the Core are taken to be universal positions because

---

[2] Within core arguments, RRG distinguishes between direct core arguments, which are unmarked or marked by case alone, and oblique ones, which are adpositionally marked.

[3] Genuine zero anaphora, i.e., the complete failure of expression of an argument, whether as a pronoun or in inflection, is dealt with in a system of direct mapping from discourse to the semantic representation of the clause, and vice versa, with the argument being represented in both of these domains, but not in syntax (see Section 3.5). Zero morphemes are, however, admitted in RRG in morphological paradigms, the key difference between these and phonologically null syntactic elements being that the latter type of element is redundant, on the assumption that the linking can occur directly from the semantic representation to discourse.

[4] This is not to say that nouns and noun phrases have no status in RRG. On the contrary, nouns and verbs are taken to be universal lexical categories, by contrast with adjectives, which are not found in all languages.

all languages predicate and refer. Any adjuncts that modify the nucleus, or the core, or indeed any of the more external syntactic layers figure in a Periphery as M(odifier) P(hrases). Every syntactic layer (Clause, Core, Nucleus) can have its own Periphery.

Both the core-internal positions and the peripheries of the various layers of the clause can host constituents with particular discourse roles. To give but one example, to the extent that they are overt, topical subjects normally occur in the core-initial pre-nuclear position in SVO languages. However, these positions are not defined in pragmatic terms, but rather in terms of the referential and predicative functions of language. The more external positions, instead, tend to be associated with pragmatically salient functions. The Pre- and Post-Core Slot normally host foci, although there can be language-specific restrictions on the kinds of foci that they admit. In a large number of languages the Pre-Core Slot hosts pre-verbal *wh*-words and the same position has been claimed to be involved in contrastive focus fronting in some Romance languages (Bentley 2008). The Pre-Core Slot hosts topics, as well as foci, in languages with a V2 constraint on word order (Diedrichsen 2008). The Post-Core Slot is the position of secondary foci which non-canonically occur in post-verbal position in Japanese, a verb-final language (Shimojo 1995). The Pre-Detached Position (formerly called Left-Detached Position) is the position of detached topics and can iterate, thus allowing the utterance to have several topics, while the Pre- and Post-Core Slot cannot be repeated.[5] The Post-Detached Position (formerly called Right-Detached Position) hosts afterthoughts or topics.[6] The pragmatically salient positions are not universal: the languages that provide no evidence for these positions are not assumed to have them. The building blocks of the Layered Structure of the Clause are the building blocks of complex predicates and clauses, as will be explained in Section 3.4.

The structure of the RP and of adpositional phrases is built following the same principles as the structure of the clause (see Cortéz-Rodríguez 2023, Ibáñez Cerda 2023.). Thus, RPs have their own Constituent Projection, with Nucleus and Core, and their respective peripheries. RPs also have their Operator Projection, which defines the scope of the functional categories of definiteness, deixis, quantification, and number.

---

[5] This raises the question of the position of initial sequences of *wh*-words in languages which allow them, for example Bulgarian, an issue which to our knowledge has only been addressed from an RRG perspective by Eschenberg (1999).

[6] The reason for the relabelling of the Left- and Right-Detached positions is that these names reflect a bias towards western languages, which are written from left to right. The problem does not arise with Pre-Detached and Post-Detached, which reflect the before and after dimensions of speech.

In RRG the functional markers of closed-class grammatical categories such as aspect, modality, tense and illocutionary force are not mapped to the Constituent Projection, but rather to the Operator Projection, and hence the framework does not incorporate an inventory of functional heads. The Operator Projection is the mirror image of the Constituent Projection because RRG assumes that the order of the morphemes that express grammatical categories is a function of their syntactic and semantic scope (Foley & Van Valin 1984, Bybee 1985). Thus, the Nucleus comes first, in the Operator Projection, as the domain of aspect, nuclear negation and directionals. Core negation and root modality have scope over the Core. Finally, status (epistemic modality), tense, evidentials, and illocutionary force have scope over the Clause.

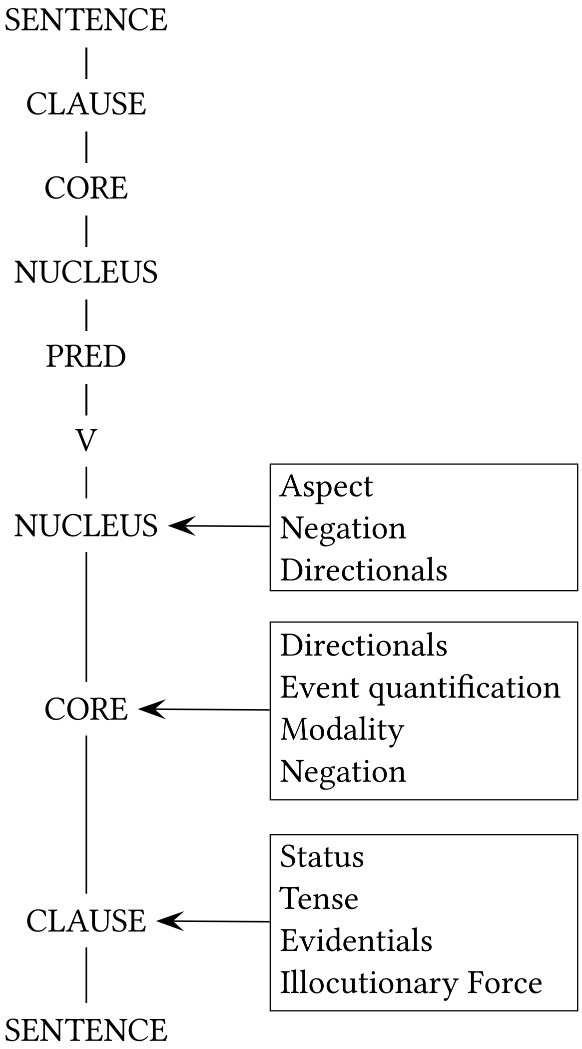

Figure 3: The operator projection in the layered structure of the clause

The Constituent Projection is not built incrementally in the linking. Rather, the syntactic structure of the clause, and of the RPs and PPs contained in it, are drawn as templates from the syntactic inventory of the given language at the relevant stage in the linking. The selection of syntactic templates in the linking is governed by the *Syntactic Template Selection Principle* (Van Valin & LaPolla 1997b: 324, Van Valin 2005: 130) and by discourse considerations (Section 3.6), to which we return below. The syntactic inventory of a language comprises all the templates that are necessary to form grammatical sentences in that language. It reflects universal linearization principles concerning the position of the extra clausal positions shown in Figure 2, as well as the word order preferences of the language: primarily, its branching directionality, in the sense of Dryer (1992). Broad typological properties, such as head and dependent marking, and configurationality, also play a role in word order. Instead, the position of the operators in the clause largely depends on their semantic scope (see Figure 3). The syntactic inventory complements the lexical inventory as well as an inventory of constructional schemas, to which we shall also return.

2.2 Logical Structures, semantic roles and macroroles

The lexicon is an important component of grammar in RRG, since the semantic representation of the clause is based on the semantic representation of the verb and any other predicating elements figuring in it, for example, any predicative adpositional phrases. The semantic representation, or Logical Structure, of a verb is based on a theory of lexical decomposition which relies on Vendler's (1967: 97-121) Aktionsart types *state*, *activity*, *achievement* and *accomplishment*, to which Van Valin & LaPolla add the distinction between plain and active accomplishment (see below) and Van Valin (2005: 32) adds the non-Vendlerian class of *semelfactives* (Smith 1997: 55-58). State and activity are the basic types upon which all the others are built. Both states and activities are [−telic] and [−punctual]. However, states describe static situations, whereas activities describe dynamic ones, that is, situations that involve change, albeit not of the type leading to a result state. We provide below the semantic representations of the states 'red' and 'know' and of the activities 'march' and 'sing'.

(1) States
   a. **be′**(x, [**red′**]) 'red'
   b. **know′**(x, y) 'know'

(2) Activities
  a. **do′**(x, [**march′**(x)]) ‘march’
  b. **do′**(x, [**sing′**(x, (y))]) ‘sing’

Predicates are presented in bold, followed by a prime, and English is the metalanguage used to represent them; **be′** figures in the Logical Structure of attributive, identificational and specificational states, alongside the constant identifying the given state. Instead, **do′** marks the Logical Structure of all activities.

Achievements and accomplishments are [+telic], which means that they describe change leading to the attainment of a result state. The former predicate type, being [+punctual], does not include a PROC(ess) component (cf. (3)), which instead characterises the latter (cf. (4)).[7] PROC and the other Logical Structure components in capital letters are operators, or markers of templatic facets of meaning, which combine with the constants representing the idiosyncratic meaning of individual lexical items. The RRG theory of lexical decomposition stands out from others in differentiating accomplishments from active accomplishments (cf. (5)). These are built on the basis of the logical structures of an activity plus an accomplishment. The process that is part of the accomplishment is simultaneous with the activity, and both are followed by the attainment of a result state (Van Valin 2018). Simultaneity is represented with the notation ∧, whereas the symbol & stands for “and then”.

(3) Achievements
  a. INGR **appear′**(x) ‘appear’
  b. INGR **be-at′**(x) ‘arrive’

(4) Accomplishments
  a. PROC INGR **dead′**(x) ‘die’
  b. PROC INGR **know′**(x, y) ‘learn’

(5) Active accomplishments
  a. **do′**(x, [**run′**(x)]) ∧ PROC **cover.path.distance′**(x, (y)) &
  INGR **be-at′**(**path.endpoint**, x) ‘run to a location’
  b. **do′**(x, [**write′**(x, y)]) ∧ PROC **create′**(y) &
  INGR **exist′**(y) ‘write (tr.)’

---

[7] See Bentley (2019) and Van Valin (2023b) for proposals on the differentiation of quantized and non-quantized change in the Logical Structure of accomplishments.

Semelfactives (Smith 1997: 55–58) describe repeatable punctual events, which may be [+static] or [+dynamic] (cf. (6a) vs. (6b)), and do not lead to a result state, as testified by the absence of result state participles of these verbs in attributive function in the noun phrase.

(6) Semelfactives
  a. SEML **see′**(x, y) ‘glimpse’
  b. SEML **do′**(x, [**cough′**(x)]) ‘cough’

There are standard diagnostics to determine the Aktionsart of the predicate of a clause, based on Dowty’s (1979) seminal work. No *a priori* assumption is made as to whether verbs describing comparable eventualities should belong to the same Aktionsart type across languages, although it is acknowledged that there are striking cross-linguistic similarities of this kind, whose rationale can be captured on the basis of a system of lexical decomposition like the RRG one.

The predicate types discussed above have causative counterparts, which in principle combine any logical structure α with any logical structure β by means of the operator CAUSE. The causal event may, however, remain unspecified, as is shown in (7b), which is built upon (7a).

(7) Accomplishment vs. causative accomplishment
  a. PROC INGR **dead′**(x) ‘die’
  b. [**do′**(x, ∅)] CAUSE PROC INGR **dead′**(y) ‘kill’

Traditional thematic role labels, like *theme* or *patient*, are mere mnemonics for the position which an argument occupies in Logical Structure as determined by applying the standard tests for the Aktionsart of the predicate. It is purely on the basis of its position that a core argument derives its thematic role (Jackendoff 1976; Van Valin & LaPolla 1997b: 82-138). There are five relevant positions.

(8) Semantic positions which are relevant to the linking

Arg of DO	1st arg of **do′**(x, ...)	1st arg of **pred′**(x,y)	2nd arg of **pred′**(x,y)	arg of state **pred′**(x)

Following Van Valin & Wilkins (1996), RRG draws a distinction between agentivity as an entailment and as an inference. The first argument of verbs which entail agentivity (e.g., *murder*) is named ‘Arg of DO’, whereas the first argument of verbs which merely lend themselves to inferences of agentivity (e.g., *kill*) is represented as '1st arg of **do′**'. These argument positions are found in the Logical Structure of activities, the latter one alone, the former in combination with the latter. The other positions are found in the Logical Structure of bivalent (1st and 2nd argument of **predicate**′(x,y)) and monovalent (argument of state **predicate′**(x)) states. As can be seen in (3) to (7) these positions combine with each other and with operators of cause, semelfactivity, process and change.

Importantly, the positions in (8) are not grammatically salient *per se*, but only to the extent that they determine which generalized semantic role, or macrorole, an argument is assigned in the linking. The relation between argument positions and macroroles is captured by the Actor-Undergoer Hierarchy in (9), while the macrorole assignment principles are spelled out in (10).

(9) The Actor - Undergoer Hierarchy and its mapping onto argument positions (Van Valin 2005: 61)

ACTOR				UNDERGOER
⟶	⟶	⟶		
		⟵	⟵	⟵
Arg of DO	1st arg of **do′**(x,...)	1st arg of **pred′**(x, y)	2nd arg of **pred′**(x, y)	Arg of state **pred′**(x)

['→' = increasing markedness of realization of argument as macrorole]

(10) Default Macrorole Assignment Principles (Van Valin 2005: 63)

a. Number: the number of macroroles a verb takes is less than or equal to the number of arguments in its logical structure.
  i. If a verb has two or more arguments in its logical structure, it will take two macroroles.
  ii. If a verb has one argument in its logical structure, it will take one macrorole.

b. Nature: for verbs which take one macrorole,
  i. If a verb has an activity predicate in its logical structure, the macrorole is actor.
  ii. If a verb has no activity in its logical structure, the macrorole is undergoer.

Actor and undergoer are the two primary arguments of transitive predications. Two-place verbs belonging to different Aktionsart types, say an active accomplishment (e.g., *write a book*) and a state (e.g., *know the answer*), are not differentiated in terms of macrorole assignment: both take an actor (the highest or leftmost argument in Logical Structure) and an undergoer (the lowest or rightmost argument in Logical Structure). There is, however, a fundamental asymmetry between the two macroroles, in that the highest core argument will always be the actor, whereas the lowest one is only the default choice for undergoer. Indeed, variable selection of the undergoer from the two lower arguments of three-place predicates is allowed in some languages. This is exemplified by English *present* (as in *present a gift/prize to someone*) in (11). In addition, two-place predicates may be intransitive, in which case this is specified in the lexicon, as exemplified with English *belong (to)* in (12).

(11) a. [**do′**(x, ∅)] CAUSE [INGR **have′**(y, z)]
b. x presents z to y
c. x presents y with z

(12) **have′**(x, y) [MR1] ‘belong (to)’

In (11b) z is the undergoer, whereas in (11c) the undergoer is y. The actor is x in both cases. As for (12), [MR1] lexically specifies that this verb only takes one macrorole despite being bivalent. Finally, whether the only core argument of a one-place predicate is an actor or an undergoer is established by the principles in (10b).

An important claim of RRG is that no subcategorization requirements need to be specified for a verb, other than the argument positions in its Logical Structure and its transitivity, which is defined as the number of macroroles it takes. The prepositions that mark the oblique arguments required by some verbs (e.g., *load x with y, load y on x*) are argued to be predictable from general principles, for which we refer to Van Valin & LaPolla (1997b: 376-384).

Macrorole assignment plays a key role in the linking, allowing RRG to capture how syntactically different, but semantically comparable, structures are related. Thus, starting from the assumption that languages with nominative-accusative alignment select the actor, whereas languages with ergative-absolutive alignment select the undergoer, as the default privileged grammatical relation (Section 2.3), passive and antipassive are constructions with the marked macrorole selection as the privileged grammatical relation: undergoer in the passive and actor in the antipassive. We return below to the notion of subject, which is not considered to be a universal of grammar in RRG.

Macrorole assignment, or failure thereof, also captures the different syntax of verbs with the same number of arguments. Consider (13a) and (13b).

(13) Italian

a. Mario, la matematica, l' ha sempre amata.
Mario the maths.FSG ACC.CL.FSG has always love.PTCP.FSG

b. (A Mario), la matematica gli è sempre piaciuta.
to Mario the maths.FSG DAT.CL is always please.PTCP.FSG
'Mario, maths, he always loved/liked it.'

The contrast between nominative and dative experiencer verbs (e.g., Italian *amare* 'love' vs. *piacere* 'please, like') depends on whether both arguments are assigned a macrorole, with the result being a transitive structure, as testified by the accusative clitic and the perfect auxiliary 'have' in (13a), or the experiencer being denied macrorole status, in which case the structure has a single macrorole and is intransitive, as testified by the selection of a different auxiliary, 'be', and the dative clitic in (13b).

2.3 Grammatical relations

RRG rejects the traditional notions of subject and object as primitives or universals of syntactic theory. Following Durie's (1985, 1987) analysis of Acehnese, an Austronesian language, Van Valin & LaPolla (1997b: 255-260) claim that there are languages which group arguments in terms of their macrorole status without assigning them a syntactic function. In Acehnese, all actors are marked in the same way, as illustrated by the proclitic pronoun in (14a)-(14b), whereas undergoers are marked differently, as illustrated by the ungrammaticality of (14c) and the optional enclitic pronoun in its grammatical counterpart in (14d).[8]

(14) Acehnese (Van Valin & LaPolla 1997b: 255-256)

a. (Gopnan) geu-mat lôn.
(3SG) 3-hold 1SG
'(S)he holds me.'

b. Geu-jak (gopnyan).
3-go (3SG)
'(S)he goes.'

c. *(Lôn) lôn-rhët.
1SG 1SG-fall

---

[8] The reader should note, on the one hand, that Acehnese is a head-marking language and, on the other, that the Logical Structure of the verb 'go', in this and other languages, includes an activity. Therefore, the macrorole assigned to the direct core argument is actor, following (10b-i).

d. Lôn rhët(-lôn).
1sg fall-1sg
'I fall.'

The contrast between (14a)-(14b) and (14c)-(14d) suggests that arguments are only grouped in terms of their macrorole, as is the case with active-vs.-inactive alignment, and there is no marking that defines a syntactic function. Acehnese also has no voice constructions, such as passive or antipassive, which follows from the absence of grammatical relations.

From this it also follows that if a grammatical relation is to be postulated for a given language or construction, evidence will be required of restricted neutralizations of semantic roles for grammatical purposes (see LaPolla 2023 for an in-depth discussion of this point). Such neutralizations can be, and indeed often are, found at the level of specific constructions, although the well-known Indo-European languages tend to be consistent across constructions. With reference to the Acehnese examples in (14a)-(14d), the fact that the obligatory pre-verbal clitic only cross-references the actor indicates that this type of cross-referencing involves no such neutralization, but merely a restriction to actor. Contrastingly, the controller of person and number agreement on the English verb can be characterized as a restricted neutralization, specifically [A, S, d(erived)-S], because only the actor of a transitive (cf. (15a)), the actor or undergoer of an intransitive (cf. (15b)-(15c)) or the derived intransitive S of a passive (cf. (15d)) can control this kind of agreement. The undergoer of a transitive structure cannot (contrast (15a)-(15d) with (15e)).

(15) a. Mary$_i$ (A) has$_i$ eaten all the biscuits$_j$ (U).
b. Mary$_i$ (Sa) has$_i$ eaten.
c. Mary$_i$ (Su) has$_i$ fallen.
d. All the biscuits$_j$ (d-S) were$_j$ eaten by Mary$_i$ (A).
e. *Mary$_i$ (A) have$_j$ eaten all the biscuits$_j$ (U).

The fact that the grouping [A, S, d-S] is insensitive to the distinction between Sa and Su indicates that the control of person and number agreement on the English verb neutralizes the semantic role of the controller. The fact that the undergoer of a transitive (U) is banned from this syntactic function, and indeed a special voice construction, the passive, is needed for this argument to control agreement as a d-S, indicates that the neutralization under discussion is restricted. RRG calls this kind of restricted neutralization a privileged syntactic argument (PSA).

Importantly, there are languages that provide no evidence for such restrictions. Thus, Mandarin Chinese (LaPolla 1990, 1993, 1995, 2023) has no conventionalized associations between syntactic position, agreement on the verb, case marking on the noun, etc. and particular semantic roles. The claim in RRG is, therefore, that Mandarin Chinese is a language which does not have any grammatical relations.

PSAs can have the syntactic functions of controller or pivot. The latter is the missing argument in a construction, whereas the controller is the argument that supplies its interpretation. Observe that the pivot of the English construction with *want* is defined as [A, S, d-S].

(16) a. Mary$_i$ [CONTROLLER] wants __$_i$ [PIVOT, A] to eat the biscuits.
 b. Mary$_i$ [CONTROLLER] wants __$_i$ [PIVOT, SA] to eat.
 c. Mary$_i$ [CONTROLLER] wants __$_i$ [PIVOT, SU] to die.
 d. Mary [CONTROLLER] wants __$_i$ [PIVOT, d-S] to be loved.
 e. *Mary$_i$ [CONTROLLER] wants you to love __$_i$ [PIVOT, U].

Similar considerations are valid for the missing argument in conjunction reduction. This suggests that English is consistent in how it constrains the PSA across constructions. Nonetheless, there are English constructions in which different restrictions apply. For instance, the controller of the non-finite complementation with *persuade* is the undergoer, and cannot be the actor (cf. (17)).

(17) a. Mary$_j$ persuaded Paul$_i$ [CONTROLLER] __$_{i/*j}$ [PIVOT] to stay.
 b. Paul$_i$ [CONTROLLER] was persuaded by Mary$_j$ to __$_{i/*j}$ [PIVOT] to stay.

Given that there is a restriction in (17), but no neutralization, this is a case of semantic control, comparable to the control of the pre-verbal clitic in Acehnese.

While being comparable to English, in that they have restricted neutralizations of the kind described above, other languages define the PSA differently. Thus, Kalkatungu, an Australian aboriginal language (Blake 1979), provides evidence of the restricted neutralization [U, S, d-S], which defines ergative-absolutive alignment. The participial construction exemplified below illustrates this kind of PSA.

(18) Kalkatungu (Van Valin 2005: 97-98)
 a. Ṯuaṭu pa-ji maṛapai-∅ icaji [iŋka-ʎ-iŋka-cin-∅].
 snake.ERG that-ERG woman-ABS bite go-LNK-go-PTCP-ABS
 'The snake bit the woman$_i$ [as __$_i$ was walking along].

b. [Jaṛikajan-ati-ɲin-tu] caa ŋa-t̠u l̠aji ∅
hungry-VBLZ-PTCP-ERG here 1SG-ERG kill 3SG.ABS
‘[__$_i$ Being hungry] I$_i$ killed it.’

c. Kuntu caa ḷuŋa-n̠a ∅ [ŋa-t̠u l̠a-ɲin-ka-∅]
NEG here cry-PST 3SG.ABS 1SG-ERG hit-PTCP-SUFF-ABS
‘He$_i$ didn’t cry [when I hit __$_i$].’

d. *Nga-t̠u ṇaɲa macumpa-∅ [aṛi-ɲin-∅ kat̠ir-∅]
1SG-ERG saw kangaroo-ABS eat-PTCP-ABS grass-ABS
‘I saw the kangaroo$_i$ [__$_i$ eating grass].’

The pivot or missing argument of the Kalkatungu participial construction can be an intransitive S (Sa in (18a) and Su in (18b)) or a transitive U (cf. (18c)), but it cannot be the actor of a transitive structure (A) (cf. (18d)). Therefore, there is a neutralization of semantic macroroles in this construction and this is restricted to S and U, leaving out A. In fact, if the verb in the participial construction is antipassivized, then the construction is grammatical.

(19) Kalkatungu (Van Valin 2005: 98)
Nga-t̠u ṇaɲa macumpa-∅ [aṛi-li-ɲin-∅ kat̠ir-ku]
1SG-ERG saw kangaroo-ABS eat-ANTIP-PTCP-ABS grass-DAT
‘I saw the kangaroo$_i$ [__$_i$ eating grass].’

The data in (19) indicate that d-S is also admitted in the Kalkatungu participial construction. The PSA of this structure is thus to be defined as [U, S, d-S].

It should further be noted that some languages do not have special voice constructions, in which case they may have the restricted neutralizations [A, S] or [U, S], although the latter is claimed to be very rare. In addition, in other languages, the PSA need not be a macrorole argument. We refer to Van Valin & LaPolla (1997b: 352-363) for relevant discussion.

The RRG conception of grammatical relations poses very strong constraints on the analysis of correspondences such as the ones that other frameworks conceive of as relations between active objects and passive subjects or between transitive objects and unaccusative subjects. Not only is it not possible to rely on movement or derivation, but the very construct of object is not available either. As was briefly mentioned above, the passive, as well as the antipassive, are captured in terms of the PSA selection hierarchy that is at work in the linking in a given language, or a given construction. Starting from the ranking of arguments in

(20), which reflects the argument positions in Logical Structure (cf. (8) and (9)), the default PSA is selected in accordance with the two main principles in (21).[9]

(20) Arg of DO > 1st arg of **do′** > 1st arg of **pred′**(x,y) > 2nd arg of **pred′**(x,y) > arg of **pred′**(x)

(21) PSA Selection Principles
  a. Accusative construction: the default PSA is the highest-ranking direct core argument in terms of (20).
  b. Ergative construction: the default PSA is the lowest-ranking direct core argument in terms of (20).

The principle in (21a) captures the fact that, in English and many other languages, the actor is the PSA of a transitive construction, whereas (21b) captures the selection of undergoer as default PSA in Dyirbal transitive constructions. Conversely, the marked PSA selection found in the English passive is undergoer, while the marked PSA selection found in the antipassive is actor. The principles in (21) mention direct core arguments (see footnote 2), as opposed to macroroles, because of the existence of languages in which non-macrorole arguments can be PSAs (Icelandic, Georgian, Japanese, etc.). In the present context, however, we will not dwell on this difference.

At this point we should mention constructional templates or *schemas* (Van Valin & LaPolla 1997b: 430-436; Van Valin 2005: 132-135). These are constellations of syntactic, morphological, semantic and pragmatic instructions, which, while making reference to the general principles of grammar, complement them with the language-particular information that is necessary to form and parse the constructions of a given language. In the formation of the English passive, it is the passive constructional schema that specifies that the PSA is not chosen in accordance with the default PSA selection principle (cf. (21a)), usually owing to discourse-pragmatic factors. In addition, the constructional schema establishes that the actor cannot occur within the syntactic Core, although it can be expressed in a *by*-phrase, and that the verb carries special, passive, morphology. In *wh*-questions, it is a constructional schema that instructs the speaker on the default position of the *wh*-word in the given language and whether the *wh*-word is subject to any restricted neutralizations (Van Valin 2005: 132-133). In languages

---

[9] The Logical Structure of the predicate in the clause is ascertained by applying a number of standard tests, which include Dowty's (1979) ones, as mentioned above. Therefore, there are independent criteria to establish the status of the candidates for PSA-hood vis-à-vis the hierarchy in (20).

that have different PSAs in different constructions (for example Jakaltek), constructional schemas specify what the PSA is in the given construction.

To return to grammatical relations, in the absence of a notion of object, the correlation between the functions that in other frameworks are the transitive object and the unaccusative subject is captured in RRG in terms of the thematic properties of the PSA, with some unaccusative patterns being restricted to undergoers and others to the lowest ranking argument, regardless of whether this is assigned a macrorole or the status of PSA. Thus, unaccusative subjects in RRG are not underlying objects, but rather PSAs which are linked from the two rightmost positions in (20), similarly to passive PSAs.[10] It is to the linking that we now turn, as the final topic of Section 2.

2.4 The linking

As can be seen in Figure 4, the linking is bidirectional, to account for both language production and language comprehension, and includes both universal and language-specific steps. Whereas logical structures and macrorole assignment, which is based on the hierarchy in (9) and the principles in (10), are universal, languages differ substantially in how arguments link to syntax.

The linking is governed by the Completeness Constraint, which ensures that there is a match between the referring expressions in the clause and the arguments in the semantic representation of the clause.

(22) Completeness Constraint
All the arguments explicitly specified in the semantic representation of a sentence must be realized syntactically in the sentence, and all the referring expressions in the syntactic representation of a sentence must be linked to an argument position in a logical structure in the semantic representation of the sentence.

The semantic representation of the sentence is built on the basis of the Logical Structures of the predicators in the clause (including the predicating adpositions of adjunct modifiers). These Logical Structures are drawn from the lexicon, although the semantics of the predicate is also subject to compositional rules, which we omit here for the sake of brevity.[11] In the mapping from semantics to

---

[10] It would not be possible to review here to the wide range of crosslinguistic variation in unaccusativity. We refer to Centineo (1986, 1995), Van Valin (1990), Bentley (2006), among others, for some of the RRG treatments of this topic.

[11] We refer here to alternations between activities and active accomplishments which depend on whether the activity in the Logical Structure of the predicate combines with the Logical Structure of an adpositional phrase describing an endpoint.

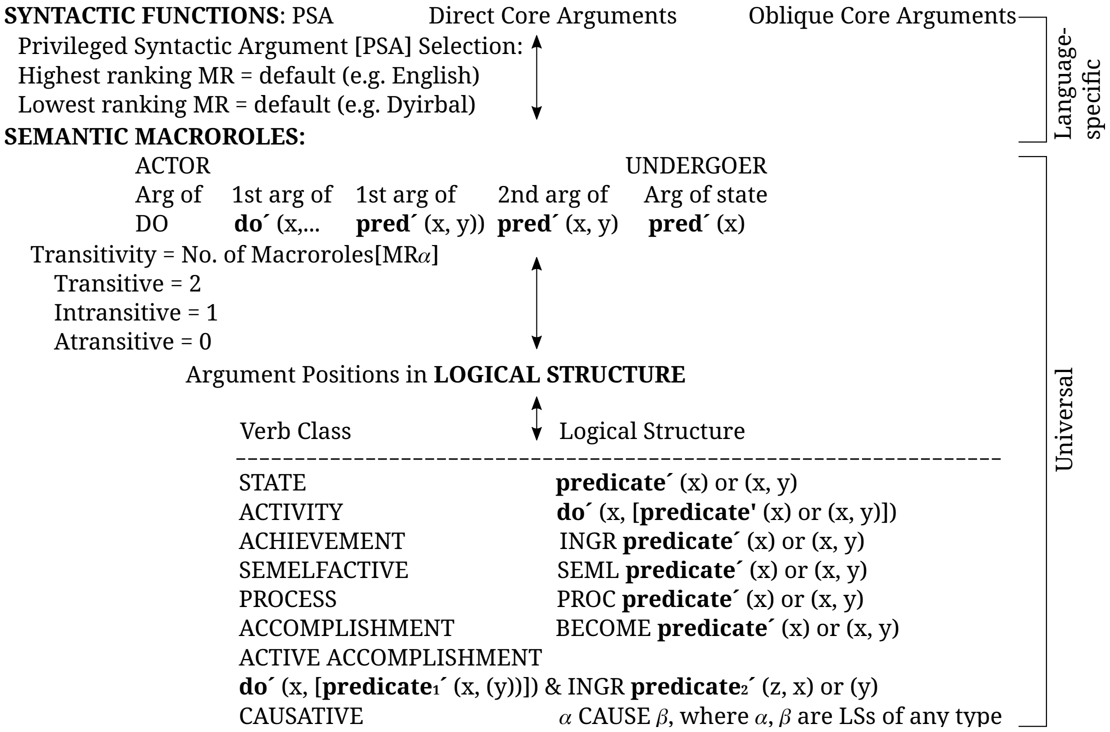

Figure 4: The linking of semantic and syntactic representation (Van Valin & LaPolla 1997b: 177)

syntax, the information in the semantic representation of the clause is key for the retrieval of the appropriate syntactic templates from the syntactic inventory. The selection of the core template is governed by the principle in (23a).

(23) a. Syntactic Template Selection Principle
The number of syntactic slots for arguments and argument-adjuncts within the core is equal to the number of distinct specified argument positions in the semantic representation of the core.[12]

---

[12] An argument-adjunct is an adposition which introduces an argument of the verb, at the same time contributing its semantics to the clause. The locative adposition required by *put* is an argument-adjunct, since it is part of the valence of the verb, and hence is an argument, but it can vary independently of the verb (e.g., *put the book on/under/next to,* etc. *the desk*) in the same way an adjunct can (e.g. *dance on/next to/beside,* etc. *the desk*). The semantic representation of *x puts y in z* ([**do′**(x, [**act.on′**(x, y)])] CAUSE [INGR **be-in′** (z, y)]) reflects the argument sharing between the verb and the adposition in a way that the semantic representation of *x dances on y* does not: in **be-on′**(y, [**do′**(x, [**dance′**(x])])) the Logical Structure of the adjunct *on* modifies the Logical Structure of *dance* taking this as one of its arguments, but there is no argument sharing between the two predicates.

b. Language-specific qualifications of the Principle in (23a):
   i. All cores in the language have a minimum syntactic valence of 1.
   ii. Argument-modulation voice constructions reduce the number of core slots by 1.
   iii. The occurrence of a syntactic argument in the Pre-/Post-Core Slot reduces the number of core slots by 1 (may override 23b-i).

The Principle in (23a) follows from the Completeness Constraint and is universal, whereas the qualifications in (23b) are language-specific (though they all apply to English). An additional, universal, qualification of (23a) is needed to capture non-subordinate complex constructions, and we refer to Van Valin & LaPolla (1997b: 546) and París (2023) for this.

In the syntax to semantics linking the syntactic representation of the clause is created by a Parser on the basis of the overt syntactic structure of a sentence. The Parser appears alongside the syntactic inventory in the general architecture of RRG shown in Figure 1 (Van Valin 2005: 131). The constructional schemas also appear in the RRG architecture, since they play a key role in providing language- and construction-specific information in both directions of the linking. The step-by-step procedures that characterize the linking, in both directions, are detailed in the Linking Algorithm(s), which are rather complex, to capture language-specific variation (Van Valin 2005: 136-158).

Having introduced how RRG is conceived and how the parts of the model fit together, in the next sections we shall engage in a more detailed comparison of the different ways things are done within RRG and LFG.

3 LFG and RRG compared

As noted above, both LFG and RRG fall within the class of linguistic models defined as parallel correspondence or level-mapping. There are nonetheless significant differences between them with respects to various dimensions of linguistic analysis and description. We consider some of these differences in a little more detail in the present section.

3.1 Grammatical relations and control

A, perhaps the, key difference between the two frameworks concerns the status of grammatical relations like subject and object. These are at the heart of LFG, where they constitute the ingredients of f-structure, a level which stands as a crucial point of intersection between lexical argument structure, sentential syntax and meaning. By contrast, as we have seen, RRG regards grammatical relations as construction and language particular instantiations of possible argument relations and as such to be defined at the level of individual grammars rather than as an intrinsic part of the cross-linguistically applicable theoretical framework. Within LFG this reliance on functional structure has meant that the inventory of functions has had to be extended to include (x)COMP and (x)ADJ in order to accommodate the full range of embedded or subordinate clauses. Although the desirability of such as extended inventory has not gone unchallenged — see for example the discussion of COMP in Patejuk & Przepiórkowski (2016) — the fact remains that some f-structural account of all the parts of a sentence is required in LFG but not in RRG, where the semantically defined primitives suffice.

One place where this difference can be seen is in the treatment of control. The RRG treatment of these constructions has its roots in Foley & Van Valin's (1984: 307-308) theory of obligatory control, which is defined in semantic terms:

1. Causative and jussive verbs have undergoer control.
2. All other (M-)transitive verbs have actor control.[13]

Examples of causative verbs are *make*, *force* and *cause*, whereas *tell*, *persuade* and *order* are examples of jussive verbs, the latter group being distinct from the former in that it describes an eventuality that relies on verbal means. Examples with *persuade* were provided in (17). Here we provide an example with *tell*. The fact that the controller remains the same regardless of passivization (cf. (24b)) indicates that this construction has a semantic controller (undergoer).

(24) a. Mary told Paul$_{\text{i}}$ [CONTROLLER]__$_{\text{i}}$ to leave.
b. Paul$_{\text{i}}$ [CONTROLLER] was told by Mary$_{\text{j}}$ __$_{\text{i/*j}}$ to leave.

The control constructions with transitive verbs that are neither causative nor jussive also have a semantic controller, although here the controller is the actor:

(25) Paul$_{\text{i}}$ [CONTROLLER] promised Mary$_{\text{j}}$ __$_{\text{i/*j}}$ to leave.

---

[13] M(acrorole-)transitivity is the number of macrorole arguments that a verb takes. It is syntactically more salient than S(yntactic-)transitivity, which is the number of direct core arguments a verb takes. The difference between the two is clear in the case of activity verbs with active accomplishment counterparts (*eat/eat the cake*). Whereas the active accomplishments (*eat the cake*) are M-transitive (and therefore also S-transitive), the activities can have an inherent argument that has no macrorole status (*eat pasta*), in which case they are S-, but not M-transitive.

The intuition behind the theory of control introduced above is that the lexical semantics of the verbs providing the controller determines the type of semantic control. Indeed, the theory is also valid in syntactically ergative languages (for example, Dyirbal), languages with active-inactive alignment (Acehnese) and head-marking languages (Lakhota) (Van Valin 2005: 241). In addition, if a verb can have causative and non-causative or jussive and non-jussive semantics (see, for example, *ask*) the semantics of the controller varies accordingly. If the verb providing the controller is intransitive, as for instance is the case with *try*, there is no issue of selection.

(26) Paul$_i$ [CONTROLLER] tried __$_i$ to leave.

The controlled missing argument, or pivot, on the other hand, is a PSA in all of the constructions above, in that it is characterized by the restricted neutralization [A, S, d-S].

(27) Mary told Paul$_i$ / Paul$_i$ promised Mary / Paul$_i$ tried __$_i$ to leave / __$_i$ to see a doctor / __$_i$ to be seen by a doctor / *a doctor to see__$_i$.

An important feature of control constructions is highlighted by the ungrammaticality of passivization of the first verb when this is neither causative nor jussive (cf. (28) vs. (24b)).

(28) *Paul was promised by Mary to leave.

The finding in (28) is explained by the type of semantic control that the structure requires (actor), combined with the type of syntactic linkage that the structure involves. This is a non-subordinate core juncture (Section 3.4), which independently requires that an argument of the second core be shared with — and realized within — the first core. The latter requirement is the additional, universal, qualification of the Syntactic Template Selection Principle (cf. (23)), which was mentioned in passing above (Van Valin & LaPolla 1997b: 546, Van Valin 2005: 244-245, París 2023).

(29) Universal qualification of (23a)
The occurrence of a core as the linked core in a non-subordinate core juncture reduces the number of core slots by 1.

The actor of the passive is independently claimed not to occur within its core in RRG, and, therefore, the specific argument sharing required cannot take place in (28). This results in a violation of the Completeness Constraint in the linking (cf. (22) in Section 2) and, hence, in ungrammaticality.

Raising to subject/raising to object/Exceptional Case Marking constructions are called Matrix Coding constructions in RRG. We give an example of matrix coding as PSA in (30a) and of matrix coding as non-PSA in (30b).[14]

(30) a. Mary seems to like football.
b. John believes Mary to like football.

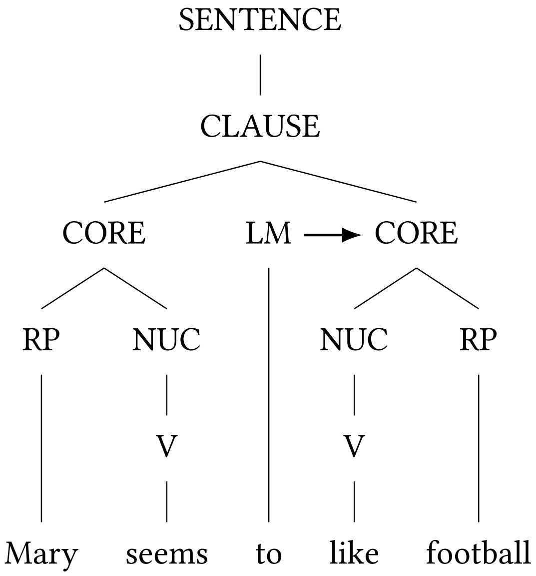
Although these structures are characterized by the sharing of an argument between two cores, similarly to control constructions, the shared argument is not a pivot. In matrix coding to PSA, the matrix verb is bivalent, but atransitive, which means that it takes no macroroles. An example is **seem′**(x, y) [MR0], where x is an optionally realized experiencer and y is a propositional argument. In English, if *seem* is followed by a finite complement (*It seems that Mary likes football*), a non-argumental expletive pronoun (*it*) fills the initial position in the core of *seem*, satisfying the language-specific requirement of a nominative-marked RP in that position.[15]

Whether finite or non-finite, the propositional argument as such is not assigned a macrorole or a grammatical relation in RRG. Instead, the individual arguments within the propositional argument have macrorole status and play a key role in the linking in the matrix coding construction with a non-finite propositional argument (cf. (30a)). This construction coordinates two cores in the syntax: the core of *seem* and that of *like* in (30a) (see Section 3.5 and Figure 5). The predicate in the second core contributes an argument to the first core in the linking. This takes the place of the direct core argument in the first core, satisfying the universal qualification in (29), as well as the language-specific requirement of a nominative RP in the core-initial position. If an argument of the second core were not linked to the first core, the Completeness Constraint would be violated, given that, to satisfy (29), an argument specified in the Logical Structure of the verb in the second core could not have any syntactic expression.

---

[14] Although other epistemic predicates figure in matrix coding as PSA (for example, *be likely, be certain*) this structure is not in principle limited to epistemic predicates: modality impersonal (*be necessary, must*) and factitives (*be sad, be fascinating*) are also known to figure in matrix coding crosslinguistically (Kimenyi 1980; Bentley 2003).

[15] The optionally expressed experiencer argument cannot satisfy this requirement because it is not a direct core argument and hence it cannot be marked with nominative.



seem′ (∅, [**like′** (Mary, football)])

Figure 5: Semantic and syntactic representations of (30a)[16]

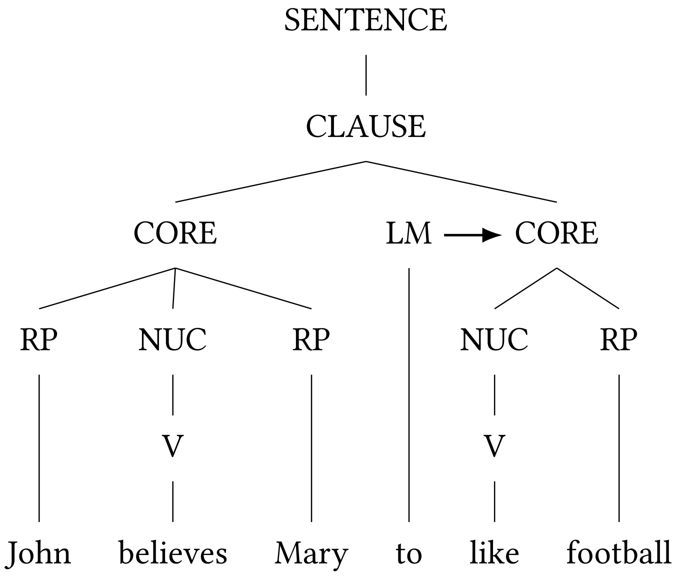
As for matrix coding to non PSA, the relevant verbs (*believe*, *expect, find, consider*, etc.) are M-transitive: an example is **believe′**(x, y). The second argument can be an NP or a proposition, i.e., a full clause (*John believes that Mary likes football*) or a core (cf. (30b)). In the latter case, an argument provided in the Logical Structure of the verb in the second core is linked to the first core to satisfy (29), again avoiding a violation of the Completeness Constraint.

Therefore, in RRG, argument sharing in matrix coding is captured by an independent property of non-subordinate core junctures, i.e., (29). The difference between the two matrix coding constructions is a function of the lexical properties of the verbs occurring in the first core. Matrix coding as PSA characterizes two-place verbs which have no direct core argument to satisfy the requirement of a nominative RP in core-initial position. With these verbs, (29) is satisfied by an argument from the predicate in the second core taking the function of PSA in the first core. The other type of matrix coding characterizes M-transitive verbs which provide an argument of their own as PSA. With these verbs, (29) is satisfied by an argument of the second core taking the second argument slot in the matrix core.

In more general terms, the contrast between control and matrix coding constructions depends on the lexical properties of the verbs involved in them, with

---

[16] LM in Figure 5 and following figures stands for Linkage Marker.



believe′ (John, [**like′** (Mary, football)])

Figure 6: Semantic and syntactic representations of (30b)

the function of the shared argument, as well as actor or undergoer control, being determined lexically.[17] Syntactically, all of these constructions are non-subordinate core junctures and they all abide by the constraints on this type of linkage.

By contrast, control in LFG makes fundamental use of the relations SUBJ and XCOMP (see Dalrymple et al. 2019: Chapter 15 and Vincent 2023 [this volume]). To take two classic instances, the entries in (31) are those proposed by Bresnan (1982a) for the functional control verbs *seem* and *try*, the difference between the two lying in the fact that for *seem* the SUBJ function is not at the same time a semantic argument whereas for *try* it is. That said, the crucial equivalence of the embedded and matrix SUBJ is formally the same in both cases.

(31) a. *seem* V (↑ PRED) = ‘SEEM⟨XCOMP⟩SUBJ’
(↑ SUBJ) = (↑ XCOMP SUBJ)
b. *try* V (↑ PRED) = ‘TRY⟨SUBJ, XCOMP⟩’
(↑ SUBJ) = (↑ XCOMP SUBJ)

---

[17] The same is true of the structure that is commonly known as tough-movement. This involves matrix coding as PSA with propositional attitude adjectives, which only have a propositional argument (*it is easy to please Mary, Mary is easy to please*), and control with psych action adjectives, which have a nominative RP of their own (*Mary is eager to please*) (see Van Valin & LaPolla 1997a: Chapter 9, exercise 6).

At the same time we should emphasise that in neither framework are the particular analyses necessarily unchallenged or unchallengeable. Although it would clearly go against the principles of LFG for an analysis not to be mediated by grammatical functions, just as it would not be consistent within RRG for direct reference to be made to subject or object, the preferred account may vary from scholar to scholar. Thus, Dalrymple et al. (2019: 561-566) offer the alternative entry for *try* as in (32):

(32) *try* V (↑ PRED) = ‘TRY⟨SUBJ, COMP⟩’
(↑ COMP SUBJ PRED) = ‘PRO’

On this version, *try* is considered to be an instance of obligatory anaphoric control rather than functional control, and hence the second argument is COMP rather than XCOMP. This in turn means that the PRED value of the embedded subject is PRO; in other words a kind of null function whose value is interpreted by reference to another argument in the clause. We return to the issue of null arguments in Section 3.3 below.

3.2 Predicate types and theta roles

The presence vs. absence of grammatical relations is also evident in the different way the two models characterise the individual lexical predicates. In LFG the lexical entry for a given item includes mention of the grammatical relations with which it is associated, which in turn are related to the appropriate theta roles by means of lexical mapping. In RRG, by contrast, the lexical entries are stated directly in logico-semantic terms (see Section 2), and it is these which are then linked to the argument structure as indicated in (8) and (9) above. Moreover, RRG adopts a distinct theory of theta roles which incorporates the two macroroles Actor and Undergoer, which are defined in terms of positions in Logical Structure. These are generalizations across argument types and have no direct analogue in LFG, or indeed in any other framework which we are familiar with. Macroroles constitute the primary interface between logical structure and syntax, and their assignment is governed by universal principles, and no further argument structure is postulated. Meanwhile, the logical structure based on Dowty’s and Vendler’s approach to Aktionsart types allows for a more fine-grained classification of predicates than is to be seen in LFG, while at the same time allowing the argument structure to emerge from the logical structure rather than having to be defined in a separate structural dimension.

One consequence of the decision within RRG not to admit as theoretical primitives a separate set of grammatical functions means that the question of how to relate these to semantic roles does not arise. In short there is no RRG equivalent of lexical mapping theory.

3.3 Argument realization

So far we have discussed for the most part issues relating to the content side, whether syntactic or semantic, of arguments. There are, however, differences between the two approaches when it comes to the way those arguments and associated clausal structure are given realization. One case in point concerns the treatment of null arguments, or so-called pro-drop, as in the contrast between French *il/elle arrive* beside Italian *arriva* 'he/she/it arrives'. Here LFG and RRG agree on rejecting the categorial solution but LFG has instead recourse to the null function seen above in the analysis of control. A verb form such as Italian *arriva* will have PRO as the value of its SUBJ function with the person/number values being determined by the appropriate features which are independently required by the language's system of verbal inflection. Not surprisingly in the literature this kind of account has been labelled 'pronoun incorporation' (Börjars et al. 2019: 68-75, Toivonen 2023 [this volume]). At the same time it is also possible for the same verb form to have an overt argument as in Italian *arriva Giorgio* 'George is arriving' and hence the PRO value for the SUBJ constitutes an optional part of the verb's lexical entry triggered only when there is no overt argument. In other languages such as Chicheŵa this optionality also extends to the OBJ, but the formal mechanism is the same in both instances. For further discussion and exemplification, see Dalrymple et al. (2019: 179-85, 500-502) and Bresnan et al. (2016: Chapter 8).

In RRG, when the argument is not expressed independently of the verb, the verb inflection bearing its person/number features is linked to the Constituent Projection, similarly to the verbal affixes of head-marking languages (Van Valin & LaPolla 1997b: 331-332). In cases of extensive discourse-driven zero anaphora, found in Thai, Mandarin and Japanese, pro-drop is dealt with as a direct linking from discourse to Logical Structure, and, following Van Valin (2005: 171-174), Kamp & Reyle's (1993) Discourse Representation Theory has been adopted to formalize this linking.

A different issue concerns the treatment of long-distance dependencies as in *wh*-questions. There is considerable cross-linguistic variation here (for a typological survey see Mycock 2006) but the crucial point is that the questioned item need not occur in the position of the corresponding answer. Within derivational models this can be straightforwardly handled by a rule of *wh*-movement which shifts the relevant item to the initial position in the clause in a language like English, while a language like Chinese has no such rule and therefore question and answer occupy the same slot. For RRG the position of the *wh*-item depends on a language-specific aspect of the linking, which is specified in a constructional schema (Section 2.3), and is directly activated with the selection of an appropriate syntactic template (Section 2.4). LFG relies instead on a further function FOCUS with the functional value of the questioned item being set as equivalent to the FOCUS and therefore being realised in that slot wherever in the language that may occur. In this way it is possible to accommodate not only languages like English with a single initial slot or Chinese where the interrogative item remains *in situ* but also languages like Bulgarian which allow several different *wh*-items to occur in sequence at the beginning of the clause.

More generally then, as we have noted in various places, LFG tends where possible to avoid the proliferation of functional heads which is a characteristic of cartographic and nanosyntactic approaches. Thus, for example, although recourse is standardly had to CP to label clauses with a fronted question word or an embedded complementizer, there is no automatic assumption that all simple main clauses are CP, nor is there any attempt to split C into separate functional heads to host topics and other fronted elements. And while some LFG accounts incorporate K as the category to be associated with items such as the Hindi-Urdu ergative particle *ne* (Dalrymple et al. 2019: 102-103), this is not the general practice (see Vincent 2021 and Przepiórkowski & Patejuk 2021 for further discussion and exemplification). By contrast, such analytical strategies have no analogue within RRG, where the categorial inventory is reduced to a minimum and functional heads do not figure at all.

Finally, in this connection, an instructive case concerns the treatment of the phenomenon of co-subordination (on which see Section 3.5 below). This is a concept unique to RRG and which has no analogue either in traditional grammar or in LFG, both of which distinguish simply co-ordination, marked by items such as *and* and *or*, and subordination, signalled by various kinds of finite and non-finite complementation patterns. Foley (2010) argues against the necessity of postulating such a third mode of clause combining and offers instead an account within LFG based on a categorial distinction between the functionally headed IP and the plain S or small clause. A response by Van Valin (2021) argues against Foley's account and more generally against the postulation of categorial solutions to what are functional/semantic problems.

3.4 Syntax and configurationality

Another dimension of linguistic realization concerns constituency and configurationality. In the various versions of Minimalism and cartography all structures are by definition configurational, and thus data such as the following Warlpiri example (cited from Austin & Bresnan 1996, example (1)) are problematic.

(33) Warlpiri
kurdu-jarra-rlu =**ka-pala** maliki wajili-pi-nyi wita-jarra-rlu
child-DUAL-ERG PRES-3DU.SBJ dog-ABS chase-NPST small-DUAL-ERG
'Two small children are chasing the dog.'

According to Hale (1983), after whom this example is cited, native speakers accept any order of the words here provided that the auxiliary element (highlighted in bold) is cliticised to the first item. Moreover, the adjective 'small' and the noun 'child' may, but do not have to, go together and if they do they can count as a constituent and occupy first position before the cliticised auxiliary. A fully configurational model can only handle this kind of data by postulating one structure as underlying and deriving the other options by movements to predetermined slots, some of which will inevitably be unfilled. In addition, the arguments of the verb in Warlpiri may remain unexpressed if derivable from context. In that case the relevant position in the tree is still present but is filled by a null pro. However, in a model such as LFG, once f-structure and c-structure are separated and not required to map onto each other in a one-to-one fashion, as Austin & Bresnan (1996) show, it is a straightforward matter to distinguish the argument structure from the way those arguments are realised in terms of linear order. Strict configurationality is then a requirement of particular languages such as English or Arabic, but it is not a property of universal grammar.

Within RRG the thinking is very similar. Not only is endocentricity not a principle of RRG, but there is also no expectation that the components of individual constituents, or units of meaning within the clause, should be contiguous. The flat structure of the RRG Layered Structure of the Clause (Section 2.1), therefore, caters straightforwardly for non-configurational languages, as in its own way does LFG by not requiring all constituents to be endocentric and thus arriving at flat structures by a different but equally satisfactory route.

3.5 Predicate and clause linkage

The RRG theory of predicate and clause linkage relies on the key notions of nexus and juncture. Nexus is the relationship established between two layers of the Layered Structure of the Clause (Section 2.1): instead of the traditional coordination vs. subordination dichotomy, RRG makes a trifold distinction between coordination, co-subordination, and subordination. Each of these types of nexus can in principle occur at three levels of juncture, nucleus, core, or clause, as can be seen in Table 1, although it is not the case that all languages exhibit all the possible nexus-juncture types.

Table 1: Nexus-juncture combinations

Juncture	Nexus
Nucleus	Coordination Co-subordination Subordination
Core	Coordination Co-subordination Subordination
Clause	Coordination Co-subordination Subordination

Nuclear junctures involve a single core containing two or more nuclei, core junctures normally feature two cores within a clause, and, finally, clausal junctures are typically characterised by two clausal nodes within a sentence. We discuss below some more complex constructions whereby a core joins with a clause. Since the operators expressing grammatical categories such as aspect, modality and tense are assumed to have scope over specific layers of the clause, operator scope is an important criterion to diagnose the level of juncture of a linkage.

We will not discuss each nexus-juncture type in detail (for exhaustive treatments see Van Valin & LaPolla 1997b: 441-492, Ohori 2023). Instead, we shall first deal with co-subordination, which is not a construct of LFG, and we shall contrast it with coordination, exemplifying at the same time the key diagnostics of linkage used in RRG. Then, we shall move on to subordination, which is subdivided into the complement and the adverbial type, in accordance with assumptions made in other frameworks.

The notion of co-subordination originated with scholarship on Papuan languages, where a type of clause linkage was found which can neither be analysed as coordination nor as subordination: on the one hand, the linked clauses cannot stand alone and are dependent on a matrix clause for the expression of clausal operators; on the other hand, they fail to exhibit the marking of subordination that obligatorily occurs elsewhere. We provide here some exemplification from Chuave (Thurmann 1975).

(34) Chuave (Papuan, Van Valin & LaPolla 1997b: 448)
Yai kuba i-re kei si-re fu-m-e.
man stick get-SEQ.SP dog hit-SEQ.SP go-3SG-IND
'The man got a stick, hit the dog, and went away.'

Although (34) translates as a coordination in English, it is not a coordination in Chuave because the first two clauses cannot stand alone, which would be expected if they were coordinated main clauses, and because they lack their own illocutionary force morpheme. Every independent utterance requires an illocutionary force marker in Chuave (see *-e* in (34), which is glossed as indicative), and the fact that this marker is shared by the clauses in (34) suggests that they are not coordinated, but rather stand in a dependence relation.

RRG thus distinguishes co-subordination from coordination, assuming that the former nexus type involves operator sharing. Specifically, the non-matrix unit(s) must depend on the matrix unit for the expression of at least one operator at the relevant level of juncture. An important corollary of this assumption is that when nuclei, cores, and clauses are joined together in a co-subordinate nexus, the first node that joins them is not of the higher type, but rather constitutes the same layer as the linked layers, as shown in Figure 7, which contrasts with Figure 8, representing coordination.

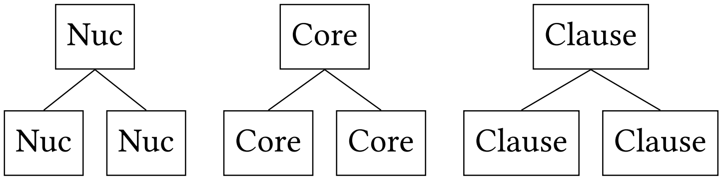


Figure 7: Nuclear, core and clausal co-subordination

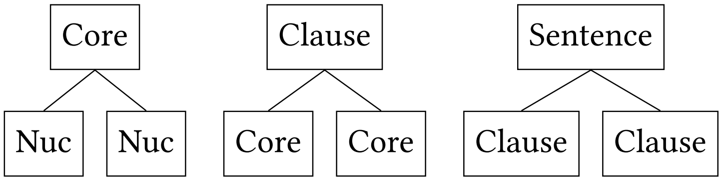

Figure 8: Nuclear, core and clausal coordination

We refer to Van Valin & LaPolla (1997b: 455) for exemplification of all the co-subordination and coordination linkages that are available in English. Here we should mention that since there are no sentence-level operators, sentences allow coordination and subordination (Van Valin 2005: 192), but not co-subordination. Sentential coordination and subordination can thus be added to the nexus-juncture types shown in Table 1, although, again, it is not predicted that all languages will allow these types of linkage.

The contrast between co-subordination and coordination emerges in non-finite complementation. Compare the English constructions in (35).

(35) a. Mary tried to open the door.
  b. Mary told Paul to open the door.

In both cases the relevant level of juncture is the Core, as suggested by the fact that in neither structure do the two predicates share the nuclear, aspectual, operators: the perfect and progressive operators only have scope over *try* and, respectively, *tell*, in (36a) and (36b).

(36) a. Mary has been trying to open the door.
  b. Mary has been telling Paul to open the door.

Sharing of all the arguments, as evidenced by passivization, would also indicate a nuclear juncture, but in both constructions *the door* is an argument of *open* alone (**The door is tried to open by Mary, *The door is told Paul to open by Mary*).

The two predicates do share one argument (*Mary* and, respectively, *Paul*), which is suggestive of a Core juncture. Yet, there is a key difference between the two constructions. The non-matrix predicate depends on *try* for the expression of deontic modality in (35a), and, therefore, (37a) can be read as (37b).

(37) a. Mary must try to open the door.
  b. Mary must open the door.

Although *must* cannot be embedded under *tell* for independent reasons (it rejects the *to* infinitive), importantly, the same operator sharing as in (37) does not apply to the structure with *tell* in (35b).

(38) Mary must tell Paul to open the door ≠ Mary must open the door.

In light of the above evidence, the linkage with English *try* is analysed in RRG as a case of core co-subordination, as opposed to the one with *tell*, which is a case of core coordination.

Similarly to the construction in (35a), the one in (39a) illustrates core co-subordination, as testified by operator sharing at the level of the core. Not only does the embedded predicate *waiting* depend on the matrix predicate *sit* for the expression of deontic modality (see (35b)), but a deontic modal operator and core negation with scope on the matrix predicate can also have scope on the embedded one (see (39c)-(39d)). In addition, the two predicates share one argument, *Mary*.

(39) a. Mary sat waiting for your call.
b. Mary sat (*must) wait(ing) for your call.
c. Mary must sit waiting for your call > Mary must wait for your call.
d. Mary didn't sit waiting for your call > Mary didn't wait for your call.

In nuclear junctures all arguments of the linked predicates are pulled together as the arguments of a single nucleus. In Italian, this is evidenced by the occurrence of accusative or locative clitics to the left of the matrix predicate, even though such clitics express arguments of the second predicate. This structure is referred to as clitic climbing in frameworks which allow movement.

(40) Italian
a. Maria lo è tornata a prendere.
Mary OBJ.CL be.3SG return.PTCP to get
'Mary went back to get it.'
b. Maria ci è cominciata ad andare.
Mary LOC.CL be.3SG start.PTCP to go
'Mary started to go there.'

Since Rizzi (1976), the structures in (40a)-(40b) have been known to be monoclausal. In RRG, they must be considered to be nuclear junctures, since the two predicates share all their arguments. The selection of the perfect auxiliary *essere* 'be' in (40) would at first seem to suggest that these are nuclear co-subordinations, whereby the non-matrix predicate depends on the matrix one for the expression of the perfect operator. This is clearly the case with (40a), since transitive *prendere* 'take' would otherwise select the perfect auxiliary *avere* 'have'.

(41) Italian
Maria lo ha preso.
Mary OBJ.CL have.3SG take.PTCP
'Mary took it.'

The case in (40b) is more puzzling, since it is *andare* 'go' that selects *essere* 'be' in the perfect, whereas *cominciare* 'begin, start' would select either auxiliary *essere* 'be' or *avere* 'have', when occurring alone, and, in fact, it would not occur with 'be' with an animate PSA.

(42) Italian

a. Lui è cambiato? – Ha cominciato.
he be.3sg change.ptcp have.3sg started
'Has he changed?' – 'He has started.'

b. Il film è cominciato.
the film be.3sg start.ptcp
'The film has started.'

In Bentley (2006: 82-83), we proposed that the structure in (40b) is a case of ad(verbial)-nuclear subordination, where *cominciare* 'start' is not a predicate because it does not contribute any arguments of its own, but merely an aspectual operator. This is represented with a Nucleus which lacks a predicate node but links to the Operator Projection to contribute aspectual information (see Figure 9). In the Constituent Projection, this Nucleus occurs in the periphery of the predicative Nucleus of the clause.

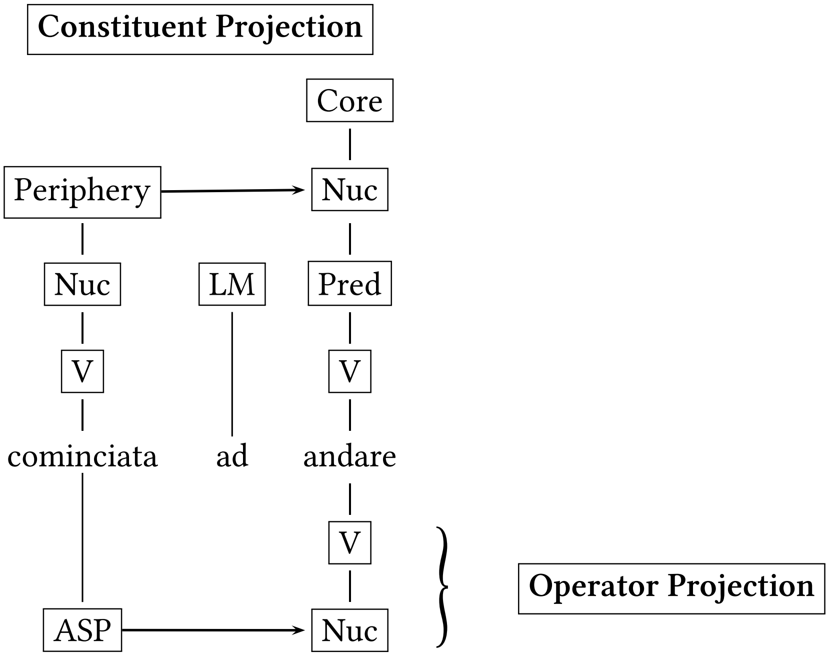

Figure 9: Ad-nuclear subordination with *cominciare* 'begin' in Italian

It is not uncommon for aspectuals, modals and indeed other classes of predicates to enter into more than one nexus-juncture type with other predicates in a given language.

RRG thus understands ad(verbial)-subordination as a structure whereby a given layer of the Layered Structure of the Clause has a peripheral modifier. While in (40b), the peripheral modification occurs at the level of the Nucleus, clausal ad-subordination — or ad-clausal subordination, as it is normally called — is illustrated in (43), which would also be analysed as a structure with an adverbial subordinate clause in other frameworks, including LFG. In this case, the subordinate clause *because you arrived* occurs in the Periphery of the main clause *Mary left*.

(43) Mary left because/even though you arrived.

Observe that, in contrast with the cases of ad(verbia)-subordination illustrated above in (40), the subordinate clause in (43) has a full-fledged predicate, which contributes its argument to the clause. It should not be assumed that by definition ad-subordination requires a modifier that lacks a predicate of its own. This can, but need not, be the case and it certainly is not the case with ad-clausal subordination.

Different semantic classes of verbs lend themselves to different nexus-juncture types (see Van Valin 2005:205-213 for a discussion of the rationale of the relevant patterns). To give but one important example: crosslinguistically, perception verbs lend themselves to forming less cohesive linkage types than causative verbs. No predictions are made in RRG on the exact nexus-juncture type that each predicate class will require in a given language. However, building upon Silverstein (1976) and Givón (1980), RRG has developed the *Interclausal Relations Hierarchy* (Van Valin & LaPolla 1997b: 481-483, Van Valin 2005: 209), which juxtaposes a scale of semantic relations with a range of nexus-juncture types, both being arranged in decreasing order of cohesion. The mapping between the two sides of the Interclausal Relations Hierarchy is many to one. However, RRG makes the strong falsifiable prediction that the tightest syntactic linkage realizing a particular semantic relation in a given language should be higher than, or as high as, the tightest syntactic linkage realizing lower semantic relations on the hierarchy in the same language. Although this prediction has been tested in work on specific languages (see, e.g., Casti 2021 on Sardinian), it ought to be further investigated in future work.

Where RRG has developed an innovative system of clausal organization and inter-clausal relations, LFG has remained more closely linked both to traditional grammar and work over the years in the generative tradition. Complex sentences involve the embedding of the c-structure of the subordinate clause within that of the matrix clause, but both are defined in terms of syntactic categories and in particular the concept of CP has been taken over wholesale from work in the Minimalist framework. It is true that the proliferation of functional heads within the clause has been avoided through recourse to the new grammatical relations (x)COMP and (x)ADJ, but, as noted above, categorial structure is still central in a way that it is not within RRG.

3.6 Pragmatics and information structure

The treatment of information structure in RRG and LFG is comparable, insofar as both frameworks consider it to be a module of grammar in its own right, which is independent from, but interacts with, the other modules. Both RRG and LFG allow information structure to be encoded in syntax (the layered structure of the clause, and, respectively, c-structure), morphology (Shimojo 1995), or prosody (see O'Connor 2006 for LFG and O'Connor 2008 for RRG). In addition, in RRG, the organization of grammar explicitly acknowledges the pervasive role of information structure at all stages of the bidirectional linking (see Figure 1). Broadly defining information structure as the organization of information in grammar, in this section we will address two principal issues, placing particular emphasis on RRG: (a) which information structure notions are adopted, and how they are defined, and (b) the place of information structure in the architecture of grammar.

Starting with the key notions, Zaenen 2023 [this volume] draws a distinction between information structure proper, or the sentence-internal organization of information, and discourse structure, which is concerned with the packaging of information in larger textual units. This contrast does not find a parallel in RRG. While in both frameworks Lambrecht's (1994) notions of presupposition and assertion play a key role in the definition of topic and focus (Van Valin 2005: 68-73 and Zaenen 2023 [this volume]), various different feature decomposition analyses have been developed in LFG to capture the nuances of salience, topicworthiness, and contrastiveness (see Zaenen 2023 [this volume] and references therein). RRG, instead, does not make use of feature decomposition, which is not to say that it does not attempt to capture the gradualness of the relevant notions, as will be explained in due course.

In RRG there is general consensus on which notions are relevant and how they should be labelled. The framework relies heavily on Lambrecht's (1994: 49) distinction between relational and non-relational constructs in information structure. The non-relational constructs are concerned with the status of the denotata of the discourse referents in the minds of the discourse participants: whether a given referent is already established or new for the hearer or both interlocutors, and, if it is new, whether it can be uniquely individuated or, alternatively, related to other referents. Although a referent is by definition brand-new, when it is first introduced into discourse, it may be possible for the interlocutors to identify it, in which case it is normally encoded as definite, in languages with overt marking of definiteness (e.g., *This morning I saw your sister / the Head of Department / the student you were taking about*). Otherwise it is unidentifiable and encoded as indefinite. Following Prince (1981) and Chafe (1987), RRG assumes that unidentifiable discourse referents can be anchored, i.e., related to established referents (e.g., *This morning I saw a student from the Physics Department)*, or, otherwise, unanchored (e.g., *This morning I saw a student*). Once a referent has been introduced, it becomes identifiable: if it is in the current focus of attention, it will be active; otherwise, it can be textually, inferentially or situationally accessible, or, alternatively, temporarily outside the focus of attention. The last type of discourse status is called inactive. Researchers in RRG have over the years investigated the grammatical correlates of the aforementioned notions in a large variety of languages (see, for example, Shimojo 1995, 2009, 2010, 2011; Pavey 2001; Belloro 2004, 2015; Matić et al. 2014; Latrouite & Riester 2018; Balogh 2021a, among others). The set of non-relational constructs which are universally adopted in the RRG treatment of information structure is illustrated in Figure 10, although we should note that other pragmatic states have been investigated by individual RRG researchers, for example saliency, or persistence in discourse (Shimojo 2009).

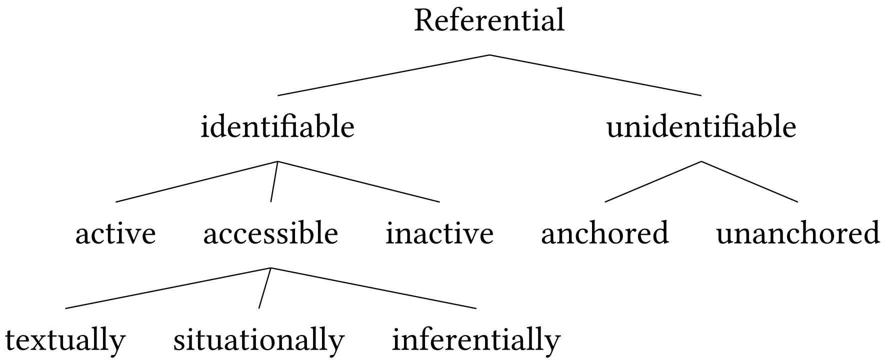

Figure 10: The cognitive states of referents in discourse (Van Valin & LaPolla 1997b: 201)

As for the relational notions, following Gundel (1988) and Lambrecht (1986, 1994, 2000), RRG defines topic as what the speaker wants to request information about, or increase the addressee's knowledge of, or get the addressee to act with respect to (Van Valin 2005: 68). The definition of topic is, therefore, inherently relational, in that it makes reference to the information unit about which new information is being requested or conveyed in the utterance. Importantly, the topic is also traditionally assumed to be part of the pragmatic presupposition, or the set of relevant propositions, and ultimately the information which is shared by speaker and hearer prior to the utterance. Drawing on Reinhart (1981), Frascarelli & Hinterhölzl (2007), Cruschina (2012), among others, in recent years, a distinction has been introduced in the framework between referential and aboutness topics, the first type being referentially old and part of the presupposition, the latter being introduced anew with the utterance, but nonetheless relational, in that it can be defined as what the utterance increases the addressee's knowledge about (see Bentley et al. 2015, Bentley (2023)).

The gradualness of the notion of topic is captured in RRG at the interface with the non-relational notions mentioned above. In particular, it is assumed that topics align with active discourse referents, as can be seen in Figure 11.

Active	Most acceptable
Accessible	
Inactive	↕
Brand-new anchored	
Brand-new unanchored	Least acceptable

Figure 11: The Topic Acceptability Scale (Van Valin & LaPolla 1997b: 204)

The morphosyntactic correlates of the alignment shown in Figure 11 are captured in Figure 12, which expresses the likelihood that the topic is marked by means of strategies that code referents in terms of their degree of accessibility.

Zero	Clitic/ bound pronoun	Pronoun [−stress]	Pronoun [+stress]	Definite NP	Indefinite NP
⟶					
Markedness of occurrence as topic					

Figure 12: Coding of referents as topic (adjusted from Van Valin & LaPolla 1997b: 205)

Focus is defined in RRG as the part of a declarative utterance that is asserted (i.e., the component of that utterance whereby the assertion differs from the presupposition) or, in an interrogative utterance, the part that is questioned (Van Valin 2005: 69). The distinction between broad and narrow focus is made in the context of Lambrecht's (1994: 221-238) theory of focus structure, which has been extremely influential in RRG scholarship.

Focus structure can be defined as the conventional association of information meanings with sentence forms or the way that presupposed and asserted information are packaged in the sentences of a given language. While all grammars have strategies to differentiate sentences which provide new information on an established topic from sentences which occur out of the blue, and would seem to be topicless, there is a great deal of crosslinguistic variation in such strategies, and such variation has received attention in connection with the broader issue of the relative language-specific flexibility of the syntactic positions of predicates and arguments, and of focal information units (Van Valin 1999, Bentley 2008, etc.). Although Lambrecht's (1994) tripartition into predicate-, argument- and sentence focus is generally adopted (argument focus being renamed as narrow focus), the assumption that sentence focus lacks a topic altogether has been challenged, in light of Erteschik-Shir's (1997) theoretical work, which finds empirical support in the study of a number of seemingly topicless constructions, such as existentials and presentationals (Bentley et al. 2015, Bentley 2018).

An important distinction made in RRG is that between the Potential Focus Domain, which is the syntactic domain in the sentence of a given language in which focus can occur, and the Actual Focus Domain, which is the syntactic component of a given sentence that is in focus. The Potential Focus Domain differs across languages, as is clearly shown by the comparison of languages that heavily rely on prosody for the encoding of focus (e.g., English, see Vallduví 1992, Van Valin 1999) with languages that rely on syntactic position (e.g., Sicilian) or on the constructional choices (e.g., French). The Actual Focus Domain differentiates the three principal types of focus structure mentioned above.

To conclude the discussion of the relational notions that have received attention in RRG, we should mention contrastiveness. This is orthogonal to the notions of topic and focus, in that the alternatives that are contrasted can be selected from the presupposition or introduced anew within the assertion. Importantly, topical and focal contrasted units exhibit the same marking in some languages, whether by syntactic or morphological means (see Shimojo 2009, 2010, 2011 for Japanese and De Cia 2019 for North-Eastern Italo-Romance). In Japanese, for example, contrastive units can be marked as topics with *-wa*. To capture the inherent informational complexity of contrastiveness, Shimojo (2011) borrows Erteschik-Shir's (1997, 2007) notion of subordinate f(ocus) structure. The essence of his claim is that *-wa* marked contrastive units in Japanese are foci, because they are selected or highlighted from a finite set, but they are embedded in and selected from a topical, contextually available, set. A Japanese clause with contrastive *-wa* marking of the argument is thus represented as follows (Shimojo 2011: 275): $[\{x_{foc}, y\}_{top}]$-wa_{top} $[\text{predicate}]_{foc}$.

As for the place of information structure in the architecture of grammar, RRG, similarly to LFG, considers information structure to be an independent module of grammar. In terms of how this view is represented in each framework, King (1997) (cited in Zaenen 2023 [this volume]) introduced an information structure projection in LFG, i-structure, and various proposals were subsequently advanced to model the flow of information from the other modules to i-structure. Similarly to LFG, RRG has a separate Speech Act Projection, which, however, does not participate in the flow of information, but rather represents the Potential and Actual Focus domain, and hence the focus structure, of an utterance in a given language.

In RRG the accessibility status of the discourse referents is conventionally represented in Logical Structure, the idea being that this status is significant in the construction of the meaning of the sentence. To give but one example, we showed in Figure 11 that an active referent lends itself more readily to the role of topic than an inactive or unidentifiable one. The topicworthiness of an active discourse referent may thus play a role in the selection of a specific lexical item as the predicate. Consider the lexical pair *fear* vs. *frighten*, or its rough Italian counterpart, *temere* vs. *spaventare*: an active stimulus will tend to be construed as the topic, which in turn will favour the choice of the *frighten* member of the pair in language production.

The activation status of the discourse referents also plays a role in the construction of meaning in language comprehension. Consider the case of an utterance which lacks an overt expression for one of the arguments of the predicate. Zero marking suggests that the position of that argument in Logical Structure can only be filled with an argument value that denotes an active discourse referent, or a referent that is textually, inferentially or situationally accessible. This referent must be retrieved from discourse.

The flow of information from the discourse context to linguistic expression is modelled in RRG by means of the tools offered by Discourse Representation Theory (Kamp & Reyle 1993), particularly in the analysis of zero anaphora phenomena, such as pro-drop (Section 3.3), in the absence of relevant morphological exponence, but also in the case of the silent predicates of Japanese and other languages. Importantly, the flow is supposed to occur directly between discourse and Logical Structure, without the intervention of syntax (or the Constituent

Projection), given that empty syntactic arguments and positions are disallowed in RRG.

As should be clear from Figure 1, information structure plays a key role in the bidirectional linking of RRG. This view has already been illustrated in the discussion of the lexical choices for predicators and the filling of silent positions in Logical Structures. PSA choice, alongside voice alternations, is also heavily affected by the informational status of the arguments, as is the morphological marking of topics and foci. To conclude, we will briefly mention the stage in the linking which requires the selection of a syntactic template for the sentence. This stage involves language-specific considerations regarding a number of pragmatically-motivated positions: the Pre- and Post-Core Slot and the Pre- and Post-Detached Position (see Section 2.1 and Balogh 2021b for further, language-specific, positions of Hungarian).

3.7 Semantic structure

Both LFG and RRG pay explicit attention to sentence semantics and, unlike Minimalism, neither theory requires the meaning of a sentence to be constructed one-to-one off syntactic heads and phrases. However, they differ in the way semantic and syntactic structure are integrated and in the type of semantic framework deployed. Within LFG, there is a separate dimension of s(emantic)-structure, which connects directly to f-structure rather than via c-structure. Although there is no strict directionality involved, it is nonetheless the case that f-structures, in turn built on the basis of the functional representations associated with lexical items, are input to the meaning construction, which is similar to the way, as described above, lexical semantics within RRG determines both the structure and overall meaning of the clause. At the same time two differences between the frameworks stand out. First, as we have seen, RRG does not use grammatical functions as an intermediary point of analysis between argument structure and sentential meaning. Second, RRG relies solely on classical predicate logic and builds the semantic representation of a sentence in the lexical phase of the semantics-syntax (or syntax-semantics) linking, retrieving the meanings of the predicates from the lexicon and combining them without recourse to specific instructions other than the rules of predicate logic. There is no linear or resource logic equivalent to the role of Glue within LFG and thus RRG corresponds more closely to what Findlay (2021: 346) describes as the ‘pre-Glue’ stage in the development of LFG.

4 LFG, RRG and diachrony

Within LFG there has been relatively little historical work to date (for recent overviews see Börjars & Vincent 2017 and Booth & Butt 2023 [this volume]) and in RRG even less (though see Ohori 1992, Eschenberg 2005, and the contributions to Kailuweit et al. 2008 and Matasović 2023). However, both approaches have much to offer in the diachronic as well as the synchronic domain, as will be explored and exemplified in this section.

Given the traditional distinction between linguistic form/*signifiant* and content/*signifié*, changes can be broadly classified into three types: changes in form, changes in content and changes in the relation between the two. As far as the first is concerned, simple change of form or sound change, neither LFG nor RRG have anything special to say. Let us start then with the last and in particular the way these changes play out in the development of the Romance causatives, and where we can detect some instructive differences in the LFG-based account in Börjars & Vincent (2017: 651-655) compared to the RRG version in Kailuweit (2008: 79-83). The basic facts are fairly straightforward. Most Romance languages have a causative construction invoving the DO verb + infinitive (see Labelle 2017, Alsina 2023 [this volume]) as in the French example (44).

(44) French

Je	ferai	manger	les	gâteaux	à	Jean
I	make.FUT.1SG	eat.INF	the.PL	cake.PL	to	John

‘I’ll make John eat the cakes’

This structure, which has parallels across the whole of Romance from the earliest attestations (Vincent 2016) is monoclausal, as evidenced among other things by the fact that if the arguments are clitics they precede the higher verb (*je les lui ferai manger* ‘I will make him eat them’) and that the structure cannot be iterated (**je ferai faire manger les gâteaux à Jean à ses enfants* – contrast the biclausal English causative *I will make John make his children eat the cakes*). In other terms, what we have here is a complex predicate construction. There are similar examples in early Romance and late Latin texts.

(45) Old French (*Chanson de Roland* 852, 12th cent.)
en Sarraguce fait suner ses taburs
in Saragossa make.PRS.3SG sound.INF his drum.PL
'in Saragossa he makes his drums sound'

(46) Latin (*Vulgate,* Numbers 11.24, late 4th cent. CE)
quos stare fecit circa tabernaculum
who.ACC.MPL stand.INF make.PST.3SG around tabernacle.ACC
'who he made stand around the tabernacle'

However, if we go back further to an earlier stage we find a biclausal accusative and infinitive construction as in:

(47) Latin (Lucilius 1224, 2nd cent. CE)
purpureamque uvam facit albam pampinum habere
purple.ACC-and grape.ACC make.PRS.3SG white.ACC vine.ACC have.INF
'and it (the sun) causes the pale vine-shoot to have purple grapes'

That this is biclausal is evidenced by the fact that there are two accusatives here, one for the actor of the embedded clause and one for the undergoer, whereas in examples like (44) the embedded actor is marked by the preposition *à*, that is to say the usual marker of the non-macrorole core argument of ditransitive verbs.

Two questions now arise:

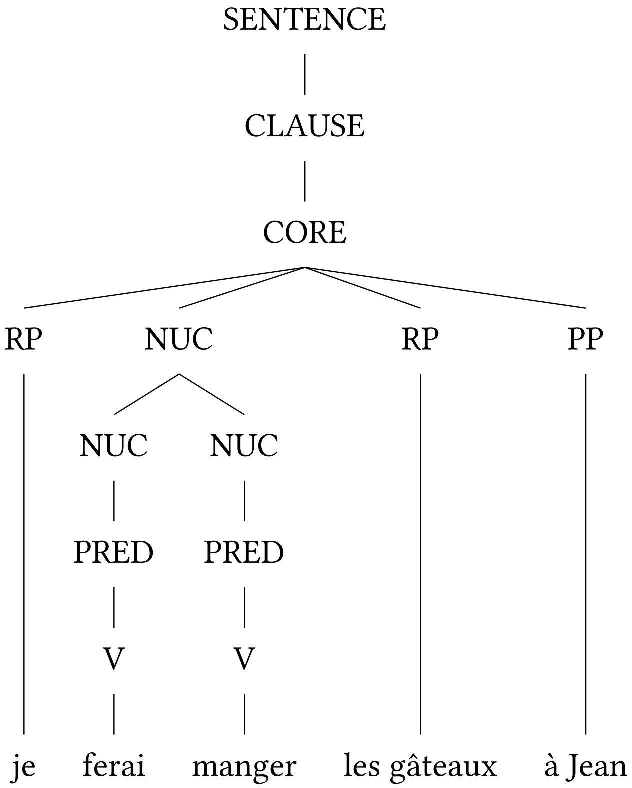
1. how do the two frameworks model such constructions?
2. what diachronic trajectories do these synchronic analyses imply?

For example (44), Van Valin (2009: Figure 28.13) proposes the following structure:[18]

---

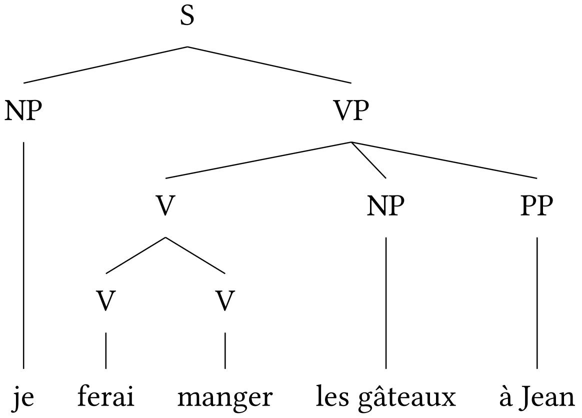
[18] Kailuweit (2008: 81) has essentially the same structure but with the verbal arguments dominated by [ARG [NP]] rather than, as here, by RP. Nothing of essence for the present issue hangs on this difference.

(48) Constituent projection of (44):



By contrast, the LFG representation in c-structure would be:

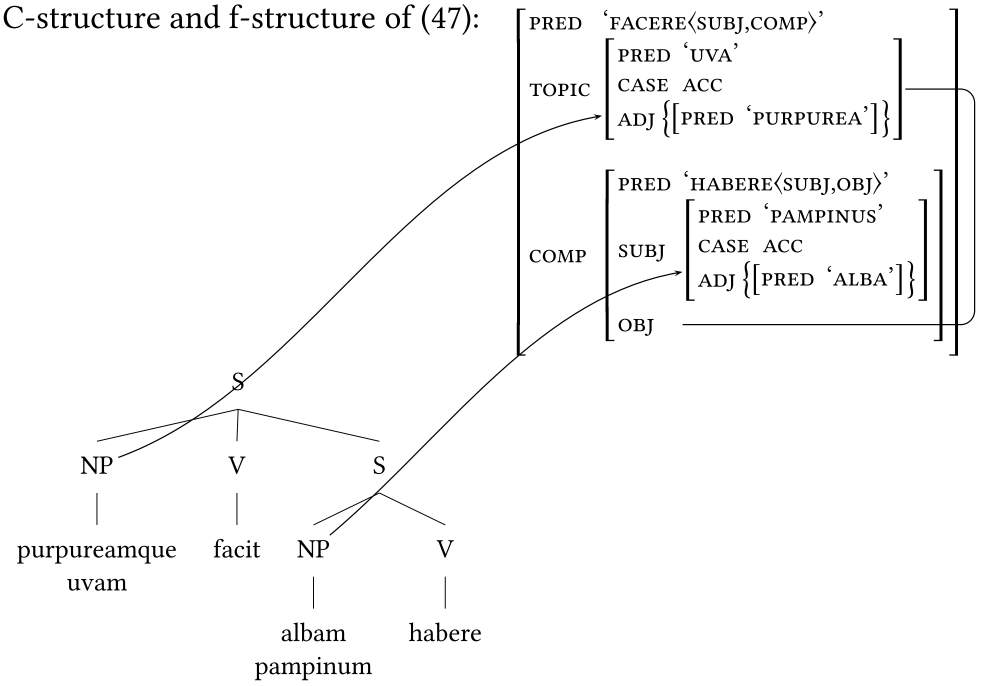
(49) C-structure of (44):



And to this would be linked an f-structure, where there is a single pred value for the verbal complex: pred ‘faire.manger⟨subj,obj,obj$_{\theta}$⟩’ with the three arguments respectively *je*.subj, *les gâteaux*.obj and *Jean*.obj$_{\theta}$. The most appropriate c-structure for Romance causatives has been a matter of some discussion within the LFG literature ever since the early work of Alsina (1997) and is discussed in Alsina 2023 [this volume] and Andrews 2023 [this volume]. The structure in (49) is the one put forward in Börjars & Vincent (2017: 652) and is modelled on the proposal for Urdu complex predicates advanced by Butt (1997). The crucial property is that the 'make' verb and its dependent infinitive constitute a complex lexical item within a monoclausal construction and in this way account for the non-iterability of Romance causatives when compared to their English counterparts.

By contrast, the LFG tree for an example such as (47) would be as follows:

(50) C-structure and f-structure of (47):



A comparison of the two LFG representations shows that the change here has been modelled at the level of f-structure; where in the Latin example there were two separate predicates *facere* 'do' and *habere* 'have', in French we have rather a single complex predicate *faire manger*. In other words, there is a shift from a biclausal to a monoclausal pattern modelled through the changing functional structures of the relevant predicates. In the RRG account by contrast there is a change from core juncture to nuclear juncture (see Section 3.4), that is to say a similar pattern of structural conflation but achieved without reference to grammatical functions.

There are, then, parallels between the accounts within the two systems of both the earlier biclausal and the later monoclausal structures, but when it comes to describing and explaining the change from the one to the other over time there is a striking difference. As Börjars & Vincent (2017: 659) note, LFG has no inherent means of accounting for the directionality of change compared to for example the

Minimalist framework. The latter includes a constraint that derivational movement, in the synchronic sense, is always upwards. Since the layers of functional structure always dominate the lexical layers, it follows that shifts can only be from lexical to functional exactly as the data from studies of grammaticalization predict. RRG by contrast, rather than relying on an abstract distinction between functional and lexical heads, incorporates the semantic-syntactic directionality directly into its overall structure via the Interclausal Relations Hierarchy (see Section 3.4 and Van Valin 2005: 209, Van Valin 2009: Fig 28.20, Matasović 2008). According to this view, there is an inherent link between semantic type and clausal structure. It is predicted therefore that a pattern containing the ingredients of causativity, if it is not already monoclausal, should move in that direction, exactly as the data we have reviewed above suggest. What neither model easily accounts for is the reversion to bicausality that is attested in some modern Romance varieties. The example in (51) is from the Piedmontese dialect of Borgomanero:

(51) Borgomanero (Tortora 2014: 155, ex. 154d)
al farissa vônga-ti lü, la strija
SBJ.CL make.COND.3SG see.INF-you.SG he DEF witch
'He would make you see the witch.'

In standard Italian or in French the clitic subject *ti* 'you' of 'see' would precede the causative in a monoclausal construction, while the fact that is attached here to the embedded infinitive leads Tortora (2014) to propose a biclausal account. Davies (1995) adduces similar evidence from modern Spanish and contrasts it with the monoclausal patterns found in the earlier stages of the language. Changes such as this suggest that it is not necessary to expect all diachronic developments to follow from asymmetries built into particular analytic frameworks, but some changes may be due to independently motivated external factors.

That said, diachrony does frequently show directionality, as is clear from the third type of change, namely those patterns that fall within the domain of grammaticalization. The emergence of grammatical markers such as tense/aspect auxiliaries, (in)definite articles and the like from former lexical items suggests that there are inherent links between different types of meaning, though the question remains open as to whether these should be attributed to forces external to language rather than to inherent properties of particular models. In this connection, Eschenberg (2005: Chapter 6), basing herself on earlier work by Rankin (2004), documents a striking series of changes in a set of particles in Umo^{n}ho^{n}

(Omaha), which serve as both articles within the NP and evidentials within the clause. Here is not the place to go into detail but Figure 13 (Eschenberg 2005: 186) demonstrates the two functions of the item *kʰe* as a marker of deixis and subsequently as indicating the evidential basis for the speaker's assertion. She concludes that the structural parallels which an account along RRG lines suggests open up the potential for grammaticalization, though in fact no directionality is predicted and indeed over time some items within this class show a shift from auxiliary to article and back to auxiliary. The general conclusion, therefore, is that whatever the analytical framework, historical and synchronic data can and do complement each other.

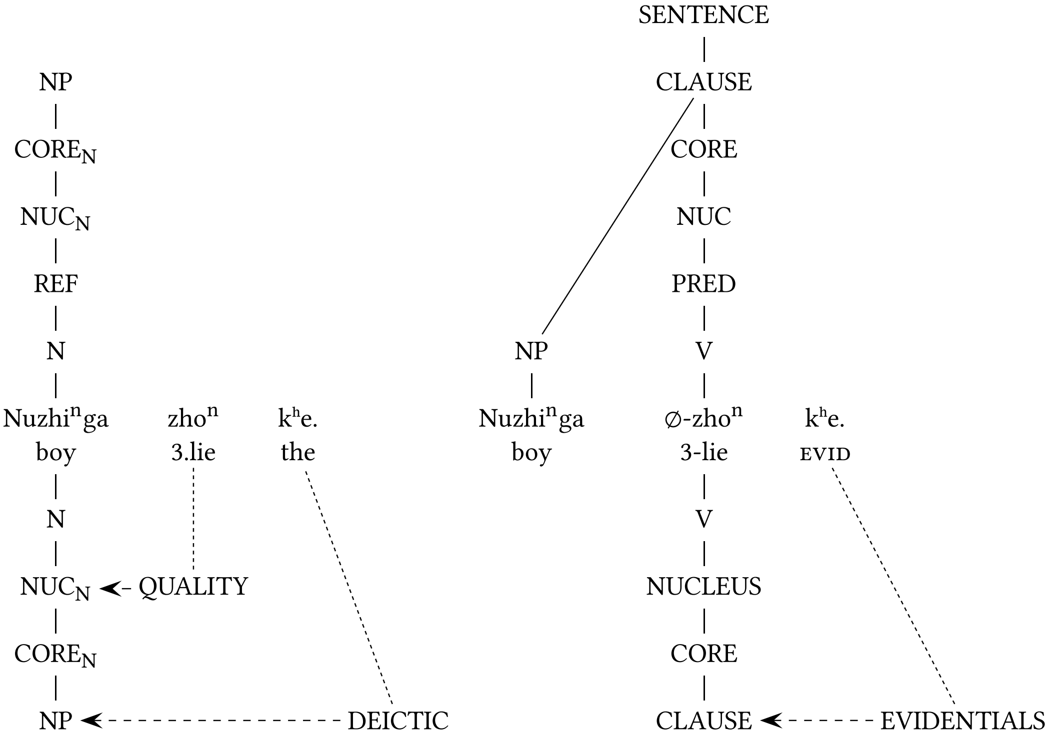


Figure 13: The marker *kʰe* in Umoⁿhoⁿ (Omaha) (Eschenberg 2005: 186)

5 Computational linguistics

Computational work has been a key component of LFG right from the outset (see the chapters in Part 5 of the present volume). By contrast, in the early stages the implementations of RRG were traditionally fewer, although there have been many relevant proposals in the last few years, and RRG now aims to offer an explanatory framework for the study of computational linguistics. While both approaches have been interested in parsing and sentence comprehension, the goal of developing more or less complete computational grammars of a range of languages has been a specific focus of LFG work, particularly but not exclusively via the ParGram project (Forst & King 2023: 3 [this volume]). The languages that figured within this project are typologically varied and in addition to the initial choice of English, French and German, the project has now been extended to include not only other Indo-European languages such as Norwegian, Polish, Urdu and Welsh but also a representative selection of languages from other families and parts of the world such as Georgian, Tigrinya, Japanese and Wolof. Comparable to the LFG ParGram project, albeit smaller in scale, are the RRG parbank project, a parallel treebank under development, which currently covers a small text corpus of German, English, Farsi, French, and Russian (Arps et al. 2021) and the RRG Biblical Hebrew treebank project (Cany Højgaard & Nielsen 2021). Moreover, Guest (2008) developed a parser which has been used to analyse a large corpus of English sentences and a somewhat smaller corpus of Dyirbal sentences (see also Nolan 2023). In addition, the cognitive scientist John Ball has, in the last decade, applied RRG in various Artificial Intelligence domains (see https://medium.com/pat-inc for details).

6 Psycho- and neurolinguistics

Language acquisition and processing are domains in which RRG and LFG line up with each other in the sense that neither requires, nor finds evidence for, an innate UG (Pinker 1989, Van Valin 2002, Weist 2023 and references therein). When it comes to acquisition both argue for the importance in the first instance of recurrent semantic patterns with syntactic structures only emerging at a later stage. Pinker (1982, 1989) in particular used LFG as a framework for the investigation and modelling of language acquisition, while Van Valin (1994, 1998, 2001, 2002) offers case studies from the perspective of RRG.

As for neurolinguistic research, RRG has been used as the grammar component of a sentence comprehension model developed in Bornkessel et al. (2004) and Bornkessel & Schlesewsky (2006). Van Valin (2023a) uses the RRG machinery to explain the ability of split-brain patients to provide grammaticality judgements with their isolated right hemisphere, developing a proposal which could potentially also capture the decoupling of grammaticality judgements and interpretation in agrammatic aphasics. For an overview of the relevant LFG-inspired work see Dalrymple et al. (2019: 726-728). Jones (2019) develops a new line of thinking for an ‘incremental’ version of LFG which addresses issues in relation to language processing and artificial intelligence.

7 Concluding remarks

In our introduction we alluded to the fact that both RRG and LFG share a commitment to formal architectures involving parallel structures and no derivations. In terms of the threefold classification of models proposed by Francis & Michaelis (2003) — (a) derivational, (b) licensing, as with the various kinds of construction grammar, and (c) level-mapping, in which each level has its own structures and theoretical primitives — LFG and RRG both fall into their third class. At the same time, in his comments on an earlier draft of this chapter, Van Valin observes that ‘RRG could be considered a kind of (generic) construction grammar, given its construction-specific theory of grammatical relations and use of constructional schemas to represent language-specific information’. That said, it must be noted that constructions are only deemed to be necessary in RRG when the general principles of the linking algorithm allow scope for variation, and thus can be applied in a construction-specific way. In similar vein, within LFG although proposals exist for integrating specific constructional types and idioms (see for example Asudeh et al. 2013), the model as a whole remains solidly based on words and phrases. The allusion to the sound-meaning link also suggests another dimension along which theories can be compared, namely the scale from syntax through semantics to pragmatics. At one extreme, there is cartography/nanosyntax with its insistence on the centrality of syntactic configurations and features while at the other there lies a purely pragmatics-driven model such as Dynamic Syntax (Kempson et al. 2016, 2017), which was set beside LFG in the workshop reported in Vincent (2009). Both LFG and RRG fall between these two extremes, but with LFG, given the importance of c-structure and the grammatical functions of f-structure, sitting nearer the syntactic end of the spectrum while RRG is more firmly based in semantic territory. However, there are signs of moves towards a larger role for semantics within LFG, as evidenced by Dalrymple et al. (2019: Chapter 8) and Asudeh 2023 [this volume] and in a different way by Findlay 2023 [this volume]. Only time will tell what the outcome of such a rapprochement might be.

Acknowledgements

Our thanks to Robert Van Valin Jr., Adams Bodomo and a third (anonymous) reviewer for their comments and suggestions. Special thanks too to Mary Dalrymple for her advice and patience. Note that we provide full bibliographical references in this chapter on the RRG side whereas for LFG we often refer readers to the relevant chapter within the present volume.

Abbreviations

Besides the abbreviations from the Leipzig Glossing Conventions, this chapter uses the following abbreviations.

CL	clitic	PROC	process
INGR	ingressive	SP	same PSA (privileged syntactic argument)
LNK	linker	SUFF	suffix
SEQ	sequential

Chapter 42

LFG and Simpler Syntax

Giuseppe Varaschin
Humboldt-Universität zu Berlin

The theories of Lexical Functional Grammar (LFG) (Kaplan & Bresnan 1982) and Simpler Syntax (SiSx) (Culicover & Jackendoff 2005) both emerged out of a dissatisfaction with the conceptual and formal assumptions of Mainstream Generative Grammar (MGG) (Chomsky 1957, 1965, 1981, 1995). Due to their similar origins, LFG and SiSx have a lot in common: the reduced role of phrase-structure in the explanation of linguistic phenomena, the adoption of constraint-based formalisms and the recognition of autonomous representations for grammatical functions. But there are also crucial differences between the two approaches that relate to some of the most lively issues in linguistics: e.g. the nature of the lexicon and the role of formal grammar in explaining linguistic judgments. The goal of this chapter is to compare these two alternatives to MGG, highlighting their differences and similarities with respect to theoretical and empirical issues.

1 Introduction

The goal of this chapter is to provide a comparison between Lexical Functional Grammar (LFG) and Simpler Syntax (SiSx). Historically, both theories were born out of a dissatisfaction with the conceptual and formal assumptions of Mainstream Generative Grammar (MGG) (Chomsky 1957, 1965, 1981, 1995). Due to their similar origins, LFG and SiSx have a lot in common: the reduced role of phrase-structure in the explanation of linguistic phenomena, the adoption of constraint-based formalisms and the recognition of autonomous representations for grammatical functions, to name a few. But there are also crucial differences that relate to some of the most lively issues in linguistics: e.g. the nature of the lexicon and the role of grammar in explaining linguistic judgments.

Giuseppe Varaschin. 2023. LFG and Simpler Syntax. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 2029–2067. Berlin: Language Science Press. DOI: 10.5281/zenodo.10186052

In Section 2, I offer a short summary of the Simpler Syntax Hypothesis (SSH). In Section 3, I lay out some goals and architectural assumptions that SiSx and LFG share, as well some important theoretical differences between the two approaches. Section 4 deals with the motivations for the constructional lexicon assumed in SiSx, which does not adhere to LFG's Lexical Integrity Principle (Bresnan & Mchombo 1995). Section 5 examines the role of constraints that are not part of the grammar, comparing SiSx with an LFG alternative. Section 6 wraps up discussing what LFG and SiSx can learn from each other.

Throughout this chapter, I will assume basic familiarity with the LFG side of the comparison and focus mainly on explaining the SiSx approach. The basic source for the latter is Culicover & Jackendoff (2005), but I will also draw freely on Jackendoff (2002, 2010), Jackendoff & Audring (2019) and Culicover (2009, 2013b, 2021).

2 The Simpler Syntax Hypothesis

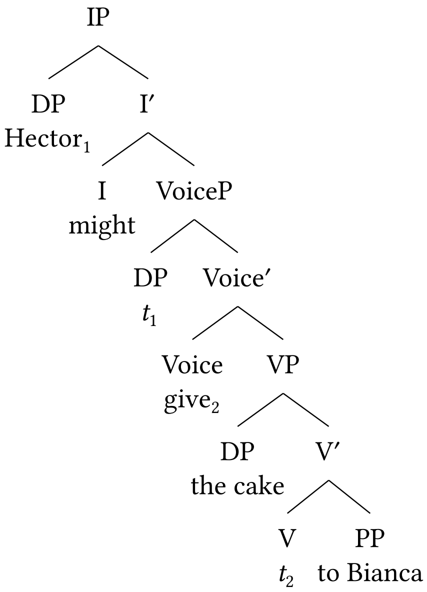
Like other syntactic theories, SiSx is an attempt to describe and explain the language user's ability to establish a correspondence between meaning and sound or gesture. What defines it is the claim that this correspondence should be as minimal as possible – i.e. that syntax should *only* be invoked when other factors (e.g. semantics, prosody, processing) are insufficient to explain the phenomena at hand. This claim is embodied in the Simpler Syntax Hypothesis (Culicover & Jackendoff 2005: 5):

(1) The Simpler Syntax Hypothesis (SSH)
The most explanatory syntactic theory is one that imputes the minimum structure necessary to mediate between phonology and meaning.

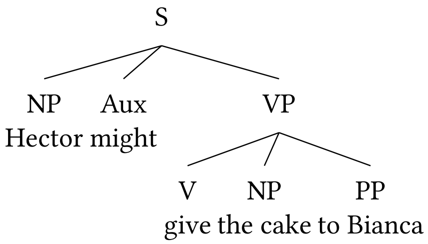
Assuming Chomsky's (1965) notions of descriptive and explanatory adequacy, what the SSH says is that, given a set of descriptively adequate grammars of a language *L*, the one the theorist should choose (i.e. the more explanatory one) is the one that assigns less structure to the expressions of *L*. The SSH favors, thus, representational economy (Chomsky 1991, Trotzke & Zwart 2014) over other notions of simplicity, such as minimizing the class of possible grammars or the number of principles in particular grammars. The latter two goals are the main driving forces of MGG since the advent of the Principles and Parameters framework (Chomsky 1973, 1981, 1995).

As an example, contrast the relatively flat constituent structure SiSx assigns to the English sentence *Hector might give the cake to Bianca* in (2b) with the MGG variant in (2a), which is based on the widely adopted VP-shell analysis (Larson 1988, Kratzer 1996, Hale & Keyser 1993, Chomsky 1995):

(2) a.



b.



MGG opts for structures like (2a) because the grammar that generates them involves *fewer* principles (and is allegedly *more restrictive*) than the one that yields (2b).[1] The idea is that (2a) follows a universal blueprint for structure-building that is virtually *invariant* across languages – one that imposes strict binary branching, endocentricity and a rigid order among heads. Moreover, the hierarchical organization of phrases in (2a) is semantically transparent, reflecting a universal THEMATIC HIERARCHY, in which AGENTS are higher than THEMES, THEMES are higher than GOALS and GOALS are higher than MODIFIERS (see Baker 1997).

The structure itself, however, is clearly much simpler in (2b): (2b) has fewer degrees of embedding (just two), no empty functional projections (e.g. VoiceP) and no phonetically null elements (traces or deleted copies). Given a suitably flexible interface, (2a) can also be placed in correspondence with a level of SEMANTIC STRUCTURE (Jackendoff 1990). The semantic properties that (2a) purports to reflect can be more naturally represented in this level, which is independently required to explain inferences that go well beyond what narrow syntax can express.[2] Thus, between representations (2a) and (2b) – the former illustrating simplicity of principles and the latter simplicity of structure – SSH recommends (2b).

---

[1] The suggestion that (2a) implies a more restrictive grammatical formalism is probably not true. As Kornai & Pullum (1990) show, as soon as empty elements are introduced, X′-theory becomes equivalent to an arbitrary context-free grammar that can generate structures like (2b). Similar considerations apply to minimalist descendants of X′-theory (cf. Chomsky 1995).

[2] Even the rich structure in (2a) fails to encode the inference that *Hector* is the Source of *the cake* (in addition to the Agent of *give*), or that cakes are artifacts typically used for eating. The latter influences the interpretation of evaluative adjectives: a *good cake* is a cake that is good to *eat* (Pustejovsky 1995). The phrase-structure formalism has no natural way to represent this.

A theoretical reason for pursuing the SSH (as opposed to other measures of simplicity) is that it approximates syntactic structures to what is directly inferable from input, thereby reducing the task of the language learner (cf. Culicover 1998, 1999, Jackendoff 2011a). The child has no direct evidence for the traces and empty elements assumed in (2a). As Chomsky (1982: 19) notes, this raises poverty-of-stimulus issues, which call for the invocation of a richer Universal Grammar (UG). Insofar as SiSx posits more concrete structures, it contributes to the minimalist project of a leaner UG (cf. Chomsky 2005, Hornstein 2009).

Aside from being more *explanatory*, the option for simpler structures is also more *descriptively adequate* than accounts based on rich uniform representations like (2a). Classic constituency tests, for example, only provide motivation for the major constituent divisions shown in (2b): VPs, PPs, NPs, etc. The empirical virtues of the SSH also manifest in accounts of specific linguistic phenomena (some of which will be mentioned in Sections 4 and 5). Most arguments for SiSx analyses have the following form:

> [G]iven some phenomenon that has provided putative evidence for elaborate syntactic structure, there nevertheless exist numerous examples which demonstrably involve semantic or pragmatic factors, and in which such factors are […] impossible to code uniformly into a reasonable syntactic level […]. Generality thus suggests that, given a suitable account of the syntax–semantics interface, all cases of the phenomenon in question are accounted for in terms of the relevant properties of semantics/pragmatics; hence no complications are necessary in syntax. (Culicover & Jackendoff 2005: 5)

As this makes clear, the SSH eschews any kind of covert structure that is motivated exclusively in order to provide a uniform mapping onto semantics. This means that SiSx rejects the syntactocentric architecture of MGG – i.e. the view that syntax is solely responsible for the combinatorial richness of language (Culicover & Jackendoff 2005: 17) –, as well as the assumption of Interface Uniformity – i.e. the view that the interface between syntax and semantics is perfectly transparent (Culicover & Jackendoff 2005: 47).

As an alternative, SiSx adopts the Parallel Architecture of Jackendoff (2002), according to which linguistic structure is determined by (at least) three independent formal systems: phonology, syntax and semantics. In addition, SiSx borrows from LFG the idea of a separate syntactic layer for representing grammatical functions: the GF-tier (Culicover & Jackendoff 2005: chapter 6). Each one of these systems is defined by its own characteristic primitives and formation rules and is connected to the others by means of more or less “messy” interfaces:

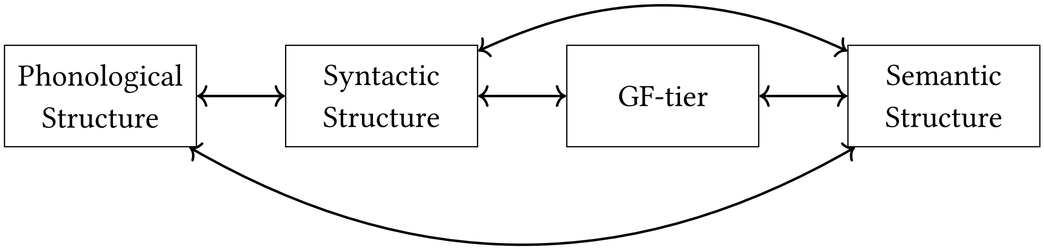


Figure 1: The Parallel Architecture of SiSx

A well-formed sentence must be well-formed in each level, in addition to having well-formed links among the interfaces.[3] A toy example is shown in (3), where natural numbers indicate interface links between the components:[4]

(3)
$$\left[\begin{array}{ll} \text{PHON} & \text{mɛəri}_1\#\text{kɪs}_2+\text{d}_3\#\text{ʤɒn}_4 \\ \text{SYN} & [_{\text{S}}\ \text{NP}_1\ [_{\text{VP}}\ \text{V}_2\ \text{-}\ \text{past}_3\ \text{NP}_4]] \\ \text{GF} & [_{\text{PRED}}\ \text{GF}_1 > \text{GF}_4]_2 \\ \text{SEM} & \mathbf{past}'_3(\mathbf{kiss}'_2(\text{AGENT}:\text{mary}_1,\ \text{PATIENT}:\text{john}_4)) \end{array}\right]$$

The structure in (3) represents the sentence *Mary kissed John.* The most opaque aspect of the formalism is likely the GF-tier. The basic units of this level are PREDS (short for syntactic predicates), which contain a sequence of ranked positions for syntactic arguments (excluding adjuncts). These positions are not explicitly labeled with grammatical function names, like SUBJECT or OBJECT. For reasons that will become clear in Section 4, these notions are relationally defined as *first GF* of PRED, *second GF* of PRED, etc. The ranking of GFs is determined according the FUNCTIONAL HIERARCHY, which has its roots in Relational Grammar (Perlmutter & Postal 1977, 1983) and Keenan and Comrie's (1977) work.

Note, furthermore, that there is nothing in SYN that signals that NP_1 in (3) corresponds to the string *Mary* – this information is phonological, and, as such, it is only represented in PHON. The terminal strings in a tree like (2b) are, thus, not strictly speaking part of the syntactic structure. A similar division between

---

[3] An interface link is well-formed *iff* it instantiates some lexeme or construction in the grammar: e.g. the links indicated by subscript 1 in (3) conform to what is stipulated by the lexical entry of *Mary.* The way SiSx represents lexemes and constructions is discussed in Section 4.

[4] Throughout this chapter, I will use the AVM notation adopted in Culicover (2021) for representing linguistic objects and the constraints that such objects must satisfy. For convenience, the formalism for SEM will be a simplified version of Montague's (1974) PTQ appended with an (implicit) event semantics. The thematic predicates (AGENT, PATIENT, etc.) are abbreviations for relations between individuals and the events they partake in, as in Parsons (1990). The SEM tier in (3) is, thus, equivalent to $\exists e[\mathbf{kiss}'(e) \& \ \mathbf{Agent}'(e, \text{mary}) \& \ \mathbf{Patient}'(e, \text{john}) \& \mathbf{past}'(e)]$.

phonological, syntactic and semantic forms is anticipated in Distributed Morphology (Halle & Marantz 1994, Marantz 1997) as well as in variants of Categorial Grammar that build on Curry's (1963) PHENOGRAMMAR *vs.* TECTOGRAMMAR distinction (e.g. Oehrle 1994, Mihaliček & Pollard 2012).

In order to capture the inner workings of the subsystems of language as well as how these systems interact with each other, SiSx abandons the formal device of derivations in favor of CONSTRAINTS (or, in the terminology of Jackendoff & Audring (2019), SCHEMAS). This and many of the other points mentioned above are shared with LFG, as we will see in the next section. SiSx also draws a lot from HPSG (Pollard & Sag 1994, Müller et al. 2021, Przepiórkowski 2023 [this volume]), as will become particularly clear in Section 4.

3 Goals and assumptions

Among all non-transformational syntactic theories, SiSx and LFG are probably the most closely related ones as far as programmatic aspirations and architectural assumptions are concerned. Most of these stem from the adherence to what Jackendoff (2007b: chapter 2) identifies as two founding themes of Generative Grammar: MENTALISM and COMBINATORIALITY.

MENTALISM is the view that language is a product of the mind/brain of individual speakers. SiSx and LFG are committed to a particularly strong version of this, which Bresnan & Kaplan (1982) and Kaplan & Bresnan (1982), following Chomsky (1965: 9), dub the COMPETENCE HYPOTHESIS. This is the suggestion that the *same* body of knowledge underlies *every* type of language-related behavior (e.g. speaking, reading, learning). In this approach, the linguist's theoretical constructs are not only *psychologically real* in an abstract sense, but must be integrated to an account of how language is actually processed and acquired by real speakers.

The second founding theme of Generative Grammar shared by LFG and SiSx is COMBINATORIALITY: i.e. the view that knowledge of language is instantiated as a finite system of *rules* that define (or "generate") an unbounded array of structured expressions. The linguist's explicit formulation of these rules (i.e. the grammar) must, ideally, entail well-formedness for all sentences judged acceptable by speakers – making no principled distinction between pure manifestations of "core grammar" and "peripheral data" (Culicover 1999).

In line with these commitments, LFG and SiSx seek to characterize the human language capacity in a way that is: (i) PSYCHOLOGICALLY PLAUSIBLE, seeking a graceful integration of linguistic theory with what is known about the structure and function of mind/brain (Bresnan 1978, Jackendoff 2011b); and (ii) FORMALLY and descriptively adequate, representing generalizations of varying granularities with sufficient precision. Different aspects of these objectives are emphasized by LFG and SiSx (e.g., LFG is much more preoccupied with the formal underpinnings and SiSx with the psychological and biological foundations). The remainder of this section summarizes some of the ways the theories converge and diverge in implementing these goals.

3.1 The structure of the grammar

The commitments to mentalism and combinatoriality lead SiSx and LFG to similar conclusions regarding the overall structure of grammar. Compare Figure 1 above, which contains the architecture of SiSx, with the LFG architecture below:

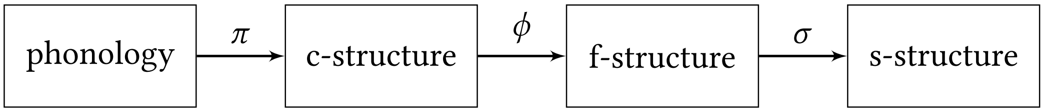

Figure 2: LFG Architecture

The most striking similarity between the two architectures above is that they abide by Representational Modularity, as defined by Jackendoff (1997):[5]

> The overall idea is that the mind/brain encodes information in some finite number of distinct representational formats or "languages of the mind." Each of these "languages" is a formal system with its own proprietary set of primitives and principles of combination, so that it defines an infinite set of expressions along familiar generative lines. For each of these formats, there is a module of mind/brain responsible for it. (Jackendoff 1997: 41)

In both theories, the primitives of phonology are things like segments (or featural decompositions thereof) and syllables. Constituent structure in syntax is built from syntactic categories (e.g. V, N, VP, and Aux) and their dominance and precedence relationships, as in a context-free grammar. The basic units of the GF-tier and f-structure are syntactic predicates and their arguments. Semantics is composed of entities, events, properties and relations (at least). These modules

---

[5] There are actually different versions of LFG's general architecture going back to Kaplan (1987) (Asudeh 2006, Findlay 2016, Dalrymple & Findlay 2019, among others), but all agree on the essentials of Figure 2. The most striking omission from Figure 2 is the separate component for a-structure proposed in Butt et al. (1997) and subsequently adopted by most researchers within LFG.

are connected to one another via systematic correspondences. In this sense, the architectures in Figures 1-2 can be called correspondence architectures.

The correspondence architecture sets LFG and SiSx apart from sign-based theories like HPSG (Pollard & Sag 1994, Przepiórkowski 2023 [this volume]) and SBCG (Sag 2012). The latter use the same kind of data structure to model all aspects of linguistic objects: i.e. typed features organized in AVMs. Different types of information are not related by means of modular correspondences, but in virtue of being values assigned to different attributes of the same sign. The design of HPSG/SBCG does not make it clear that phonology, syntax and semantics are autonomous combinatorial systems. Combinatoriality only exists at the level of signs as a whole (e.g. in features like dtrs, which take lists of *signs* as values, instead of syntactic nodes).

Even though SiSx follows HPSG/SBCG in using AVMs to represent all aspects of linguistic objects, its basic ontology is much closer to LFG's: each linguistic level is conceptualized as an autonomous formal system in its own right. Just as in LFG, this requires positing correspondence principles to link the objects independently defined by each of these systems.

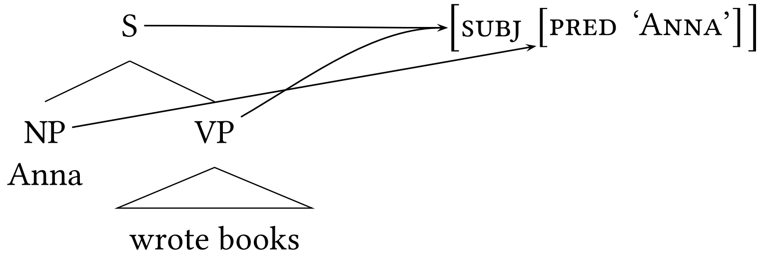
However, LFG and SiSx construe these correspondences in different ways. In LFG, structures of different types are related to each other in virtue of the projection functions π, ϕ and σ of Figure 2. This sort of mapping allows descriptions of elements in the range of a function to be defined in terms of elements in its domain. For instance, the function ϕ – whose domain and range are, respectively, c-structure nodes and f-structures – allows properties of f-structures to be "read off" from c-structure configurations.

This is crucially exploited in LFG's annotated phrase-structure rules. An example is given in (4), where "$*$" stands for the node that matches the element above it in the rule and M is the *mother-of* function (Kaplan 1995: 18):

(4)
$$\begin{array}{cccc} \text{S} & \rightarrow & \text{NP} & \text{VP} \\ & & (\phi(M(*))\textsc{subj}) = \phi(*) & \phi(M(*)) = \phi(*) \end{array}$$

This rule allows one to deduce from the c-structure of *Anna wrote books* (assuming the annotations on lexical entry of *Anna*) the correspondences in (5):

(5)



Since ϕ is a (total) function, it requires that *all* elements in its domain be mapped into elements in its range. This entails that every c-structure node – even nodes corresponding to adjuncts – must be assigned a particular f-structure.

In SiSx, on the other hand, correspondences between structures of different types are not functional, but merely relational. Therefore, there is no sense in which the properties of any level are "projected" from properties of any other, like f-structure is projected from c-structure in LFG. From the point of view of SiSx, this looks like a residue of MGG's syntactocentrism. Consider the SiSx equivalent to LFG's annotated phrase-structure rule in (4) (italics indicate that the element is a variable and not a concrete member of its respective category):

(6)
$$\begin{bmatrix} \text{SYN} & [_{S}\, \mathit{NP}_1\ \mathit{VP}_2]_3 \\ \text{GF} & [_{\text{PRED}}\, \mathit{GF}_1 > \ldots]_{2,3} \end{bmatrix}$$

Like (4), (6) expresses the information that the sister of VP corresponds to a subject (i.e. the highest ranked GF in a pred). But, unlike (4), (6) is not a phrase-structure rule: it is a correspondence rule, which is defined over independently well-formed representations on SYN and the GF-tier. No level has primacy over the others, as suggested by the symmetry of the coindexing notation. Since levels of structure are allowed more independence, the mapping between them can also be seen as only partial. This avoids the implication that all nodes in SYN must correspond to units on the GF-tier. I will come back to some positive consequences of this looser requirement below.

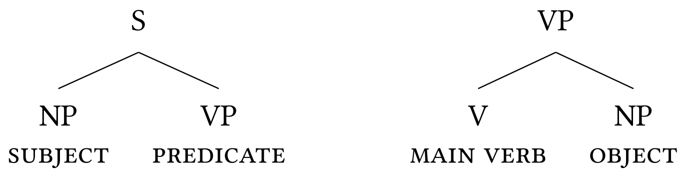
Regardless of these differences, LFG and SiSx both benefit from the general advantages of correspondence architectures, which are better suited for integration with theories of other cognitive faculties than syntactocentric models (this point is hinted at by Bresnan (1993: 45), but see Jackendoff (2007a, 2011b) for full versions of the argument). It is a given that the mind includes relations between non-linguistic representations. For instance, visual and haptic information relate to a modality-independent understanding of the spatial structure of objects (Marr 1982). This spatial structure, in turn, relates to language in a way that allows us to talk about what we perceive (Jackendoff 1987, Landau & Jackendoff 1993). Actions are also spatially guided, requiring an interface between spatial structure and schemas encoding action patterns. It does not make any sense to think of any of these representations as being *algorithmically derived* from any other – they are, rather, related in virtue of modular correspondences.

In this sense, the correspondence architectures of LFG and SiSx see the internal components of language as "connected to each other in the same way as language is connected with the rest of the mind, and in the same way as other faculties of mind are connected to each other" (Jackendoff & Audring 2019: 8). Though many details about how such connections work remain unknown, LFG and SiSx seem better suited for fruitful cross-disciplinary dialogue with cognitive science than MGG, which opts for a syntactocentric derivational design.

3.2 The role of grammatical functions

In any theory, grammatical functions (GFs) serve as abstract "relators" between a class of surface syntactic properties (e.g. linear order, case marking) and semantic roles. MGG assumes that these abstract GFs are represented in the same format as syntactic groupings – i.e. GFs are treated as epiphenomena of constituent structure configurations. An early statement of the MGG view is found in Chomsky (1965: 68–74), who claims that notions like subject and object are universally definable in terms of the structural positions in (7):

(7)



LFG and SiSx both reject this configurational design of UG for similar reasons. Consider what it implies for the English sentence in (8):

(8) Brad seems to like Janet.

In (8), *Brad* behaves like the subject of two predicates: the one headed by *seem* (where it establishes agreement) and the one headed by *like* (where it gets interpreted semantically). The configurational design requires that each of these GFs be realized in different positions, which *Brad* has to occupy simultaneously. This, however, is technically impossible in a typical phrase-structure system, since it entails multi-dominance. The alternative is to posit a sequence of phrase-markers in which these positions are occupied at separate stages, as in (9):

(9) seems [$_\text{S}$ Brad [$_\text{VP}$ to like Janet]] ⇒ [$_\text{S}$ Brad$_i$ [$_\text{VP}$ seems [$_\text{S}$ t_i to like Janet]]]

The configurational design thus calls for operations that map phrase-markers onto phrase-markers – i.e. syntactic transformations (Chomsky 1957: 44). Note, however, that these mappings are simply a way to encode the effects of multi-dominance in a system that does not naturally allow for it.

Though this might seem plausible for English (where subjects typically correspond to the configuration in (7)), it is less appealing for languages like Russian, where word order is freer and GFs are signaled mainly by case endings on nouns. A derivation for the Russian OVS sentence (10) would have to look like (11):

(10) Russian
Vaz-u razbila Olj-a (Kallestinova 2007: 30)
vase-ACC broke Olya-NOM
'Olya broke the vase'

(11)
$$\begin{aligned} &[_{\text{S}}\ \text{Olja}\ [_{\text{VP}}\ \text{razbila vazu}]] \Rightarrow [_{\text{S}'}[_{\text{VP}}\ \text{razbila vazu}]_i\ [_{\text{S}}\ \text{Olja}\ t_i]] \\ &\Rightarrow [_{\text{S}''}\ \text{vazu}_k\ [_{\text{S}'}\ [_{\text{VP}}\ \text{razbila}\ t_k]_i\ [_{\text{S}}\ \text{Olja}\ t_i]]] \end{aligned}$$

The SUBJECT and OBJECT in (11) are base-generated in the positions signaled in (7) and then scrambled to where they are actually pronounced via roll-up movements (cf. Bailyn 2003). The resulting structure is a representation of "several types of information that seem quite dissimilar in nature" (Kaplan & Zaenen 1989: 137): on the one hand, GFs like SUBJECT and OBJECT and, on the other, linear order, dominance relations and syntactic categories.

LFG and SiSx reject this on the grounds of REPRESENTATIONAL MODULARITY. Dominance, order and syntactic categories are naturally represented in a phrase-structure system but the organization of GFs has different formal properties (e.g. multi-dominance) that justify positing a separate component. This is the GF-tier in SiSx and f-structure in LFG. A SiSx analysis of (8) is sketched in (12) (from now on, tenses will be ignored and PHON will be simplified as orthography):

(12)
$$\left[\begin{array}{ll} \text{PHON} & \text{Brad}_1\ \text{seems}_2\ \text{to like}_3\ \text{Janet}_4 \\ \text{SYN} & [_{\text{S}}\ \text{NP}_1\ \text{V}_2\ [_{\text{VP}}\ \text{V}_3\ \text{NP}_4]] \\ \text{GF} & [_{\text{PRED}}\ \text{GF}_1]_2[_{\text{PRED}}\ \text{GF}_1 > \text{GF}_4]_3 \\ \text{SEM} & \textbf{seem}'_2(\textbf{like}'_3(\text{EXPERIENCER:brad}_1,\ \text{THEME:janet}_4)) \end{array}\right]$$

In the GF-tier, GF_1 (which corresponds to *Brad*) is doubly dominated by the PRED linked to *seem* and the one linked to *like*. This direct encoding of multi-dominance – which is also central to LFG's functional control analysis of raising (see Bresnan 1982a) – makes transformations like (9) unnecessary.

Likewise, the autonomy of GFs in SiSx and LFG also makes it possible to state mappings between GFs and SYN without specifying syntactic configuration or linear order. So, for dependent-marking languages like Russian, GFs can be linked directly to Ns with the appropriate case morphology, as in (13) (Culicover 2009: 154).

(13)
a. $$\left[\begin{array}{ll} \text{SYN} & [_{S}\ \ldots\ N\text{-NOM}_1\ \ldots\ ]_2 \\ \text{GF} & [_{\text{PRED}}\ GF_1 > \ldots]_2 \end{array}\right]$$
b. $$\left[\begin{array}{ll} \text{SYN} & [_{S}\ \ldots\ N\text{-ACC}_3\ \ldots\ ]_4 \\ \text{GF} & [_{\text{PRED}}\ GF > GF_3 \ldots]_4 \end{array}\right]$$

This proposal avoids abstract *ad hoc* MGG derivations like (11), opening the possibility of licensing flat structures. A SiSx analysis for (10) in this spirit could be something like (14). Note that configuration does not play a role in determining GFs in this case. (This does not mean that it cannot play a role in defining information structure properties, which are not being represented in (14).)

(14)
$$\begin{bmatrix} \text{PHON} & \text{Vaz-u}_3\ \text{razbila}_2\ \text{Olj-a}_1 \\ \text{SYN} & [_{\text{S}}\ \text{N-}\textsc{acc}_3\ \text{V}_2\ \text{N-}\textsc{nom}_1] \\ \text{GF} & [_{\textsc{pred}}\ \text{GF}_1 > \text{GF}_3]_2 \\ \text{SEM} & \textbf{break}'_2(\textsc{agent}{:}\text{olya}_1,\ \textsc{patient}{:}\text{the-vase}_3) \end{bmatrix}$$

The idea that word parts can carry information about GFs bypassing syntax is shared with LFG (Bresnan 2001). The proposal sketched in (13–14) bears a particularly close resemblance to Nordlinger's (1998) constructive case theory.

Notwithstanding their similar motivations, LFG's f-structures and the GF-tier in SiSx have very different formal properties. The most striking of these is the fact that GFs in SiSx are unlabeled; hence, notions like subject and object are not primitives of the theory. They are defined relationally in terms of a hierarchy of arguments, as in Relational Grammar (Perlmutter & Postal 1977, 1983) – the most direct inspiration for the GF-tier, according to Jackendoff (personal communication). A motivation for this will be given in Section 4.[6]

Another peculiarity of the GF-tier is that it lacks the unlimited embedding found in LFG's f-structures. Each pred in the GF-tier is represented as a self-contained unit. There is no sense in which the pred that corresponds to *like* in (12) is embedded under the one that corresponds to *seem*. The f-structure LFG assigns to the same sentence, on the other hand, virtually mirrors the hierarchical organization of the c-structure from which it is projected:

(15)
$$f_1{:}\begin{bmatrix} \textsc{pred} & \text{`}\textsc{seem}\langle\textsc{xcomp}\rangle\ \textsc{subj}\text{'} \\ \textsc{subj} & f_2{:}\begin{bmatrix}\textsc{pred} & \text{`}\textsc{brad}\text{'}\end{bmatrix} \\ \textsc{xcomp} & f_3{:}\begin{bmatrix} \textsc{pred} & \text{`}\textsc{like}\langle\textsc{subj},\ \textsc{obj}\rangle\text{'} \\ \textsc{subj} & f_2 \\ \textsc{obj} & f_4{:}\ \begin{bmatrix}\textsc{pred} & \text{`}\textsc{janet}\text{'}\end{bmatrix} \end{bmatrix} \end{bmatrix}$$

---

[6] Patejuk & Przepiórkowski (2016) argue that a similar move is advantageous for LFG as well. Following Alsina (1996), they show that most GF labels redundantly represent information already available in morphosyntax and s-structure. Borrowing ideas from HPSG (Przepiórkowski 2023 [this volume]), they propose to replace GF attributes by a single ordered deps list which looks a lot like SiSx's GF-tier. This also allows a direct encoding of the functional hierarchy, which is used in LFG analyses of binding (Falk 2001) and control (Bresnan 1982a).

Moreover, since SiSx is not committed to an exhaustive mapping from SYN nodes to the GF-tier, the inventory of GFs can be much smaller than in LFG. Only elements whose morphosyntactic forms are unrevealing about their semantic roles – e.g. direct NP or CP arguments – actually need a representation on the GF-tier (Culicover 2021: chapter 6). This is not the case for adjuncts and (most) obliques, whose θ-roles are transparent in the morphology or choice of preposition. In English, for instance, PPs headed by *near* and *under* are always LOCATIONS while those headed by *during* and *after* are invariably interpreted as TIMES. Correspondence rules for these elements can, thus, be stated directly as relations between SYN and SEM, circumventing the GF-tier (as anticipated in Figure 1).

The GF-tier in SiSx is, therefore, restricted to LFG's CORE GFs (Bresnan 2001: 96): SUBJ, OBJ and OBJ2 (relations 1, 2 and 3 in Relational Grammar). These are the GFs that most strongly justify a tier for GFs in the first place, because they are the typical targets for phenomena like agreement, raising, passive, and structural case-marking– none of which can be stated in terms of direct correspondences between SEM and SYN (Culicover & Jackendoff 2005: 188–189). LFG's NON-CORE functions (e.g. ADJ, OBL_θ, COMP, XCOMP) are not necessary in SiSx.

What this shows is that, all in all, most of the richness that is present in SYN and SEM is absent from the GF-tier, which ends up being a much *simpler* level than LFG's f-structure. This derives from the fact that SiSx builds upon a more radical version of representational economy than the one LFG assumes – one that applies not only to phrase structure, but to ALL LEVELS OF GRAMMAR. If some correspondences *can* be stated as direct relations between SYN and SEM, SiSx can do this without invoking an intermediate mapping through the GF-tier.

This, however, is only possible because SiSx also abandons the assumption of INTERFACE UNIFORMITY (discussed in Section 2), which is pervasive in MGG and survives – albeit in a much lighter fashion – in LFG's version of the correspondence architecture in Figure 2. It is the idea that the mapping to semantics is established uniformly on the basis of GFs that forces LFG to populate f-structure with semantically relevant c-structure information.

SiSx's more sparing use of GFs is partly motivated by the commitment to what Jackendoff (2011a) calls the EVOLUTIONARY CONSTRAINT – namely, the idea that the architecture of grammar should be compatible with a plausible evolutionary scenario. Proponents of SiSx concur with mainstream evolutionary psychologists in assuming that the emergence of human language was gradual, involving a series of incremental steps (protolanguages), each of which offered some adaptive advantage over the previous one (Pinker & Bloom 1990, Corballis 2017, Dennett 2017, Fitch 2017, Boeckx 2017, Martins & Boeckx 2019, de Boer et al. 2020).

Given the absence of a fossil record, one of the main ways to investigate the particular stages of this incremental process is reverse-engineering: i.e. asking what components of language are advantageous without the whole system in place (Jackendoff 1999, Jackendoff & Pinker 2005, Progovac 2016). In this spirit, Jackendoff (2002: 261) speculates that the GF-tier is probably "the latest developing part of the architecture", since its properties are asymmetrically dependent upon the existence of articulated systems of constituent structure and semantics – i.e. the latter two components can exist without the GF-tier, but not vice-versa. It is hard to reconcile the LFG architecture – where f-structures are essential to the mapping between c-structure and semantics – with these considerations.

Regardless of these differences, the point remains that autonomous levels for GFs (as we see in LFG and SiSx) contribute to the overall simplification of the grammar. Insofar as these levels liberate syntax from encoding GFs configurationally, constituent structure can become more concrete. The next section shows that this is an advantage for theories that take psychological plausibility as a goal.

3.3 Surface-oriented and model-theoretic grammars

Like HPSG (Przepiórkowski 2023 [this volume]) and Construction Grammar (Matsumoto 2023 [this volume]), LFG and SiSx are SURFACE-ORIENTED. A model of grammar is SURFACE-ORIENTED if it posits syntactic structures that are directly associated with observable word strings, with a minimum of empty elements and degrees of embedding. In LFG and SiSx, this WYSIWYG flavor is a consequence of the correspondence architecture – which provides *other* levels for encoding GFs and semantic relations – along with principles that enforce representational economy on phrase-structure representations: Economy of Expression in LFG (Bresnan 2001: 91) and the SSH in SiSx.

Surface-orientation is driven by matters of psychological plausibility. Empty elements are not easily detectable from linguistic input. This raises the question of how they come to be learned (as discussed above in connection to the SSH) and inferred in real-time language processing (see Sag & Wasow 2011). The common conclusion is that they are *not learned*, but constitute part of UG. Though this move does solve the learnability problem (albeit by raising the more difficult question of how these elements evolved in humans), it hardly addresses the concern over language processing.

However, learnability and processing issues do not arise if empty elements *can* be inferred on the basis of language-internal evidence. This is arguably the case in situations where invisible structure systematically alternates with visible material, such as gaps in unbounded dependency constructions (see Kluender & Kutas 1993, Clark & Lappin 2011).[7] In these cases LFG and SiSx *do* allow them as a kind of "last resort" to maintain the generality of the mapping between form and meaning (Bresnan 2001: 193; Culicover & Jackendoff 2005: 304).

The status of empty elements in LFG and SiSx is very different from their status in MGG: they are not leftovers of transformations, but directly licensed by CONSTRAINTS. This distinction reflects the contrast between the PROOF-THEORETIC design of MGG and the MODEL-THEORETIC flavor of SiSx, LFG and many other syntactic theories (Pullum & Scholz 2001, Pullum 2013). A PROOF-THEORETIC GRAMMAR (PTG) relies on the technology of stepwise algorithmic derivations to recursively enumerate the infinite set of grammatical expressions in a language. A MODEL-THEORETIC GRAMMAR (MTG), on the other hand, formulates its basic statements as declarative constraints. The objects that satisfy the constraints (i.e. their models, in the logician's sense) are the expressions licensed by the grammar.

The manner of characterizing expressions in PTGs invites the dynamic and procedural metaphors that are routinely employed in the MGG literature. The problem with such locutions is that it is unclear what they should mean in terms of real-time processing. The practical consequence of this has been a gradual stiffening of the competence/performance distinction through the history of MGG.

The MTG formalism avoids all such problems, lending itself to a much more direct relation to processing models (Sag & Wasow 2011, Jackendoff 2007a, 2011b). Since constraints have no inherent directionality, they can be invoked in *any* order. Starting with a fragment of phonology, one can pass through its mappings to syntax and semantics and do the same the other way around. This accounts for the fact that the processor is "opportunistic" and uses diverse types of information as soon as they become available (Acuña-Fariña 2016). It also makes MTGs neutral with respect to production (which goes from semantics to phonology) and comprehension (which goes from phonology to semantics).

Moreover, constraints also yield a monotonic mapping from form to meaning – i.e. there are no destructive operations that throw out information inferable from parts of a structure. This makes MTGs suitable to deal with the grammaticality of linguistic fragments and with the incremental nature of parsing – yet another

---

[7] For most of these scenarios, it can also be shown that grammars *with* empty elements are extensionally equivalent to grammars *without* them. This effectively reduces empty elements to notational devices for stating generalizations more directly and reducing the overall complexity of the grammar (see Müller (2018: chapter 19) for discussion). If one assumes a simplicity-based evaluation metric like the one in Chomsky (1951), this notational choice actually has empirical consequences for language acquisition (see Chomsky (1965: 45) for a similar point).

desirable property in light of psychological adequacy (Cahill & Way 2023 [this volume]).

SiSx and LFG can both be naturally stated as MTGs (cf. Blackburn & Gardent 1995, Pullum 2019 for some caveats). This has practical consequences for the general architecture of the grammar. As we will see below, in a full-blown MTG, it is no longer necessary to uphold a rigid distinction between the lexicon and the grammar, because BOTH can be stated in the same format: i.e. as CONSTRAINTS.

4 The structure of the lexicon

Up to now, I have talked mostly about how SiSx and LFG represent the structure of LINGUISTIC OBJECTS. This section turns to the kinds of CONSTRAINTS that are responsible for licensing these objects. A widespread assumption is that these constraints fall into two radically different classes, depending on whether they apply to WORDS and their internal parts or to larger PHRASAL UNITS. This view is famously expressed in LFG's LEXICAL INTEGRITY PRINCIPLE (LIP):

(16) THE LEXICAL INTEGRITY PRINCIPLE (Bresnan & Mchombo 1995: 181): Words are built out of different structural elements and by different principles of composition than syntactic phrases.

LFG enforces LIP by separating the LEXICON from the RULES OF (PHRASAL) GRAMMAR. The latter are responsible for the organization of novel phrases while the former is supposed to register idiosyncrasies as well as capture some partial regularities among stored items (in the form of LEXICAL RULES).[8]

SiSx argues that there is much to be gained by abandoning this distinction. The first step of the argument involves asking WHAT THE LEXICON IS. Due to the MENTALIST commitment, SiSx frames this issue in essentially psycholinguistic terms, taking the lexicon to be whatever the language user has to learn and store

---

[8] In its contemporary form, this distinction dates back to Chomsky's (1970) LEXICALIST HYPOTHESIS. In that framework, however, the divide between LEXICAL RULES and RULES OF GRAMMAR overlapped with the distinction between CONSTRAINTS and ALGORITHMS. In a MTG – where ALL rules are stated as constraints – these two kinds of rules can only be distinguished by the types of variables they contain: variables on lexical constraints range over word-like elements and the ones on grammatical constraints range over phrases. LIP is, then, a requirement that constraints containing different types of variables involve fundamentally different relations (i.e. "different principles of combination"): e.g. constraints on word formation should not mention long-distance relationships between items, like the ones found in phrasal grammar. Though this is requirement is formulable in a MTG setting, it is not clear whether it can be empirically justified. See Bruening (2018) for some relevant discussion.

in long-term memory. The argument then goes on to show that a lexicon thus conceived must contain entries of such variety that a sharp distinction between lexical items and grammatical rules becomes artificial (see Jackendoff 1997, Culicover et al. 2017, Jackendoff & Audring 2019, among others). The slippery slope from words to rules of grammar prompts SiSx to view the latter as PART OF the lexicon, as in Construction Grammar (Goldberg 1995, Sag 2012). This looks natural under an MTG design, where lexicon and grammar are equally stated as CONSTRAINTS.

A typical instance of a lexical item is an individual word like *cow*. SiSx, following the Parallel Architecture in Figure 1, treats this as an interface rule, linking a small piece of phonology, a syntactic category and a meaning, as in (17):

(17)
$$\begin{bmatrix} \text{PHON} & \text{cow}_1 \\ \text{SYN} & \text{N}_1 \\ \text{SEM} & \lambda x[\mathbf{cow}'_1(x)] \end{bmatrix}$$

The same format can be used to represent items with idiosyncratic subcategorization properties that do not follow from general linking rules. The verb *depend*, for example, subcategorizes for an NP within a PP headed by *on*, as in (18):

(18)
$$\begin{bmatrix} \text{PHON} & \text{depend}_1\ \text{on}_2\ \varphi_3 \\ \text{SYN} & [_{\text{VP}}\ \text{V}_1\ [_{\text{PP}}\ \text{P}_2\ \mathit{NP}_3]] \\ \text{SEM} & \lambda y[\lambda x[\mathbf{depend}'_1(\textsc{experiencer}{:}x,\ \textsc{theme}{:}y)]](\sigma_3) \end{bmatrix}$$

Italicized elements and Greek letters represent typed variables that must be contextually instantiated in order for the item to be licensed (Culicover 2021). They are what give lexical items their combinatoric potential. Productive morphology receives a similar treatment. Since regular forms *can* be computed online – and MUST be so computed in agglutinative languages like Turkish (Hankamer 1989) – we cannot require every one of them to be stored in the lexicon (Jackendoff 1997, 2002). Therefore, regular affixes must have their own lexical entries with variables specifying the phonology, category and semantics of their putative roots – as was also assumed in American Structuralist models of immediate constituent analysis (Bloomfield 1933). (19) is an entry for the English past suffix.

(19)
$$\begin{bmatrix} \text{PHON} & \varphi_2\text{-ed}_1 \\ \text{SYN} & [_V V_2\text{-}\textsc{past}_1] \\ \text{SEM} & \mathbf{past}_1(\sigma_2) \end{bmatrix}$$

Note that, as far as SiSx is concerned, there is no deep formal distinction between the *syntactic* combinatoriality of the verb in (18) and the *morphological* combinatoriality of the affix in (19). The only difference has to do with the nature of the variable in SYN: NP_3 in (18) is phrasal and V_2 in (19) is not. So SiSx, unlike LFG (see Sadler & Spencer 2004), has no separate MORPHOLOGICAL COMPONENT.

A lexicon conceived in these terms should also contain a variety of multiword entries (Culicover et al. 2017). Among these are idioms with fully specified material on all tiers, such as *kick the bucket.* In SiSx, these expressions can be stored as whole phonological/syntactic units, linked to noncompositional semantics, as in (20). We know that this particular idiom instantiates the canonical syntactic structure of an English VP because *kick* inflects just like an ordinary verb (e.g. *John kick**ed** the bucket*, *John **will** kick the bucket*, etc.).

(20)
$$\begin{bmatrix} \text{PHON} & \text{kick}_1\ \text{the}_2\ \text{bucket}_3 \\ \text{SYN} & [_{\text{VP}}\ \text{V}_1\ [_{\text{NP}}\ \text{Det}_2\ \text{N}_3]]_4 \\ \text{SEM} & \lambda x[\mathbf{die}'_4(\textsc{patient}{:}x)] \end{bmatrix}$$

Like the verb in (18) and the affix in (19), some idioms have variables that grant them combinatorial potential of their own. These are cases like *stab NP in the back*, *put NP on ice* and *catch NP's eye*. Here is a lexical entry for this last one:

(21)
$$\begin{bmatrix} \text{PHON} & \text{catch}_1\ \varphi_2\text{'s}_3\ \text{eye}_4 \\ \text{SYN} & [_{\text{VP}}\ \text{V}_1\ [_{\text{NP}}\ NP_2\text{-}\textsc{genitive}_3\ \text{N}_4]] \\ \text{SEM} & \lambda x[\mathbf{notice}'(\textsc{experiencer}{:}\sigma_2, \textsc{theme}{:}x)] \end{bmatrix}$$

The entries in (20) and (21) pose a kind of ordering paradox for theories that assume a radical separation between grammar and lexicon, as prescribed by the LIP. The information that *kick the bucket* and *catch NP's eye* are VPs has to be stated *in* the lexicon, because their semantics is idiosyncratic. However, the phrase-structure rule that generates VPs can only apply *outside* the lexicon.

In addition to these cases, the lexicon also has to include a class of CONSTRUCTIONAL IDIOMS that use normal syntax to unusual (i.e. noncompositional) semantic ends (Jackendoff 1997, 2002). An example is the SOUND+MOTION CONSTRUCTION in (22) (Levin & Rappaport Hovav 1995, Goldberg & Jackendoff 2004):

(22) The car [$_{\text{VP}}$ rumbled past Sue].
$\mathbf{go}'(\textsc{theme}{:}\text{the-car}, \textsc{path}{:}\text{past-Sue}, \textsc{effect}{:}\mathbf{rumble}'(\text{the-car}))$

Syntactically, the VP in (22) is merely a sequence of a verb followed by a PP. Its semantics is unusual because the verb is not interpreted as a functor over the PP, but as specifying the EFFECT of a motion that is not codified by any of the words in the sentence. The effect of the motion, is, moreover, predicated of whoever is interpreted as the THEME (i.e. the entity undergoing the motion). A lexical entry with these properties is sketched in (23).

(23) SOUND+MOTION CONSTRUCTION (adapted from Culicover 2013b: 42):

$$\begin{bmatrix} \text{SYN} & [_{VP}\ V_1\ PP_2] \\ \text{SEM} & \lambda x[\mathbf{go'}(\textsc{theme}{:}x, \textsc{path}{:}\sigma_2, \textsc{effect}{:}\sigma_1(x))] \end{bmatrix}$$

What is peculiar about constructional idioms is that the SYN tier in their lexical entries consists *entirely* of variables that are completely unlinked to phonology.[9] This makes them much more rule-like than word-like.[10] However, since their interpretation does not follow from general principles, they have to be explicitly learned and stored just like words are (see Culicover 1999).

Two other examples of constructional idioms along with the relevant lexical entries proposed in the SiSx literature are given below: (24) represents the DITRANSITIVE CONSTRUCTION (Jackendoff 1990, Goldberg 1995, Asudeh et al. 2014); and (25) represents the PROXY CONSTRUCTION (Nunberg 1979, Jackendoff 1997, Varaschin 2020), wherein the meaning of NP is coerced into a proxy of its literal denotation.

(24) DITRANSITIVE CONSTRUCTION (adapted from Culicover 2021: 40):

a. Brad kicked Janet the ball.

b. $$\begin{bmatrix} \text{PHON} & \varphi_1\ \varphi_2\ \varphi_3 \\ \text{SYN} & [_{VP}\ V_1\ NP_2\ NP_3] \\ \text{SEM} & \lambda x.\mathbf{transfer'}(\textsc{source}{:}x, \textsc{goal}{:}\sigma_2, \textsc{theme}{:}\sigma_3, \textsc{means}{:}\sigma_1(x)) \end{bmatrix}$$

(25) PROXY CONSTRUCTION (adapted from Varaschin 2020: 11):

a. I put ⟨ *book-by* ⟩ Keynes on the top shelf.

---

[9] The existence of "defective" lexical items lacking terms in some level is not surprising in a correspondence architecture. Jackendoff (1997: 94) notes that there are words with phonology, syntax and no meaning (e.g. expletives), others with meaning, phonology and no syntax (*hello, ouch, yes*) and even sequences with nothing but phonology (*e-i-e-i-o, inka-dinka-doo, tra-la-la*). All of these are clearly stored in long-term memory and recognized in the same way typical words are. Moreover, they fit into the phonotactic and stress patterns of English. This indicates that, though some of them have no syntax, they are still part of language. The only reason for excluding them from the lexicon is syntactocentrism – which is abandoned in SiSx and LFG.

[10] This is what drives Asudeh et al. (2013) to propose that idioms like (23) are not derived from lexical entries, but from phrase-structure rules annotated with templates. Other idioms, like the WAY CONSTRUCTION (e.g. *Sue laughed her way out of the restaurant*), would be lexically encoded by individual words (in that case, by *way*). However, it is not clear how this account extends to idioms like (20–21), which are specified by *discontinuous* portions of morphosyntax. Space prevents me from exploring further details of LFG's template-based accounts of constructions.

b. $\begin{bmatrix}\text{SYN} & \mathit{NP}_1 \\ \text{SEM} & \textbf{proxy}'(\sigma_1)\end{bmatrix}$

Language turns out to be full of constructional idioms like these (see Goldberg 1995, Jackendoff 1997, 2008, Culicover 1999). However, insofar as recognizing their existence commits us to syntactically complex lexical items without phonology, nothing stops us from seeing general syntactic and interface rules – usually thought of as part of the GRAMMAR – in the same way. The context-free rule for a transitive VP can be construed as a declarative schema for licensing a particular configuration of labeled nodes, as in (26):

(26) TRANSITIVE VP CONSTRUCTION (adapted from Jackendoff 2002: 180):
$\begin{bmatrix}\text{SYN} & [_{VP}\; V\; NP\;]\end{bmatrix}$

As far as SiSx is concerned, this is simply one of the possibilities allowed by the system: a lexical item with no idiosyncratic phonology or semantics, just syntactic category variables arranged in a particular configuration. In this respect, SiSx deviates from variants of Construction Grammar which require every syntactic configuration to be paired with a meaning (e.g. Goldberg 1995).

Default principles of compositional type-driven interpretation can also be represented as lexical items which license a maximally general correspondence between syntactic variables and meaning variables of the appropriate type. (27) represents the two possible scenarios of Heim & Kratzer's (1998) Functional Application rule (where X, Y and Z are variables over syntactic categories).[11]

(27) COMPOSITIONALITY CONSTRUCTIONS:
a. $\begin{bmatrix}\text{SYN} & [_{X}\; Y_1\; Z_2] \\ \text{SEM} & \sigma_1(\sigma_2)\end{bmatrix}$ b. $\begin{bmatrix}\text{SYN} & [_{X}\; Y_1\; Z_2\;] \\ \text{SEM} & \sigma_2(\sigma_1)\end{bmatrix}$

Likewise, the main intuition guiding linking hierarchies – such as the one in LFG's Lexical Mapping Theory (Bresnan & Kanerva 1989) – can also be formalized, within SiSx, as constructions that establish a correspondence between GF variables and SEM variables. (28) represents the rule that says that the highest thematic argument maps to the first GF.

---

[11] These general constraints on form and interpretation do not need to be instantiated by ALL grammatical expressions in a language. Many of them are not satisfied in idioms, for instance. For a linguistic object to be licensed in SiSx, it suffices that each of its terms and correspondences fully instantiate SOME constraint (Culicover 2021). This entails that a linguistic object can fail to satisfy a given constraint and still be grammatical AS LONG AS there is some other constraint in the grammar which it satisfies. For instance, the idiom in (22) fails to meet the compositional constructions in (27). Since there is another (more specific) construction which it satisfies (the SOUND+MOTION CONSTRUCTION in (23)), SiSx predicts that (22) is grammatical.

(28) LINKING CONSTRUCTION (adapted from Culicover & Jackendoff 2005: 185):

$$\begin{bmatrix} \text{GF} & [_{\textsc{pred}}\ GF_1\ (> ...)]_2 \\ \text{SEM} & \sigma_2(\theta{:}\sigma_1, ...) \end{bmatrix}$$

Correspondences between GFs and SYN – which are accomplished by functional annotations in LFG – can be stated as abstract lexical items as well. The canonical correspondence for SUBJECTS and (transitive) OBJECTS in English are (29a) and (29b), respectively:

(29) ARGUMENT STRUCTURE CONSTRUCTIONS:

$$\text{a.} \begin{bmatrix} \text{SYN} & [_S\ NP_1\ \ VP_2]_3 \\ \text{GF} & [_{\textsc{pred}}\ GF_1(> ...)]_{2,3} \end{bmatrix} \qquad \text{b.} \begin{bmatrix} \text{SYN} & [_{VP}\ V_2 NP_1]_3 \\ \text{GF} & [_{\textsc{pred}} GF > GF_1]_{2,3} \end{bmatrix}$$

In this set-up, the PASSIVE can be seen as a more complex strategy for linking the GF-tier to SYN, as in (30) below. The same applies to relation-changing constructions in other languages (e.g. applicatives, anti-passives) (Culicover 2009).

(30) PASSIVE CONSTRUCTION (adapted from Culicover & Jackendoff 2005: 203):

$$\begin{bmatrix} \text{PHON} & \varphi_1\ (\text{by}_2\ \varphi_3) \\ \text{SYN} & [...\ V\text{-}\textsc{passive}_1\ ([_{PP}\ P_2\ NP_3])]_4 \\ \text{GF} & [_{\textsc{pred}} GF_3 > [_{\textsc{pred}}\ GF]_{1,4}] \end{bmatrix}$$

The construction in (30) looks very much like a non-derivational version of the Relational Grammar account of passivization (Perlmutter & Postal 1977). It expresses two fundamental intuitions: (i) that the first GF (i.e. the "logical subject") is "demoted" to an optional *by*-phrase (without disrupting the link between this GF and its θ-role, as defined by (28)); and (ii) that the second GF gets mapped to SYN like a typical SUBJECT would in virtue of (29a). This last result is accomplished by adding a second pair of brackets around the second GF.[12] A concrete example of a linguistic object which instantiates (30) is given in (31):

(31)

$$\begin{bmatrix} \text{PHON} & \text{The-cake}_1\ \text{was-eaten}_2\ \text{by}_3\ \text{Hector}_4 \\ \text{SYN} & [_S\text{NP}_1[_{\text{VP}}\text{V-}\textsc{passive}_2[_{\text{PP}}\text{P}_3\text{NP}_4]]_5] \\ \text{GF} & [_{\textsc{pred}}\ \text{GF}_4 > [_{\textsc{pred}}\ \text{GF}_1]_{2,5}] \\ \text{SEM} & \textbf{eat}'_{2,5}(\textsc{agent}{:}\text{hector}_4,\ \textsc{theme}{:}\text{the-cake}_1) \end{bmatrix}$$

---

[12] This also happens to be the main technical reason why GFs in SiSx are unlabeled. If GFs were defined in terms of substantive roles (e.g. SUBJ, OBJ), as in LFG, a constructional account of relation-changing rules like PASSIVE would involve replacing one function name by another. This would violate monotonicity and Kaplan & Bresnan's (1982) DIRECT SYNTACTIC ENCODING principle. LFG avoids this problem by stating PASSIVE as a LEXICAL RULE (Bresnan 1982c). For evidence that lexical accounts of argument structure (like the one found in LFG) are superior to the SiSx constructional account sketched here, see Müller (2013, 2018). For a lexical account of PASSIVE in SiSx (which resembles the LFG one), see Culicover (2021).

SiSx's rule-like lexical entries can play two roles in the grammar: a GENERATIVE ROLE, where they are used in on-line processing to derive novel structures *via* UNIFICATION with other lexical entries; and a RELATIONAL ROLE, where they function like nodes in an inheritance hierarchy, "lending" their structure to other independently stored items (Jackendoff & Audring 2019).

The relational role of lexical entries can be defined in terms of ENTAILMENT between separate constraints stored in the lexicon. A lexical entry α entails an entry β *iff* every linguistic object which is a model of α is a model of β. When a specific lexical entry α entails a more general entry β we can say that α inherits structure from β. In this sense, the *kick the bucket* idiom in (20) inherits structure from the more general VP construction in (26), which, in turn, inherits from a more abstract HEAD-COMPLEMENT CONSTRUCTION, akin to the head-complement schema of HPSG (Pollard & Sag 1994: 33–34; Przepiórkowski 2023: 1867–1868, 1878 [this volume]).

Likewise, if particular passive or past tense verbs happen to be overtly stored due to high frequency, they will inherit from the past tense and passive schemas in (19) and (30). These relational links can be represented in an inheritance hierarchy, where the more dominated nodes entail the less dominated ones. SiSx assumes that, other things being equal, a lexical item with relational links should be easier to store and learn than one without such links (see Jackendoff 1975).

There is an obvious connection between this relational function of lexical entries and the use of templates in LFG and constructions in HPSG/SBCG (Sag et al. 2003, Dalrymple et al. 2004, Asudeh et al. 2013). These devices all do the work of lexical rules in earlier approaches going back to Chomsky (1970). But there is a difference: since many of SiSx's abstract entries can *also* be used generatively, unmarked lexical properties (e.g. regular morphology, subcategorization) can, *in principle*, be kept out of individual lexemes. There is no need to list separately the active, passive and regular past tense forms for ALL verbs. These forms can be "built" by unification with abstract items like (29b), (30) and (19) (respectively) (Culicover & Jackendoff 2005: 188). In LFG terms, it is as if schemas like (29b), (30) and (19) were, at once, templates that can be invoked in particular lexical entries and rules to license novel structures that are not in the lexicon.

The SiSx view, is, in sum, that rules of grammar ARE lexical items. There is a *continuum* from stereotypical words, which specify fully linked phonology, syntax, and semantics (cf. (17)), through idioms with a few variables (cf. (21)), constructional idioms with *nothing but* variables (cf. (23–25)) to fully general rules (cf. (26–30)), from which many constructions can inherit structure. All of these things are stated in the same format: as declarative schemas, either licensing structures at a single level (e.g. (26)) or establishing correspondences between various levels (e.g. (17)). Theories like LFG, which adopt a rigid lexicon/grammar distinction, must draw an artificial line somewhere in this *continuum*.

5 Constraints outside of the grammar

If language is indeed integrated into the larger ecology of the mind, it is expected that grammatical constraints are not all there is to explain the (un)acceptability of sentences. Since Miller & Chomsky (1963), the influence of extra-grammatical factors on linguistic judgments has been a major topic of investigation – one that is very much relevant to the pursuit of the SSH. In this section, I explore this issue in connection with the phenomena of unbounded dependencies (UDs).

The hallmark of UDs is the presence of a gap, by means of which a constituent in a non-canonical position (i.e. a filler) acquires its semantic role. In SiSx – as in HPSG (Pollard & Sag 1994: 161) – the effect of a gap can be reproduced by a lexical item that establishes a correspondence between an arbitrary phonological sequence containing the empty string (ε), a constituent containing an XP and a property which results from λ-abstraction over whatever semantics the XP would have (see Muskens 2003 for a similar proposal in Categorial Grammar):

(32) gap construction: (adapted from Culicover 2021: chap.7)

$$\begin{bmatrix} \text{PHON} & /\ldots\ \varepsilon\ \ldots/_2 \\ \text{SYN} & [\ldots\ \text{XP}\ \ldots]_2 \\ \text{SEM} & \lambda z[\sigma_2(z)] \end{bmatrix}$$

SiSx also needs a phrase-structure construction akin to (26) in order to license fillers in the left-periphery of clauses. (33) accomplishes this effect:

(33) filler construction:

$$\begin{bmatrix} \text{SYN} & [_{S'}\ \mathit{YP}\ \mathit{S}\ ] \end{bmatrix}$$

Consider how this works in the simple case of topicalization in (34) (I ignore the GF-tier and the information structure status of topics). The construction in (32) licenses an empty NP as the complement of *Janet kissed*, which, in turn, gets interpreted as a property (i.e. $\lambda z[\mathbf{kiss}'(\textsc{agent}\text{:janet}, \textsc{theme}\text{:}z)]$). (33) licenses a filler (i.e. *Brad*) in sentence-initial position. In virtue of the compositional construction in (27b), the property attained by (32) is applied to the semantics of the filler, yielding the right interpretation.

(34)

$$\begin{bmatrix} \text{PHON} & \text{Brad}_1,\ /\text{Janet}_2\ \text{kissed}_3\ \varepsilon/_4 \\ \text{SYN} & [_{S'}\ \text{NP}_1\ [_{S}\ \text{NP}_1\ [_{VP}\text{V}_3\ \text{NP}]]_4] \\ \text{SEM} & \lambda z[\mathbf{kiss}'_{3,4}(\textsc{agent}\text{:janet}_2, \textsc{theme}\text{:}z)](\text{brad}_1) \end{bmatrix}$$

A similar structure is ascribed to the *wh*-question in (35). I follow Culicover (2021) in positing a quantifier-like entry for the *wh*-word, as in (36).

(35) [What$_i$ [did [Sue say Don bought t_i]]]?

(36) $\begin{bmatrix} \text{PHON} & \text{what}_1 \\ \text{SYN} & NP_1 \\ \text{SEM} & \lambda P[\mathbf{WH}x_1(P(x))] \end{bmatrix}$

The GAP CONSTRUCTION licenses a property interpretation for the portion of (35) which excludes the *wh*-phrase (*Sue say Don bought ε*). This property, in turn, is fed as an argument to the **WH** quantifier (licensed in initial positon by (33)), which ends up binding a variable corresponding to the gap. (37) illustrates the β-reductions in the SEM tier of (35):

(37) $\lambda P[\mathbf{WH}x(P(x))](\lambda z[\mathbf{say}'(\textsc{agent}\text{:sue}, \textsc{theme}\text{:}\mathbf{buy}'(\textsc{agent}\text{:don}, \textsc{theme}\text{:}z))])$
$\rightarrow \mathbf{WH}x(\lambda z[\mathbf{say}'(\textsc{agent}\text{:sue}, \textsc{theme}\text{:}\mathbf{buy}'(\textsc{agent}\text{:don}, \textsc{theme}\text{:}z))](x))$
$\rightarrow \mathbf{WH}x(\mathbf{say}'(\textsc{agent}\text{:sue}, \textsc{theme}\text{:}\mathbf{buy}'(\textsc{agent}\text{:don}, \textsc{theme}\text{:}x)))$

The constructions (32–33) and standard principles of type-driven interpretation are all SiSx needs to model the syntactic and semantic effects of UDs.[13] The dependency between the filler and the gap is represented as variable-binding, while a null XP in SYN guarantees that the subcategorization requirements of the head that licenses the filler are locally satisfied.

However, since this mechanism assumes that gaps can be freely introduced into representations, it does not explain why sentences like (38) are bad:

(38) * Who$_i$ does that Brad admires t_i disturb Janet?

It is entirely possible to derive a perfectly well-formed structure for (38) given the principles laid out so far. Most approaches to UDs take this "overgeneration" to be a flaw and attempt to encode into the grammar restrictions that prevent gaps from occurring in ISLAND environments like (38) (Ross 1967).

Kaplan & Zaenen's (1989) LFG account of island constraints exemplifies this tendency. Their proposal represents UDs in terms of functional identity in f-structure (Kaplan 2023 [this volume]). So, for the sentence (35) above, the identification between the focalized *wh*-word and the OBJ of *buy* is accomplished by the equivalence (*f* FOCUS)=(*f* COMP OBJ). This expression is an instantiation of a

---

[13] Note incidentally that the type-driven rules in (27) make the presence of subject gaps in sentences like *Who sang?* unnecessary. In those cases, the **WH** quantifier can combine directly with the bare property semantics of the VP, with no need to invoke the GAP CONSTRUCTION.

more general functional uncertainty equation which is annotated to the phrase-structure rule that introduces discourse functions (namely TOPIC or FOCUS). The particular equation Kaplan & Zaenen (1989: 153) suggest for English is (39).

(39) $(f\ \text{DF}) = (f\ \{\text{COMP}, \text{XCOMP}\}^{*}\ \text{GF}{-}\text{COMP})$

What (39) says is that the f-structure for any discourse function (DF) will be identical to a subordinate f-structure somewhere along a (possibly empty) path of COMP and XCOMP functions, as long as that path terminates in a GF function which is not a COMP. The specifications on the BODY (i.e. the middle) and on the BOTTOM of uncertainty paths like (39) are how LFG records restrictions on UDs.

For example, an identification between the filler and the gap in (38) requires passing through SUBJ, which is not specified as a possible attribute in the body of (39). This accounts for SUBJECT ISLAND violations in general. Likewise, COMPLEX NP ISLANDS like (40) are also covered, because RELMOD (the GF Kaplan & Zaenen (1989) assign to relative clauses) is not designated on the body of (39) either.

(40) * What castle$_i$ does Janet know the strange man [who owns t_i]?

From the point of view of SiSx, the functional uncertainty formalism is unobjectionable as a device to model UDs. However, it is not clear whether it should really embody substantive restrictions to account for the unacceptability of UDs in syntactic terms. Upon closer examination, there does not seem to be a purely grammatical characterization of precisely the contexts in which certain patterns of UDs are ruled out by speakers. The explanation for most (if not all) island constraints must, therefore, lie outside of the grammar, in pragmatics, discourse structure or in processing complexity. A growing body of literature points to this conclusion (Hofmeister et al. 2007, Hofmeister & Sag 2010, Hofmeister et al. 2013, Kluender 1991, 1992, 2004, Kluender & Kutas 1993, Sag et al. 2007, Chaves 2013, Chaves & Dery 2014, 2019, Culicover 2013a,b). In what follows, I briefly summarize some of the empirical evidence against grammatical theories of islands. Space limitations prevent me from getting into the details of particular performance-based alternatives.

The suspicion that something is amiss in purely grammatical accounts of island phenomena comes from the observation that concrete proposals tend to be both too weak and too strong. The constraint in (39), for example, is too weak because it fails to explain real contrasts like (41–42), originally due to Erteschik-Shir (1973: 84).

(41) a. What$_i$ did Janet claim that veganism can do t_i for you?
b. ?? What$_j$ did Janet transcribe that veganism can do t_j for you?

(42) a. What$_i$ did Frank say that Brad would like t_i for lunch?
    b. ?? What$_j$ did Frank snarl that Brad would like t_j for lunch?

The equation in (39) predicts the b-cases to be just as good as the a-cases since, in both of them, the value for the FOCUS attribute is identified with the value of OBJ through a path consisting of a single COMP – exactly as in (35). That is, the a-cases and b-cases both contain (f FOCUS)=(f COMP OBJ) in their f-descriptions.

It is, of course, possible to assign different GFs to the complement of *transcribe* and *snarl* other than COMP (something like ISLANDCOMP). In this case (41b) and (42b) would be excluded due to the body constraint in (39). But this move is simply a stipulation – one that is hard to imagine how a child could learn. The ultimate explanation might be related to the lexical semantics of the verbs (i.e. UDs are impossible with verbs that specify *manner* of speaking) or simply to frequency (*claim* and *say* are more frequent than *transcribe* and *snarl*). Whatever the ultimate truth is, no apparent syntactic difference – in f-structure or otherwise – can be identified for pairs such as (41–42).

There are also cases in which grammatical principles that purport to account for island phenomena are too strong – i.e. they exclude sentences that are actually acceptable. I observed above that (39) derives the effects of SUBJECT ISLANDS and COMPLEX NP ISLANDS. However, UDs whose gaps are contained within Subjects and Complex NPs are reasonably acceptable under suitable conditions (Kluender 2004, Sag et al. 2007, Chaves 2013), as the b-cases in (43–44) show:

(43) a. * Who$_j$ does [that you baked ginger cookies for t_j] irritate you?
    b. Who$_i$ does [baking ginger cookies for t_i] irritate you?

(44) a. * Who$_i$ did Phyllis hear the claim [that Bob is dating t_i]?
    b. Who$_j$ did Phyllis make the claim [that Bob is dating t_j]?

The equation in (39) rightly excludes (43a) and (44a). The problem is that, by the same token, it also bars (43b) and (44b). Since the a-b pairs are functionally indistinguishable – the bracketed strings map to the same GFs (SUBJ in (43) and RELMOD in (44)) – the real explanation for the contrasts must lie elsewhere.

Kluender (2004) argues that the contrast in (43) is due to a difference in the amount of discourse referential processing. In (43a), the SUBJECT is a finite clause, which introduces the reference to a temporal event. This reference is absent for the non-finite form in (43b), which makes the sentence in question less complex in processing terms (see Gibson (2000) for a similar account).

For (44), Culicover & Jackendoff (2005) suggest an explanation along the lines of Kroch (1998): (44a) presupposes the existence of *the claim* while (44b) doesn't.

The unacceptability of (44a) follows from a general principle which says that a gap cannot be referentially dependent on an operator if its reference is part of a presupposition in the discourse. This principle extends to contrasts like (45), which are also hard to account for in purely syntactic terms.

(45) a. * Who$_i$ did he buy that picture of t_i? (presupposes there is a picture)
b. Who did he buy a picture of t_i? (no presupposition)

The debate on whether all island constraints reduce to extra-grammatical factors is still very much ongoing (see Newmeyer (2016) for a useful survey). What this section meant to illustrate is that the SiSx view – which might seem too unconstrained at first glance – could turn out to be just what the data requires. If there is no grammatically coherent characterization of when UDs are unacceptable, then island constraints should not be built into the rules that license UDs (in SiSx terms, they should not be registered as conditions on the GAP CONSTRUCTION). On this view, sentences that incur island violations are not technically ungrammatical, but merely unacceptable for performance-related reasons.[14]

The overall view SiSx ends up with is this: Explanations about our intuitions regarding which structures are possible divide between grammatical constraints (as recorded in the lexicon) and extra-grammatical factors (pragmatics, processing, etc.). The former tend to correlate with sharp judgments, while the latter tend to show more variability and dependence on contextual factors (see Culicover 2013c). Sources of universals are mostly confined to extra-grammatical factors and to the pressure to reduce constructional complexity (Culicover 2013b). These correspond to the THIRD FACTOR properties of Chomsky (2005).

This leads to a very minimalist conception of UG – as it happens, one that conforms (in an unorthodox way) to what Baker (2008: 353) calls the BORER-CHOMSKY CONJECTURE: the hypothesis according to which all parameters of variation among languages are attributed to individual properties of lexical items. In this respect, SiSx is closer to MGG than to LFG. But the difference between SiSx and MGG is that, as discussed in Section 4, lexical items are highly structured

---

[14] Extra-grammatical accounts of island constraints have a long history in SiSx. They go as far back as Jackendoff & Culicover (1972), In this early paper, the authors propose that "perceptual strategy constraints on acceptability" explain otherwise puzzling contrasts like (i):

(i) a. Who$_i$ did John give a book to t_i?
b. *? Who$_j$ did John give t_j a book?

Note that (i) is also not explained by Kaplan & Zaenen (1989), since the equation required to establish the dependency in (ib) – i.e. (f FOCUS) = (f OBJ) – satisfies the constraint in (39).

and include what are traditionally thought of as rules of grammar. The result is that most aspects of speakers' knowledge of language end up being potentially subject to variation.

6 What can SiSx and LFG learn from each other?

The purpose of this chapter was to survey the theoretical landscape of SiSx and compare it to LFG. This exercise revealed that both approaches seek to reconcile formal theories of grammar and psychological reality – a common goal that leads them to adopt similar architectures and analyses for particular phenomena.

However, despite these programmatic and architectural similarities, the two theories differ in important respects. Many of these differences stem from SiSx's radical commitment to representational economy, which is sustained even when this entails messier and less systematic interfaces. Another source of discrepancies is the explicit recognition, on the part of SiSx, of extra-grammatical influences on linguistic judgments, as discussed in Section 5.

Insofar as SiSx posits fewer constraints and fewer representational devices, less knowledge about abstract linguistic structure (of all kinds) is attributed to learners. This reduces the impulse to posit rich principles of UG, which, in turn, alleviates some of the burden on evolutionary accounts of the language faculty (Jackendoff 1999, 2002, Jackendoff & Pinker 2005). A similar concern with evolutionary adequacy drives current Minimalist work in MGG (Hornstein 2009, Berwick & Chomsky 2015). This does not seem to be much of a worry in LFG, which is more preoccupied with providing a formally precise and computationally tractable framework.

There is sometimes a trade-off between formal refinement and the general goal of unification with other sciences. As we saw in Section 3, the fact that the mapping from form to meaning can bypass the GF-tier in SiSx helps integrating the theory into gradualist scenarios of language evolution, given that it is implausible that stages of protolanguage had anything like abstract GFs (Jackendoff 1999, 2002, Progovac 2016). Since LFG makes the mapping to semantics critically dependent on f-structure, it is hard to imagine a story of how these simpler sound-meaning pairings could have existed in the evolutionary antecedents of language. On the other hand, LFG's rich conception of f-structure lends itself to a much more complete and computation-friendly formalization, which makes the theory more easily testable.

SiSx and LFG can, therefore, learn a lot from each other. LFG can profit from SiSx's more ambitious aspiration of connecting linguistics to human biology.

This implies seeking theories of language which are not only descriptively and explanatorily adequate, but which also offer the prospect of integration with plausible evolutionary scenarios. Simpler Syntax, in turn, can benefit from a number of the virtues found in LFG, such as: (i) the development of a formally precise and fully explicit architecture which can feed computational applications and simulations; (ii) the great variety of typologically oriented work which constantly submits the theory's formal assumptions to the test of descriptive adequacy (Part VI).

Once SiSx and LFG assimilate each other's merits, some of the differences between them might diminish and some others might become even sharper. Regardless of the outcome, the process of cross-theoretical comparison is a fruitful one, as it often leads to formal innovations and surprising discoveries about the foundations of linguistic theory.

Acknowledgements

I would like to express my gratitude to Peter Culicover, Ray Jackendoff and Rafaela Miliorini for the constant dialogue and for the numerous comments on previous drafts of this chapter. I would also like to thank Bob Levine, Vitor Augusto Nóbrega and Symon Stevens-Guille for discussions about some of these topics, as well as Mary Dalrymple for the help with LaTeX. This research was partially funded by CAPES with a PROEX scholarship 88882.344838/2019-01, a PDSE scholarship 88881.189650/2018-01. and by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) – SFB 1412, 416591334.

Chapter 43

LFG and Tree-Adjoining Grammar

Jamie Y. Findlay
University of Oslo

This chapter gives an introduction to Tree-Adjoining Grammar (TAG) and draws some comparisons with Lexical Functional Grammar (LFG). It is primarily aimed at those familiar with LFG who are looking to learn about TAG and see where the two formalisms differ/overlap, but the comparisons will also be of interest to those coming from a TAG background. After introducing TAG, the chapter considers questions of generative capacity, lexicalisation, and the factoring of redundancies from grammars. It then concludes by illustrating the potential for combining LFG and TAG, and discusses the theoretical implications of doing so.

1 Introduction and roadmap

The purpose of this chapter is to give an introduction to some of the properties of Tree-Adjoining Grammar (TAG: Joshi et al. 1975, Joshi & Schabes 1997, Abeillé & Rambow 2000, Joshi 2005; Kallmeyer 2010: ch. 4) and to draw some comparisons with Lexical Functional Grammar (LFG: Kaplan & Bresnan 1982, Bresnan et al. 2016, Dalrymple et al. 2019; Belyaev 2023b [this volume]). It is primarily aimed at those familiar with LFG who are looking to learn about TAG and see where the two formalisms differ/overlap, but the comparisons will also be of interest to those coming from a TAG background (although details of the LFG formalism will not be covered – the interested reader is directed to the references above and other chapters in this volume).

A TAG is a mathematical formalism for describing a set of trees, just as a context-free grammar (CFG) is a mathematical formalism for describing a set of strings. Unlike a CFG, which generates or recognises a string by repeatedly rewriting symbols until the target string is produced, a TAG does so by combining members from a starting set of ELEMENTARY TREES using two operations

Jamie Y. Findlay. 2023. LFG and Tree-Adjoining Grammar. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 2069–2125. Berlin: Language Science Press. DOI: 10.5281/zenodo.10186054

(called SUBSTITUTION and ADJUNCTION) until a tree whose yield is the target string is produced. This gives TAGs a greater generative capacity than CFGs, which is why they are of particular interest to researchers in natural language syntax: since Shieber (1985), we have known that the complexity of natural language syntax exceeds the context-free space which CFGs are capable of describing. In Section 2, I will briefly discuss this finding and the choice it has forced modern linguistic theories to make regarding their formal foundations. Section 4 delves more deeply into the generative power of TAG and compares it to that of LFG.

When TAG is used in a linguistic capacity, a number of properties are generally added to the basic formalism in order to better align it with certain theoretical assumptions and to enable more natural or transparent analyses of particular grammatical phenomena (e.g. the inclusion of feature structures on nodes to facilitate an analysis of agreement). In Section 3, I introduce some of the details of the TAG formalism along with these linguistically-motivated theoretical assumptions.

One important property generally assumed in linguistic applications of TAG is known as LEXICALISATION, the property whereby each of the basic structures of a grammar is associated with a single lexical item. Lexicalised grammars purportedly have a number of desirable traits, and I discuss lexicalisation in more detail in Section 5. This property sets TAG apart from CFG-based formalisms such as LFG, since the latter cannot in general be lexicalised – a perhaps surprising result given the lexical focus of LFG.

Section 6 briefly compares the TAG and LFG approaches to the factoring out of redundancies from grammars. TAG makes use of a so-called METAGRAMMAR, a formal system used to produce grammars, which can capture high-level generalisations and make grammar engineering easier. LFG uses TEMPLATES, which are part of the grammar proper, and allow pieces of linguistic description to be given names and reused.

Lastly, Section 7 considers the possibility of incorporating a TAG into the LFG architecture, replacing the standard CFG-based description of c-structure. This offers fertile new analytical possibilities, and has pleasing consequences for the descriptive power of LFG more generally, since it allows templates to be extended to the domain of phrase structure, opening the door to a fully constructional LFG.

2 Moving beyond context-free grammars

Context-free grammars have played (and continue to play) a major role in the development of syntactic theory at least since their formal elaboration in the

1950s (Chomsky 1956), with their conceptual roots going back even further (at least to e.g. Harris 1946, Wells 1947). However, there was also always a sneaking suspicion that natural language syntax was formally more complex than CFGs could describe. Nevertheless, by the early ’80s there had been no successful proof of this fact (Pullum & Gazdar 1982). Bresnan et al. (1982) demonstrated that the presence of cross-serial dependencies means that the dependency structure of Dutch requires more than context-free power to describe, although owing to the lack of morphological marking of such dependencies, the *string* language of Dutch remains context free. It turns out, however, that Swiss German exhibits the same cross-serial dependencies, but its nouns are case-marked, and since different verbs can assign different cases to their objects, this means that the dependencies show up in the string language as well. Thus, greater-than-context-free power is definitely needed to describe Swiss German (Shieber 1985). Since there is no reason to suspect that speakers of Swiss German are biologically distinct from speakers of other languages, or that some people would be intrinsically unable to learn Swiss German as a first language, this means that the human language faculty generally allows for languages which require greater than context-free power to describe, and so CFGs alone are inadequate as the basis of a grammatical formalism.

Given this fact, there are two different kinds of response for the syntactic theorist. We can either

1. replace the CFG with something more powerful; or
2. beef up the CFG with something extra, so that the *combination* is more powerful.

Chomskyan generative grammar had already taken the second approach from the start: the addition of transformations to a CFG base pushes the formalism well beyond context-freeness, into the space of Type-0, unrestricted grammars (Peters & Ritchie 1973). LFG similarly adds something extra to the CFG component: in this case, a separate level of representation, f(unctional)-structure; the combination of the two takes the formalism as a whole at least into the Type-1, context-sensitive space (Berwick 1982 – although see Section 4).

However, in order to account for cross-serial dependencies, we do not need a full-blown context-sensitive (or even more powerful) grammar. Instead, we only need a more modest MILDLY CONTEXT-SENSITIVE grammar (Joshi 1985). Such grammars have the useful property, shared with context-free grammars, of being parsable in polynomial time, unlike the (worst case) exponential parsing time of context-sensitive grammars (Joshi & Yokomori 1983, Vijay-Shanker & Joshi 1985), though they still go beyond the expressive power of CFGs in permitting the description of cross-serial dependencies. Responses to the challenge of the non-context-freeness of natural language which take approach number 1 above, and replace the CFG wholesale, tend to do so with a formalism which is explicitly mildly context sensitive, therefore, rather than anything more powerful. One example of this is Combinatory Categorial Grammar (CCG: Steedman 1987, 2000); another is TAG.[1]

3 An introduction to TAG

A TAG is a tree rewriting system which consists of a set of ELEMENTARY TREES and the two operations of SUBSTITUTION and ADJUNCTION for combining them. Substitution simply inserts one tree at the frontier of another (at a non-terminal node), while adjunction inserts a tree *inside* another, attaching it at a non-frontier node (more formal definitions of these processes will be given below).[2]

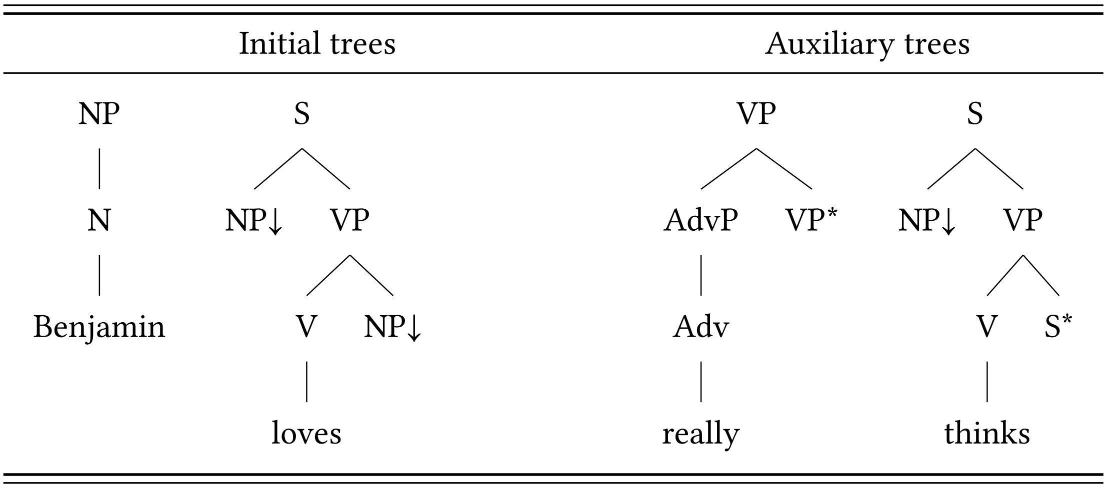
Most linguistic work in TAG now assumes a LEXICALISED version, LTAG (Schabes et al. 1988), in which each tree is anchored by, i.e. has as its terminal node(s), a single lexical item (which may still consist of several words, as in the case of phrasal verbs, idioms, etc.). Similarly, while trees in a TAG (*qua* mathematical formalism) can be of any size, in linguistic applications the general principle applied is that trees should correspond to the EXTENDED MAXIMAL PROJECTION (Grimshaw 2000, 2005) of a lexical item, i.e. the syntactic projection which includes all functional heads and the full argument structure of the item. Some examples of elementary trees matching these restrictions are given in Table 1. In this chapter, I will use "TAG" to refer specifically to this sub-class of lexicalised,

---

[1] In fact, things are a little more complex than this. In some definitions of mild context sensitivity (e.g. Kallmeyer 2010: 23–24), "permutation-complete" languages like MIX (the language consisting of the subset of $\{a, b, c\}^*$ with an equal number of *a*s, *b*s, and *c*s; see Bach 1981) are included (Salvati 2015, Nederhof 2016); in others (e.g. Joshi et al. 1991), they are not (Kanazawa & Salvati 2012). TAG and CCG are in the class which does not contain MIX, and so Steedman (2019: 415) suggests they should be called SLIGHTLY NON-CONTEXT-FREE to distinguish them from the larger class which does contain MIX. Nothing in this chapter hinges on this distinction, so I continue to use the more traditional "mildly context sensitive", without taking a position on whether or not this refers to the class of languages containing MIX or not.

[2] In the original formulation (Joshi et al. 1975), TAG only has one combining operation – adjunction. The addition of substitution, however, improves the descriptive capabilities of the framework, making it easier to use for linguistic purposes, while leaving its formal expressive power the same, since adjunction can be used to simulate substitution (Abeillé 1988: 7). In this chapter I will therefore continue to assume that both operations are used.

Table 1: Some elementary trees



linguistically-constrained TAG rather than merely to the mathematical formalism, except where otherwise indicated.

Elementary trees come in two types, illustrated in Table 1. An INITIAL TREE is one where all of the frontier nodes are either terminals or non-terminals marked as SUBSTITUTION SITES using the down arrow (↓).[3] Substitution sites indicate arguments of a predicate. An AUXILIARY TREE is like an initial tree except that one of the frontier nodes, called the FOOT node, shares the same label as the root, and is marked with an asterisk (*). Auxiliary trees are combined with other trees via adjunction, to be described below. When two elementary trees have been combined, we have a DERIVED TREE, which can then be further manipulated just like an elementary tree.

In the next two subsections, I introduce the two operations used to combine trees in TAG: substitution and adjunction.

3.1 Substitution

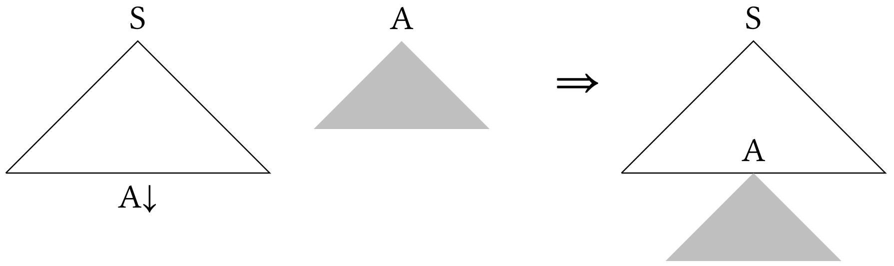
When the root of a tree has a label which matches that of a non-terminal frontier node in another tree, the first tree can be inserted at that frontier node in the second; this is called substitution, and is the process normally used to combine a predicate and its arguments. Example (1) shows this process schematically, while

---

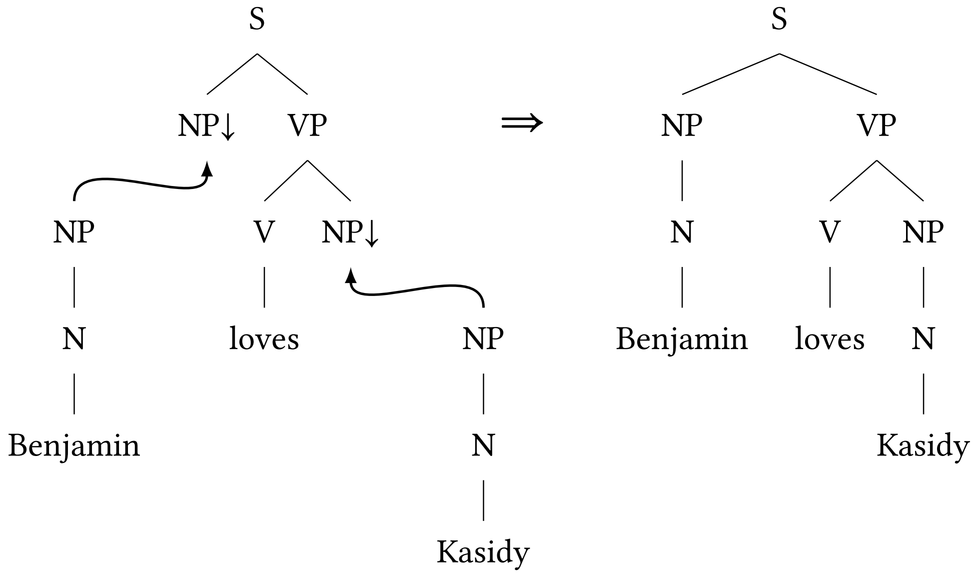
[3] In fact, every non-terminal frontier node can serve as a substitution site, so the ↓-annotation is formally redundant. Nevertheless, it is often included in expository text (if not in computational implementation) to make it clear at a glance that a tree does not represent a fully completed derivation.

(2) gives a linguistic example involving two cases of substitution: the derivation for *Benjamin loves Kasidy.*

(1) **Substitution** (after Abeillé & Rambow 2000: 5)



(2)



A tree rewriting grammar which makes use of substitution alone is called a Tree Substitution Grammar (TSG), and is at least weakly equivalent to a CFG – that is, such grammars describe the same set of string languages (weak equivalence), although there are some tree languages which can be described by a TSG for which an equivalent CFG does not exist (so strong equivalence is not guaranteed).[4] This is easy to see if we imagine converting a CFG into a TSG: all we do

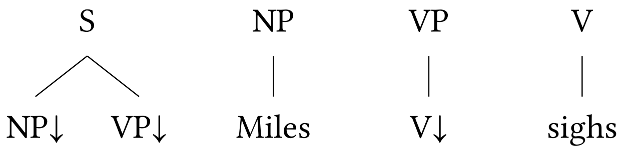
---

[4] Any CFG can easily be converted into a TSG by simply turning each phrase-structure rule into a tree rooted in the left-hand symbol with the right-hand symbols as daughters, as will be illustrated in the text. But to convert a TSG into a CFG, it may be necessary to relabel some nodes, since the dependency between a mother and its daughters may be tree-specific, and so not hold generally (for example, it might be the case that only trees anchored by transitive verbs have a VP dominating both a V and an NP node) – so the CFG might have to have more non-terminal symbols than the TSG (e.g. VP_{trans} and $\text{VP}_{\text{intrans}}$ instead of just VP).

is replace each phrase-structure rule with the equivalent tree which it describes (cf. McCawley's 1968 conception of phrase-structure rules as node admissibility conditions, i.e. descriptions of trees). For example, the CFG in (3) corresponds to the TSG in (4):

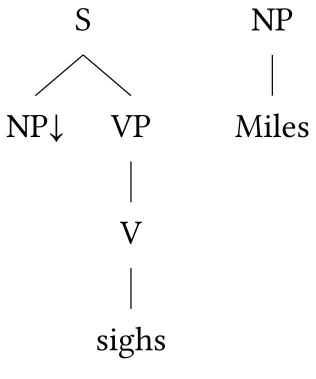
(3) S ⟶ NP VP
NP ⟶ Miles
VP ⟶ V
V ⟶ sighs

(4)



Although TSGs and CFGs are formally very close (at least weakly equivalent), there is an important theoretical difference between them: TSGs have an EXTENDED DOMAIN OF LOCALITY with respect to CFGs. Every rule in a CFG describes a tree of depth 1, but trees in a TSG can be of arbitrarily large size, which means that certain grammatical dependencies, like agreement or extraction, can be described locally in a TSG (i.e. in a single elementary tree) when they cannot be in a CFG (i.e. they cannot be described in a single rule). For example, the TSG in (5) is equivalent to that in (4), except that now the verb and its subject are in the same elementary tree, and so the agreement relationship between the two could be described locally.

(5)

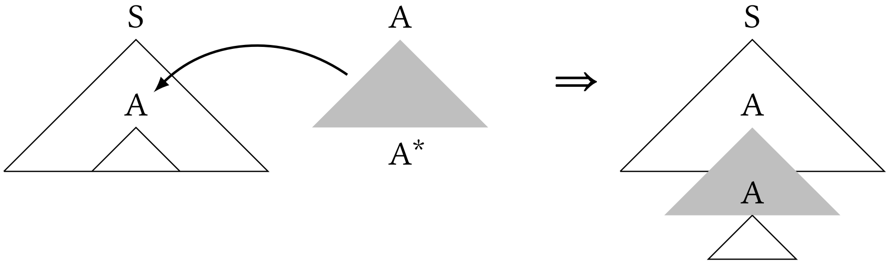


Many possibilities exist as to *how* to describe such a dependency – for example, by using complex categories in the style of GPSG (on which see Gazdar et al. 1985), or by using feature structures (on which see Section 3.3); but the point is that however one chooses to represent this relationship, it can be described locally in a TSG when it can only be described indirectly in a CFG, e.g. by percolating features up from V to VP, thus making them visible to the S → NP VP rule which introduces the subject.

3.2 Adjunction

If we add adjunction, a second type of combining operation, to a TSG, we obtain a TAG. While substitution allows a tree to be inserted at a frontier node of another tree, adjunction allows insertion at a *non*-frontier node: the adjoining tree expands the target node around itself. A tree which adjoins into another tree, called an auxiliary tree, must therefore have at least one frontier node with the same label as its root – this is called the foot node. The process of adjunction is represented schematically in (6):

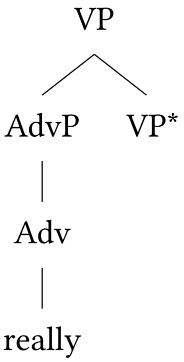
(6) **Adjunction** (after Abeillé & Rambow 2000: 9)



Because of the requirement that the root and foot of an auxiliary tree have the same label, such trees can be seen as factoring recursion out of the grammar. Rather than having a cyclic path through the rewrite rules (as in a CFG), we have a tree which directly encodes such a cycle (in (6), an A contained within an A), which can then be added into a structure via adjunction. For this reason, such auxiliary trees are used to model the recursive aspects of natural language syntax – most notably modification and sentential embedding.

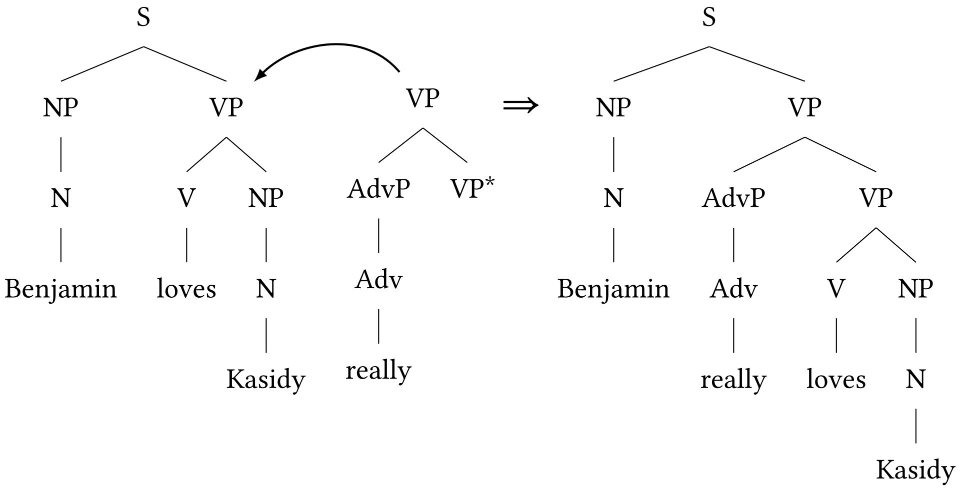
Modifiers such as adjectives and adverbs, but also e.g. relative clauses, are represented as auxiliary trees. For example, *really* is a VP-adverb which appears to the left of the VP it modifies, and so is represented by the tree in (7):

(7)



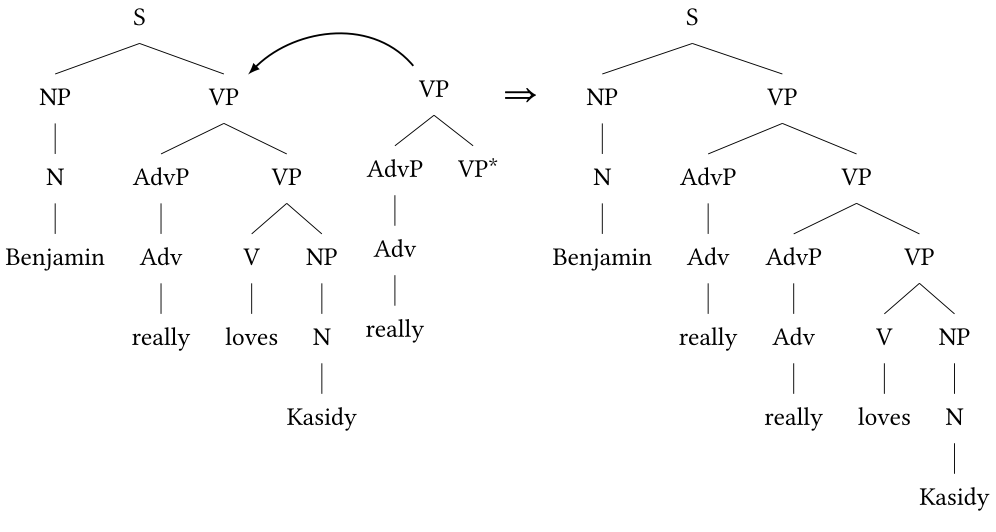
To see this in use, consider the derivation for the sentence *Benjamin really loves Kasidy*: after the substitutions shown above in (2) to generate *Benjamin loves Kassidy*, we can then adjoin the tree from (7) at the VP node in the clause, as in (8):

(8)



Of course, such a process can be repeated indefinitely many times, since there is always still a tree-internal VP node available to be adjoined to, as in (9):

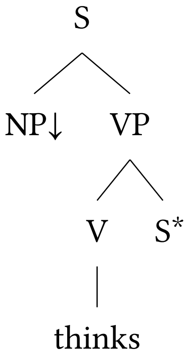
(9)



This accounts for the iterability of modifiers like *really*.

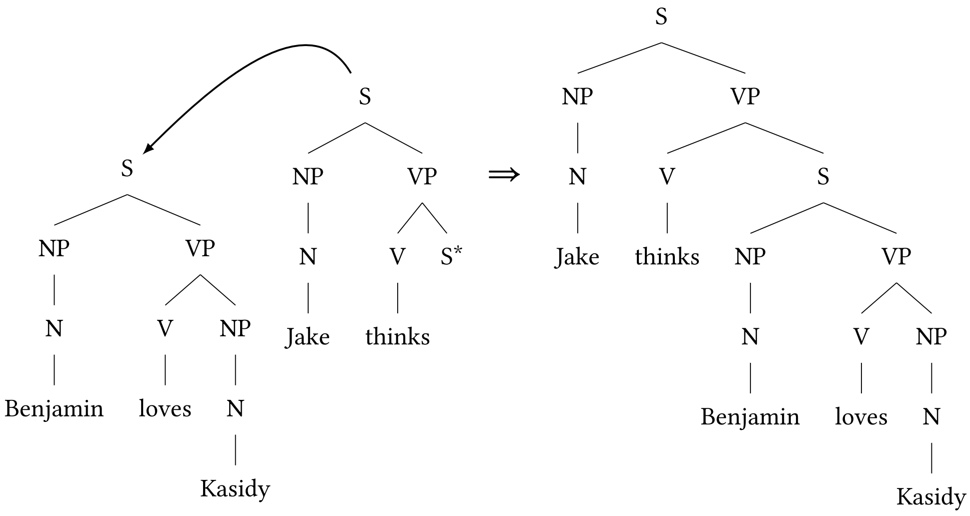
Another, perhaps more theoretically interesting, area of recursion in the grammar is in the domain of subordination, i.e. sentential embedding. Verbs which take sentential complements are represented as auxiliary trees, as in (10), for example:

(10)



Notice that this means that sentential arguments are treated rather differently from other arguments in TAG: while arguments are normally combined with their governors by means of the former being substituted into the latter, sentential arguments combine with their governors by means of the latter being adjoined into the former – this is shown in (11):

(11)

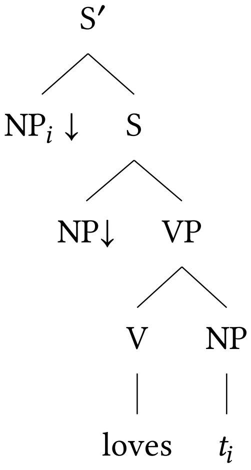


For simple declarative sentences this is a rather unnecessary complication, since the same effect could be achieved by making the foot node of the sentential-embedding verb a substitution site instead. However, the factoring of recursion into auxiliary trees interacts with another TAG principle – the local representation of syntactic dependencies. Owing to their extended domain of locality, it is possible to represnt many kinds of syntactic dependencies locally (i.e. in a single elementary structure) in TAG that would require some additional mechanism in other frameworks. This principle extends to filler-gap relations as well, such as that between a fronted focus phrase and its verbal governor, as in (12):

(12) *Kassidy* Benjamin loves (whereas Kira he merely likes).

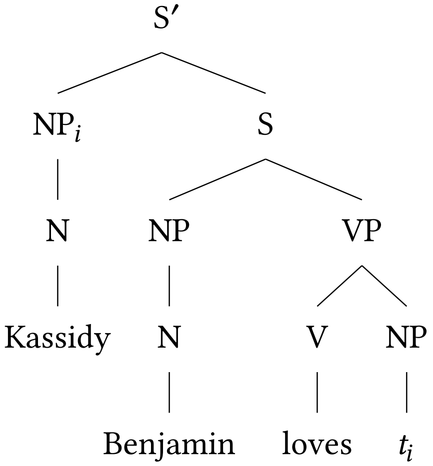
The tree in (13) represents the appropriate form of the verb *loves*, with its object extracted:[5]

(13)



Through substitution alone, this can be used to derive (14):

(14)



But of course the distance between the fronted phrase and the gap can span multiple clauses, and can be arbitrarily large, as shown in (15):

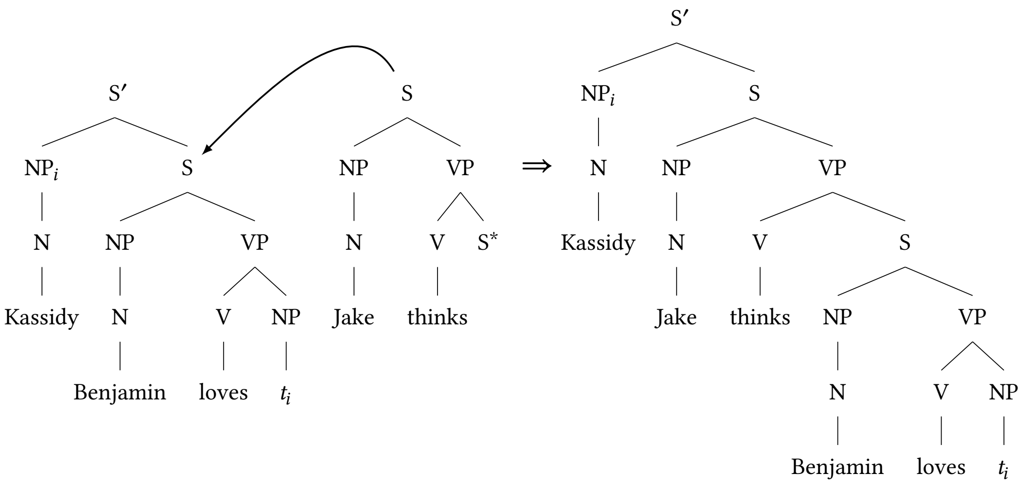
(15) *Kassidy* [Jadzia knows [Jake thinks … [Benjamin loves]]].

---

[5] The use of a trace in object position here is not an essential part of the TAG analysis, though in practice it is common. One reason for this, as argued for by Kroch (1987) and Kroch & Joshi (1985), is that empty elements allow for easier specification of some constraints on extraction in terms of the topology of trees, rather than necessitating additional mechanisms, like functional uncertainty and off-path constraints in LFG. A reviewer points out that traces are also useful in the metagrammar (see Section 6 on this concept), since they allow tree fragments to be reused more easily.

Since sentential embedding verbs are treated as auxiliary trees, this poses no problem – they are adjoined to the internal S node, and thus extend the distance between the gap and the filler:

(16)



What is more, this can clearly be repeated: other trees can be adjoined at the topmost S node, further increasing the distance between the filler and the gap. Thus, a potentially quite radically non-local dependency, between the fronted expression and its governing verb, can be expressed locally in the grammar, in a single elementary tree, because the operation of adjunction allows for the distance between nodes in a tree to grow over the course of a derivation. This same process can be applied to other kinds of filler-gap dependencies, such as *wh*-questions and relative clauses, though for ease of exposition I have chosen not to illustrate these here (since for these we must also account for things like subject-auxiliary inversion and *do*-support).[6] The TAG approach is in contrast to that of many other syntactic theories which instead derive or infer the relation between filler and gap via some additional syntactic mechanism, be that movement or, in the case of LFG, a functional uncertainty path.

3.3 Expressing constraints

Adjunction of an auxiliary tree, which has a root and foot node with the same label, captures the effects of recursion in other formalisms. However, once an auxiliary tree has been adjoined in, there will be two nodes with the same label where there was previously just one. This means that if we adjoin the same

---

[6] The interested reader should consult the detailed analyses of these and other constructions in English provided by the XTAG project (XTAG Research Group 2001).

tree again (e.g. as in (9), where we adjoin *really* twice), there are two distinct possible targets (and after that adjunction there will be three, etc.). This has the potential to dramatically complicate parsing, since there will be multiple distinct possible derivations for the same tree (without there also being a genuine ambiguity of interpretation), and so we would like a means of controlling where adjunction takes place. TAG originally did this by using local constraints on adjunction (Joshi 1987: 100ff.), annotations added to the nodes of elementary trees indicating which auxiliary trees can be adjoined there. If the list of adjoiners is empty, we have a NULL ADJUNCTION (NA) constraint, which prohibits adjunction at the node. If the list is non-empty, then we have a SELETIVE ADJUNCTION (SA) constraint, which limits the trees which can adjoin. There are also OBLIGATORY ADJUNCTION (OA) constraints, which are like SA constraints except that one of the listed trees *must* be adjoined at the annotated node. In classic TAG, this is achieved simply by a diacritic indicating that the constraint is an OA one rather than an SA one. We will see below how this can be achieved in a less stipulative way by making use of feature structures.

Using these constraints, we can avoid having multiple possible parses for sentences by marking the foot node of auxiliary trees with an NA constraint (as is done in the XTAG grammar of English, for example – XTAG Research Group 2001). This means we do not add an extra potential target for adjunction each time such a tree is adjoined in, since only the root of the auxiliary tree is available for further adjunction.

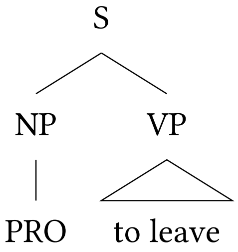
In addition to this practical motivation, adjunction constraints play a crucial theoretical role: they are a vital part of what makes TAG mildly context sensitive. Without adjunction constraints, the formalism is still more powerful than a CFG, but there are several mildly context-sensitive languages which it cannot express, such as the copy language $\{ww \mid w \in \Sigma^*\}$, or the language $\{a^n b^n c^n \mid n \geq 0\}$, also called COUNT-3 (Kallmeyer 2010: 27, 58; we return to COUNT-3 in Section 4).

Let us now consider an example illustrating the linguistic utility of selective and obligatory adjunction constraints. Vijay-Shanker (1987: 134–135) considers non-finite sentential complements such as (17):

(17) John tried [PRO to leave].

Assuming the subordinate clause has the tree in (18), our analysis needs to do two things: ensure that such clauses cannot appear on their own as full sentences – as illustrated in (19) – and ensure that they can be embedded only under verbs that select for infinitival forms – as illustrated in (20).

(18)



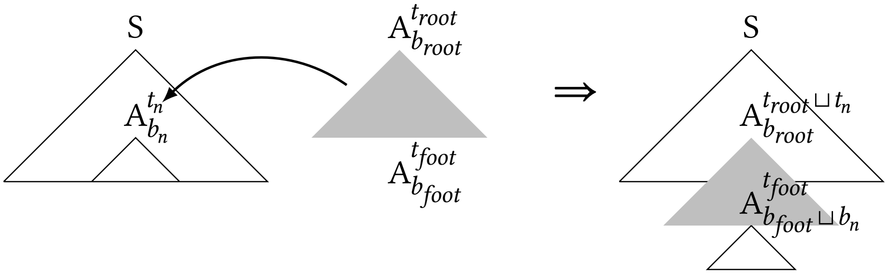
(19) *To leave.

(20)
   a. John tried to leave.
   b. *John imagined to leave.

In other words, *something* must be adjoined into the root node S (an OA constraint), and that something must only be a sentential embedding verb that selects for a non-finite complement clause (an SA constraint).

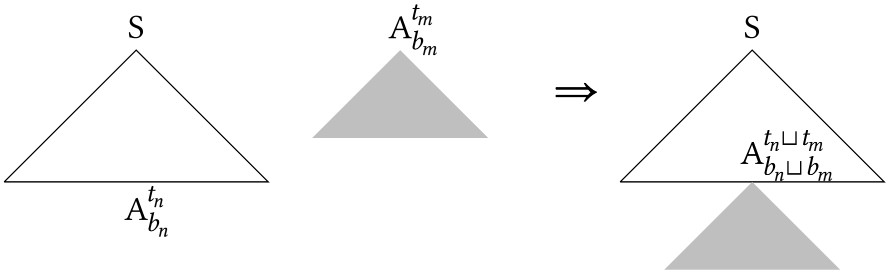
Originally, these constraints were simply seen as listings of (permitted/required) auxiliary trees, but this is not particularly linguistically illuminating, and also difficult to maintain for a grammar writer. This is remedied in later TAG work through the use of feature structures. It is common to associate nodes with feature structures in CFG-based grammars (e.g. in GPSG – Gazdar et al. 1985) in order to represent grammatical features such as case, number, tense, etc. Indeed, this is what LFG's f-structures do too (although there multiple structures from different nodes are merged into one). However, in a TAG, we cannot guarantee the integrity of each node in the tree: through adjunction, it may be split up into two nodes, corresponding to the root and foot nodes of an auxiliary tree. For this reason, in feature structure-based TAG (FTAG: Vijay-Shanker 1987: ch. 5; Vijay-Shanker & Joshi 1988), each node is associated with a *pair* of feature structures, called the TOP and BOTTOM feature structures. The top features refer to the relation of the node to its siblings and its ancestors, i.e. the view from above the node in a tree. The bottom features refer to its relation to its descendants, i.e. the view from below (Vijay-Shanker 1987: 129). Ultimately, the top and bottom features of a node must unify, to give a single description of the properties of that node. However, during the course of a derivation, adjunction may split up the node so that it is now two nodes instead; in that case, its top features will be unified with the top features of the root of the auxiliary tree involved, and its bottom features will be unified with the bottom features of the auxiliary tree's foot node. This is shown schematically in (21):

(21) **Adjunction in FTAG** (after Vijay-Shanker 1987: 130)



Substitution is simpler, since the root node of the substituted tree is simply identified with the substitution site, and so both top and bottom feature structures unify, as shown in (22):[7]

(22) **Substitution in FTAG**

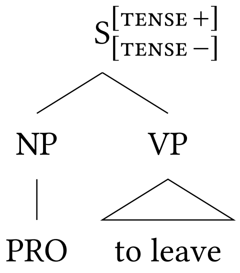


These feature structures can be used to enforce various linguistic constraints. For example, we can enforce subject agreement in initial trees for verbs by specifying number and person features on the subject NP position. More interestingly, we can use features to account for the constraints on adjunction discussed above. Because the features associated with whatever tree is adjoined at a node have to unify appropriately with its top and bottom features, we can control which trees are compatible by giving them (mis)matching features which make unification possible or not. What is more, we can give a more principled account of obligatory adjunction constraints by making the top and bottom features of a particular node incompatible with one another. This means that unless adjunction takes place and the node is split up, unification will be impossible, and the derivation will fail. Returning to our example from above, (23) shows the tree from (18) with two added feature annotations:

---

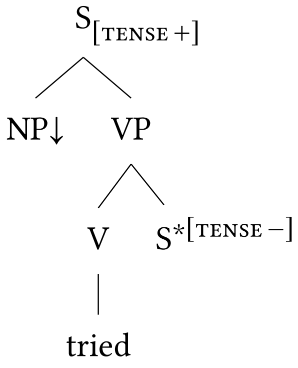
[7] The diagram in (22) follows Vijay-Shanker's (1987) original formulation, where substitution sites also contain bottom features. In much other work using FTAG, this is not the case, so b_n in (22) would be absent, and the final bottom features of A in the derived tree would simply be b_m (XTAG Research Group 2001: 13). This is of course equivalent to (22) with b_n instantiated as the empty feature structure.

(23)

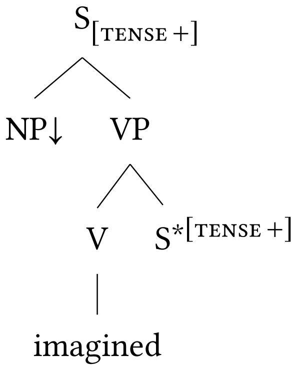


Since these features are incompatible and cannot unify, we have achieved the first of our goals, which is to ensure that this tree cannot appear on its own – i.e., to implement an OA constraint. Owing to the feature mismatch, this tree is illicit unless something adjoins to the root node. To achieve the SA constraint, we need to consider the elementary trees of verbs like *tried* and *imagined*. In (24) and (25) we present them with just the relevant features added:

(24)

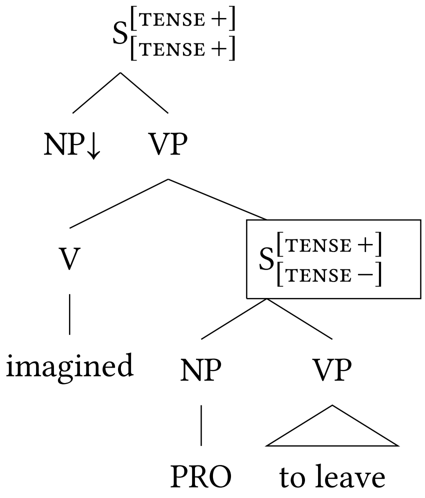


(25)



The difference between the two verbs is that *tried* selects for a non-finite, untensed, complement clause, whereas *imagined* selects for a tensed one – this is indicated by the top features on their foot nodes. If we attempt to adjoin *imagined* into the tree for the subordinate clause in (23), then we end up with mismatching features on the foot node, which means they cannot unify, and the tree remains illicit, as shown in (26):

(26)



If we adjoin the tree for *tried*, however, then there is no mismatch, and the derivation succeeds.

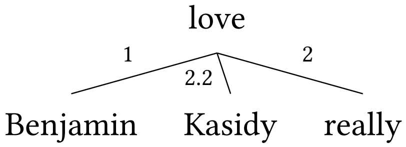
If we allow a fully-fledged unification-based feature system in FTAG, with recursive feature structures of potentially unbounded size, then FTAG becomes undecidable (Vijay-Shanker 1987: 155f.). This is a very bad result given the emphasis that TAG places on tractable, polynomial parsing. For this reason, the feature structures in FTAG are more restricted, and do not permit recursion/re-entrancy, which makes them quite unlike LFG's f-structures.

3.4 Derivation trees and dependencies

In a CFG as classically conceived, the familiar phrase-structure tree is in fact a representation of the derivation, i.e. of the process by which the output, namely the string, was produced. TAGs also have these DERIVATION TREES, representing the way in which trees were combined during a derivation – but, of course, in a TAG, the output of the derivation is already a tree, called the DERIVED TREE to set it apart. The derived tree represents word order, constituency, and category information, like LFG's c-structure. So what linguistic information does a TAG derivation tree encode? Since each elementary tree in a (lexicalised) TAG corresponds to a lexical item, the derivation tree actually represents relations between lexical items, and so has much in common with a dependency grammar representation of the sort illustrated by Meaning-Text Theory (Mel'čuk 1988), the more contemporary Universal Dependencies project (UD: Nivre et al. 2016), or, indeed, an LFG f-structure (on the relationship between dependency grammars and LFG, see also Haug 2023b [this volume]).

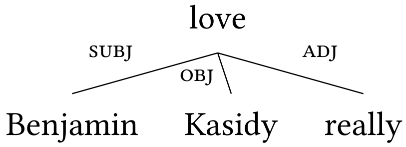
A derivation tree for *Benjamin really loves Kasidy*, the derivation for which was shown in (2) and (8), is given in (27) (cf. Joshi & Schabes 1997: 74ff.):

(27)



Here nodes are labelled with the lexeme corresponding to the elementary tree in question. Whenever a tree is substituted or adjoined into another tree, it becomes its daughter in the derivation tree. The derivation tree in (27) shows that three trees, corresponding to *Benjamin*, *Kasidy*, and *really*, were combined with the tree for *love*. Each edge is also labelled, standardly with a node address which indicates where the tree was substituted or adjoined.[8] However, we can equally well use different labels, such as assigning grammatical function names to argument positions and then treating other positions as ADJ (cf. Rambow & Joshi 1997: 175). This would give us the derivation tree in (28) instead of (27), making the parallel with dependency structures quite explicit:

(28)



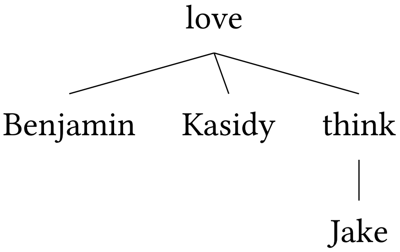
Rambow & Joshi (1997) discuss the relationship between TAG and dependency grammars in more detail.

Unfortunately, the TAG treatment of sentential embedding somewhat undermines the neat parallel between derivation trees and dependency structures (Rambow et al. 1995, 2001). Recall that arguments are normally substituted into their governors, but that clausal complements have their governors adjoined into them. This reverses the normal dependency relations, and means that "(standard) LTAG derivation trees do *not* provide a direct representation of the dependencies between the words of the sentence, i.e., of the predicate-argument and modification structure" (Rambow et al. 2001: 117, emphasis in original). To see why this is so, consider the derivation tree for (11), *Jake thinks Benjamin loves Kasidy*:

---

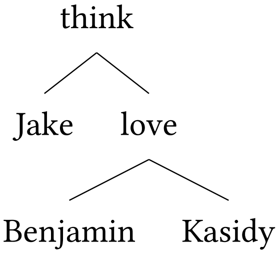
[8] These are so-called GORN ADDRESSES (Gorn 1967). The root has the address 0 (or sometimes ϵ, i.e. the empty string), the kth child of the root (reading left-to-right) has the address k, and for all other nodes, the qth child of a node with address p has the address $p.q$ (Joshi & Schabes 1997: 75).

(29)



In (30) *think* is a dependent of *love*, because the *think* tree is adjoined into the *love* tree, when of course in any real dependency grammar the relation would be reversed:

(30)



There are technical means of handling this unhappy result (see e.g. Joshi & Vijay-Shanker 2001, Kallmeyer & Kuhlmann 2012), but it nevertheless makes the parallel with dependency structures rather less direct. All the same, we might be tempted to see the division of labour between derived trees and derivation trees in TAG as analogous to that between c-structure and f-structure in LFG, where the former represents constituency, word order, and category information, and the latter encodes a sentence's dependency structure. This is certainly true to a point, but the parallel is imperfect, because f-structure also represents other information beyond the dependency structure of a sentence – syntatic features like person, number, tense, aspect, etc., which in TAG are encoded in the feature structures associated with each node instead. Still, one thing that derivation trees and f-structures have in common is that they are both seen as the appropriate level of representation to serve as input to the semantic component of the grammar.

3.5 Semantics

There have been a variety of different proposals for interfacing TAG with a semantic theory, and space precludes a full presentation here. Nonetheless, this section gives a (superficial) overview of the relevant literature, so that the interested reader can investigate further.

An early proposal for doing semantics with TAG makes use of Synchronous TAG (STAG: Shieber & Schabes 1990). In STAG, elementary trees from one grammar are paired with those from another, and links are established between individual nodes in those trees. Then, when adjunction or substitution applies in one grammar, it must also take place in the other, at the linked node, and using the equivalent, paired tree. By pairing a TAG grammar with a tree-based semantic representation, we can therefore implement a "rule-to-rule" approach to semantic derivation (to use Bach's 1976 terminology).[9] Nothing requires the paired trees to be isomorphic, so on the syntactic side it is the structure of the derivation tree, not the derived tree, which determines the meaning. Although this approach has largely fallen out of favour in TAG circles, see Nesson & Shieber (2006, 2007, 2008) for a modern revival.

Another approach which uses the derivation tree as the basis for semantic interpretation is that of Joshi & Vijay-Shanker (2001). Here elementary trees are associated with triples of semantic expressions, the first of which specifies the main variable of the predication, the second of which gives the predicate with its arguments, and the third of which specifies which argument variables are associated with which nodes in the tree. When a tree is substituted into another tree, its main variable is identified with the corresponding argument variable in the target tree's semantics (special consideration has to be made for adjunction, as discussed above: the order of dominance in the derivation tree will be different for sentential vs. non-sentential complements – see Joshi & Vijay-Shanker 2001: 152f.). Since this makes use of a unification-based semantics, the order of combination of the elementary trees is irrelevant, and the derivation tree thus offers an appropriate level of representation, since it abstracts away from order, and simply says how and where trees were combined. This unification-based approach has been developed more recently by Laura Kallmeyer and colleagues, introducing a new focus on underspefication (Gardent & Kallmeyer 2003, Kallmeyer & Joshi 2003, Kallmeyer & Romero 2004, 2008). This has also been integrated with Frame Semantics (Kallmeyer & Osswald 2013).

In LFG, the *de facto* standard approach to the syntax-semantics interface is Glue Semantics (Asudeh 2023 [this volume]). Observing that, for example, the operation of function application as used in natural language semantics is order insensitive, and that quantifier scope ambiguities show that semantic interpretation does not (always) respect the constituent structure of a sentence (see Asudeh 2012: ch. 5), Glue rejects c-structure as the appropriate level of input to semantics, and uses (a projection of) f-structure instead (where order is irrelevant and

---

[9] Alternatively, by pairing two TAG grammars from different languages, we can implement a machine translation system – see Abeillé et al. (1990).

many c-structure hierarchies are collapsed). Thus, as in TAG, it is the dependency structure, not the phrasal structure, which is taken as relevant for semantic interpretation. Interestingly, however, one of the only examples of TAG theorists criticising the derivation-tree-based approach to semantic interpretation is when Glue Semantics has been combined with TAG (Frank & van Genabith 2001). Frank & van Genabith argue that the derivation tree is not suitable as the input to semantic interpretation, mostly on the basis that, as discussed above, it provides the wrong dependency structure, and they instead make use of the derived tree in their Glue-based framework.

3.6 The big picture

Linguistic theories based on TAG have two key properties (Joshi & Schabes 1997: 95f.):

1. Extended domain of locality: Since TAG elementary trees encompass the whole extended projection of a lexical item, dependencies which in a simple CFG-based grammar would be spread across multiple rules, e.g. agreement, can be expressed “locally” in a TAG (i.e. in the same elementary structure). This is what enables a TAG to lexicalise a CFG (see Section 5).

2. Factoring recursion from the domain of dependencies: Relatedly, the elementary trees are the structures over which the vast majority of dependencies are stated, and that includes filler-gap relations. Such dependencies are therefore local in nature, but can become long distance via the adjunction operation. Recursion is thereby factored out of the domain over which these dependencies are initially stated.

This approach is summed up by Bangalore & Joshi (2010: 2) in the slogan “complicate locally, simplify globally”. That is, local, elementary representations are where almost all linguistic constraints are stated, meaning that they can become quite complex, but the payoff is that the composition of elementary trees can be achieved by just two, very general, operations: substitution and adjunction. This also means that cross-linguistic variation is entirely a matter of what elementary trees a grammar contains, a position very much in keeping what Baker (2008: 353) calls the Borer-Chomsky Conjecture, after Borer’s (1984) proposal and Chomsky’s (1995) later adoption of it, whereby parametric variation is restricted to the lexicon.

How does this compare with LFG? The second property certainly divides the frameworks: LFG grammars include recursive c-structure rules, and filler-gap dependencies are expressed syntactically, not lexically. This means, moreover, that the lexicon is not the only source of complexity in LFG grammars; many constructions are analysed as instantiating complex annotated phrase structure rules (see e.g. the analysis of long-distance dependencies in Dalrymple et al. 2019: ch. 17). There is more overlap between the two frameworks when it comes to the first property. Via the parallel projection architecture (see Belyaev 2023b: sec. 5 [this volume]), LFG does obtain an extended domain of locality: for example, agreement can be encoded locally in the agreement controller's lexical entry via the use of paths through f-structure (see Haug 2023a [this volume]). However, since c-structure is generated by a CFG, any non-local dependencies between c-structure nodes (i.e. those spanning more than one "generation" in the tree) can only be expressed indirectly via other levels of representation. That is, we have no extended domain of locality at c-structure *per se*, only parasitically via other levels. To the extent that phrasal constructions larger than a tree of depth 1 are objects we want to be able to represent in the grammar, this is a shortcoming. We return to this point in Section 7.2.

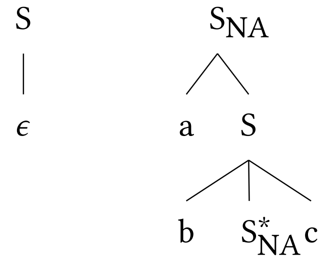
Construction Grammar (CxG: Fillmore et al. 1988, Goldberg 1995, 2006, Kay & Fillmore 1999, Boas & Sag 2012, Hoffmann & Trousdale 2013, *i.a.*) of course considers such objects as basic to linguistic theorising, and for this reason it has been argued that TAG is a natural means of formalising CxG (Lichte & Kallmeyer 2017). For example, among the properties of constructions listed by Fillmore et al. (1988: 501), one is that they "need not be limited to a mother and her daughters, but may span wider ranges of the sentential tree" – precisely the enlarged definition of locality which a TAG provides, and which LFG denies (at least directly). TAG has a natural means of representing both "formal" and "substantive" idioms, to use Fillmore et al.'s (1988) classification: formal idioms can be included in the set of trees associated with each lexical item of the appropriate class (Lichte & Kallmeyer 2017: 208f.), and substantive idioms can be represented as elementary trees in their own right (Abeillé 1995). While LFG can quite well represent formal idioms at the more schematic end of the scale (see e.g. Asudeh et al. 2013), it struggles with substantive idioms, precisely because it lacks an extended domain of locality at c-structure (Findlay 2023: sec. 4).

4 Generative capacity

TAG was designed specifically as a formalism with only mildly context-sensitive power (in the technical sense of Joshi 1985). This means there are languages out of the reach of context-free grammars that TAGs can describe, but also that there are languages properly considered context sensitive which TAG cannot. Such a constrained expansion into the context-sensitive space enables parsing algorithms for TAG to preserve the computationally appealing property of a polynomial run time.

As a simple demonstration of the increased generative capacity of a TAG when compared to a CFG, consider the artificial formal language $\{a^n b^n c^n \mid n \geq 0\}$, also known as count-3 – that is, the language which contains all strings consisting of some number of *a*s followed by the same number of *b*s, then the same number of *c*s. Partee et al. (1990: 497) demonstrate through application of the pumping lemma for context-free languages that count-3 is not context free. By contrast, there is a quite straightforward TAG grammar for count-3, shown in (31):[10]

(31)



So, we can see that TAGs are more powerful than CFGs. They are not, however, very much more powerful. There are many kinds of language which they cannot describe, including those which it has been shown can be described by similarly modest extensions to context-free grammars. One example of this is the language MIX (Bach 1981), mentioned in footnote 1, which consists of all permutations of each string in the set $\{a^n b^n c^n \mid n \geq 0\}$, i.e. any number of *a*s, *b*s, and *c*s, in any order, provided there is the same number of each. Salvati (2015 – originally circulated as a technical report in 2011) showed that MIX is in the class of multiple context-free languages, where a multiple context-free grammar (MCFG) is itself a mildly context-sensitive grammar formalism, for which the parsing problem is also decidable in polynomial time. However, MIX is *not* a tree-adjoining language, as conjectured by Joshi et al. (1991) and proved by Kanazawa & Salvati (2012): so there are languages which are only slightly within the context-sensitive space and which are still not describable by a TAG. More generally, although count-3 and count-4 (i.e. $\{a^n b^n c^n d^n \mid n \geq 0\}$) are tree-adjoining languages, count-5 is not (Joshi 1985: 223f.).

---

[10] Recall that a node annotated with "NA" bears a null adjunction constraint – see Section 3.3. As mentioned above, without adjunction constraints, TAG becomes less expressive, and cannot describe count-3: see Kallmeyer (2010: 222) for a proof.

The carefully constrained computational complexity of TAG is in marked contrast to the situation in LFG (although see below for attempts to constrain the power of the LFG formalism). Whereas the class of tree-adjoining languages is equivalent to that of the mildly context-sensitive languages (or, perhaps, the slightly non-context-free languages: see fn. 1), the languages described by LFGs are equivalent to the class of recursively enumerable languages (Nakanishi et al. 1992). This has the expected deleterious effect on computational complexity: the parsing problem for LFGs is NP-complete (Berwick 1982), and so, in the worst case scenario, computationally intractable (assuming $\mathsf{P} \neq \mathsf{NP}$).

There have been attempts to remedy this situation, however. While the LFG formalism as a whole may be computationally very complex, some of the properties responsible for this are not relevant for the description of natural languages – this opens the possibility that the formalism could be constrained to allow tractable parsing (i.e. in polynomial time) while still preserving its usefulness as a tool for describing natural languages. Seki et al. (1993) propose one such restriction, which limits the kinds of functional annotations permitted on c-structure nodes, and the number of nodes which can correspond to a single f-structure. This successfully buys tractability for the resulting formalism, but at a heavy theoretical cost: many staple aspects of LFG analyses are no longer available, including the very common $\uparrow = \downarrow$ head-sharing annotation, or functional control equations like $(\uparrow \textsc{xcomp subj}) = (\uparrow \textsc{subj})$. More recently, Wedekind & Kaplan (2020) have addressed this limitation, describing a more expressive but still tractable version of the LFG formalism, which is provably equivalent to a Linear Context-Free Rewriting System (LCFRS), and therefore in the mildly context-sensitive space. (See also Kaplan & Wedekind 2023 [this volume] and references therein for discussion of the formal and computational properties of LFG.) This approach only covers the original LFG formalism of Kaplan & Bresnan (1982), however, and it remains to be seen whether certain extensions to this basic formalism, such as functional uncertainty (Kaplan et al. 1987, Kaplan & Zaenen 1989), can be accommodated as straightforwardly in this new approach.

One point worth noting is that even in the absence of a tractable version of LFG, this contrast between TAG and LFG should not automatically be viewed as a failing on the part of the latter. In fact, it reflects a rather deep meta-theoretical question: do we want the formalism *itself* to say something interesting about the class of natural languages? The view embodied by TAG is that we should be interested in "finding a grammar formalism that, by itself, gives already a close characterization of the class of natural languages" (Kallmeyer 2010: 7).[11] By

---

[11] This view is also shared by Combinatory Categorial Grammar (CCG: Steedman 2000) and Multiple Context Free Grammars (MCFGs: Seki et al. 1991), among others.

contrast, the view embodied by LFG is that "it is the theory that imposes the constraints, not the language in which the theory is expressed" (Pollard 1997: 9).[12] In theoretical terms, at least, it does not seem obvious that one approach is *better* than the other – they are merely different perspectives on the problem.[13]

5 Lexicalisation

I mentioned at the start of Section 3 that linguistic applications of TAG assume that the grammar is "lexicalised". Abeillé & Rambow (2000: 7) give the following definition of this term (emphasis in original):

> We will call a grammar *lexicalised* if every elementary structure is associated with exactly one lexical item (which can consist of several words), and if every lexical item of the language is associated with a finite set of elementary structures in the grammar.

In contrast to (L)TAG, LFG grammars are not in general lexicalised, which is perhaps somewhat surprising given what the "L" in "LFG" stands for. Although there is a focus in LFG on the lexicon as a richly structured respository of grammatical information, there is no requirement that this information *cannot* be expressed through non-lexical means. This section begins by sketching the potential for lexicalising CFG-based formalisms, like LFG, and then explores what the potential advantages of lexicalised grammars are.

In general, CFGs are not lexicalised. For example, the toy grammar in (3), repeated below, is not lexicalised, since the first and third rules are not associated with any lexical item – they consist purely of non-terminals.

(3) S ⟶ NP VP
NP ⟶ Miles
VP ⟶ V
V ⟶ sighs

---

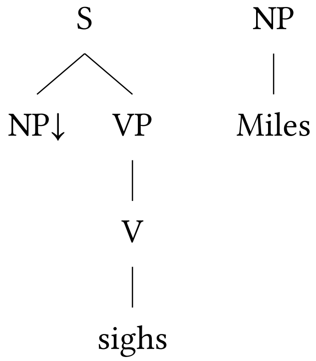
[12] This view is also shared by Head-Driven Phrase Structure Grammar (HPSG: Pollard & Sag 1994) and Minimalism (Chomsky 1995), among others.

[13] Of course, from a more practical point of view, it matters very much whether a formalism is tractable if it is to be used in some natural language processing task. However, there is already a very successful computational implementation of LFG in the form of the Xerox Linguistic Environment (XLE: Kaplan & Newman 1997; Crouch et al. 2011), which employs various "packed computation" (Lev 2007) heuristics to ensure efficient parsing (Maxwell & Kaplan 1989, 1993, 1996). So whatever limitations may exist in principle, they do not necessarily apply in practice.

Since LFG is based on a CFG, via c-structure, LFG grammars standardly make use of many non-lexicalised rules like these, which means that LFG grammars are generally not lexicalised.

It is possible to convert a non-lexicalised grammar into a lexicalised one, but this can require a change to the formalism used. We can speak of one grammar (weakly or strongly) lexicalising another if the former is (weakly or strongly) equivalent to the latter, except that the former is lexicalised whereas the latter is not.[14] For example, the Tree Substitution Grammar shown above in (5), and repeated below, strongly lexicalises the grammar in (3), since each elementary object in (5) is associated with a lexical item, and the grammar describes the same string and tree language as (3).

(5)



Sometimes it is possible to use a CFG to strongly lexicalise another CFG, but it turns out that this cannot be guaranteed in principle. For, although there is a way of converting any CFG into so-called Greibach normal form (Greibach 1965), where the right-hand side of each rule begins with a terminal symbol – thereby lexicalising the grammar – such grammars do not in general generate the same set of trees as the grammars they normalise, since they will include different (and many more) rules. That is, converting a CFG into Greibach normal form only weakly lexicalises it. The extended domain of locality of a TSG/TAG allows us to avoid this problem, however, and makes tree grammars like this "naturally" lexicalised (Schabes et al. 1988: 579). In fact, to strongly lexicalise an arbitrary CFG, we require a TAG, not simply a TSG (see Kallmeyer 2010: 22f. for a proof). And although a TSG may be sufficient to lexicalise many linguistically relevant CFGs, it places syntactically undesirable restrictions on the resulting grammar,

---

[14] Two (classes of) grammars are weakly equivalent if they describe the same (sets of) string languages (though the corresponding (sets of) tree languages may differ). They are strongly equivalent if they also describe the same (sets of) tree languages.

and so a TAG is preferable here too (Schabes et al. 1988: 579; Schabes 1990: ch. 1). But why should we care whether a grammar is lexicalised or not?

One early advantage touted for lexicalised grammars was based on parsing. In a lexicalised grammar, a given sentence can contain at most as many elementary structures as there are words in the sentence. Since each lexical item is associated with a finite number of elementary structures, this also means that the number of analyses for the sentence is finite, thus guaranteeing that the recognition problem is decidable (Schabes et al. 1988: 581f.). As Kallmeyer (2010: 21; emphasis in original) puts it, "[l]exicalized grammars are *finitely ambiguous*, i.e., no sequence of finite length can be analyzed in an infinite number of ways". However, in practice, the dangers of non-terminating parses are virtually non-existent in sensibly-written natural-language grammars, and so this advantage is not so great as it may seem.[15]

A related claim is that lexicalised grammars assist parsing because "parsing need consider only those trees of the grammar that are associated with the lexical symbols in the input string" (Eisner & Satta 2000: 79f.), rather than searching the whole grammar, and so the specific words used in a sentence "help to restrict the search space during parsing" (Kallmeyer 2010: 20). Once again, however, this argument carries less practical weight than it might seem, since parsing times for TAG grammars are actually rather slow: the best parsing algorithms for TAGs have a time complexity of $\mathcal{O}(n^6)$, as opposed to $\mathcal{O}(n^3)$ in the case of CFGs, for example (Kallmeyer 2010: ch. 5).[16]

There are, however, more theoretical reasons to be interested in lexicalised grammars. Firstly, it is by virtue of lexicalisation that the derivation tree of a sentence corresponds to its dependency structure (Kuhlmann 2010: 4ff.), as discussed in Section 3.4. Because each elementary object in a lexicalised grammar corresponds to a lexical item, by tracking the combination of those objects we are in fact tracking the combination of lexical items. Especially given the recent interest in dependency grammars prompted by the Universal Dependencies project (Nivre et al. 2016), it is clearly advantageous if our formalism has a transparent connection to dependency structures (see also Haug 2023b [this volume] on the relationship between LFG and dependency grammars).

Secondly, a lexicalised grammar fits very well with a lexicalist view of syntactic theory. Since the 1970s (at least since the publication of Chomsky 1970), there

---

[15] My thanks to Adam Przepiórkowski and Timm Lichte for discussion of this point.

[16] Although this is true of TAGs in general, if our only concern is lexicalising an existing CFG-based grammar, then we could likely devise a parser specialised for TAG grammars that lexicalise CFGs which would have a complexity below $\mathcal{O}(n^6)$. My thanks to a reviewer for this observation.

has been a trend in linguistic theory towards giving lexical analyses of many phenomena which were previously treated as purely syntactic. Indeed, driven by this trend, a plethora of linguistic frameworks have emerged which very deliberately place the lexicon front and centre, treating it as a "richly structured" object, and assuming "an articulated theory of complex lexical structure" (Dalrymple 2001: 3) – this includes LFG, as well as (to a greater or lesser extent) Generalized Phrase Structure Grammar (GPSG: Gazdar et al. 1985), Head-Driven Phrase Structure Grammar (HPSG: Pollard & Sag 1994, Müller & Wechsler 2014), Combinatory Categorial Grammar (CCG: Steedman 2000), Minimalism (Chomsky 1995), and others. Such a focus on the richness of the lexicon is in stark contrast to the historically more prominent view of it as a mere "collection of the lawless", to use Di Sciullo & Williams's (1987: 4) term, where it is simply a repository of exceptions, "incredibly boring by its very nature", about which "there neither can nor should be a theory" (*ibid.*: 3f.). Given that a lexicalist syntactic theory assumes a richly detailed lexicon, in its most parsimonious form this is *all* it would require, the syntactic component being encoded in the lexical entries themselves. In fact, this is just what lexicalisation provides: in TAG, for example, aside from the basic operations of adjunction and substitution, any other grammatical constraints are described in the elementary trees of lexical items; that is, in the lexicon. In a lexicalised grammar, the lexicon essentially *is* the grammar.[17] This means that every language shares the same computational component, and the only differences between languages are in the lexicon (cf. the Borer-Chomsky Conjecture, mentioned above). This is unlike LFG, for example, where languages differ both in their lexica and in the set of c-structure rules they employ.

6 Factoring out redundancies

Natural language grammars involve a large amount of redundancy: for example, the TAG elementary trees for *loves* and *thinks* shown in Table 1 are identical except for their lexical anchors and for the fact that *loves* takes an NP complement where *thinks* takes an S complement. Similarly, all proper nouns will have elementary trees like *Benjamin*, and all VP adverbs will have elementary trees like *really*, except they may follow rather than precede the VP they modify (i.e. the

---

[17] Note that it is possible to collapse the lexicon/grammar distinction without also collapsing the word/phrase (or, equivalently, morphology/syntax) distinction: the processes which build word forms, i.e. the leaf nodes of elementary trees in TAG, need not be the same as those which build derived trees in the syntax. Thus, the formal language theory objections to Construction Grammar presented by Asudeh et al. (2013: 4f.) are only objections to the most radical version of the theory, and need not be taken as objections to constructional approaches generally.

order of the foot node VP* and the AdvP node may be reversed). There is less redundancy when it comes to trees in an LFG grammar, because elementary trees are broken down into smaller-scale phrase-structure rules, but there is plenty of repetition in functional descriptions, where, for example, all 3sg verbs in English will bear the same annotations describing the person and number of their subjects.

Such redundancy or repetition is unavoidable, but it brings with it two undesirable properties: firstly, from a theoretical perspective, it means that certain generalisations may not be expressed; e.g. there are things that *thinks* and *loves* have in common, such as requiring a 3sg subject, and so it is not a mere coincidence that there is overlap in their TAG elementary trees or in their LFG functional descriptions. But nowhere in either grammar is this generalisation expressed *qua* generalisation. Secondly, from a grammar engineering perspective, this kind of redundancy makes updating and extending grammars very difficult: if we change how we analyse a particular phenomenon, we have to make sure we change every instance of it in the grammar (e.g. change every transitive elementary tree); and if we introduce a new feature to deal with some new phenomenon, we have to make sure it is handled correctly in all the existing structures, by manually adapting them one by one. This is clearly likely to lead to inconsistencies and inaccuracies due to human error.

It is therefore desirable to find a means of factoring out redundancies from a grammar, and expressing the generalisations they capture in a single place. Both LFG and TAG have a means of achieving this. In TAG, it is common practice to make use of a METAGRAMMAR, essentially a grammar responsible for generating grammars, where such redundancies can be described just once. Candito (1996, 1999) was one of the first to develop such a metagrammar;[18] her version describes elementary trees along three dimensions: 1) subcategorisation (i.e. how many arguments a verb selects for), including the canonical syntactic functions of the subcategorised arguments; 2) valency alternations/redistribution of syntactic functions; i.e. the actual syntactic function of the arguments; 3) the surface syntactic manifestation of these functions. Each of these dimensions is described by an inheritance hierarchy, and the classes of the metagrammar, corresponding to specific linguistic constructions, such as the English *by*-passive, inherit from

---

[18] Candito's approach was the first to make use of non-destructive inheritance hierarchies, a move which has served as the basis for more modern metagrammar implementations (such as XMG, to be introduced below), but it was not the first to tackle the question of factoring redundancies from TAG grammars. Earlier approaches (Becker 1994 and Srinivas et al. 1994), however, make use of (destructive) lexical rules, which has made them less appealing to researchers who prefer a monotonic approach (I thank a reviewer for bringing this to my attention).

one of the terminal classes in the first dimension, one of the terminal classes in the second dimension, and as many of the terminal classes in the third dimension as there are arguments to realise. Constructions can therefore be described by listing the terminal classes they inherit from each of the three dimensions, a label which Kinyon (2000) calls a HYPERTAG (following from the notion of SUPERTAG introduced by Bangalore 1997 – see also Bangalore & Joshi 2010).

The most recent implementation of the concept of metagrammar is the EXTENSIBLE METAGRAMMAR (XMG) of Crabbé et al. (2013). This does away with Candito's three explicit dimensions, and instead employs a highly expressive description language that enables linguistic structures to be given a single, complex description, including multiple levels of representation (e.g. syntax and semantics). It is also designed so that it can be extended to cover new phenomena or linguistic formalisms, and so fewer theoretical assumptions are baked into the formalism. XMG makes use of an inheritance hierarchy, but a single hierarchy instead of Candito's three: rather than taking the approach of describing default syntactic function assignments (dimension 1) and then overriding them with specific valency frames (dimension 2), which might vary, e.g. in the case of diathesis alternations, XMG makes heavy use of disjunctions between alternating descriptions, which enables such alternations to be described fully declaratively, and in just one place. For example, we can express the familiar active-passive diathesis of English as in (32), where each term in italics refers to a class in the metagrammar's inheritance hierarchy that gives a partial description of a (sub-)tree (Crabbé et al. 2013: 616).

(32) $$\begin{aligned} \mathit{TransitiveDiathesis} \rightarrow \quad & (\mathit{Subject} \wedge \mathit{ActiveVerbForm} \wedge \mathit{Object}) \\ & \vee (\mathit{Subject} \wedge \mathit{PassiveVerbForm} \wedge \mathit{ByObject}) \\ & \vee (\mathit{Subject} \wedge \mathit{PassiveVerbForm}) \end{aligned}$$

Each of the disjuncts in (32) combines these descriptions to give a partial description of a full elementary tree schema (an elementary tree minus its lexical anchor). For now I leave aside the details of how these classes actually describe trees; a simplified version of the logical description language employed will be introduced in the next section. The crucial observation here, and the move which sets XMG apart from earlier approaches to metagrammatical analysis, is that the description in (32) does not privilege one elementary tree/realisation of arguments as basic, but simply describes all possible realisations simultaneously.

The terminal classes of the metagrammar are families of trees which are then associated with lemmas, and represent all the different ways of realising that lemma's arguments (e.g. active vs. passive, *wh*-extraction, clefting, etc.). The *TransitiveFamily* associated with a lemma like LOVE might just consist of (32), while the *DitransitiveFamily* of a verb like GIVE might inherit from the *TransitiveFamily* but add an additional object argument:

(33) *TransitiveFamily* → *TransitiveDiathesis*
DitransitiveFamily → *TransitiveDiathesis* ∧ *IndirectObject*

This modular and structured approach to the metagrammar means that, for instance, if the analysis of a particular phenomenon changes, we just need to modify the relevant class(es): when the grammar is compiled anew, all of the implicated elementary trees will be altered accordingly. The choice of classes can also have theoretical implications, and may shed light on important linguistic generalisations.[19]

Although the metagrammatical approach has been used to generate LFG grammars as well as TAGs (Clément & Kinyon 2003a,b), this is not common practice in LFG work. Rather, since redundancies in an LFG grammar are far more abundant in the functional descriptions associated with lexical entries than in phrase structure, the standard solution employed here is to make use of TEMPLATES, a type of macro which can be used to abbreviate pieces of functional description that are re-used across lexical entries (Dalrymple et al. 2004, Crouch et al. 2011; see also Belyaev 2023a: sec. 5.1 [this volume]). These templates can take arguments, and can also call other templates, creating a hierarchical organisation – though it should be noted that this is an *inclusion* hierarchy rather than an inheritance hierarchy, since template calls can be negated (Asudeh et al. 2013: 18f.). The semantics of template invocation (represented by prefixing the template name with a '@' symbol) is substitution: the template name is replaced by its contents. This means that a grammar without templates is extensionally equivalent to one with them, but in the latter it will be possible to express generalisations that cannot be expressed in the former.

By way of illustration, (34–35) present some templates which capture some of the same information present in the XMG classes shown above. The TRANSITIVEDIATHESIS template takes a predicate name as its argument, and consists of a disjunction of three other templates; it will be called by the lexical entry of any transitive verb which participates in the active/passive alternation in English. Each of the three templates it invokes provides a PRED value for the verb in

---

[19] Although metagrammars of this sort can certainly be useful theoretical tools, this is not to say that they are intended as models of how the human language faculty functions. As a reviewer points out, it is perhaps implausible that, in the process of language acqusition, the language learner has to recompile their entire grammar every time they make a change or add a new observation. In this regard, LFG's templates (to be introduced below), which are nothing more than abbreviations, might seem more promising as a model of the learner's competence.

question, associating it with the correct set of grammatical functions, and also provides mapping equations which link the GFs to argument positions at semantic structure, or express the fact that the argument is not syntactically realised, in the case of the short passive (this approach to mapping is described in Asudeh & Giorgolo 2012 and Findlay 2016; see also Findlay et al. 2023: sec. 6.2 [this volume]).

(34) $\textsc{TransitiveDiathesis}(P) \equiv$
$@\textsc{ActiveTransitive}(P) \vee @\textsc{ByPassive}(P) \vee @\textsc{ShortPassive}(P)$

(35) a. $\textsc{ActiveTransitive}(P) \equiv (\uparrow \textsc{pred}) = \text{‘}P\langle\textsc{subj}, \textsc{obj}\rangle\text{’}$
$(\uparrow_\sigma \textsc{arg1}) = (\uparrow \textsc{subj})_\sigma$
$(\uparrow_\sigma \textsc{arg2}) = (\uparrow \textsc{obj})_\sigma$

b. $\textsc{ByPassive}(P) \equiv (\uparrow \textsc{pred}) = \text{‘}P\langle\textsc{subj}, \textsc{obl}_{\textsc{by}}\rangle\text{’}$
$(\uparrow_\sigma \textsc{arg1}) = (\uparrow \textsc{obl}_{\textsc{by}})_\sigma$
$(\uparrow_\sigma \textsc{arg2}) = (\uparrow \textsc{subj})_\sigma$

c. $\textsc{ShortPassive}(P) \equiv (\uparrow \textsc{pred}) = \text{‘}P\langle\textsc{subj}\rangle\text{’}$
$(\uparrow_\sigma \textsc{arg1})_{\sigma^{-1}} = \emptyset$
$(\uparrow_\sigma \textsc{arg2}) = (\uparrow \textsc{subj})_\sigma$

One noteworthy difference between the use of a metagrammar and the use of templates is that the latter but not the former are part of a grammar itself. A metagrammar, as the name suggests, sits outside the grammar proper: it outputs grammars, where the elementary objects do not (necessarily) contain information about which metagrammar classes they instantiate. Templates, on the other hand, are part of the description language of the grammar, although of course they are merely names for pieces of functional description, and so have no special formal status themselves.

7 Combining LFG and TAG

Now that we have seen some of the key concepts of TAG, along with their motivations and apparent benefits, we might wonder whether LFG could also benefit from some of these boons if we were to combine the two approaches – most naturally, by using a TAG instead of a CFG to describe LFG’s c-structure. Joshi (2005: 496) described this idea as being “of great interest”, and it was previously explored by Kameyama (1986) and Burheim (1996) – but unfortunately only in unpublished work, which has proved impossible to track down. More recently, the idea has been revived by Findlay (2017a,b, 2019). In this section, I outline two different approaches to achieving the goal of combining LFG and TAG, and discuss some of the consequences of adopting such a merger.[20]

7.1 Two approaches

The most straightforward way of combining TAG and LFG is simply to take a TAG grammar and add appropriate LFG annotations to the elementary trees. Of course, once we have access to the whole tree, we gain a greater degree of flexibility in how we express functional annotations. Most notably, we can refer to any node in the tree directly, rather than being limited to the current node or its mother – a consequence of TAG's extended domain of locality. For example, instead of relying on a sequence of $\uparrow = \downarrow$ annotations to pass information from a lexical item to the top of its extended projection, we can refer to the top directly. For the sake of simplicity, let us use node labels as shorthand for the nodes themselves.[21] Then the ($\uparrow$ PRED) = 'love' annotation on the verb *loves*, for example, could be rewritten as (S_ϕ PRED) = 'love', using S_ϕ to refer to the f-structure of the clause directly, rather than indirectly via V_ϕ (the instantiation of $\uparrow$), which is equated with both VP_ϕ and S_ϕ. Indeed, since we can use absolute rather than relative labels for the nodes in the tree, there is no need to mark annotations actually on the tree at all; instead, we can treat lexical entries as pairs consisting of the tree on the one hand and the annotations on the other, which refer to nodes in the tree. This arguably simplifies the process of determining an f-structure from an annotated c-structure, since many identities which would normally have to be computed are instead already given in the descriptions. Table 2 shows the elementary trees from Table 1 augmented in this fashion.

The trees then combine as usual for a TAG, using the operations of substitution and adjunction, albeit understood in a particular fashion. Substitution involves identifying two nodes, so that, e.g. if the tree for *Benjamin* were substituted into the subject position of the tree for *loves*, NP and NP1 would be identified (and therefore so would their f-structures, requiring the nodes to bear compatible annotations – and thereby accounting for the agreement facts, for example). Ad-

---

[20] One concern about replacing the CFG component of LFG with a more powerful TAG might be that it makes the formalism as a whole more computationally complex. However, since TAGs are strictly less powerful than LFGs (see Section 4), such a concern is ultimately baseless.

[21] Of course, in reality nodes and their labels are distinct: several nodes can bear the same label, for example (e.g. there can be more than one NP in a tree). When this happens, I follow the TAG convention of suffixing node labels with numbers (e.g. NP1 and NP2), but it should be borne in mind that this is just a representational choice, and that in reality such nodes have identical labels.

junction involves three steps: first we excise a sub-tree rooted at the adjunction site; next, we *replace* it with the adjoining auxiliary tree; finally, we unify the foot node of the auxiliary tree with the root node of the excised sub-tree it replaced.[22] This way, we identify the target of adjunction with the foot of the auxiliary tree, and correctly distribute the annotations between the two "parts" of the expanded node without the need for top and bottom feature structures.[23,24]

This first approach is much more in the spirit of TAG than of LFG, since the c-structure component is derivational, making use of the combining opera-

---

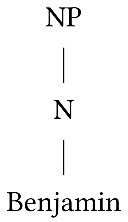
[22] Note that it is particularly important in this setting that adjunction is only defined where the adjoining tree's root and foot nodes are of the same category. In some TAG settings this would not need to be stated explicitly, depending on how adjunction is defined, but here the root of the auxiliary does not unify with anything, and so there is nothing which formally requires the root and foot nodes of such a tree to have the same category (I thank a reviewer for this observation). Allowing trees with mismatched root and foot nodes to participate in adjunction would have undesirable consequences: for example, we do not want the tree for *loves* in Table 2 to act as an NP modifier (e.g. **the Benjamin loves boy*).

[23] A reviewer asks how obligatory adjunction can be implemented in this setting, since in FTAG it exploits the possibility of mismatching top and bottom features (see Section 3.3). Ultimately, the answer is that the greater expressive power of the LFG projection architecture means that the effects of obligatory adjunction constraints will be captured in different ways in different situations. Constraining equations will frequently be relevant: for example, returning to the example of *to leave* from (18), to implement the SA constraint we might specify that *tried* requires its comp to contain the feature [finite −], whereas *imagined* requires it to contain [finite +]; if *to leave* specifies that its f-structure contains [finite −], then it will be compatible with the former but incompatible with the latter. If we wish to avoid *to leave* appearing on its own (i.e. we rule out fragments), we might implement a general ban on root f-structures containing [finite −], or we might rely on the resource sensitivity of Glue Semantics, since an infinitive alone will not permit a linear logic proof terminating in the goal type of propositions.

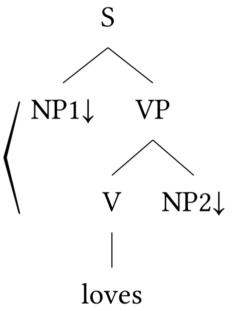
[24] Findlay (2017a: 222, fn. 12) claims that we are forced to adopt the second proposal to be discussed below, using descriptions of trees, because adjunction means that the ↑ and ↓ chains in annotations will be disrupted. This would be true if we were forced to refer to f-structures only indirectly, via mother-daughter links, but fails to appreciate the additional freedom afforded by being able to refer to nodes absolutely, as discussed above. There is, however, a small wrinkle when it comes to verbal trees for extraction constructions (e.g. *wh*-questions): if nothing is adjoined to them, we want to unify the f-structures of the root S′ and the S node it immediately dominates; but if a sentential embedding verb is adjoined there, we cannot identify the two f-structures, or else we will end up with a cyclic f-structure which is its own comp. All this shows us though is that we have to take care when writing the functional annotations. Here, for example, we can solve the problem by actually reintroducing an element of relativity: we identify the root node's f-structure with the f-structure of its S daughter (e.g. by defining a predicate CatDaughter(n, C) which identifies the unique daughter of node n which bears label C, and is undefined if there is none or more than one), regardless of which node that actually ends up being. I omit the formal details of how this can be achieved, since ultimately we will settle on the second approach to integrating TAG and LFG described below, but it is important to note that this first approach is not unworkable.

Table 2: Some elementary trees with associated LFG annotations

Initial trees

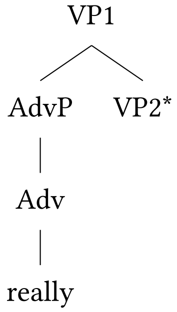


$$\begin{gathered}\mathrm{NP}_\phi = \mathrm{N}_\phi \\ (\mathrm{NP}_\phi\ \textsc{pred}) = \text{‘Benjamin’} \\ (\mathrm{NP}_\phi\ \textsc{num}) = \textsc{sg} \\ (\mathrm{NP}_\phi\ \textsc{pers}) = 3\end{gathered}$$

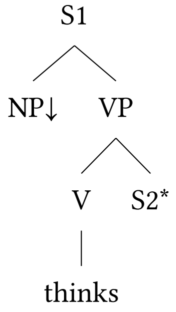


$$\begin{gathered}\mathrm{S}_\phi = \mathrm{VP}_\phi = \mathrm{V}_\phi \\ (\mathrm{S}_\phi\ \textsc{pred}) = \text{‘love’} \\ (\mathrm{S}_\phi\ \textsc{tense}) = \textsc{pres} \\ (\mathrm{S}_\phi\ \textsc{subj}) = \mathrm{NP1}_\phi \\ (\mathrm{S}_\phi\ \textsc{obj}) = \mathrm{NP2}_\phi \\ (\mathrm{NP1}_\phi\ \textsc{num}) = \textsc{sg} \\ (\mathrm{NP1}_\phi\ \textsc{pers}) = 3\end{gathered}$$

Auxiliary trees



$$\begin{gathered}\mathrm{VP1}_\phi = \mathrm{VP2}_\phi \\ \mathrm{AdvP}_\phi = \mathrm{Adv}_\phi \\ (\mathrm{AdvP}_\phi\ \textsc{pred}) = \text{‘really’} \\ \mathrm{AdvP}_\phi \in (\mathrm{VP1}_\phi\ \textsc{adj})\end{gathered}$$



$$\begin{gathered}\mathrm{S1}_\phi = \mathrm{VP}_\phi = \mathrm{V}_\phi \\ (\mathrm{S1}_\phi\ \textsc{pred}) = \text{‘think’} \\ (\mathrm{S1}_\phi\ \textsc{tense}) = \textsc{pres} \\ (\mathrm{S1}_\phi\ \textsc{subj}) = \mathrm{NP}_\phi \\ (\mathrm{S1}_\phi\ \textsc{comp}) = \mathrm{S2}_\phi \\ (\mathrm{NP}_\phi\ \textsc{num}) = \textsc{sg} \\ (\mathrm{NP}_\phi\ \textsc{pers}) = 3\end{gathered}$$

tions of substitution and adjunction. Let us therefore call it LFG-TAG. But as Kaplan (1995: 11) points out, this PROCEDURAL, or CONSTRUCTIVE, approach to grammatical analysis is in contrast to the DESCRIPTIVE (a.k.a. DECLARATIVE or MODEL-BASED) approach which is the “hallmark of LFG” (*ibid.*). Findlay (2019: ch. 5) therefore explores another way of combining the two frameworks which is more in keeping with the LFG spirit. In brief, we associate lexical entries with *descriptions* of trees, rather than with the trees directly, as is standard practice in metagrammars, for instance.[25] In the simplest cases there is a one-to-one correspondence between a description and the (minimal) tree it describes, and so we could straightforwardly translate LFG-TAG into a more LFG-like format. However, descriptions can also make use of negation, disjunction, or other operations that go beyond simple conjunction of propositions, and in this case the relation between descriptions and trees is no longer isomorphic (Kaplan 1995: 14).

---

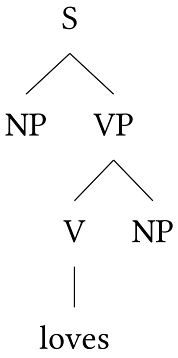
[25] The use of tree descriptions has been discussed extensively in the context of TAG – see, for instance, Vijay-Shanker (1992), Rogers & Vijay-Shanker (1994), Rambow et al. (1995, 2001), Kallmeyer (2001).

In order to add descriptions of trees to LFG lexical entries, we need a suitable language to write the descriptions in. There are a variety of different possibilities, but here we will assume a fairly simple language based on that used in XMG (Crabbé et al. 2013: 599), which will consist of the following:[26]

(36)
1. a set N of node variables
2. a set P of unary labelling predicates, including all terminal and non-terminal labels
3. the following binary predicates:
    - $\rightarrow$, immediate dominance (the *mother-of* relation)
    - $\rightarrow^*$, dominance (the transitive, reflexive closure of $\rightarrow$)
    - $\prec$, linear precedence[27]

The tree in (37) can then be described by the set of constraints in (38):[28]

(37)



(38)

$$\begin{array}{lll}
\mathrm{S}(n_1) & n_1 \rightarrow n_2 & n_2 \prec n_3 \\
\mathrm{NP}(n_2) & n_1 \rightarrow n_3 & n_4 \prec n_5 \\
\mathrm{VP}(n_3) & n_3 \rightarrow n_4 & \\
\mathrm{V}(n_4) & n_3 \rightarrow n_5 & \\
\mathrm{NP}(n_5) & n_4 \rightarrow n_6 & \\
\mathrm{loves}(n_6) & &
\end{array}$$

However, as it stands, the constraints in (38) are too rigid. Specifically, they will not allow adjunction at the VP node, since then at least one statement in the

---

[26] We will also assume that sufficient axioms are in place to ensure the usual well-formedness conditions on trees, e.g. that they are singularly rooted, that branches cannot cross, etc. Rogers (1998: 15f.) gives one such set of axioms.

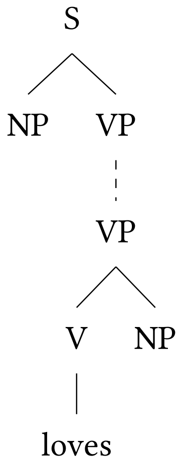
[27] Here this is to be understood as the transitive closure of immediate linear precedence, i.e. what Crabbé et al. (2013: 599) represent as $\prec^+$. In other words, a node linearly precedes everything to its right, but does not linearly precede itself.

[28] In descriptions, we will assume that all node variables are ultimately existentially bound.

description will no longer be true: if we identify the target n_3 with the root of the adjoining tree, then $n_3 \rightarrow n_4$ will no longer hold (the foot node of the auxiliary tree will dominate n_4 instead), and if we identify it with the foot node of the adjoining tree, then $n_1 \rightarrow n_3$ will not be true instead. The basic problem is that "[t]he composition operation of adjoining creates a new structure that does not maintain all of the properties that held in the original (fully specified) structures of which it is composed" (Vijay-Shanker 1992: 486). What this means is that we cannot operate with fully specified descriptions, but must make use of partial descriptions instead.

For each node where adjunction can apply, we instead describe a pair of quasi-nodes which stand in the dominance relation (Vijay-Shanker 1992: 486ff.). That is, instead of (38), we have (40), which is represented schematically in (39) (where a dashed line represents dominance rather than immediate dominance):

(39)



(40)			
	S(n_1)	$n_1 \rightarrow n_2$	$n_2 \prec n_3$
	NP(n_2)	$n_1 \rightarrow n_3$	$n_5 \prec n_6$
	VP(n_3)	$n_3 \rightarrow^* n_4$	
	VP(n_4)	$n_4 \rightarrow n_5$	
	V(n_5)	$n_4 \rightarrow n_6$	
	NP(n_6)	$n_5 \rightarrow n_7$	
	loves(n_7)		

As elsewhere in LFG, we take the solution to a set of constraints to be the *minimal* structure (or structures) which satisfies all the constraints. Since the dominance relation is reflexive, the minimal tree which satisfies (40) remains (37), i.e. one where we equate n_3 and n_4. But, crucially, if something is adjoined here, the nodes can come apart, with the result that n_3 is identified with the root of the auxiliary tree and n_4 with its foot node.

Now that we have a description of this tree, we can combine it with functional descriptions to form a full LFG lexical entry:[29]

(41)
$$\begin{array}{llll}
\mathrm{S}(n_1) & n_1 \rightarrow n_2 & n_2 \prec n_3 & n_{1\phi} = n_{3\phi} \\
\mathrm{NP}(n_2) & n_1 \rightarrow n_3 & n_5 \prec n_6 & n_{4\phi} = n_{5\phi} \\
\mathrm{VP}(n_3) & n_3 \rightarrow^{*} n_4 & & (n_{5\phi}\ \textsc{pred}) = \text{‘love’} \\
\mathrm{VP}(n_4) & n_4 \rightarrow n_5 & & (n_{5\phi}\ \textsc{tense}) = \textsc{pres} \\
\mathrm{V}(n_5) & n_4 \rightarrow n_6 & & (n_{1\phi}\ \textsc{subj}) = n_{2\phi} \\
\mathrm{NP}(n_6) & n_5 \rightarrow n_7 & & (n_{4\phi}\ \textsc{obj}) = n_{6\phi} \\
\text{loves}(n_7) & & & (n_{2\phi}\ \textsc{num}) = \textsc{sg} \\
 & & & (n_{2\phi}\ \textsc{pers}) = 3
\end{array}$$

To parse a sentence, we just collect up all of the constraints associated with each lexical item and find the minimal structures – both c-structure and f-structure – which satisfy them.

Of course, (41) is not particularly readable, so we might prefer to collect some parts of the description in various templates. For example, the tree for any transitive verb will share most of the description in (41), so we can factor out this part of the description, parametrising the only variable, namely the lexical anchor:

(42) $\textsc{TransitiveTree}(s, np_1, vp_1, vp_2, v, np_2, a, \textit{ANCHOR}) \equiv$
$$\begin{array}{llll}
\mathrm{S}(s) & s \rightarrow np_1 & np_1 \prec vp_1 & s_{\phi} = vp_{1\phi} \\
\mathrm{NP}(np_1) & s \rightarrow vp_1 & v \prec np_2 & vp_{2\phi} = v_{\phi} \\
\mathrm{VP}(vp_1) & vp_1 \rightarrow^{*} vp_2 & & (s_{\phi}\ \textsc{subj}) = np_{1\phi} \\
\mathrm{VP}(vp_2) & vp_2 \rightarrow v & & (vp_{2\phi}\ \textsc{obj}) = np_{2\phi} \\
\mathrm{V}(v) & vp_2 \rightarrow np_2 & & \\
\mathrm{NP}(np_2) & v \rightarrow a & & \\
\textit{ANCHOR}(a) & & &
\end{array}$$

---

[29] Here I have kept to a more conservative annotation scheme than above, whereby e.g. lexical contributions are associated with the f-structure of n_5, i.e. the V node, rather than with that of the root S. This is because adjunction may in principle alter the structure of the tree so that it is no longer the case that the f-structure of the S node is the same as the f-structure of the V node. In fact, with verbal trees like this, that will not be the case, because the only auxiliary trees which target VPs in a TAG grammar will be auxiliary verbs or adverbial modifiers, neither of which will break the link between V and S in terms of f-structure-identity. But it will, for example, be relevant for verbal trees containing extraction sites, which can be targetted by sentential embedding verbs, thereby separating the root's f-structure from the head verb's.

We have to "expose" all nodes as parameters of the template, so that they can be referred to by other constraints in the same lexical entry, thereby taking advantage of the extended domain of locality afforded by having the description of the whole tree in one place. However, since all of the parameters in (42) except the lexical anchor will simply be node variables, I propose a shorthand: when calling the template, all but the last parameter will be omitted (though, to repeat, when defining it all the parameters must be specified); if we wish to refer to any of the other parameters, we can do so by using the template name and suffixing it with the appropriate parameter.[30] For example, TransitiveTree.s refers to the first parameter, a node variable which corresponds to the root node s in (42). With these conventions in place, we can write a more readable lexical entry for *loves* as in (43), using a local name, %up, to refer to the verb's f-structure – see Belyaev 2023a: sec. 3.2.5 [this volume] for the details on local names):[31]

(43) @TransitiveTree(loves)
%up = TransitiveTree.v_{ϕ}
(%up pred) = 'love'
(%up tense) = pres
(%up subj num) = sg
(%up subj pers) = 3

One theoretical advantage of this approach is that we can build up trees from smaller parts by making use of nested template calls. This allows us to capture connections between phrasal configurations in a way which CFG rules do not. For example, there is no relationship between the two rules in (44), even though the latter is obviously partially described by the former:[32]

---

[30] This is based on the conventions of XMG for exported variables (Crabbé et al. 2013: 602–604).

[31] Here I have reverted to describing the agreement constraints on the subject via the verb's f-structure rather than via the NP's, to make this lexical entry closer to the LFG standard. But of course the option is still open to us to describe it via the tree directly, by associating TransitiveTree.$np_{1\phi}$ with a name, e.g. %subj-np, and then declaring that (%subj-np num) = sg. Although these options are extensionally equivalent here, there can be theoretical/descriptive reasons to prefer one over the other. Cross-linguistically, for example, we might want to treat subject agreement as the same kind of phenomenon both in languages where phrase-structure position is a clear guide to grammatical function (like English) and in languages where it is not (like Warlpiri); so it would make sense to retain the standard LFG approach of describing agreement via f-structure. But in other cases it might make more sense to refer to a particular phrase-structure position, and the integration of an extended tree description into the lexical entry means we now have that choice.

[32] Of course, we can use the convention of surrounding optional nodes in parentheses, and then we can express the relationship between the two rules within a single phrase-structure rule as follows:

(44) a. $$\begin{array}{llll} \text{VP} & \longrightarrow & \text{V} & \text{NP} \\ & & \uparrow=\downarrow & (\uparrow \textsc{obj}) = \downarrow \end{array}$$

b. $$\begin{array}{lllll} \text{VP} & \longrightarrow & \text{V} & \text{NP} & \text{NP} \\ & & \uparrow=\downarrow & (\uparrow \textsc{obj}) = \downarrow & (\uparrow \textsc{obj}_{\theta}) = \downarrow \end{array}$$

On the other hand, if we have a template DitransitiveTree which calls the TransitiveTree template (as well as another template which adds a secondary object), then this containment relationship is made explicit, as shown in (45).

(45) DitransitiveTree(*anchor*) ≡ @TransitiveTree(*anchor*)
@SecondaryObject

Of course the TransitiveTree template can also be decomposed into a call of an IntransitiveTree template plus a PrimaryObject one, and so on. By continuing along these lines, we can capture all the various generalities across trees in a template inclusion hierarchy, recreating the class hierarchies of a TAG metagrammar inside an LFG grammar itself.

7.2 Implications

Having now seen how LFG and TAG can be combined, let us consider the consequences of such a merger. There are several potential gains which such a move could bring, along with several unanswered questions which require further research.

Firstly, the second approach described above offers a pleasing harmonisation of LFG lexical entries. Standard LFG lexical entries contain descriptions of all levels of the projection architecture, but since such lexical entries are really just context-free phrase-structure rules, the description of c-structure is limited to information about the word itself and its mother. In contrast, descriptions of all other levels of structure can refer to arbitrarily distant elements (via functional uncertainty). The inclusion of tree descriptions removes this irregularity from the grammar, since now non-local elements of c-structure can also be included.

(i) $$\begin{array}{lllll} \text{VP} & \longrightarrow & \text{V} & \text{NP} & \left(\begin{array}{c} \text{NP} \\ (\uparrow \textsc{obj}_{\theta}) = \downarrow \end{array}\right) \\ & & \uparrow=\downarrow & (\uparrow \textsc{obj}) = \downarrow & \end{array}$$

However, once we move beyond simple examples like this, such an approach becomes unwieldy, with multiply nested parentheses and very complex disjunctions. Unlike the templatic approach, which provides a readable front-end to the formal complexity, and allows us to represent the relationship(s) between sub-trees in an inclusion hierarchy, this approach forces us to create fewer but more complex rules, which does nothing to aid human-readability.

Secondly, we now have the opportunity to lexicalise an LFG grammar (indeed, Findlay 2019: ch. 5 calls the description-based approach described above "Lexicalised LFG"). As outlined above, the extended domain of locality of a TAG means that all dependencies, including long-distance ones, can be encoded locally in a lexical entry. Lexicalisation seems a natural goal for a lexicalist theory like LFG, and it is perhaps lamentable that it was not possible before.

Thirdly, we can now straightforwardly account for idioms (Findlay 2019: ch. 6). These are problematic for the current leading account of constructions in LFG (Asudeh et al. 2013), since they do not simply add additional constructional meaning to existing lexical meaning, but rather *replace* the lexical meaning with another, different meaning (that is, *shooting the breeze* involves neither shooting nor a uniquely contextually salient breeze). This forces lexicalist theories like LFG to adopt an approach which treats idioms as conspiracies of independent lexical items that select for one another (see Findlay 2023: sec. 4.3). Such approaches face a host of problems, not least of which is that they singularly fail to capture our intuitions about idioms – *viz.* that they are "things" (as Williams 2007 puts it), and not mere epiphenomena of the grammar (see Findlay 2019: 58ff. for discussion of various other problems). But now that we can have lexical entries containing multiple, separable word forms, something which is not possible in vanilla LFG, there is no obstacle to encoding multiword expressions in a single place, thus enabling a much more satisfying analysis. Findlay (2019: ch. 3) provides detailed discussion of the need for this kind of constructional approach to idioms, as well as arguments against other types of analysis.

Fourthly, in addition to idioms, we have a straightforward account of constructional phenomena more broadly. Similar arguments can be made here about the need for constructions to have some ontological status in the theory – to be "things".[33] Admittedly, Asudeh et al. (2013) demonstrate that we do not need to admit constructions as first-class entities in our theory in order to explain *some* kinds of constructional effects, but they only consider constructions which can be described by a single lexical entry or a single context-free phrase-structure rule, and so the constructions in question can be described in a single place. Other constructions require reference to wider spans of phrase structure, or require

---

[33] There is suggestive psycho- and neurolinguistic evidence that the way we process language makes heavy use of prefabricated chunks ("prefabs") (Pawley & Syder 1983, Wray 2002) and of constructions more generally (Bencini & Goldberg 2000, Kaschak & Glenberg 2000, Goldwater & Markman 2009, Pulvermüller 2010, Allen et al. 2012, Johnson & Goldberg 2012). Obviously grammatical theory need not have anything to say about how language is processed in the mind, but it might still be seen as an advantage if it at least makes available the kinds of objects the mind seems to work with – e.g. constructions.

the presence of multiple specific words, potentially in quite distant parts of the phrase, and here the approach will once again have to rely on multiple interacting lexical entries and phrase-structure rules which conspire to give the correct constructional effects. Even if this gives the right results, one might, again, object that it does so for the wrong reasons, since it fails to account for the unitary nature of constructions as grammatical objects. By contrast, in the description-based approach to merging TAG and LFG, although constructions are still not added as new objects in the ontology of the theory, they nevertheless have a kind of first-class status, since they can either be entire (complex) lexical entries or be a part of a lexical entry in the form of a tree template which can be called by all the different words which can fill the empty slots in the construction. See Findlay (2023) for a broader discussion of the connection between LFG and Construction Grammar, and for arguments that vanilla LFG is inadequate to give a satisfactory analysis of certain multiword (substantive) constructions.

Alongside these advantages of combining LFG and TAG, there remain some unexplored implications which are ripe for future work. Firstly, one of the parade examples of LFG's utility is in describing languages with highly flexible word orders, such as Warlpiri (see e.g. Bresnan et al. 2016: ch. 1). With TAG's focus on configurational properties, we need to ensure that incorporating a TAG into LFG does not undo its ability to describe these non-configurational languages. Given the flatter tree structures generally assumed for such languages (Simpson 1991, Austin & Bresnan 1996), a first pass solution in the present framework would be to simply make use of looser tree descriptions, which, for example, lack linear precedence relations between a verb and its arguments, so that the the entry for a verb does not describe a unique minimal tree, but rather several minimal trees which represent the different orderings of arguments. Of course, these different orderings are not just random, and actually correspond to different information structures, so simply allowing free choice between them is inadequate. Instead, we should once again make use of disjunction, this time between the descriptions corresponding to the different orderings of verb and arguments, where each of the different word orders is also accompanied by the correct information-structural annotations.

Such languages also often permit discontinuous constituents, and these will require their own solution. For example, some adjuncts might be represented not as auxiliary trees that induce a more articulated structure, but rather as simpler trees whose root merely unifies with another node, such as the clausal root S, adding the adjunct as a sister to the existing daughters. Obviously this sketch needs to be developed into a fully fleshed-out proposal before we can be confident that no analytical clout has been lost.

Another open question arises from the fact that using a TAG as the basis of the c-structure component means that we can employ adjunction to account for long-distance dependencies. This then removes a foundational motivation for functional uncertainty (Kaplan & Zaenen 1989), one of the major sources of formal complexity in LFG. Unfortunately, this does not mean we can simply remove functional uncertainty from the formalism, since it has been employed by researchers in various other domains beyond filler-gap dependencies – most notably in LFG's binding theory (e.g. Dalrymple 1993, Dalrymple et al. 2018). Determining whether these analyses can be reformulated so that functional uncertainty could be done away with altogether remains a task for future work, perhaps drawing on existing TAG analyses of binding (e.g. Ryant & Scheffler 2006, Champollion 2008, Storoshenko et al. 2008, Storoshenko & Han 2013).

Lastly, including a description of a tree which incorporates the full extended projection of a predicate in its lexical entry means that we can take a rather different view of argument structure. A predicate's arguments and the possibilities for their realisation can be encoded directly in its lexical entry, rather than relying on a separate level of representation like a-structure (on which see Findlay et al. 2023 [this volume]). And alternative argument realisations, e.g. diathesis alternations, can be expressed through disjunctive templates, as discussed above in parallel with XMG, rather than through a separate mechanism of mapping between a-structure and f-structure. Work on developing templatic approaches to argument structure include Asudeh & Giorgolo (2012), Findlay (2016, 2020), and Przepiórkowski (2017), but these do not take c-structure into account: with the new TAG perspective, the phrase-structural effects of argument structure/mapping phenomena can also be directly expressed.

8 Conclusion

Tree-Adjoining Grammar offers a rather different perspective on some grammatical phenomena from that of CFG-based formalisms.[34] For instance, it allows us to describe constraints on filler-gap relationships via the structure of the elementary trees in the grammar rather than via an independent principle like Subjacency. It also provides a natural account of the fact that many "lexical" items in fact incorporate several distinct word forms (e.g. phrasal verbs, compounds, idioms), and of constructional meaning, by virtue of its expanded concept of locality. And, computationally speaking, it possesses just the right degree

---

[34] TAG has also played an important role outside of theoretical linguistics – specifically in both computational linguistics (see e.g. Kallmeyer et al. 2008, Kasai et al. 2017, Koller 2017) and psycholinguistics (see e.g. Ferreira 2000, Ferreira et al. 2004).

of context-sensitivity to account for natural languages while remaining parsable in polynomial time. Nonetheless, its representation of dependency structures is imperfect, and its focus on the primacy of phrase structure leaves it somewhat impoverished when compared to the richly expressive parallel projection architecture of LFG, which facilitates a much fuller view of the grammar as a whole. Combining the two approaches might therefore offer a tempting opportunity to acquire the best of both worlds. In Section 7 we saw how this could be achieved, and the possibilities this affords for LFG, both in terms of descriptive power and in terms of potentially further-reaching formal or architectural changes.

Acknowledgements

Much of this work stems from my D.Phil. thesis (Findlay 2019), which was funded by a UK Arts and Humanities Research Council studentship (grant reference AH/L503885/1), and for which I am indebted to my fantastic supervisors, Ash Asudeh and Mary Dalrymple. The writing of this chapter was completed while I was employed under a Norwegian Research Council grant (number 300495, “Universal Natural Language Understanding”), which I gratefully acknowledge.

Appendix A:

Glossary

Mary Dalrymple
University of Oxford

↑ (‘UP’)	In an annotation on a daughter category in a phrase structure rule, the f-structure corresponding to the mother node. See Belyaev 2023c: 4.2 [this volume].
↓ (‘DOWN’)	In an annotation on a daughter category in a phrase structure rule, the f-structure corresponding to the daughter node on which the ↓ annotation appears. See Belyaev 2023c: 4.2 [this volume].
$\hat{*}$	In an annotation on a daughter node in a phrase structure rule, the mother node in the constituent structure tree. See Belyaev 2023c: 4.2 [this volume].
$*$	In an annotation on a daughter node in a phrase structure rule, the daughter node on which the $*$ annotation appears. See Belyaev 2023c: 4.2 [this volume].
$<*$	In an annotation on a daughter node in a phrase structure rule, the immediate left sister of the daughter node on which the annotation appears. See Belyaev 2023a: 4.2.1 [this volume].
$*>$	In an annotation on a daughter node in a phrase structure rule, the immediate right sister of the daughter node on which the annotation appears. See Belyaev 2023a: 4.2.1 [this volume].
←	In an off-path constraint, the f-structure immediately containing the feature on which the annotation appears. See Belyaev 2023a: 3.2.2 [this volume].

Mary Dalrymple. 2023. Glossary. In Mary Dalrymple (ed.), *Handbook of Lexical Functional Grammar*, 2127–2149. Berlin: Language Science Press. DOI: 10.5281/zenodo.10186056

$\rightarrow$ In an off-path constraint, the f-structure value of the feature on which the annotation appears. See Belyaev 2023a: 3.2.2 [this volume].

$>_f$ See Functional precedence.

$=_c$ See Constraining equation.

$\multimap$ See Linear implication.

$\wedge$ See Conjunction.

$|$ See Disjunction.

$\vee$ See Disjunction.

/ At the end of the list of daughters in a phrase structure rule: see 'Ignore' operator.

\ Following an f-structure reference: see Restriction.

_ After a symbol: see Instantiated symbol.

, (COMMA) Between daughter categories in a phrase structure rule: see ID/LP rule. Between sequences of categories enclosed by square brackets in a phrase structure rule: see 'Shuffle' operator.

ϕ PROJECTION The ϕ projection is a projection function from nodes of the constituent structure to their corresponding functional structures.

$^{-1}$ See Inverse correspondence function.

ϵ The empty string.

X^0 In X-bar theory, a zero-level or lexical category, usually a single word. For example, the noun *horse* is of category N^0, and can appear as the head of a phrase of category NP.

X' In X-bar theory, a single bar level category, projected from the X head.

$\widehat{X}$ See Non-projecting word.

A-STRUCTURE The linguistic representation of the information in argument structure.

ADJ The adjunct grammatical function. At functional structure, a feature whose value is a set of f-structures.

ADJUNCT CONTROL A construction in which a control relation holds between an argument in the matrix clause and an unexpressed argument in an adverbial subordinate clause. See Vincent 2023 [this volume].

ANAPHORIC CONTROL A control construction in which an argument of a matrix clause is required to corefer with the subject of a closed clause such as COMP. See Vincent 2023 [this volume].

ANNOTATED PHRASE STRUCTURE RULE A phrase structure rule in which the daughter categories are annotated with constraints on the functional structures and other levels of representation to which they correspond. See Belyaev 2023c: 4.2 [this volume].

ARGUMENT STRUCTURE A level of linguistic structure which represents the aspects of meaning that are relevant for determining the syntactic role of the argument of a predicate. Its representation is referred to as A-structure. See Findlay et al. 2023 [this volume] and, for a historical perspective, Booth & Butt 2023: 3.2 [this volume].

ATOMIC VALUES Feature values which have no internal structure, as opposed to complex values such as functional structures or semantic forms.

ATTRIBUTE See Feature.

ATTRIBUTE-VALUE MATRIX See Attribute-value structure.

ATTRIBUTE-VALUE STRUCTURE A structure containing attributes (features) and values, usually represented graphically as a list in which each line contains an attribute followed by its value, with the entire list enclosed in square brackets. Functional structure is generally represented as an attribute-value structure.

BACKWARD CONTROL A control construction in which the controller appears overtly in the embedded clause and the controlled argument is in the matrix clause. See Vincent 2023 [this volume].

BACKWARD RAISING A construction which shares all the distributional properties of a raising construction except that the embedded subject appears in the embedded clause and not in the matrix clause. See Vincent 2023 [this volume].

C See CP.

C-COMMAND A relation between nodes of the constituent structure tree. Several slightly different definitions of c-command have been proposed, but a commonly accepted one states that a node *n*1 c-commands a node *n*2 if and only if all of the nodes which dominate node *n*1 also dominate node *n*2.

C-PRECEDENCE The left-to-right precedence relation holding between nodes of the constituent structure tree. See Belyaev 2023a: 3.2.6 [this volume] and Rákosi 2023: 2.3 [this volume].

C-STRUCTURE See Constituent structure.

CAT PREDICATE A predicate relating a functional structure to the category labels of the constituent structure nodes that correspond to it via the inverse of the ϕ projection. CAT takes two arguments: an f-structure, and a set of constituent structure category labels. The CAT specification requires that at least one of the c-structure nodes corresponding to the specified f-structure has one of the labels in the set. For instance, assume that an f-structure f is related via the inverse ϕ correspondence to c-structure nodes labeled NP, N′, and N; in this case, all of the following predicates hold: CAT(f, {NP, N′, N}); CAT(f, {NP}); CAT(f, {NP, AP}). The CAT predicate is interpreted distributively and thus may help in describing unlike category coordination: if f is a set of f-structures representing a coordination, each f-structure in f must correspond to at least one node with a label in the set. For example, the specification CAT(f, {AP, PP}) allows f to correspond to a conjunction of APs, a conjunction of PPs, or a conjunction of unlike categories composed of APs and PPs. See Patejuk 2023 [this volume]. A related definition is sometimes assumed: in Belyaev 2023c [this volume], Bond 2023 [this volume], and Sadler 2023 [this volume], CAT is a function over f-structures, returning the set of labels of the c-structure nodes to which the f-structure corresponds. According to this definition, if f is related to c-structure nodes with categories NP, N′, and N, CAT(f)={NP, N′, N}.

CLAUSE-TYPE Feature whose value is the type of the clause. Typical values are DECL for declarative, IMP for imperative, and INT for interrogative. Sometimes as CLTYPE.

CLTYPE See CLAUSE-TYPE.

Codescription The simultaneous description of more than one level of linguistic structure, as opposed to description by analysis. See Belyaev 2023c: 5 [this volume].

(F-structure) Co-head At constituent structure, an X^0 node is an f-structure co-head with another X^0 node if both nodes correspond to the same functional structure.

Coherence The requirement that an f-structure may not contain governable grammatical functions that are not selected by the predicate (the semantic form value of the pred feature). See Belyaev 2023a: 3.4.3 [this volume].

comp A grammatical function typically associated with sentential complements.

Comp,X In constituent structure, the complement of X; that is, the non-head daughter of X′ which is sister to the head, X^0. See X-bar theory.

compform Feature whose value is the form of the complementizer, for example that or whether for English. Sometimes as comp-form, especially in the ParGram grammars.

Completeness The requirement that all governable grammatical functions required by the predicate (the semantic form value of the pred feature) must be present. See Belyaev 2023a: 3.4.2 [this volume].

Complex category A constituent structure category consisting of a category label (such as I, NP, or V′) and a set of features or parameters. For example, VP[fin] is a complex category, with category VP and parameter ‘fin’ for finite. See Booth & Butt 2023: 4.2 [this volume], and for an implementational perspective, Forst & King 2023: 2.2 [this volume].

Complex predicate A construction in which there is a mismatch in the number of predicates at functional structure and the number of forms at constituent structure which express them. See Andrews 2023b [this volume].

concat Built-in template in XLE taking two or more arguments. All arguments except the last one are concatenated, and the result is the final argument. For example, in @(CONCAT look ‘- up %FN) the first argument is ‘look’, the second argument is ‘-’ (which must be explicitly quoted with the back quote in XLE), the third argument is ‘up’, and %FN would be ‘look-up’.

concord Feature whose value is an f-structure containing certain agreement features, typically including the features gend, num, and case and their values. See Haug 2023a: 3 [this volume].

Configurational language See Configurationality.

Configurationality A language type in which grammatical functions are often or always associated with particular constituent structure positions. Also see Non-configurationality.

conj Feature whose value is the form of the conjunction in a coordinate phrase, for example and or or in English. Sometimes represented as conjform or conjtype.

conjform See conj.

conjtype See conj.

Conjunction of functional descriptions Conjunction of functional descriptions is usually implicit, but is sometimes represented as $\wedge$.

(Principle of) Conservation A general constraint on linguistic derivations that requires a bounded relationship between the amount of information (the sizes) of every pair of corresponding structures. This is a sufficient condition for the decidability of many important computational problems. See Kaplan & Wedekind 2023 [this volume].

Consistency The requirement for a feature to have exactly one value, and not more than one. See Belyaev 2023a: 3.4.1 [this volume].

Constituent structure The linguistic level representing word order and phrasal constituency, represented as a phrase structure tree. See Belyaev 2023c: 3 [this volume] and Andrews 2023a [this volume]; for a historical perspective, see Booth & Butt 2023: 4 [this volume].

Constrained lexical sharing A restricted theory of lexical sharing. See Booth & Butt 2023: 4.4 [this volume].

Constraining equation An equation that must hold of the minimal f-structure solution to all of the defining equations in a functional description. Constraining equations are distinguished from defining equations by the presence of a subscript *c* on the equals sign: $=_c$. See Belyaev 2023a: 3.2.2 [this volume].

Constructive case The view that case specifications on an argument determine its grammatical role. Formally, constructive case specifications are encoded by means of Inside-Out Functional Uncertainty. See Butt 2023 [this volume].

Control a) Structures in which an overt argument in one clause is partially or fully co-referential with and determined by an expressed argument in another clause, most commonly but not necessarily a higher clause. There are various sub-types: adjunct, backward, exhaustive, implicit, partial, split control. b) The mechanisms by which such structures are analysed, namely functional control, anaphoric control, quasi-anaphoric control. See Vincent 2023 [this volume].

Copy raising A construction in which the subject argument of an embedded predicate is realized as the grammatical subject of the matrix verb, and its place in the embedded clause is occupied by a pronominal copy, as in English *Sarah*$_i$ *seems like she*$_i$ *is asleep*. See Vincent 2023 [this volume].

Correspondence function A function which relates components of one level of linguistic structure to components of another level. For example, the ϕ projection is a correspondence function relating nodes of the constituent structure to functional structures.

CP Originally 'complementizer phrase', a constituent structure category. Now used for a phrase that consists of a full clause and possibly additional material such as a complementizer or a displaced phrase.

D Determiner. See DP.

Decidability theorems for LFG Decidability can be relevant for parsing, generation, or other properties of linguistic systems. For example, if the parsing problem for a linguistic system is decidable, it is possible to determine for any given sentence whether it is licensed (admitted) by a particular grammar of that system in a finite number of computational steps. If it is not always possible to make that determination, the parsing problem for that system is not decidable. The parsing problem for LFG has been shown to be decidable under certain constraints: the Nonbranching Dominance Constraint of earlier formulations has now been replaced by the linguistically more appropriate Proper Anchoring Condition. See Kaplan & Wedekind 2023 [this volume].

Defining equation An equation requiring an f-structure to contain a feature with a particular value. See Belyaev 2023c: 4.1 [this volume] and Belyaev 2023a: 3.2.1 [this volume]. Also see Constraining equation.

Description by analysis The description of one level of linguistic structure on the basis of properties of another level, as opposed to codescription. See Belyaev 2023c: 5 [this volume].

Differential object marking Non-uniform grammatical marking of objects. See Zaenen (2023) and Laczkó (2023).

Direct Syntactic Encoding, Principle of A principle stating that syntactic rules may not alter grammatical functions, originally proposed by Kaplan & Bresnan (1982). For example, according to the Principle of Direct Syntactic Encoding, passivization cannot be treated as a syntactic operation that converts an active clause into a passive clause by converting the object into a subject.

dis A grammatical function for displaced phrases, for example the displaced or fronted object in an example like *Who did you meet?*. Sometimes as op or udf. Also see Overlay function, and Kaplan 2023 [this volume] for discussion of an alternative analysis in terms of information structure.

Discourse configurationality A language type in which discourse functions are often or always associated with particular constituent structure positions. See Zaenen (2023), Booth & Butt (2023), and Laczkó (2023).

Disjunction A disjunction over functional descriptions or over sequences of categories on the right-hand side of a phrase structure rule is generally enclosed in curly brackets, with the options separated by a vertical line: ‘A or B or C’ is represented as {A|B|C}. Sometimes ∨ is used instead of the vertical line: {A∨B∨C}. If the scope of the disjunction is clear, the curly brackets are sometimes omitted.

Distributive/nondistributive feature If the value of a distributive feature is specified for a set of attribute-value structures, each structure in the set is required to have the specified value for that feature. If the value of a nondistributive feature is specified for a set of attribute-value structures, the set of f-structures as a whole has the specified value for the feature. The distributive/nondistributive distinction is relevant only when specifying the value of a feature for a set of attribute-value structures. See Haug 2023a [this volume].

DP Determiner phrase (a constituent structure category).

Economy of Expression A principle of competition among different potential constituent structure analyses for a sentence which allows only the smallest constituent structure analyses, and rules out larger structures.

Endocentricity A principle of phrasal organization which requires phrases of a particular phrasal category to contain a head of the same category. It is a central principle of X-bar theory. For growth of endocentric structure in historical change, see Booth & Butt 2023: 4.3 [this volume].

Equi A label for the class of control verbs in which the controlling argument has a semantic role with respect to both the matrix and the embedded predicate. This class is traditionally contrasted with raising verbs, in which the shared argument has a semantic role only in the embedded clause. See Vincent 2023 [this volume].

Evidentiality The linguistic marking of the nature of evidence for a given statement. See Laczkó (2023).

Exhaustive control Control constructions in which the embedded argument is coreferential with the controlling argument. See Vincent 2023 [this volume]. Also see Partial control.

Existential constraint A requirement for the presence of a feature in the minimal f-structure solution to all of the defining equations in a functional description, but with no constraints on the value of that feature. For example, the requirement for a clause to be tensed can be enforced by the existential constraint (f tense), which requires the f-structure f for the clause to contain the tense feature, without specifying a particular value for tense.

Exocentric category A phrasal category which does not contain a head in the sense of X-bar theory, but can be headed in the sense of the mapping from constituent structure to functional structure by a node of any category with annotation $\uparrow=\downarrow$. LFG assumes at least one exocentric category, the clausal category S. See Belyaev 2023a: 2.1 [this volume].

Extended Coherence Condition An extension of the Coherence condition which requires f-structures with non-argument roles such as dis, focus, or topic to be integrated into the f-structure by functionally or anaphorically binding an argument. See Kaplan 2023 [this volume].

Extended Head See (F-structure) co-head.

f-command There are several definitions of f-command. According to a commonly assumed definition, an f-structure $f1$ f-commands an f-structure $f2$ if $f1$ does not contain $f2$, and there is some f-structure g which immediately contains $f1$ and also contains $f2$. F-command is analogous to the c-command relation on constituent structure nodes.

f-description See Functional description.

f-precedence See Functional precedence.

f-structure See Functional structure.

Feature An attribute which has a value in an attribute-value structure. For example, the f-structure [tense pst] has the feature/attribute tense with value pst.

focus The new information contributed by a sentence, or the portion of a sentence which contributes the new information. At functional structure or information structure, the value of the focus feature is the linguistic material associated with the focus role. See Zaenen 2023 [this volume].

form Feature whose value is the form of a particular word. For example, weather verbs in English (such as *rain* or *snow*) require their subject to have the form *it*. To allow this requirement to be enforced, one of the lexical entries for *it* has the feature form with value it, and accordingly the verb *rain* requires its subject to include the feature form with value it.

Fragmentability of language A principle stating that incomplete fragments of utterances are able to be assigned partial syntactic and semantic analyses on the basis of their lexical and phrasal properties.

Function-Argument Biuniqueness A principle of alignment between the semantic roles and grammatical functions of a predicate, stating that no grammatical function can be associated with more than one semantic role, and no semantic role can be associated with more than one grammatical function.

Functional category A phrase structure category generally associated with closed-class function words. Commonly assumed functional categories are D/DP, C/CP, and I/IP. For the emergence of functional categories in historical change, see Booth & Butt 2023: 4.3 [this volume].

Functional control A control construction in which an argument of a matrix clause is also the subject of an open grammatical function such as XCOMP or XADJ. See Vincent 2023 [this volume].

Functional description A set of defining equations and constraining equations describing a set of linguistic structures and the relations among them. See Belyaev 2023c: 4.1 [this volume] and Belyaev 2023a: 3.2.1 [this volume].

Functional precedence A precedence relation holding between f-structures, defined in terms of the c-precedence relation at constituent structure. See Belyaev 2023a: 3.2.6 [this volume].

Functional structure The linguistic level representing grammatical functions such as subject and object, and grammatical features such as voice, person, number, and case. See Belyaev 2023c: 4 [this volume].

Functional uncertainty A type of constraint on the relation between two attribute-value structures which is stated in terms of a regular expression over a sequence of features. See Belyaev 2023a: 3.2.3 [this volume] and Kaplan 2023 [this volume]. Also see Inside-Out Functional Uncertainty.

Generation In LFG, the problem of finding the set of sentences that the grammar assigns to a particular functional structure, if the f-structure is realized by the grammar. Also see Realization.

GF Metavariable representing any grammatical function.

$\widehat{\text{GF}}$ The grammatical function borne by the thematically most prominent argument. See Belyaev 2023b [this volume].

GGF Metavariable representing any governable grammatical function.

Glue A theory of the syntax-semantics interface which expresses constraints on the combination of meanings via statements in a resource logic, Linear logic. See Asudeh 2023 [this volume].

Governable grammatical functions Governable grammatical functions are those which can be subcategorized, or required, by a predicate. The governable grammatical functions that are usually assumed are SUBJ, OBJ, OBJ_θ, COMP, XCOMP, and OBL_θ.

GRAMMAR WRITER'S WORKBENCH A computational grammar development platform for LFG, developed in the 1980s and 1990s at the Xerox Palo Alto Research Center. See Forst & King 2023: 1.1.3 [this volume].

GRAMMATICAL FUNCTION HIERARCHY An ordering of grammatical functions, with SUBJ at the top of the hierarchy, followed by OBJ and OBL_θ. See Belyaev 2023b [this volume].

GWW See Grammar Writer's Workbench.

I See IP.

ID/LP RULE A phrase structure rule in which precedence relations are specified separately from mother-daughter relations: an ID (Immediate Dominance) rule specifies the permissible daughters of a mother node, and an LP (Linear Precedence) rule specifies the permissible order among the daughters. In an ID rule, the daughters are separated by commas.

'IGNORE' OPERATOR (/) In a phrase structure rule, the Ignore operator is written as a forward slash at the end of the rule, and is followed by the Ignore category sequence. Such a rule licenses any number of instances of the Ignored category sequence, interspersed at any position among the specified daughter nodes. For example, the rule 'VP⟶ [V NP]/AdvP' (VP dominates V and NP, ignoring AdvP) is a shorthand for 'VP⟶ AdvP* V AdvP* NP AdvP*' (using the Kleene star '*'), allowing VP to dominate any sequence of categories containing V and NP, and also any number of AdvPs in any position.

IMPLICIT CONTROL Structures in which a missing argument is inferred from the extrasentential context rather than being determined within the clause by a controlling argument. See Vincent 2023 [this volume].

INDEX Feature whose value is an f-structure containing the INDEX feature bundle, typically including the features PERS, NUM, and GEND and their values. See Haug 2023a: 3 [this volume].

INFORMATION STRUCTURE The linguistic level representing how linguistic information is structured for presentation in a particular context, distinguishing old from new information, focused from background information, and other distinctions. See Zaenen 2023 [this volume] and, for historical change, Booth & Butt 2023: 4.5.2 [this volume].

Inside-out functional uncertainty A type of constraint on the relation between two attribute-value structures, stated in terms of a regular expression, and specified in terms of the position of the more embedded of the two attribute-value structures. See Belyaev 2023a: 3.2.3 [this volume].

Instantiated symbol A feature value which can be instantiated only once. A well-formed functional description may not contain more than one equation specifying an instantiated value. Notationally, an instantiated symbol ends with an underscore: X_.

int Interrogative. Sometimes as inter.

Inverse correspondence function The inverse of a function α, written α^{-1}, reverses the argument and result of α. For example, the ϕ projection is a function from c-structure nodes to f-structures, and the inverse ϕ^{-1} projection is a relation between f-structures and the c-structure nodes to which they correspond.

IP Originally 'inflection(al) phrase', a constituent structure category. Now used for a clausal constituent. Also see CP.

Kleene star (*) In a regular expression, an operator that allows repetition of a string zero or more times.

KP 'Case phrase', consisting of a nominal phrase with a case clitic (a constituent structure category. See Belyaev 2023a: 2.1 [this volume].

LDD See Unbounded dependency.

Lexemic Index (LI) A unique identifier associated with a morphological root in the lexicon. See Asudeh & Siddiqi 2023 [this volume].

Lexemic entry An entry in the lexicon specifying the form of a root morpheme, any non-predictable morphological alternations, the syntactic, semantic, and other information associated with the root, and a lexemic index for the root. See Asudeh & Siddiqi 2023 [this volume].

Lexical (redundancy) rules Rules stating generalizations over classes of lexical items.

Lexical Integrity Principle The principle that the properties of words are established in the lexicon, and cannot be modified in the course of syntactic derivation. See Belyaev 2023a: 2.2 [this volume] and Asudeh & Siddiqi 2023 [this volume].

Lexical Mapping Theory A version of Mapping Theory which assumes that the relation between argument roles and grammatical functions is established in the lexicon. See Findlay et al. 2023 [this volume].

Lexical Sharing The view that a single word can be dominated by more than one node in the Constituent structure tree. See Belyaev 2023a: 5.2.2 [this volume] and, for a historical perspective, Booth & Butt 2023: 4.4 [this volume].

Lexicalist Hypothesis See Lexical Integrity Principle.

LFG-DOP A hybrid grammatical model combining LFG and Data-Oriented Parsing. See Cahill & Way 2023 [this volume].

Linear implication A linear logic connective similar to implication, written as ⊸. See Asudeh 2023 [this volume].

Linear logic A resource logic in which each premise is a resource which can be used only once. See Asudeh 2023 [this volume].

Linking rules See Lexical Mapping Theory.

LMT See Lexical Mapping Theory.

Local name A name used to refer to a particular f-structure in a functional description. The reference of the local name is restricted to the functional description in which it appears. A local name begins with a percent sign, %. See Belyaev 2023a: 3.2.5 [this volume].

Logical subject The most prominent argument of a predicate at argument structure.

Long-distance dependency See Unbounded dependency.

Macro A macro is used in capturing generalizations across phrase structure rules. It associates a name with a sequence of annotated constituent structure categories. As with templates, a call to a macro is preceded by an ‘at’ sign, @.

Mapping Theory The theory of the relation between argument structure and functional structure roles. See Findlay et al. 2023 [this volume] and, for a historical perspective, Booth & Butt 2023: 3.2 [this volume].

Maximal projection In X-bar theory, the XP level. LFG often assumes a two-level version of X-bar theory in which XP = X″.

Meaning constructor In the glue theory of the syntax-semantics interface, a complex expression with two parts: one part expresses a linguistic meaning, and the other part is an expression of linear logic expressing how the meaning combines with other meanings in semantic composition. See Asudeh 2023 [this volume].

Minimal Complete Nucleus Relative to a designated f-structure f, the smallest f-structure which properly contains both f and a PRED feature. The minimal complete nucleus is often assumed to be relevant for specification of anaphoric binding constraints: see Rákosi 2023 [this volume].

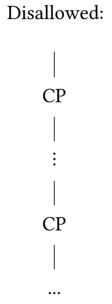
Minimal Finite Domain Relative to a designated f-structure f, the smallest f-structure which properly contains both f and a feature specifying a value for the TENSE feature. The minimal finite domain is often assumed to be relevant for specification of anaphoric binding constraints: see Rákosi 2023 [this volume].

Morphological Blocking Principle A principle stating that the existence of a more specified form blocks the use of a less specified form. See Asudeh & Siddiqi 2023 [this volume] and Kuhn 2023 [this volume].

N Noun. See NP.

Negative existential constraint A constraint forbidding the appearance of a feature in an attribute-value structure. For example, the constraint $\neg(f$ TENSE$)$ prevents the f-structure f from having an attribute TENSE with any value.

Nonbranching Dominance Constraint A constraint disallowing constituent structure trees in which two nodes of the same category dominate the same terminal substring, as in the illustration. This constraint is sufficient to ensure decidability of LFG parsing, but is not sufficient to ensure decidability of LFG generation. The stronger principles of Conservation and Proper Anchoring guarantee decidability of both computational problems. See Kaplan & Wedekind 2023 [this volume].



Non-configurationality Refers to a language type in which grammatical functions are not associated with particular constituent structure positions, but can often be identified via agreement and/or casemarking. Also see Configurationality.

Nondistributive feature See Distributive/nondistributive feature.

Non-projecting word A word that does not project a larger phrase and so cannot have a phrase structure complement or specifier. Non-projecting words of category X are annotated with a circumflex, as $\widehat{\mathrm{X}}$. See Belyaev 2023a: 2.1 [this volume].

Nonthematic argument An argument that is not assigned a semantic role. In English, the pleonastic/‘dummy’ subject *it* of a weather verb like *snow* is a nonthematic argument, as is the raised argument of a raising verb like *seem*.

NP Noun phrase (a constituent structure category).

nsem Feature whose value is a bundle of syntactically relevant semantic features of nouns and noun phrases. Used in ParGram grammars. The value of this feature is an f-structure with features common, number-type, proper, time.

nsyn Feature whose value is a bundle of syntactic features of nouns and noun phrases. Used in ParGram grammars. The value of this feature is an f-structure with features common, pronoun, proper.

ntype Feature whose value is an f-structure containing the set of syntactic and semantic features of nouns and noun phrases. Used in ParGram grammars. The value of this feature is an f-structure with two features, nsyn and nsem.

$\pm o$ ‘Objective’ (object-like) feature cross-classifying grammatical functions. The objective grammatical functions obj, obj2, obj$_\theta$ are $+o$, and the non-objective grammatical functions subj, obl$_\theta$ are $-o$. Used in Mapping Theory (see Findlay et al. 2023 [this volume]).

obj The grammatical function borne by (primary) objects.

obj$_\theta$ The grammatical function borne by thematically restricted objects.

obj2 The grammatical function borne by secondary objects.

obl$_{\text{agent}}$ The grammatical function borne by oblique agent phrases.

Oblique argument An argument of a predicate which is marked by an adposition or by casemarking marking a particular semantic role. See Belyaev 2023b: 3.5.2 [this volume].

obl$_{\theta}$ The family of oblique grammatical functions associated with particular semantic roles: for example, obl$_{\text{agent}}$.

OCR Optical character recognition: converting an image of text into the corresponding text.

Off-path constraint A constraint on a feature which specifies required properties of the f-structure containing the feature, or of the f-structure value of the feature. See Belyaev 2023a: 3.2.2 [this volume] and Kaplan 2023 [this volume].

op See dis.

Open grammatical function Grammatical function corresponding to a phrase which does not contain an internal subj, and whose subject is functionally controlled by an external argument. The open grammatical functions that are usually assumed are xcomp and xadj. See Vincent 2023 [this volume].

OT-LFG Optimality Theoretic LFG, a hybrid grammatical model combining LFG and Optimality Theory. See Kuhn 2023 [this volume] and, for a perspective from historical change, Booth & Butt 2023: 5 [this volume].

Overlay function A secondary grammatical function which may be borne by an argument. Overlay grammatical functions are sometimes associated with discourse functions such as focus or topic.

P Preposition or postposition. See PP.

ParGram A consortium of grammar development efforts by industrial and academic institutions, with the aim of producing computational LFG grammars for a typologically diverse set of languages, written under a commonly-agreed set of linguistic assumptions. ParGram grammars are written using the XLE grammar development platform. See Forst & King 2023: 3 [this volume].

Parsing In LFG, the problem of finding the set of functional structures that the grammar assigns to a particular sentence, if the sentence is recognized by the grammar. Also see Generation.

Partial control Control constructions in which the reference of the controlled argument includes but is not restricted to the controlling argument. See Vincent 2023 [this volume]. Also see Exhaustive control.

passive Feature encoding voice. When this feature appears, its value is + if its clause is passive, and either − or absent if its clause is not passive. A common alternative is to encode voice via a voice feature with values such as active or passive.

pcase Feature encoding the grammatical function borne by a prepositional phrase, as required by the preposition. For example, the English preposition *to* is associated with the oblique goal function, so it would contribute a pcase feature with value OBL_{GOAL}.

Phrase structure rule A rule specifying well-formed phrase structure configurations involving a mother node and its daughters. In LFG, the right-hand side of a phrase structure rule is a regular expression. See Belyaev 2023c: 3 [this volume].

pivot (grammatical function) A grammatical function which plays a role in connecting its clause to other clauses. pivot is often assumed to be an overlay function.

poss (grammatical function) The grammatical function borne by possessors in a nominal phrase.

PP Prepositional or postpositional phrase (a constituent structure category).

pred The f-structure feature whose value is a semantic form. See Belyaev 2023a: 3.3.4 [this volume].

predlink (grammatical function) The grammatical function of a predicative complement. The English verb *be* is sometimes analyzed as taking as its arguments a subj and a predlink.

Priority union (/) An operation that combines two attribute-value structures, with one of the structures having a distinguished status: the priority union of f with g, where f is the distinguished structure, is written as f/g. The features of the resulting structure are the union of the features in f and g, and the value of each feature a in the resulting structure is the value of a in f if it exists, and otherwise the value of a in g (in cases of conflict, the distinguished structure 'wins'). Unlike unification, priority union does not fail.

Projection architecture Levels of linguistic representation and the relations among them. See Belyaev 2023c: 5 [this volume].

Projection function A projection function relates components of one level of structure to components of another level. For example, the ϕ projection is a function relating c-structure nodes to their corresponding f-structures.

Proper Anchoring Condition A specific, easily computable condition on strings, constituent structures, and functional structures that guarantees that they satisfy the bounding requirement of Conservation. See Kaplan & Wedekind 2023 [this volume].

Proto-Role argument classification A classification of roles at argument structure which distinguishes roles in terms of their agent-like or patient-like properties. See Findlay et al. 2023 [this volume].

Quasi-anaphoric control A control construction in which an argument of the matrix clause co-refers with the subject of the embedded clause but where the connection is defined in semantic rather than syntactic terms. See Vincent 2023 [this volume]. Also see Anaphoric control.

$\pm r$ (mapping feature) 'Restricted' feature cross-classifying grammatical functions. The (thematically) unrestricted grammatical functions subj, obj are $-r$, and the restricted grammatical functions obj_θ, obl_θ are $+r$. Used in some versions of Mapping Theory (see Findlay et al. 2023 [this volume]).

Raising A construction in which the subject argument of an embedded predicate is realized as the grammatical subject or object of a matrix predicate, but does not receive a semantic role from the higher predicate. The term is still widely used as a descriptive label even when, as in LFG, the argument in question is not thought to have undergone a syntactic movement process. See Vincent 2023 [this volume].

Realization In LFG, the problem of determining whether there exists at least one sentence that is assigned to a given f-structure by a given LFG grammar. Also see Generation.

Recognition The problem of determining whether a given sentence belongs to the language of a grammar. Also see Parsing.

Re-entrancy See Structure sharing.

Regular expression An expression that allows the combination of regular predicates via disjunction, conjunction, or negation. A regular expression describes a *regular language*. The right-hand side of a phrase structure rule in LFG is a regular expression; see Belyaev 2023c: 3 [this volume]. Regular expressions are also used in the encoding of functional uncertainty.

Regular predicate An expression that can include disjunction, optionality (via parentheses), and unbounded repetition (via the Kleene star). In LFG, regular predicates can also include operators such as the 'Ignore' operator and the 'Shuffle' operator.

Restricted grammatical functions (OBJ_θ, OBL_θ) See $\underline{+}r$.

Restriction (\) In a functional description, the Restriction operator is written as an f-structure reference, followed by a backslash, followed by one or more features: for example, $f\backslash_{\text{SUBJ}}$ refers to the f-structure f with the attribute SUBJ and its value restricted out. The f-structure $f\backslash_{\text{SUBJ}}$ has all of the features and values of the f-structure f except for the feature SUBJ and its value, which may then be specified differently from the value of SUBJ in f.

Resumption A construction involving an unbounded dependency containing a resumptive pronoun.

Resumptive pronoun A pronoun which participates in an unbounded dependency and is bound by an overlay function. See Sadler 2023 [this volume].

S The clausal category S is exocentric, meaning that it has no head. See Belyaev 2023a: 4.3.5 [this volume].

Semantic form Value of the PRED feature at functional structure, encoding syntactic predicate-argument structure. A semantic form consists of the name of the predicate and its arguments, with thematic arguments enclosed in angled brackets, and nonthematic arguments outside the angled brackets. A semantic form is instantiated to a unique value on each occasion of use of the word or construction which contributes it. See Belyaev 2023a: 3.3.4 [this volume].

‘Shuffle’ operator (,) In a phrase structure rule, the ‘shuffle’ operator indicates that two sequences of daughters can be interspersed. Each sequence is enclosed by square brackets, and the two sequences are separated by a comma. For example, the rule ‘S $\longrightarrow$ [XP1 XP2], [XP3 XP4]’ licenses any order of the four daughters XP1, XP2, XP3, XP4 as long as XP1 precedes XP2, and XP3 precedes XP4. See ID/LP rule.

Spec,XP In constituent structure, the specifier of XP; that is, the non-head daughter of XP which is sister to the head X′. Also see X-bar theory.

Split control A control construction in which two different matrix arguments taken together provide the antecedent for the unexpressed subject argument of an embedded clause. See Vincent 2023 [this volume].

Structure sharing The situation when two features in an attribute-value structure share the same value. See Belyaev 2023c: 4.4 [this volume].

Structure-Function Mapping A general term for the mapping between structure (in LFG, usually constituent structure) and syntactic function (in LFG, usually functional structure).

subj The grammatical function borne by subjects.

Subject Condition The requirement for clausal functional structures to contain a subj. See Belyaev 2023b: 4.2 [this volume].

Subject, logical See Logical subject.

Subsumption An f-structure f subsumes an f-structure g ($f \sqsubseteq g$) if all of f’s features and values are also in g. Notably, g may contain additional features that are not present in f. For example, if f is the structure $\begin{bmatrix} a & b \\ c & d \end{bmatrix}$ and f subsumes g, then g contains the feature a with value b and the feature c with value d, and may also contain additional features and values.

Template A template associates a name with a set of constraints, and allows that name to be used to represent those constraints. See Belyaev 2023a: 5.1 [this volume].

Thematic argument An argument of a predicate which is associated with a semantic role.

TOPIC (grammatical function) A grammatical function associated with the information structure role of topic. When it is assumed, TOPIC is usually analyzed as an overlay function.

UD (UNIVERSAL DEPENDENCIES) A system for annotating grammatical functional dependencies. See Haug 2023b [this volume].

UDF See DIS.

UNBOUNDED DEPENDENCY A potentially unbounded relation between a displaced constituent and the position normally associated with its syntactic role. See Kaplan 2023 [this volume].

UNIFICATION ($\sqcup$) An operation that combines two attribute-value structures. If the structures are compatible, the resulting structure contains all of the structure from both of the input attribute-value structures. If the structures are not compatible, unification fails. There is a straightforward relation between unification and conjunction of descriptions: if f-structure $f1$ satisfies a description $d1$, and $f2$ satisfies a description $d2$, then if $d1$ and $d2$ are consistent, $f1 \sqcup f2$ satisfies $d1 \cup d2$.

UNIQUENESS See Consistency.

V Verb. See VP.

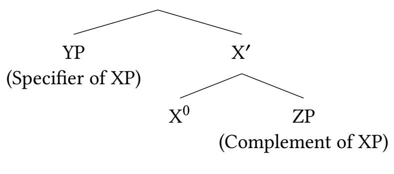
VERBAL MODIFIERS (VMS) A categorially heterogeneous group of constituents that must occupy the immediately preverbal position in neutral sentences in some Finno-Ugric languages. See Laczkó (2023).

VFORM Feature whose value specifies the form of a verb, for example PPART for past participle. Also see VTYPE.

VP Verb phrase (a constituent structure category).

VTYPE Feature whose value specifies verb type. Typical values are FIN for finite, INF for infinitive, and PST.PTCP for past participle.

X-BAR THEORY A theory of the organization of constituent structure. Many LFG analyses assume the version of X-bar theory that is depicted in the figure, ignoring linear order (that is, the specifier may precede or follow the X′ head, and the complement may precede or follow the X head. See Belyaev 2023a: 2.1 [this volume].



xadj The open grammatical function borne by adjunct phrases.

xcomp The open grammatical function borne by complement phrases.

xcomp-pred (grammatical function) A grammatical function for a non-verbal open grammatical function. Used in ParGram.

XLE A computational grammar development platform for LFG, developed at the Xerox Palo Alto Research Center. See Forst & King 2023: 1.1.3 [this volume].

Handbook of Lexical Functional Grammar

Lexical Functional Grammar (LFG) is a nontransformational theory of linguistic structure, first developed in the 1970s by Joan Bresnan and Ronald M. Kaplan, which assumes that language is best described and modeled by parallel structures representing different facets of linguistic organization and information, related by means of functional correspondences. This volume has six parts. Part I, *Overview and introduction*, provides an introduction to core syntactic concepts and representations. Part II, *Grammatical phenomena*, reviews LFG work on a range of grammatical phenomena or constructions. PartIII, *Grammatical modules and interfaces*, provides an overview of LFG work on semantics, argument structure, prosody, information structure, and morphology. Part IV, *Linguistic disciplines*, reviews LFG work in the disciplines of historical linguistics, learnability, psycholinguistics, and second language learning. Part V, *Formal and computational issues and applications*, provides an overview of computational and formal properties of the theory, implementations, and computational work on parsing, translation, grammar induction, and treebanks. Part VI, *Language families and regions*, reviews LFG work on languages spoken in particular geographical areas or in particular language families. The final section, Comparing LFG with other linguistic theories, discusses LFG work in relation to other theoretical approaches.
