Editor's Notes

This is the first volume of two-volume Proceedings of the 14th International Congress on Mathematical Education, held in Shanghai, China, from July 11−18, 2021.

This volume begins with the opening ceremony and ends with the closing ceremony. They are the procedural contents of the Congress.

Opening Ceremony: My host words introduce and connect the main procedures of the opening ceremony, but we separately include the speeches/addresses of some attenders of the ceremony (government officials and heads of relevant academic groups). The second half of the opening ceremony is the presentation of ICMI Awards (Felix Klein awards and Hans Freudenthal Awards of 2017 and 2019, as well as Emma Castelnuovo Award of 2020) chaired by Frederick Leung, the President of the International Commission on Mathematical Instruction. Although there were no awardees present on site to receive the awards, we still include citations for all awardees and their acknowledgements from the pre-recorded videos.

Closing Ceremony: The Local Organizing Committee introduced the basic situation of the preparation and convening of ICME-14. Then the Executive Committee of ICMI gave reports on ICMI EC's work and changes over the five years since ICME-13. As a routine action, the Convenor of the 15th International Congress on Mathematical Education delivered the welcome speech. Finally, I made closing remarks to thank all the people who offered help and support from bidding to organizing the 14th International Congress on Mathematical Education.

Except for these two procedural contents, all contents in this book are academic in nature. They are

Plenary Lectures: There are four plenary lectures in which speakers share their understanding, practices, and research outcomes with the audience in the field of mathematics and mathematics education. Full texts of these lectures are included, with one transcribed based on the recorded video during the lecture.

Plenary Panels: Three panels involve researchers discussing and debating on topics regarding current challenges facing mathematics educators around the world. Especially in the context of the COVID-19 pandemic, a related panel was designed and added to the Congress program, exploring the challenges, responsibilities, and roles faced by mathematics and mathematics education. These full-length individual reports are included in this volume.

Lectures of Awardees: Five lectures were delivered, representing Felix Klein Award and the Hans Freudental Award of 2017 and 2019, and the Emma Castelnuovo

Award of 2020 respectively. Full texts of these lectures are included, with one transcribed based on the recorded video.

Survey Teams: Four pre-established survey teams conducted their investigation and research on their designated themes before the Congress, and presented their work results brilliantly on the Congress. The full-length survey reports are included in this volume.

Topic Study Groups: The International Program Committee of the Congress designed 62 Topic Study Groups, the largest number in history of ICME's. Participants actively submitted papers/posters. Unfortunately, we do not have enough space to showcase the papers/posters of contributors. Instead, we only include a summary of each TSG provided by the organizers.

Discussion Groups: These are activities designed and organized by the participants themselves, which can to some extent reflect academic concerns. Thirteen discussion groups worked out their succinct reports.

Workshops: These are also participants' self-organized activities. Twenty reports covering a wide range of topics in mathematics education are included.

Thematic Afternoon: This is designed as an event that showcases local mathematics education practices from multiple perspectives. There are a total of thirteen activities presenting mathematics education with Chinese characteristics. An overview of these activities is included.

Early Career Researcher Day: This program was initiated in the 13th International Congress on Mathematical Education. This event is not part of but is attached to an ICME. It aims at providing early career researchers with opportunities to develop their research competencies and establish their contacts with international academic networks. We include in this volume an overview about the Early Career Researcher Day on ICME-14, introducing its general aims, focuses and activities.

The above describes the main contents of this volume.

Invited Lectures of ICME-14 will appear in Volume II of the proceedings, while National Presentations will not be included in the proceedings.

The Opening Ceremony

Opening Address and Host Words

Jianpan Wang[1]

Distinguished Guests,
Dear Participants, on-site and online,
Ladies and Gentlemen,

I'm Jianpan Wang, the Congress Chair and the Chair of International Program Committee (IPC) of the 14th International Congress on Mathematical Education (ICME-14). First of all, on behalf of the International Program Committee and the Local Organizing Committee (LOC) of ICME-14, I'd like to extend warm welcome and best regards to all the guests present in the hall and the participants both on-site and online!

Fig. 1. Prof. Jianpan Wang presided over the opening ceremony of the 14th International Congress on Mathematical Education

[1] Professor, East China Normal University; Chair of the 14th International Congress on Mathematical Education. E-mail: jpwang@admin.ecnu.edu.cn.

Please allow me to introduce some distinguished guests to you.

Mr. Qiang Li, Secretary of Communist Party of China (CPC) Shanghai Committee[2],

Ms. Tiehui Weng, Vice Minister of the Ministry of Education of the People's Republic of China,

Mr. Shaoliang Yu, Vice Secretary of CPC Shanghai Committee[3],

Mr. Yujie Zhuge, Secretary General, CPC Shanghai Committee[4],

Mr. Frederick Leung, President of the International Commission on Mathematical Instruction (ICMI),

Mr. Gang Tian, President of Chinese Mathematical Society, and

Mr. Xuhong Qian, President of East China Normal University (ECNU).

Mr. Carlos Kenig, President of International Mathematical Union (IMU) and Mr. Jinpeng Huai, Executive Vice President of China Association of Science and Technology[5], cannot make it to be present for some reason, but they sent us their address for the Congress.

Let's welcome all the distinguished guests with warm applause!

Fig. 2. A glance at the on-site venue

The 14th International Congress on Mathematical Education (ICME-14), originally set to be held in 2020, would have been a perfect chance for fellow scholars of mathematics education all over the world to visit China, an ancient country with vitality, and Shanghai, a city in which East meets West, tradition blends with modernity, and art integrates perfectly with technology.

Unfortunately, as a result of the COVID-19 pandemic, many participants miss the

[2] Mr. Qiang Li is currently the Premier of the State Council of the People's Republic of China.
[3] Mr. Shaoliang Yu is currently the chief editor of the *People's Daily*.
[4] Mr. Yujie Zhuge is currently Vice Secretary of CPC Hubei Committee.
[5] Mr. Jinpeng Huai is currently the Mister of Education of the People's Republic of China.

opportunity to visit this wonderful city, and the Congress, after a whole year's delay, has to adopt a hybrid mode of participation to ensure the health for all. However, we've overcome the challenges of physical distance and time difference, we meet here as scheduled from all over the world at the call of our common dream and mission of mathematics education. I believe, with your strong support and active participation, this Congress will surely become a memorable chapter in the history of international mathematics education regardless of the twists and turns we've left behind.

Now, let's welcome the Secretary of CPC Shanghai Committee Mr. Qiang Li to give a speech.

[Mr. Qiang Li gives his address (Fig. 3).

Fig. 3. Mr. Qiang Li gave an opening address at the Congress

Thank you, Mr. Li. I'd like to extend our sincere thanks to Mr. Qiang Li for his great attention to and support for the Congress during the preparation period, and to Shanghai government, particularly the education and foreign affairs departments, for the consistent help and support.

Now let's welcome the Executive Vice President of China Association of Science and Technology, Mr. Jinpeng Huai to give a speech (Fig. 4). Mr. Huai was supposed to be at the Congress in person, but unfortunately, he was not able to make it due to a business trip. Instead, he sent us a video of his speech.

[Mr. Jinpeng Huai's prerecorded speech is broadcasted (Fig. 4).

Fig. 4. Mr. Jinpeng Huai's video speech at the Congress

Thank you, Mr. Huai.

Vice Minister of the Ministry of Education, Ms. Tiehui Weng, has a close relationship with ICME-14. In 2015, Ms. Weng, then vice mayor of Shanghai, received the investigation group of International Commission on Mathematical Instruction while the group was making an investigation in Shanghai. Now let's welcome Ms. Tiehui Weng to give a speech.

[Ms. Tiehui Weng delivers her speech (Fig. 5).
[Full transcript of Ms. Weng's speech can be found on page 11.

Fig. 5. Ms. Tiehui Weng delivered a congratulatory speech at the Congress

Thank you, Ms. Weng.

Let's welcome the President of International Mathematical Union, Mr. Carlos Kenig to give a speech. International Mathematical Union is the super organization of International Commission on Mathematical Instruction. Mr. Carlos Kenig would have been present today in the Congress if it were not for the COVID-19 pandemic. Now we can only watch the video of his speech.

[Mr. Carlos Kenig's prerecorded speech is broadcasted (Fig. 6).
[Full transcript of Mr. Kenig's speech can be found on page 14.

Fig. 6. Mr. Carlos Kenig's video address at the Congress

Thanks a lot to Mr. Kenig.

Now, let's welcome the President of the International Commission on Mathematical Instruction, Mr. Frederick Leung to give a speech.

[Mr. Frederick Leung delivers his speech (Fig. 7).
[Full transcript of Mr. Leung's speech can be found on page 16.

Fig. 7. Mr. Frederick Leung delivered a welcome address at the Congress

Thank you, Mr. Leung.

The Chinese Mathematical Society represents China in the International Commission on Mathematical Instruction, and it is the main body in the bidding of ICME-14. In the past six years beginning from the bidding of ICME-14, Chinese

Mathematical Society has been through three sessions of councils, and all the three sessions have given us strong leadership and firm support. Now let's welcome President Gang Tian of Chinese Mathematical Society to give a speech.

[Mr. Gang Tian delivers his speech (Fig. 8).

[Full transcript of Mr. Tian's speech can be found on page 18.

Fig. 8. Mr. Gang Tian delivered a welcome address at the Congress

Thank you, Mr. Tian.

East China Normal University (ECNU) is the host of the Congress. It is the tremendous support of ECNU that makes this Congress possible. Let's welcome President Xuhong Qian of ECNU to give a speech.

[Mr. Xuhong Qian delivers his speech (Fig. 9).

[Full transcript of Mr. Qian's speech can be found on page 20.

Fig. 9. Mr. Xuhong Qian gave a welcome address at the Congress

Thank you, Mr. Qian.

Distinguished guests,
Dear participants on-site and online,
Ladies and gentlemen,

Now we're going to solemnly welcome the flag of ICME-14 (Fig. 10).

Fig. 10. Display the ICME-14 flag

After the success of our bidding for ICME-14, the Local Organizing Committee designed the logo and flag of the Congress, and displayed and introduced them at ICME-13 held in Hamburg, Germany in 2016. The flag we're going to welcome today is exactly the one we displayed in Hamburg, on which many mathematics educators left their precious signatures.

Thank you, young ladies.

Now, I'd like to invite

Ms. Tiehui Weng, Vice Minister of the Ministry of Education of the People's Republic of China,
Mr. Shaoliang Yu, Vice Secretary of CPC Shanghai Committee,
Mr. Frederick Leung, President of the International Commission on Mathematical Instruction,
Mr. Gang Tian, President of Chinese Mathematical Society, and
Mr. Xuhong Qian, President of East China Normal University

to come over to the stage. Let's push the rod start countdown, and declare the opening of the 14th International Mathematical Education Congress (Fig. 11).

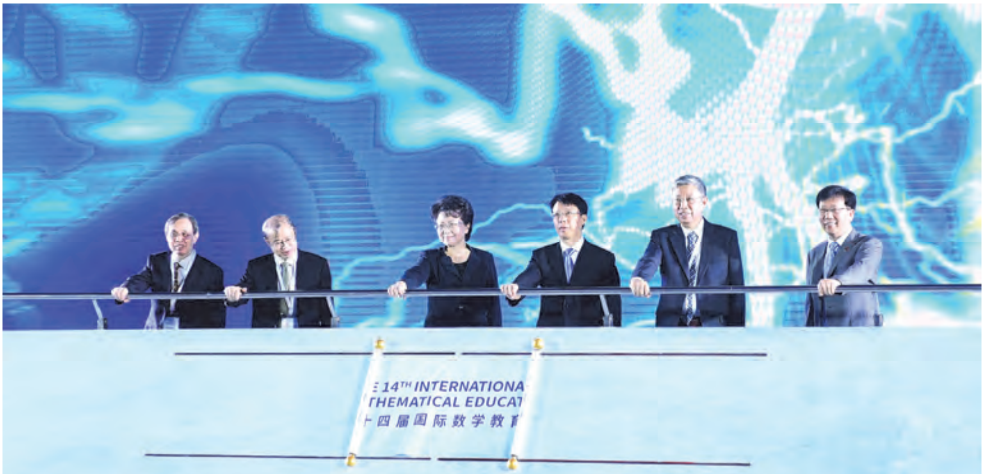

Fig. 11. Pushing the rod to declare the opening of the 14th International Mathematical Education Congress

From left: Jianpan Wang, Frederick Leung, Tiehui Weng, Shaoliang Yu, Gang Tian, Xuhong Qian

https://doi.org/10.1142/9789811287152_0002

The Opening Ceremony

Congratulatory Remarks from Ministry of Education

Tiehui Weng[1]

Honorable Mr. Qiang Li, Secretary of CPC Shanghai Municipal Committee,
Honorable Mr. Carlos Kenig, President of International Mathematical Union,
Professor Fredrick Leung, President of ICMI,
Professor Jianpan Wang, and
Mr. Gang Tian, President of Chinese Mathematical Society,
Dear guests,

In 2015, China succeeded in bidding for the 14th International Congress on Mathematical Education after years of considerable preparations and tiding over the Covid-19 pandemic as a major challenge. Today the Congress is successfully convening at the East China Normal University.

On behalf of the Ministry of Education, People's Republic of China, I would like to take this opportunity to extend warm congratulations at the convening of the Congress and send heart-felt regards to participants both online and on-site.

Recently, China has attached great importance to the international exchanges in the sector of mathematics education. The launching of the Congress serves as an important platform for the International Mathematical Education Committee to have reflections, learnings and plans for the future, which is of great significance. I would like to take this opportunity, based on my pragmatic work and reflections to share with you the ideas from the following four perspectives.

Firstly, to lay a solid foundation and to allow the crystal of mathematics to bloom. Mathematics is the manifestation of human civilization. The famous Chinese mathematician Shiing-Shen Chern once said "No matter how complex the world is, everything can be handled by addition, subtraction, multiplication and division. No matter how huge is universe is, points, lines and planes involve in everything". For teenagers, the significance of learning mathematics well not only lies in the good command of basic knowledge, but also allows them to sufficiently perceive the marvel of number and space, the wonder of the combination of sciences and arts, the secrecy of the combination of simplicity and complexity, to learn to identify clues from the seemingly different sources and to develop vertical thinking and logic reasoning for

[1] Vice Minister of the Ministry of Education of the People's Republic of China

the life benefit. We would sufficiently dig the rational beauty, natural beauty and exploration beauty of mathematics so as to pave the way for more excellent teenagers and inspire top talents to contribute and dedicate to mathematics along their journey to perceive and enjoy the beauty of mathematics.

Secondly, to teach students in accordance to their aptitude and innovate teaching approaches to achieve top-class mathematical education. Children's interest and teaching efficiency are the two key factors. We need to focus on making teaching more entertaining and motivating classroom activation, changing our perception that if a child does not know mathematics at the very beginning, it is impossible to change along the way so as to make mathematics approachable to children and allow them to fall in love with mathematics. Meanwhile, we need to further enhance the transmission efficiency of knowledge, proactively motivate the logic thinking, and avoid simple repetition and mechanical trainings. Taking domestic and overseas practices of mathematics teaching into account, we need to attach more importance to the smart transition from particularity to commonality, simplicity to complexity, proper use of teaching techniques, difficulty in spiral learning, content design for linking theories with practices, more protection of students' personalities and cultivation of diverge thinking and innovative thinking so as to give a full role to play students' personalities, strength, and thinking abilities.

Thirdly, to enhance capability and catch up with and surpass outstanding faculty team. A high-profile faculty team serves as a key to innovate mathematical education. For a long time, China's mathematical education represented by Shanghai has been focusing on pulling senior teachers and young teachers together by means of teaching and research groups and systematically leading teachers to jointly explore problems and cheer spirits by launching collective teaching and research programs, resulting in building up framework of science-oriented teaching and teaching-oriented researches, which has won high evaluation worldwide. However, we are fully aware of the fact that China's education is featured with inequity and insufficiency. We are making efforts to allow rural children and children in mountains to enjoy education the same as the children in Shanghai. China has a total of 618,000 rural mathematics teachers. In order to promote their overall teaching competencies, we've launched a training program with specific responsibilities at states, provinces, cities, counties at school level. The five-tier training program covered most rural teachers, with 42,000 teachers first trained over the 3 years. It is anticipated that participants attending this Congress will give suggestions and advices for the better professional development of mathematics teachers in China and such contributions will boost the modern teaching theories, scientific teaching approaches, and targeted coaching and mentoring.

Fourthly, to intensify cooperation and to expand the path of international teacher learning. Mathematics is the common language of the world. Mathematics education is taking the course for the joint efforts for development since the launch of the exchange program between China and United Kingdom in Shanghai in 2014. There have been over 20,000 British teachers and Shanghai teachers, closely interacting with each other both online and offline to share experiences, export mathematics teaching materials and benefit from such exchanges from mathematics teachers around the world. Based on this interaction, in 2018, United Nations Educational, Scientific and Cultural Organization (UESCO) set up the Teacher Education Center, which has further enhanced international training exchanges. China has given full support to the Center and hope it will play a bigger role. IMU and ICMI are also extremely important platforms to this Congress. We hope to take this Congress as a new starting point to accelerate the building of long-term mechanism of win-win cooperation to make greater contributions to the world scientific advancement, human civilization progress.

Last but not least, I wish the Congress a great success.

https://doi.org/10.1142/9789811287152_0003

The Opening Ceremony

Welcome Address from International Mathematical Union

Carlos Kenig[1]

It is a pleasure and an honor to represent the International Mathematical Union at the opening ceremony of ICME-14.

I would first like to give a warm welcome, on behalf of the IMU, to all the participants, both in person and virtual, in this very important event, which took years of sustained effort to plan and organize.

The IMU is extremely grateful to all the colleagues that have worked so hard and so well, to make this event possible, under the most difficult circumstances imaginable. Our heart-felt gratitude for their heroic efforts goes to our Chinese colleagues involved in the organization of ICME-14, to the Chinese institutions that supported them, to the International Program Committee and the Local Organizing Committee and to the two Executive Committees (EC) of ICMI involved in this enterprise. In particular, I would like to extend our gratitude to Jianpan Wang, the chair of the IPC and of ICME-14, to Yulin Wang, the academic secretary of ICME-14, to Binyan Xu and Jiansheng Bao, the co-chairs of the local organizing committee, to Jill Adler, past president of ICMI and Abraham Arcavi, past Secretary General of ICMI and to Frederick Leung, President of ICMI and Jean-Luc Dorier, Secretary General of ICMI, and to the many others who have worked tirelessly to make this event possible.

I became President of the IMU two and a half years ago, and during this time I have had the privilege of working closely with two Executive Committees of ICMI, as ex-officio member. This has been a very interesting learning experience for me, during which I came to learn something about the crucial work that ICMI and the world community of mathematical educators carries out, dealing with both theoretical research in mathematical education and with the practice of mathematics education, at all levels. All of this is of fundamental importance in the modern world, and particularly so for the developing world, in order for its full potential to be reached. This is one of the areas of direct cooperation between the IMU and ICMI, through the Capacity and Networking Project (CANP). The aim of CANP is to enhance the mathematical education in developing countries, at all levels, by developing the educational capacity of those who educate math teachers (from all levels of instruction). This has a large potential pay-off, since each teacher reaches many students, thus

[1] Professor, University of Chicago; President (2019−2022), International Mathematical Union.

widely propagating the acquired knowledge. We will be hearing more about CANP in this congress.

Even though historically, going back at least to the work of Felix Klein and others, there has been close cooperation between mathematicians and mathematics educators, a gulf seems to exist at the moment in many countries and institutions, between mathematicians and mathematics educators. This seems to me to be very artificial, and very damaging to both communities, since research and education cannot and should not be separated. I hope that both our communities will continue to work together to close this regrettable gap.

I conclude by thanking all the participants for their endurance and grit, and for their attendance, and wish all of you a very successful and memorable congress.

https://doi.org/10.1142/9789811287152_0004

The Opening Ceremony

Welcome Address from International Commission on Mathematical Instruction

Frederick Leung[1]

Honorable Mr. Li,
Professor Wang,
Other honorable guests present here, and
Participants of ICME-14, both in this hall and all over the world,
Ladies and gentlemen:

I echo Professor Wang and Professor Kenig in welcoming you to ICME-14. In the more than 50 years of the history of ICME, this is the first time when ICME is held in China. And being a Chinese myself, I am particularly proud of this.

ICME stands for International Congress on Mathematical Education. The use of the word "congress" means that this is not just an international conference, it is a gathering of all those involved in mathematics education worldwide. We gather together to share our findings in research, and our experiences and best practices. So solidarity and fellowship, and not only exchange of academic ideas, are salient features of ICME. I hope that at least those of us who are present physically here in Shanghai will make use of this opportunity to interact and to socialize, in addition to attending the academic sessions.

ICMI, or International Commission on Mathematical Instruction, is a worldwide organization devoted to research and development in mathematical education and to promote international cooperation. And ICME, the congress, fulfills the most important mission of ICMI in promoting excellence and inclusiveness of research and practices in mathematical education.

There are two important pairs of words here: research and practices, and excellence and inclusiveness. Educational research without relevance in the mathematics classroom is a pure intellectual or philosophical exercise. It may help a university professor to get tenure, but it doesn't contribute to enhancement of mathematics learning of our students. On the other hand, simply sharing of best practices from our classroom experiences will degrade mathematics education to simply a bag of tricks of the trade.

The other pair of words: excellence and inclusiveness, set the standard of our work in research and classroom practices. Our educational research must satisfy the rigorous

[1] Professor, Hong Kong University; President of the International Commission of Mathematical Instruction (ICMI).

criteria of scientific research in order to establish mathematics education as an academic discipline, and our practices must be based on evidence supported by sound research. On the other hand, we need to realize that the worldwide mathematics education community comes from very diverse backgrounds, economically, socially and culturally. So in attaining excellence in educational research and practices, we must reflect different cultural traditions. In fact, our research and our practices will be enriched by such cultural diversity. And ICME is the perfect venue for excellence and diversity of research and practices to be shared and treasured.

COVID-19 has posed a tremendous challenge to the mathematics education community worldwide, and it has posed a great challenge to the organizers of ICME-14 as well. Holding a hybrid congress like this is not a trivial task at all. It is equivalent to holding a physical conference *and* an online conference at the same time. And unfortunately, one plus one is much bigger than two in this case — that is it is even more difficult to hold a hybrid conference than to hold one physical conference and one online conference!

I salute and thank members of the organizing committee for their great efforts and excellent work in the past years which has made this congress possible. I am sure that all the participants of ICME-14, whether physical or online, will benefit tremendously from the congress, and that the hard work of the organizers will pay off.

I wish ICME-14 a great success! Thank you very much.

https://doi.org/10.1142/9789811287152_0005

The Opening Ceremony

Welcome Address from Chinese Mathematical Society

Gang Tian[1]

Your excellency, Mr. Qiang Li,
Mr. Shaoliang Yu,
Ms. Tiehui Weng,
Mr. Calos Kenig,
Mr. Frederick Leung,
Mr. Xuhong Qian,
Distinguished guests,
Ladies and gentlemen,
Friends, both online and in the audience,

Today, in China's metropolitan Shanghai, we usher in the 14th International Congress on Mathematics Education (ICME-14). On behalf of the Chinese Mathematical Society and the organizers of this Congress, I would like to extend a warm welcome to all our guests and friends.

Mathematics and mathematics education have never been separate entities. As called for in the mission of the International Mathematical Union, the Chinese Mathematical Society has dedicated itself to encouraging and supporting various international mathematical activities, including theoretical mathematics, applied mathematics, and mathematics education. The Chinese Mathematical Society sent a delegation, headed by Professor Shisun Ding of Peking University, to the 4th International Congress on Mathematics Education (ICME-4) in 1984, at which the well-known mathematician Hua Luogeng was invited to give a plenary lecture.

Besides international activities, the Chinese Mathematical Society has also been organizing, participating in and supporting various research projects and activities in domestic mathematics education, such as the reform of mathematics curriculum in primary and secondary schools. China's basic mathematics education system is internationally renowned, but not without areas that could be improved.

At the 2002 International Congress of Mathematicians (ICM) held in Beijing, I once said, "Some people find mathematics dry and difficult, but I think mathematics is elegant and clear-cut. Mathematics will reveal its beauty to those who love it. Once you have found an interest in mathematics, it will look completely different in your eyes. Behind different phenomena lies a fundamental connection, once you have found

[1] Professor, Peking University; President of Chinese Mathematical Society

it, you will be drawn towards the call of mathematics.” I hope that, through our joint efforts, not only will our youths achieve excellent results in mathematics, but more so that they will grow to like mathematics, and believe that mathematics is fun and elegant.

Currently, there are two influential international mathematics Congresses organized by the International Union of Mathematics. One is ICM, the other is ICME. In 2002, we held ICM 2002 in Beijing, which provided an excellent opportunity for Chinese mathematicians to interact and exchange ideas, to facilitate discussions with international mathematical luminaries, and also acted as center stage for Chinese mathematicians to showcase their work to their international counterparts.

ICM 2002 and its related events were instrumental in promotion and popularization of mathematics in Chinese society. It focused public attention on mathematics, prompted the application of mathematics in all fields and industries, it also strengthened academic exchanges between Chinese mathematicians and their peers abroad, and propelled global mathematics into a new era. I have no doubt that this current International Congress on Mathematics Education (ICME-14) shall bring our mathematicians a more global perspective, broader and more in-depth international exchanges, and serves to drive many exemplary traditions and innovations of Chinese mathematics education and learning onto a global platform.

The Chinese Mathematical Society was established in Shanghai in 1935. This society has always placed profound significance on mathematics education. Just this afternoon, the Mathematics Education Branch of the Chinese Mathematical Society held its inaugural meeting in Shanghai. This marks the establishment of closer ties between the Chinese Mathematical Association, the International Union of Mathematics (ICM) and the International Commission on Mathematical Instruction (ICMI).

We would like to thank the International Commission on Mathematical Instruction for entrusting the important task of holding ICME-14 to the Chinese Mathematical Society. I believe that we will be presenting to the world a splendid and unique celebration. We would also like to thank the ICME-14 International Program Committee, the local organizing committee and, especially, Professor Jianpan Wang, our Congress chairman. In the process of bidding for the Congress, your perseverance was proven to be formidable. Due to the COVID-19 pandemic, the Congress was forced to be postponed for one year. Not only did the venue have to change, but also the mode of the conference. I can only imagine the challenges and hardship you all overcame.

We are also grateful to the Chinese Association for Science and Technology, the city government of Shanghai, and East China Normal University in extending a helping hand during the difficulties experienced by the organizing committee. Thank you to all those who have contributed to the making of this Congress. Without your contribution, we would not be able to gather here today. Today is a day that will not be forgotten in China’s mathematics education.

I wish the Congress a great success!

Thank you.

https://doi.org/10.1142/9789811287152_0006

The Opening Ceremony

Welcome Address from East China Normal University

Xuhong Qian[1]

Honourable Mr. Qiang Li, Ms. Tiehui Weng,
Dear Professor Kenig, Professor Leung, Professor Gang Tian, Professor Jianpan Wang,
Distinguished guests joining us from around the globe,
Ladies and gentlemen, dear friends, Welcome!

The 14th International Congress on Mathematical Education is being held today at East China Normal University (ECNU), and on behalf of all the teachers and students of the University, I would like to extend a warm welcome to all the participants from all over the world! I would like to express my sincere gratitude to all the leaders, colleagues and friends who have shown their interest in and support for the Congress.

The International Congress on Mathematical Education is the most prestigious event in the field of mathematics education. Seven years have passed since our initial bid to host this international "Olympiad" in mathematics education. The preparation and holding of this event have been fraught with twists and turns, not least because of the impact of the COVID-19 pandemic.

And yet not only have we succeeded in organizing this event, we will also be marking some historic achieving some "firsts":

- It is the first ICME to be held in China;
- The first ICME to be held in hybrid format — both online and offline;
- And this edition will have the largest number of invited lectures and topic study groups ever.

I am sure therefore that this Congress will be remembered for years to come in the history of mathematics education in the world.

Mathematics has played a major role in the development of human civilisation. More recently, in particular, mathematics has become an important foundation for the advancement of various disciplines. Furthermore, mathematical knowledge and thinking are the bedrock of technologies such as artificial intelligence and big data. It is evident that mathematics education is crucial to the development of tomorrow's world and will play a key role in shaping the way we think in the future. This is why it is increasingly important to strengthen mathematics education and expand the new paradigm of mathematics education in the age of artificial intelligence.

As a comprehensive research university with special strengths in education, East China Normal University (ECNU) entered the ranks of national first-class universities

[1] Professor; President of East China Normal University

in 2017. Over the past few years, the university has focused on the mission of "educating, enlightening and developing" students. Our efforts aim to forge the foundations for achieving happiness across society as a whole. The university has made clear that it strives to "achieve excellence through education", which clearly encapsulates the unique approach to education at ECNU. Mathematics education is one of the core components underpinning educational excellence at ECNU. Our aim is to revisit the way we think, in order to unlock the essence and shape of mathematics education for the new era; to remould mathematics education for the future with universal values; and reach new heights in exploiting AI in order to map new methods of mathematics education for the road ahead. Our goal is to open a new chapter in the training of outstanding talent by applying mathematical thinking to teaching and learning. Through mathematical thinking, we can build systems of knowledge which stretch from East to West. By building these bridges, we can contribute to world civilisation, and at the same time harness the potential of mathematics as a new lever for development and source of energy to drive civilisation in the age of artificial intelligence.

Mathematics at ECNU already has a long history, and is developing today faster than ever. Our mathematics education research team, has its roots here in Shanghai. At the same time, this team embraces a broad international vision, and attaches equal importance to research and practice. As such, they have made outstanding contributions to mathematics education research, which has benefited not only Shanghai but China as a whole. The establishment of the Asian Centre for Mathematical Education has given greater international visibility and weight to Chinese mathematics education research and practical pedagogy. The Shanghai maths programme, "One Lesson One Exercise" (English version), edited by ECNU's Professor Lianghuo Fan, is now applied around the world and is used in over 400 schools in the UK. ECNU's score in the European Skills Index (ESI) for maths currently lies within the global top 1%, and is a pillar for cross-disciplinary work in our school.

Today, we have the honour of welcoming researchers and practitioners of mathematics education from all over the world to meet both here on our campus at ECNU and online, to discuss the future of mathematics education together, and to inject new blood into our School's priority, which is to nurture excellence.

Distinguished guests, ladies and gentlemen, in October this year, East China Normal University (ECNU) will celebrate its 70th anniversary. We hope that by virtue of this conference, our school will maintain its momentum and make fresh progress in basic and applied research in mathematics education, and advance in its endeavour to cultivate talented mathematical minds. In doing so, we hope not only to bolster mathematics education in China but also contribute to mathematics education around the world!

Finally, I would like to wish you all fruitful discussions during this congress, and for those here in Shanghai, a wonderful week at East China Normal University!

Thank you!

https://doi.org/10.1142/9789811287152_0007

The Opening Ceremony

ICMI Awards Ceremony

Frederick Leung[1], Jill Adler[2], Anna Sfard[3], Konrad Krainer[4], Deborah Loewenberg Ball[5], Terezinha Nunes[6], Tommy Dreyfus[7], Gert Schubring[8], Nancy Brickhouse[9], and Trena Wilkerson[10]

The ICMI Awards Ceremony was presided by Frederick Leung. Jill Adler gave an introduction of ICMI awards, followed by the award ceremony. Adler presided over the 2017 awards (Fig. 1), Leung presided over the 2019 awards and the 2020 Emma Castelnuovo award.

***Introduction to ICMI Awards by Jill Adler*:**

Greetings to

- Professor Frederick Leung, ICMI President,
- Professor Wang, ICME-14 Congress Chair and all on the Congress LOC,
- Professor Carlos Kenig, President of IMU,

Greetings to all colleagues, friends and our ICMI community world-wide. Ni Hao to all participants in Shanghai, I wish I could be there with you today. I am Jill Adler, immediate past president of ICMI 2017– 2020. Welcome all to the 2021 ICMI Awards Ceremony.

Our ICMI awards — and you can see there are three different awards — medals — are a highlight of the work of ICMI — and we celebrate these at our ICME congress.

[1] Professor, Hong Kong University; President of the International Commission of Mathematical Instruction (ICMI). Email: icmi.president@mathunion.org

[2] Professor, University of the Witwatersrand, South Africa. 2017−2020 President of the International Commission on Mathematical Instruction (ICMI). Email: Jill.Adler@wits.ac.za

[3] Professor (Emerita), University of Haifa, Israel; Chair of the ICMI Felix Klein and Hans Freudenthal Awards Committee 2016−2020. Email: Annasfard@gmail.com

[4] Professor, Alpen-Adria-Universität Klagenfurt, Austria, Chair of the ICMI Emma Castelnuovo Award Committee 2017−2020.

[5] Professor, University of Michigan, United States of America, awardee of 2017 Felix Klein Award. E-mail: dball@umich.edu

[6] Professor, Oxford University, United Kingdom, awardee of 2017 Hans Freudenthal Award. E-mail: edst0248@nexus.ox.ac.uk

[7] Professor, Tel Aviv University, Israel, awardee of 2019 Felix Klein Award. E-mail: tommyd@tauex.tau.ac.il

[8] Professor, Universität Bielefeld, Germany, and Universidade Federal do Rio de Janeiro, Brazil, awardee of 2019 Hans Freudenthal Award. E-mail: gert.schubring@uni-bielefeld.de

[9] Vice President and Provost, Baylor University, United States. Email: Nancy_Brickhouse@baylor.edu

[10] Professor, Baylor University; President of National Council of Teachers of Mathematics (NCTM). Email: Trena_Wilkerson@baylor.edu

The first two awards were established in 2000 to recognize outstanding achievement in mathematics education research:

Fig. 1. Left: Jill Adler presided over the 2017 awards
Right: Frederick Leung presided over the 2019 and 2020 awards

The Felix Klein Award, named after the first president of ICMI (1908–1920), honours lifetime achievement.

- The Hans Freudenthal Award, named after the eighth president of ICMI (1967–1970), recognizes a major cumulative program of research.

More recently, in 2013, we established a third award that reflects the ICMI principles to promote the reflection, collaboration, exchange and dissemination of ideas on the teaching and learning of mathematics, from primary to university level.

- The Emma Castelnuovo Award, named after the Italian mathematics educator born in 1913 to celebrate her 100th birthday and honour her pioneering work, to recognize outstanding achievements in the practice of mathematics education.

Together these three awards pay tribute to outstanding scholarship in mathematics education. They serve not only to encourage the efforts of others, but also to contribute to the development of high standards for the field through the public recognition of exemplars.

In the ceremony today we present the medals and certificates to the Felix Klein and Hans Freudenthal awardees of 2017 and 2019; and the Emma Castelnuovo award of 2019/2020.

Two committees were charged with making these awards, and this is also an opportunity to thank them and their Chairs, for the work done. As you might know the Chairs are public positions. The committee members, however, are kept confidential to protect the integrity of the process. It is important to add that once the committees are appointed, they work completely independently of ICMI and the EC.

In particular I would like to thank Professor Anna Sfard, Chair of the Felix Klein and Hans Freudenthal Awards committee (Fig.2, left). Anna Chaired the awards

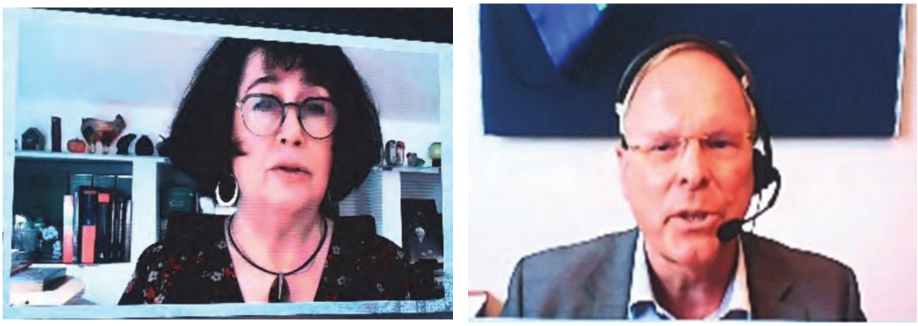

Fig. 2. Chairs of the two award committees

Left: Anna Sfard, the Chair of the Felix Klein and Hans Freudenthal Awards committee (2016−2020), read a citation
Right: Konrad Krainer, the chair of Chair of the Emma Castelnuovo Award committee (2017−2020), read the citation

process for both the 2017 and 2019 awards. Anna, thank you for the integrity and commitment with which you undertook this most important task in ICMI, and for a report on the process that has helped ICMI add refinements needed. Similarly, to Professor Konrad Krainer, Chair of the Emma Castelnuovo committee (Fig. 2, right), thank you too not only for the work done over eight years, but also for contributing to our refining the criteria for this award as well. Both Anna and Konrad have served their terms and new Chairs have been appointed.

Recipients of the ICMI Awards, 2017−2020

- *The awardee of 2017 Felix Klein Award: Deborah Loewenberg Ball, University of Michigan, United States of America*
- *The awardee of 2017 Hans Freudenthal Award: Terezinah Nunes, Oxford University, United Kingdom*
- *The awardee of 2019 Felix Klein Award: Tommy Dreyfus, Tel Aviv University, Israel*
- *The awardee of 2019 Hans Freudenthal Award: Gert Schubring, Universität Bielefeld, Germany, and Universidade Federal do Rio de Janeiro, Brazil*
- *The awardee of 2020 Emma Castelnuovo Award: National Council of Teachers of Mathematics (NCTM)*

2017 Felix Klein Award

The Citation[11] read by Anna Sfard.

The Felix Klein Award, with which ICMI honors the most meritorious scholars within the mathematics education community, is given in 2017 to Deborah Loewenberg Ball,

[11] https://www.mathunion.org/icmi/awards/felix-klein-award/2017-felix-klein-award

the William H. Payne Collegiate Professor in Education and an Arthur F. Thurnau Professor in the University of Michigan, Ann Arbor, MI, US. The Felix Klein Award 2017 is awarded to Professor Ball in recognition of her outstanding contributions and her leadership role in deepening our understanding of the complexities of teaching mathematics and in improving the practice of teaching and of teacher education.

These achievements are grounded in Deborah Ball's firm belief that research and practice of teaching are co-constitutive and must always be developed in tandem. Early in her life, Deborah Ball, at that time an exceptionally talented elementary school mathematics teacher, set out to investigate what was involved in the work of teaching children mathematics "for understanding." Her intention was to uncover the work in order to support the learning of teaching practice. Ever since then, her ambition has been to contribute in a substantial way to the project of improving ways in which mathematics teachers support their students' learning. This goal gave rise to two lines of work, both of them combining research with development in the domain of teacher education. The first strand, in which the research element came first, has been generating studies revolving around the question of what mathematical knowledge is required for teaching learners. In the second line of work, related to the practice of education in a more immediate way, the development of innovative teacher preparation programs has been combined with research, through which Deborah Ball has been trying to gain a better grasp of the moment-to-moment dilemmas with which teachers grapple in the classroom.

The first of these pursuits gave rise to the theory of MKT, Mathematical Knowledge for Teaching, the kind of knowledge that requires competence in both everyday and academic mathematical discourses, but is identical to neither. In her multiple studies, Deborah Ball and her colleagues have been able to identify many unique features of MKT, and then to corroborate the conjecture about a correlation between teachers' competence in this special brand of mathematics and the achievements of their students. With the support of a group of mathematicians, the theory has been translated into an instrument for measuring teachers' knowledge of mathematics for teaching. The MKT project proved highly influential, as evidenced by the widespread use of the term MKT and by the great popularity of Deborah Ball's publications on the topic. Her 2008 paper "Content knowledge for teaching: What makes it special?" co-authored with Mark Hoover and Geoffrey Phelps Thames, which appeared in the *Journal of Teacher Education*, is one example of such a widely read article.

The second, newer strand of Deborah Ball's work is centered in TeachingWorks, a national organization she established at the University of Michigan to help in improving teachers' preparation and to define "a professional threshold for entry to teaching." The mission of the institute is to identify "high-leverage" teaching practices, that is, those recurring elements of teacher's classroom activities that are central to what Deborah Ball terms "the work of teaching." It is also part of the mission to work in partnerships with others to improve the preparation of teachers. To this end, Deborah

Ball has been carrying in-depth analyzes of the ways in which mathematics teachers juggle their multiple classroom tasks, such as interpreting the learner's often idiosyncratic ways of thinking, gradually transforming the children's special understandings into more canonical ones, sustaining equitable learning dialogue and taking care of the emotional well-being of the students. This line of Deborah Ball's research, while relatively new, seems to be an attempt to close the circle that opened with the early reflection on her intuitive efforts, as a teacher, to identify and to bridge the gap between her own mathematics and the mathematics of her students. Indeed, this current research project harks back to Deborah Ball's early publications, such as her now classical 1993 article "With an eye on mathematical horizon: Dilemmas of teaching elementary school mathematics", in which the memorable case of "Sean numbers" helped the author to highlight challenges of classroom teaching.

Deborah Ball has played multiple leadership roles, and not only within community of mathematics education but also within that of education at large, and not only within United States, but internationally. In all these arenas, hers was a systematic effort to build bridges. Her years-long work on bringing together research and practice of mathematics education is just one example of these attempts. Another expresses itself in her striving for a fruitful collaboration between the communities of mathematicians and of mathematics educators. In this later undertaking, she has been acting on her strong belief that certain differences of opinions on mathematics and on teaching that arise occasionally between these two communities, far from being an obstacle, are likely to help in creating a synergetic partnership.

Deborah Ball's achievements as a researcher and a leader have been recognized nationally and internationally. This recognition is signaled, among others, by the unprecedented frequency with which her publications are cited by other authors, by her great popularity as a speaker, by her multiple roles within ICMI and by her membership of numerous policy-making or advisory committees, such as the National Science Board, appointed by President Barack Obama. Whereas her work is firmly grounded in mathematics education, the recognition of its outcomes goes well beyond the community of mathematics education. This is evidenced by Deborah Ball's prestigious membership in the National Academy of Education and by her current roles as the President of the American Educational Research Association and as a member of the American Academy of Arts and Sciences.

Deborah Ball has been an elementary classroom teacher before and during her studies at Michigan State University, which she completed in 1988 with a PhD in mathematics education. Upon graduation, she joined Michigan State University, and in 1996 she was recruited to the University of Michigan to develop the mathematics education group. She has been teaching at the University of Michigan ever since then and also spent over a decade serving as Dean of the School of Education there.

With more than thirty years of outstanding achievements in mathematics education research and development, Deborah Ball is a most distinguished member of mathematics education community and a highly deserving recipient of the 2017 Felix Klein Award.

Acknowledgement from the awardee, Deborah Ball (Fig. 3)

Thank you, Jill. Thank you, Anna. Thank you, Hyman. Thank you, to the International Commission on Mathematical Instruction and the members of the Felix Klein Award Committee, for this honor. I am truly humbled.

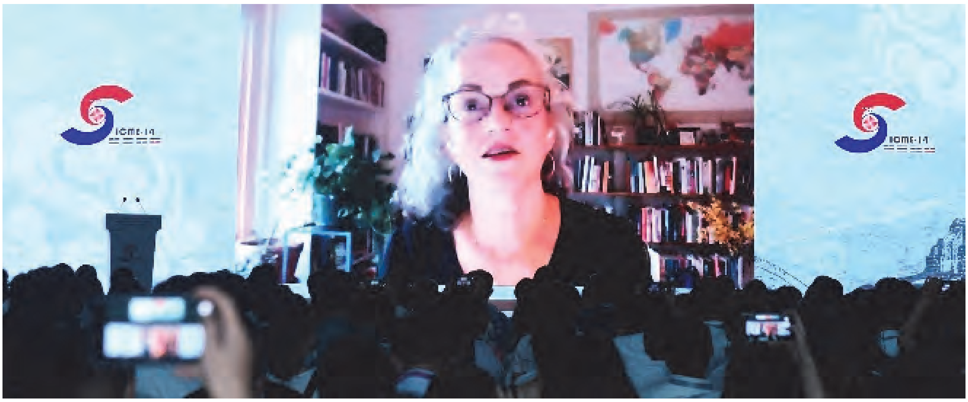

Fig. 3. Deborah Ball gave an awardee speech

Are you going to say that an award in academic world so often singles out individuals for recommendation, as with this award? In fact, it is crucial to say that my work and my learning are so much a product of collaborative work. And for opportunities to work with and learn from so many other scholars, teachers and students, this award actually celebrates those relationships and those opportunities as much as it does my own achievements.

My learning has also been the product of the contexts where I have been supported to work, to learn, to grow and to develop. Starting with the public elementary school right top for almost 20 years, to the Michigan State University where I began my academic career, and now the University of Michigan — these have been the places that have supported me and the wonderful places for me to grow and learn with others. As a beginning teacher in that public elementary school, I was mentored by a strong, experienced and loving principal — or head of school — and a usually diverse and experienced set of colleagues who supported me in developing my own ways, learning from others and also breaking out of times. They encouraged me and supported me.

As an early careered scholar as well as across my whole career, I have been nurtured by colleagues and managers who had urged me to probe and pursue the questions that preoccupy me and puzzle me; they helped me build connections to so many kinds of work and learn theories and methods, and also supported me when I had crazy ideas or other ways to go back to work different conceptualizations or different methods. My mentors, colleagues and friends asked me really tough questions. They could see what I was trying to do and encouraged me when I was discouraged. They pushed me, they took my work seriously, they read it, they responded, and they were there for me. And as I worked hard to figure out what it meant to cultivate my experience and my core identity as a teacher, to be a critical resource for my own research, I feel like I was really lucky to have colleagues who had always valued that.

My students have quite been among my most important teachers. I realized when I was reflecting that I have been blessed to teach over 1000 primary grade students by now, and they have really been among my most important teachers. I learned from children just all the time. I also learned incredibly from my undergraduate students who were courageously setting out to become teachers and to learn to do this complex work. I have learned so much from all my undergraduate students with whom I have been incredibly fortunate to work and learn from they themselves are up there now, contributing and adding to the field, changing, and making change. Thank you to all of you from whom I have been so fortunate to work, to learn, and to figure out how to pursue things that really matter and for which our research can actually make a difference, together.

I also want to thank my colleague and friend, Hyman Bass, who has done so much to shape his organization ICMI. As the President of ICMI from 1999 to 2006, Hyman worked deciduously to center on mathematics education research and mathematics educators, and it was really because of his respect for the field that he was determined to conceptualize and inaugurate these awards, like the Felix Klein Medal. He thought it was crucial to foreground mathematics education research, particularly in the context of the International Mathematics Union. Thank you, Hyman, for all of that work that you did for others to make this possible.

I really cannot express how deeply honored I am to be among the awardees of this Felix Klein Award, scholars whom I so deeply respect and admire, and from whom I have learned so much. Guy Brousseau, Ubiratan D'Ambrosio — may his memory be forever blessing, Jeremy Kilpatrick, Gilah Leder, Alan H. Schoenfeld, Michèle Artigue, Alan Bishop, and now, Tommy Dreyfus.

Thank you, everybody. I am so deeply grateful for this honor and I will take that as a continued mandate to support other scholars and to develop our sense that whatever work we do, whatever progress we can make, it is absolutely and fundamentally collective. Thank you.

2017 Hans Freudenthal Award

The Citation[12] read by Anna Sfard

The Freudenthal Award, with which ICMI honors innovative, consistent, highly influential and still ongoing programs of research in mathematics education, is being awarded in 2017 to Professor Terezinha Nunes, University of Oxford, UK, for her outstanding contribution to our understanding of mathematical thinking, its origins and

[12] https://www.mathunion.org/icmi/awards/hans-freudenthal-award/2017-hans-freudenthal-award

development. For more than 35 years now Terezinha Nunes has been researching children's mathematical learning, as it takes place in formal and informal settings. The results of her numerous, exemplarily designed studies combine into an insightful, consistent, and comprehensive story of the emergence and evolution of mathematical thinking. This constantly developing account has been inspiring the work of mathematics education researchers and informing mathematics teachers' practices all over the world. It has had a major impact on both what we know about children's learning of mathematics and on how we know and think about it.

Terezinha Nunes' research has been immensely innovative and influential from its earliest stages. In one of her first studies, she documented the mathematical skills of young Brazilian street vendors who, although almost unschooled and incapable of executing paper-and-pencil arithmetic tasks, proved impressively proficient in complex money transactions. Understandings gained through this research have echoed throughout the mathematics education literature ever since the project's completion, for almost three decades now. It was one of those studies that, in the last quarter of the 20th century, revolutionized our thinking about learning — about its nature, origins and development. Conducted with David Carraher and Analucia Schliemann and summarized in their seminal book *Street Mathematics* (1993), this research made a decisive contribution to what is now known as the "situative turn" in the learning sciences at large, and in mathematics education in particular. Terezinha Nunes' contribution to this conceptual revolution has been evidenced, among others, by the widespread use of the term *street mathematics* and by the large number of cross-situational and cross-cultural studies on mathematics learning inspired by her work.

Terezinha Nunes' later research on the development of mathematical thinking, conducted in Brazil and the UK, spans multiple mathematical topics, from additive and multiplicative reasoning to fractions, variables, randomness and probability. She has studied children's logical reasoning and its role in the learning of mathematics, as well as problem solving and the way mathematics is being used in science. A special place in her work has been reserved for research on the mathematics learning of deaf children and for developing and testing innovative intervention programs based on insights thus gained. In parallel to the work of scrutinizing different types of mathematical thinking and their development, Terezinha Nunes has also systematically constructed a big picture of this development. As research findings have accumulated, she has been adjusting and refining her syntheses. Different versions of these cumulative, integrative accounts have been disseminated, among others, through her 2000 ICME plenary address, her 1996 book written with Peter Bryant *Children Doing Mathematics*, and the 2016 ICME monograph *Teaching and Learning about Numbers in Primary School*, which she co-authored with colleagues.

While forging her stories on children's thinking about numbers, Terezinha Nunes has been transforming her own thinking as a researcher. She has come a long way from being a traditionally trained clinical psychologist, whose research was firmly grounded in Piaget's ideas about human development, to being inspired by cultural psychology and the work of Vygotsky and his followers to at least the same extent. Hers is a special type of synthesis between cognitivist and sociocultural approaches. Today, she speaks about "mathematics learning as the socialization of the mind" and claims the utmost importance of cultural shaping. At the same time, she asserts the existence of cross-cultural invariants in children's mathematical thinking. If these two tenets may sometimes appear incompatible, she argues, it is only because different cultures build on the common elements to produce forms of mathematical competences diverse enough to make the cross-cultural invariants almost invisible. Another basic tenet of her work is that children's quantitative reasoning may and should be developed independently of, and possibly prior to, their numerical skills. These and many other of her research-generated insights on mathematics learning were novel to the mathematics education community when first announced. Careful to notice phenomena that have escaped the attention of investigators wedded to the "deficit model" of research, she portrayed children's mathematics in unprecedented detail and depth.

Terezinha Nunes' tendency for bridging apparent opposites and bringing the separate together finds its expression also in her attempts to improve the practice of teaching mathematics. Not a typical dweller of the ivory tower of academia, she has always made sure that her work finds its way to those for whom it was meant in the first place — educators, parents, and anybody interested in promoting children's learning. She has been consistently translating her research-generated insights into innovative pedagogies.

Trained as a psychologist, Terezinha Nunes began investigating children's mathematical thinking because of her professional interest in human development. Her studies soon began to attract the attention of mathematics education researchers, leading to her membership in the International Committee of PME (1986–1990; in 1989–1990 she served as Vice-President of PME) and on editorial boards of major mathematics education journals, *Educational Studies in Mathematics* (1989–1995) and *For the learning of mathematics* (2000–2004). Since then, she has been one of the most widely recognized members of the community of research in mathematics education. This, however, was not her only professional membership. An interdisciplinary thinker, who has been investigating children's evolving reading and writing skills in parallel to her work on mathematical thinking, Terezinha has enjoyed a prominent status also among developmental and cultural psychologists. Her insights about numeracy and about literacy constantly informed and enriched each other and combined together into a major advancement in our understanding of human development and learning in general.

Terezinha Nunes began her studies in psychology in her native Brazil and earned her masters and PhD degrees at City University of New York (1975, 1976, respectively). She began her academic career in Brazil at the Federal University of Minas Gerais and the University of Pernambuco. Later, she moved to the United Kingdom, where she taught at the Institute of Education, University of London, Oxford Brookes University and, since 2005, at the University of Oxford. She is now Professor Emerita at the University of Oxford and a Fellow of Harris Manchester College, Oxford. Throughout her career, she has completed tens, if not hundreds of studies, most of which were conducted in Brazil and in the UK. An exceptionally prolific writer, she has authored or co-authored more than a dozen books and almost two hundred journal papers, book chapters and encyclopedia entries in English and Portuguese. An ardent team player and highly appreciated teacher, Terezinha Nunes has been an inspiration to her colleagues and to her many students.

As an outstanding researcher driven by an insatiable passion for knowing, one who has made a paramount contribution to mathematics education and is likely to continue adding substantial insights for years to come, Terezinha Nunes is an eminently deserving recipient of the Hans Freudenthal Award for 2017.

Acknowledgement from the awardee, Terenzinha Nunes

I am very grateful to ICMI for this award and I want to stress today that my research is the outcome of the fantastic opportunities to learn about mathematics education that ICMI offered me (Fig. 4). ICME-5 was the first conference organised by mathematicians I ever attended and it radically changed the way I thought about children learning mathematics. My colleagues David Carraher, Analucia Schliemann and I had encountered a phenomenon that we decided to call street mathematics. We knew that many children and unschooled adults in Brazil were competent at using mathematics as they worked in street markets and in trades such as building, fishing, and carpentry. But they were perceived as culturally deprived and did not succeed in school. Psychological theories did not help us to investigate this phenomenon but ICME-5 did. I will mention five events at ICME-5, but these were not the only ones: the three plenary lectures, the PME sessions and the discussions on mathematics for all.

Fig. 4. Terenzinha Nunes gave an acknowledgement speech

Ubiratan D'Ambrosio's unforgettable lecture on the socio-cultural basis of mathematical thinking showed me how I needed to change my view of what mathematics is. I had thought of mathematics as crystallised knowledge to be taught and learned in school. Ubi's demonstration that mathematics is a human activity, which at the same time produces and uses cultural tools, became for me the starting point of a new way of thinking about how children learn mathematics.

Jeremy Kilpatrick's lecture on reflection and recursion was a call to reflection. Many psychologists at the time treated learning as information processing and teaching as programming and debugging to correct the mistakes made in programming. Kilpatrick provided a critical analysis of the computer metaphor and revived the ghost in the machine. His suggestion that consciousness and personal experience cannot be ignored in teaching and learning influenced how I viewed children's learning and the task of investigating teaching and learning.

When the plenary by Renfrey Potts on discrete mathematics was announced, I thought I would go to sleep. The lecture hall was dark, I was jet-lagged, and I had no idea what discrete mathematics was. I thought that mathematicians may be discrete or indiscrete, but I could not see how mathematics could be discrete or not. But I could not go to sleep as Potts questioned whether the floor he stood on and time are discrete or continuous. As he moved back and forth between experience and scientific models, he gave me a glimpse of what it means to think of numbers as mathematical models for quantitative reasoning about the world. This radically changed my thinking about numbers.

The symposium by the study group on the psychology of mathematics education, organised by its president Gérard Vergnaud, proved to be a demonstration of the power of inter-disciplinary research. Researchers moved back and forth between psychology and mathematics, forming conjectures about the students' thinking on the basis of mathematical ideas, and returning to the students' work and explanations to check their conjectures.

Finally, the sessions on mathematics for all, organised by Peter Damerow, changed the way I thought about curriculum. I had naively thought of mathematics as a body of knowledge to be taught to everyone in the same way, and so a curriculum was only a matter of how to organise the mathematical topics sensibly. What I had learned about mathematics at ICME-5 helped me to understand the discussions on mathematics for all.

This is why today I am so deeply grateful for this award and truly indebted to ICME for what I have learned at all the ICME conferences that I attended ever since ICME-5.

2019 Felix Klein Award

The Citation[13] read by Anna Sfard

The Felix Klein Medal, with which ICMI honors the most meritorious members of the mathematics education community, is given in 2019 to Tommy Dreyfus, Professor Emeritus at Tel Aviv University, Israel, in recognition of his life-time achievement.

[13] https://www.mathunion.org/icmi/awards/felix-klein-award/2019-felix-klein-award

This distinction acknowledges Professor Dreyfus's contribution to research as well as his leading role in shaping and consolidating the research community and in fostering communication between researchers.

For four decades, Tommy Dreyfus's research has been systematically deepening our understanding of mathematics learning. Trained as a mathematical physicist, Tommy has been drawing in this work on his deep understanding of mathematics and his first-hand familiarity with ways in which mathematical ideas come into being and evolve. Since the late 1970s and for the next two decades his research has been focusing on students' conceptualization of mathematical objects such as function, and on the role of intuition, visualization and aesthetics in mathematical thinking. With years, his interests have been gradually shifting from the individual student to learning-teaching processes of the classroom. In the last twenty years, his empirical and conceptual work has been devoted to the study of epistemic activities such as proving and abstracting. These efforts resulted in the theory known as AiC — *Abstraction in Context*, which he developed with Baruch Schwarz and Rina Hershkowitz. Conceived in the late 1990s, the AiC framework has become increasingly influential. Since its inception, it has generated much empirical research all over the world. The theory has been found to be useful also to teachers, whom it provides with tools for monitoring student learning.

As impressive in its scope, breadth, depth and impact as Professor Dreyfus's research is, it constitutes only a part of the contribution for which he is honored today with this special distinction. Another outstanding part of his work is his ongoing project of shaping and consolidating the international community of research in mathematics education, a goal that he tries to attain in multiple ways. First and foremost, through his extensive editorial work he has been setting standards and giving directions for research in mathematics education. Particularly influential has been his 30-year long association with *Educational Studies in Mathematics*, which included his three-year long term as the editor-in-chief. Professor Dreyfus has also been serving in, and shaping, numerous professional organizations, with PME (the international group for the Psychology of Mathematics Education) and ERME (the European Society for Research in Mathematics Education) among them.

In addition, he played key roles in numerous professional committees in Israel, Europe and America. His influence on research and on policy directly affecting mathematics teaching is keenly felt over the world. In all these activities, Professor Dreyfus has been consistently promoting cross-discursive dialogues. He has done this by organizing international meetings, establishing trans-continental collaborative research projects, appearing world-wide as an invited speaker and by extensive mentoring in his own country and beyond. Probably the most important and innovative among Professor Dreyfus's consolidating activities have been his multifarious efforts to spur and improve communication among researchers working within differing theoretical frameworks. Being concerned about the fragmentation of the field of mathematics education, Professor Dreyfus has been looking for ways in which community members can engage in a productive dialogue across discursive boundaries.

These attempts began with his own cross-theoretical research collaborations. It continued with his conceptual work on the possibility of "networking theories", the activity of employing multiple theories in the attempt to produce a synergetic, cumulative effect. Through these initiatives, Professor Dreyfus has contributed to changing the dominant narratives about theoretical diversity. With his help, the multiplicity of research discourses is now seen less as a problem to solve than as an opportunity to embrace.

Born in Switzerland and now living in Israel, Tommy is fluent in a number of languages, which makes him particularly well equipped for the project of consolidating the international community. After his 1975 doctorate in mathematical physics from the University of Geneva, endowed with several prestigious fellowships and awards, Tommy began visiting universities all over the world. Since then, he never stopped. In parallel to his work at the Weizmann Institute and at the Center for Technological Education in Holon, and later as a full professor of mathematics education at Tel Aviv University, Tommy served as a visiting professor in 14 universities over the world, including in Canada, Germany, Finland, Israel, New Zealand, Norway, Sweden, Switzerland, and the USA. On all these occasions, he spent much time teaching and working with both young and seasoned researchers. By all accounts, he left an indelible mark in all the places he visited.

This owes, among others, to his ability to communicate fluently and easily, to his sensitivity to other cultures and to his general sense of inclusiveness. His willingness to listen and to share his own insights and his devotion to a common effort of understanding and improving mathematics education have touched everyone with whom he has come into contact. Officially retired since 2015, he remains as active and engaged as ever.

To sum up, over the 40 years of his career, Professor Dreyfus has been contributing to our collective endeavor of promoting mathematics education in great many ways: as a researcher, as an editor, as an organizer and policy adviser, and as a teacher and mentor. So far, he has published more than 120 research papers and book chapters, 9 edited volumes, and diverse teaching materials. His writings continue to be read and cited widely, and research programs he initiated or helped establish continue to thrive and inform the field. Even now in his retirement, he continues to shape the field, to foster young researchers and to influence research and policy, both in his own country and abroad. For all this and his many other contributions to our community, Tommy Dreyfus is an eminently worthy candidate for the Felix Klein Award.

Acknowledgement from the awardee, Tommy Dreyfus (Fig. 5)

I am very much honored by receiving the Felix Klein award. And since many people have contributed to this honor in different ways, I feel that I receive the award in the name of all of us.

I would like to thank ICMI, its presidents, its secretaries general, its committees, and especially the award committee chaired by Anna Sfard.

Fig. 5. Tommy Dreyfus gave an awardee speech

My thanks also go to Angelika Bikner-Ahsbahs, to Michael Fried and to all those other friends and colleagues who invested considerable amounts of thought, time, and energy in the submissions of my candidature. I say submissions because there were repeated submissions over several years. I am aware that the decision-making process is very complex: There are many worthy candidates each year, and the decision depends on how the candidature is presented.

True, my career does have something to do with it, and such a career is also a very complex process, on which very many people have a strong influence, starting from a very young age.

Being aware of this, I would like to thank my parents, who have consistently supported my education without pushing me. I am also grateful to my wife of many years Marianne and to our children, Rafael, Judka and Eytan, who have both profited and suffered from my academic career, for example from its many displacements for sabbaticals and conferences.

I have profited from a supportive education system in Switzerland with teachers who have encouraged my intellectual curiosity and consultants who have directed me towards studying mathematics, physics and teaching.

Once I turned toward mathematics education, four people have had an early and lasting influence on my career:

- I would like to thank Ted Eisenberg who taught me what mathematics education is all about and that mathematics is central to it.
- I would like to thank Rina Hershkowitz who taught me that and how research is closely connected to practice, namely real students learning in actual classrooms.
- I would like to thank Pat Thompson who taught me the importance of original and rigorous analysis of both, mathematical content and students' thinking.
- And I would like to thank Dina Tirosh who somewhat later integrated me into a top-level research team, which offered me the atmosphere and opportunity to focus my activity on research and teaching.

Many others have contributed to my career, including my PhD students. They are too many to name here, but it is important for me to mention David Clarke, whom so many of us are missing at this time. David has shown us by example what it means to do international and intercultural research on a large scale, and how much we can learn from it.

Due to people like David and many others, mathematics education as a scientific domain, has achieved a lot over the past 40+ years, both empirically and theoretically. I think, our research has shown that there is huge potential for improving the mathematical education of students from pre-kindergarten to graduate school everywhere, even if we haven't yet quite learned how to bring the insights from research to bear on a majority of classrooms. I think we live in an exciting period of innovation. This finds its expression, among others, in several new journals which are not simply additions to the literature, but which incorporate new directions in the field: The *International Journal on Research in Undergraduate Mathematics Education*, *Digital Experiences in Mathematics Education*, and most recently *Implementation and Replication Studies in Mathematics Education*. This makes me optimistic about the domain of mathematics education, and I wish a dynamic development to this domain for the coming decades.

2019 Hans Freudenthal Award

The Citation[14] read by Anna Sfard

The Hans Freudenthal Medal, with which ICMI honors innovative, consistent, highly influential and still on-going programs of research in mathematics education, is being awarded in 2019 to Professor Gert Schubring, a long-time member of the *Institut für Didaktik der Mathematik* at Bielefeld University, Germany, and an extended visiting professor at the *Universidade Federal do Rio de Janeiro* in Brazil. This award is being granted to Gert Schubring in recognition of his outstanding contribution to research on the history of mathematics education.

Gert's studies of over four decades has opened new, important avenues of research into the phenomenon of mathematics education. Trained as a mathematician, Gert has been a member of the *Institut für Didaktik der Mathematik* since 1973, when this interdisciplinary research institute for mathematics education was founded. In his doctoral dissertation, defended in 1977, Gert wrote on the genetic principle in approaching historical research in mathematics. Afterwards, he extended his interests, producing wide-ranging writings on the history of mathematics education within and across countries, and publishing on the history of mathematics. One of Schubring's earliest publications came out of the symposium, *Comparative Study of the Development of Mathematical Education as a Professional Discipline in Different Countries*, presented at the Fourth ICME conference in Berkeley in 1980. This set the

---

[14] https://www.mathunion.org/icmi/awards/hans-freudenthal-award/2019-hans-freudenthal-award

stage for the mathematics education community's reflection on itself as a discipline, and on how its own social context had framed its objects and methods of study. By inviting us to place ourselves in front of a mirror, Gert also sparked interest in the history of earliest efforts in mathematics education, including the work of Felix Klein, on which Gert has recently co-edited the important book, The *Legacy of Felix Klein* (2019, Springer).

His seminal works have helped to realize the importance of considering the social context in the study of the history of mathematics education. If this field of research is now well acknowledged, it is in large part due to his theoretical and methodological contributions, as well as to his leadership in scientific communication.

Another, related but separate, strand of Gert's pioneering work was the study of textbooks, which he began in his investigations on the evolution of mathematics teaching in Latin America. This is yet another area of research that he helped to recognize as worth attention. In 2017 he also chaired the International Program Committee for the *Second International Conference on Mathematics Textbook Research and Development* held in Rio de Janeiro, Brazil.

Schubring has also laid out the formal structures that helped in turning the study of the history of mathematics education into an academic field. He was the founding co-organiser of *International Conference on the History of Mathematics Education* (ICHME), a forum that since 2009 has already met six times. After leading the Study Group on the 'History of Teaching and Learning Mathematics' at the 10th ICME conference in 2004, Gert became the founding editor of the *International Journal for the History of Mathematics Education*. Gert also co-edited the *Handbook on the History of Mathematics Education* published in 2014, in which he contributed to four of the handbook chapters. He is co-editor of the new book series *International Studies in the History of Mathematics and its Teaching*, which includes the 2019 volume he edited himself, titled *Interfaces Between Mathematical Practices and Mathematical Education*.

An important aspect of Gert Schubring's work was his straddling of the communities of the history of mathematics and of mathematics education. His own book in the former field, *Generalization, Rigor and Intuition*, published in 2005, is a major reference in the history of mathematics focused on 17th–19th–century mathematics. Additionally, several publications in mathematics education journals (such as *For the Learning of Mathematics*) introduced tools and concepts from the history of mathematics, such as methodologies for analyzing historical texts, that greatly enrich mathematics education research. Similarly, Gert brought ideas in mathematics education, such as the notion of "mathematics for all" back into the fold of the history of mathematics, to examine what kind of knowledge mathematics has been taken to be in different cultures and historical periods.

For decades, Gert has been actively promoting the study of the history of the field of mathematics education, while simultaneously conducting significant historical studies of his own. No other researcher has had a greater impact on establishing the social history of mathematics education as a dynamic field of scholarly endeavor. His work has not only made us aware of the past of mathematics education but has also provided important insights into mathematics education as it stands today and sets directions for its future. His work informs current teaching by showing ways in which historical mathematical texts can inspire pedagogy. It makes us aware of future possibilities and of the fact that they do not have to be merely determined by the past, but rather can be moulded by new understandings of past practices, values and ways of thinking. All these important contributions make Professor Gert Schubring an eminently deserving recipient of the Hans Freudenthal Medal for 2019.

Acknowledgement from the awardee, Gert Schubring (Fig. 6)

Fig. 6. Gert Schubring gave an awardee speech

I am deeply impressed, feeling gratitude to be honored by being awarded the Hans Freudenthal medal of ICMI (Fig. 6). I am thanking so much the award committee, and I am thanking, in particular, Anna Sfard for her so even emotionalizing citation, and I am thanking the entire executive committee of ICMI.

As I will explain a bit more in my awardee lecture, I am maybe the one Freudenthal awardee who has been in the most various contexts in contact with Hans Freudenthal. Thus, at first when beginning my mathematical research upon results he had obtained about Lie groups, later on meeting him and being in personal conversations at meetings on mathematics education, then being instigated by his remarks on research about the history of mathematics. And more recently, being in involved in discussions about politics of mathematics education, in particular regarding the impact of the program of 'realistic mathematics education', launched by him. I am most grateful for the analysis and presentation of my research, just exposed in the citation by Anna Sfard, which gives a highly fitting insight to the research program established and developed by me, together with a still growing number of co-workers. Actually, coming from mathematics history, my understanding always was that history of mathematics contributes substantially to the entire field of mathematics education.

But let me make a remark on terminology, namely on English terminology: while one has, in French, in German and in Italian, different terms for the discipline, say Didactique des mathématiques, and Didaktik der Mathematik — to be distinguished from Enseignement des mathématiques and Mathematikunterricht, in English one has just one generic term "mathematics education" — thus, let us say, for theory and practice. Yet, Mogens Niss in 2004, when he created for ICME-10 the first proper Topic Study Group, he chose a more specific term for this research program. It was him who established, by creating this TSG, the research program as an international field and he called it quite appropriately as "history of mathematics teaching and learning", instead of using "mathematics education". In fact, my principal aim with his research always was to approach as much as possible the reality of mathematics teaching, the reality in the mathematics classroom — thus going beyond mere descriptions of, say, administrative decisions. And I will comment more in my awardee lecture upon the methodological challenges facing this approach and upon achievements resulting from this research program.

Regarding the second meaning of 'mathematics education', Didaktik der Mathematik, I have always also researched about the history of mathematics education as a scientific discipline. Thus, besides the workshop organized within ICME 4 in Berkeley, in 1980, about the emergence of mathematics education as a scientific discipline, mentioned already in the citation by Anna Sfard, I might mention that I published even a book about the history of IDM at Bielefeld University (*Institut für Didaktik der Mathematik*), which proved to act so decisively for the development of the discipline. I should also like to mention my lecture at the ICMI Centenary, in Rome in 2008, so amazingly well prepared by the ICMI executive committee to celebrate the hundred years of ICMI, which had been created in 1908 as IMUK, Internationale Mathematische Unterrichtskommission and CIEM, Commission Internationale de l'Enseignement des Mathématiques. And I should like to recall the reaction to my historical lecture about the first period of IMUK by Michèle Artigue, one of the ex-presidents of ICMI who had so well emphasized the challenges for international cooperation, showing the importance of being really careful since one is devoted to international cooperation in education — not becoming instrumentalized for political strategies, as practiced by the victorious Allied Powers after World War I.

Thus, I am thanking you all very much, thanking very much the ICMI executive committee, thanking the award committee, including Lena Koch who is the ICMI administrator, who has done so much for the administrative processes enabling all of this. Finally, I am waiting questions after my awardee lecture. Thank you.

2020 Emma Castelnuovo Award

The Citation[15] read by Konrad Krainer

ICMI is delighted to announce that the 2020 Emma Castelnuovo Award for

[15] https://www.mathunion.org/icmi/ 2020-emma-castelnuovo-award

Outstanding Achievements in the Practice of Mathematics Education goes to NCTM — the National Council of Teachers of Mathematics (USA and Canada) — in recognition of 100 years of development and implementation of exceptionally excellent and influential work in the practice of mathematics education.

Founded in 1920, NCTM is the world's largest mathematics education organization, with 40,000 members and more than 230 state, provincial, and local affiliate organizations and other affiliates whose scope covers the USA and Canada.

The Award Committee found evidence to fulfill all criteria related to the Emma Castelnuovo Award. In the following, some exemplary activities of NCTM's past 30 years are highlighted. These activities fall into a wide range of domains — principles and standards as foundations for policy and practice, publications including research journals, professional development, legislative and policy leadership, and international collaboration.

In 1989, NCTM presented Curriculum and Evaluation Standards for School Mathematics, which turned out to be a highly influential document, not only in North America, but all over the world. This document was followed by a series of further book-length reports aimed at establishing a broad framework to guide reform in school mathematics, Professional Standards for Teaching Mathematics (1991), Assessment Standards for School Mathematics (1995), Principles and Standards for School Mathematics (2000), Curriculum Focal Points (2006), Principles to Actions: Ensuring Mathematical Success for All (2014) and Catalyzing Change in High School Mathematics: Initiating Critical Conversations (2018).

Since its inception in 1920, NCTM has published professional journals for teachers of mathematics. Starting with January 2020, a single journal Mathematics Teacher: Learning and Teaching PK-12, published 12 times a year, will replace what has been for the past 30 years three journals. In 1970, NCTM began publishing the Journal for Research in Mathematics Education, one of the world's first journals devoted to this subject. These periodic publications are supplemented by an extensive publication catalogue for teachers at all levels. Some NCTM publications have been translated into other languages, including Arabic, Chinese, German, Korean, Portuguese, Spanish and Swedish.

For the professional development of teachers, principals, and other stakeholders important for mathematics teaching, NCTM holds an annual meeting and exposition along with three regional meetings each year, with a combined attendance of about 25,000. In addition, NCTM offers multiple professional development activities, professional services, and resources via its webpage. NCTM's Mathematics Education Trust (MET), established in 1976, provides funds directly to classroom teachers, affiliates, and institutions to enhance mathematics education. MET offers 30 grants annually, totaling USD 125,000. In addition, it offers scholarships, award programs, and — usually two — annual lifetime achievement awards.

NCTM is influentially engaged in constructive policy discussions among all stakeholders (in particular in the USA), focusing on improving mathematics teaching for all students. This process is supported by the NCTM Advocacy Toolkit, a collection of materials which provides NCTM members with tools and the guidance they need to advocate for mathematics and education.

For spreading NCTM ideas internationally and for establishing contacts and collaboration worldwide, NCTM founded the International Corresponding Societies, currently with 19 organizations in all continents, and has supported several initiatives with educators in Latin, Central, and South America.

NCTM's work has influenced the efforts by teachers, researchers, administrators, and other stakeholders to foster excellence in the practice of mathematics education. Here are some selected quotations from letters supporting NCTM's nomination for the Emma Castelnuovo Award.

An internationally well-known mathematics educator stresses: "I have never lived or worked in the United States, and yet, as a teacher and as an academic, I was aware of the work of the NCTM. I drew on their resources and publications knowing that I could access a wealth of high quality materials developed by expert practitioners in the field. … (T)he NCTM Principles and Standards and the Curriculum Focal Points are curricular documents that I return to frequently when looking at putting together mathematics teacher education courses for pre- and in-service teachers in ways that ensure breadth and depth, with inclusion of the big ideas in mathematics. I have often passed these documents on to students from many parts of the world to use to think about the relative emphases and absences in their own national and regional curricula. Later, as an academic, I made widespread use of articles published across the raft of NCTM journals. … The NCTM has worked tirelessly to advocate for high quality mathematical access for all children. ... The NCTM is an organization that has succeeded in doing this kind of work at a scale that is bigger than any other organization that I can think of."

An internationally well-known mathematics educator from the USA emphasizes, among other considerations, the important role NCTM plays in supporting ICMI activities, for example by providing grants to NCTM members for attending ICME conferences, and by supporting the writing and distribution of documents about mathematics education in the USA since ICME-9 in 2000.

Finally, here is the voice of a former mathematics teacher in the USA:

> "NCTM has been an integral part of every stage of my nearly 50-year career in mathematics education, from classroom teacher, to school and district supervisor, to state mathematics director, to my varied leadership efforts that continue at the state, local, national, and international levels. … It is clear that the National Council of Teachers of Mathematics has been the voice of mathematics education for at least these past five decades of my personal involvement. More than that, there is no doubt in my mind that the Council has also served as the leader within our profession — articulating a shared vision of professional mathematics educators, supporting and disseminating research behind that vision, and providing resources for the classroom and the board room to make that vision

a reality. NCTM is absolutely indispensable to anyone who cares about or works in any area related to mathematics teaching and learning".

There are many more such quotations that could have been included. It is fully evident that NCTM is an outstanding organization that well deserves the recognition of the Emma Castelnuovo Award for excellence in the practice of mathematics education.

Congratulations from Baylor University, by Nancy Brickhouse

Welcome virtually to Baylor University in Waco, Texas, USA. Our mission as a university is to prepare leaders for worldwide service. So, we are thrilled to take part in this global event held by International Commission on Mathematics Instruction, and honored to present the Emma Castelnuovo Award for excellence in the practice of mathematics education which celebrates international leadership in mathematics education.

Welcome to Baylor's School of Education, where Dr. Trena Wilkerson is a professor of mathematics education and a leader in the university's efforts to train future teachers of mathematics and to conduct impactful research to advance the study of mathematics.

Dr. Wilkerson, because of her outstanding leadership in mathematics education, is serving a two-year term as President of the National Council of Teachers of Mathematics and she accepts this award in that capacity.

Thank you to the International Commission on Mathematics Instruction for your worldwide leadership and for presenting this significant award to NCTM in recognition of NCTM's advocacy, research, policy work and support of mathematics educators at all levels. And thank you to Dr. Trena Wilkerson for representing Baylor University as well as NCTM and all teachers of mathematics in accepting this award. Congratulations to NCTM for this prestigious award in recognition of your leadership in and support for mathematics education for more than 100 years. I am honored to make this presentation of the Emma Castelnuovo Award for excellence and practice of mathematics education to the National Council of Teachers of Mathematics.

Dr. Wilkerson, as you come to receive this award, the first thing I have to give you is a gold medallion of the Emma Castelnuovo Award given again to the National Council of Teachers of Mathematics.

Acknowledgement from Trena Wilkerson*, *in name of the NCTM (Fig. 7)

I appreciate the support and leadership in mathematics education of Dr. Nancy Brickhouse, Provost of Baylor University, who is here with me today to present the award in our virtual environment. I extend gratitude to Dr. Brooke Blevins who is the chair of my department, the Department of Curriculum and Instruction and Dean Shanna Hagen-Burke, Dean of the School of Education for their continued support. The focus of this award aligns well with our Baylor School of Education's vision which is to prepare leaders, impact the world and shape the future.

The National Council of Teachers of Mathematics is honored to receive the International Commission on Mathematical Instruction Emma Castelnuovo Award for

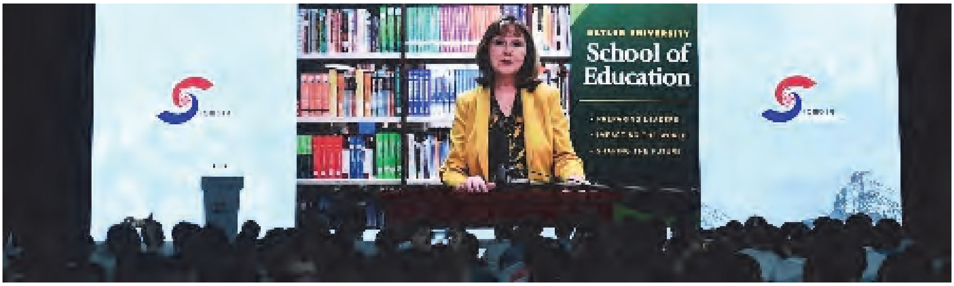

Fig. 7. Trena Wilkerson gave an awardee speech on behalf of NCTM

Excellence in the Practice of Mathematics Education. It is an honor to receive such a prestigious award that was named after Emma Castelnuovo, an Italian mathematics educator, to honor her pioneering work in mathematics education. Her work aimed at a way of teaching that actively engaged students, marked a key point in history for teaching and learning mathematics that fostered a discovery learning environment for all students from elementary through university. NCTM is honored to continue to build on this legacy so that each and every student has an engaging, high-quality experience in learning mathematics.

As President of the National Council of Teachers of Mathematics, I would like to thank The United States Commission on Mathematics Instruction, chaired by John W. Staley for submitting the nomination of NCTM for this award.

The U.S. Commission noted that the National Council of Teachers of Mathematics is the public voice of mathematics education, supporting teachers to ensure equitable mathematics learning of the highest quality for each and every student through vision, leadership, professional development, and research. We also are grateful for the multiple letters of support that were included in the nomination.

Our thanks go to the International Commission on Mathematical Instruction for awarding the 2020 Emma Castelnuovo Award to the National Council of Teachers of Mathematics. I would like to thank Dr. Jill Adler, President of the International Commission on Mathematical Instruction. It was an honor for NCTM to receive notification of the award from Dr. Adler in October of 2019. I also thank Professor Konrad Krainer, Chair of the Emma Castelnuovo Awards Committee and the entire committee for their work in reviewing nominations. We are honored.

NCTM's work in mathematics education is consistent with the International Commission on Mathematical Instruction's principles which are:

- The development of mathematical education at all levels and;
- The promotion of reflection, collaboration, exchange, and dissemination of ideas on the teaching and learning of mathematics from the primary to the university level.

NCTM's mission is to advocate for high-quality mathematics teaching and learning for each and every student from early childhood through secondary school and beyond. NCTM includes mathematics educators from preschool, elementary, middle grades, high school, universities and colleges across the United States and Canada and 171 other countries across the world with over 30,000 members and more than 230 Affiliates. NCTM also established the International Corresponding Societies (currently 19 organizations with representatives from South and Central America, Europe, Asia, Africa and Australia) to build ties with professional associations of mathematics education in other countries.

I would like to take this opportunity to recognize Ken Krehbiel as Executive Director of NCTM. He has provided professional leadership for the organization for over 20 years. He has guided NCTM in multiple efforts to further the mission and vision of the organization. I also want to acknowledge the work and leadership of Dr. Robert Q. Berry, III who was NCTM President at the time of the nomination and continues as Past President and Matt Larson who was serving in the role as Past-president of NCTM at the time of the nomination.

On behalf of the National Council of Teachers of Mathematics, I want to again thank the International Commission on Mathematical Instruction for honoring NCTM with the Emma Castelnuovo Award for Excellence in the Practice of Mathematics Education. It is an honor to accept the award on behalf of NCTM.

The Opening Ceremony

Final Remark by LOC Co-chair

Binyan Xu[1]

Distinguished guests,
ladies and gentlemen on-site and online,

The long-awaited ICME-14 finally opens.

Due to COVID-19 pandemic, ICME-14 has been postponed for a whole year and has to adopt a hybrid mode of participation. Rather, the academic activities of ICME-14 are not affected.

Fig. 1. Ms. Binyan Xu delivered the final remark on the Opening Ceremony

During the Congress, there will be 4 Plenary Lectures, 3 Plenary Panels, 4 Survey Team reports and 5 reports by ICMI Award winners. In addition, more than 60 invited lectures are also in store for you.

ICME-14 sets up 62 Topic Study Groups, As the most active form of academic activities, TSGs will provide opportunities for mathematics educators from all over the world to communicate in different fields, about different themes, concepts, technology, key elements and methods from different perspectives and viewpoints.

Furthermore, the Congress has received more than 300 academic posters, 15 discussion groups and 27 workshops.

There will be 4 national presentations hosted by 4 countries or regions. Besides, ICMI study will report its research results, and ICMI Affiliated Organizations will also

[1] Professor, East China Normal University; one of the Co-chair of the Local Organizing Committee of ICME-14. E-mail: byxu@kcx.ecnu.edu.cn

organize relevant academic activities. ICME-14 sets up “A Special Thematic Activity of Chinese Mathematics Education” for this special thematic afternoon. A total of 13 teams will report their research results, presenting to the world the features of mathematics education in China in a comprehensive way.

Regarding the specific schedule of the Congress, please check out the program brochure. Please don’t hesitate to contact our staff members should you have any questions. Thank you very much for your support for the Congress! I believe, with our joint participation and concerted effort, this congress will be a unique event in the history of international mathematics education conferences.

Today, we feel honored and proud that ICME is held in China for the first time and mathematics educators get together from all over the world. The only pity is that many distinguished guests are not able to be present at the congress because of the pandemic. Here, I’d like to tell you that the invitation from Shanghai is always valid. After we pull through the pandemic, you are welcome to visit Shanghai and China in person to feel the cultural development of Shanghai and China and the latest condition of Chinese mathematics education. We’ll have a communication of thoughts by Liwa River of ECNU — a cradle of mathematics educators.

Finally, I hope all the guests will express your opinions freely at the congress, demonstrate the latest achievements in mathematics education worldwide, communicate about international mathematics education issues, acquire inspirations about the development of mathematics education and promote jointly the vigorous development of mathematics education.

Wish the Congress a great success!

Plenary Lecture 1

Mathematics in the Society[1]

Cédric Villani[2]

ABSTRACT Mathematics is an art as old as civilization. Most of the time hidden and respected, sometimes appearing in bright light, mathematicians have always had a privileged role in society, as problem solvers, guardians of an art, deeply attached to values of intellectual freedom and opinion challenge. "The essence of mathematics lies in its freedom", said Georg Cantor. But mathematicians are also accountable to society, which is in need of keeping a link to its most singular and respected science, especially at a time of algorithmic transformation. I was lucky enough to experience the role of mathematician as a public spokesperson, advocating for mathematical sciences as both an art and a technology creator. Later, as a member of Parliament, then head of the Scientific Parliamentary Office, I experienced the intensity and complexity of science in politics, at a time when public action needs to rest on science and when human factors are more challenging than ever.

Keywords: Mathematics; Science; Art; Society; Politics.

1. On Challenging Established Knowledge and Finding Your Way

This is Cédric Villani, speaking from Paris, delighted to be here as part of this 14th International Congress on Mathematical Education.

It's my pleasure to address to such a large audience. All my life has been devoted to sharing and transmitting knowledge, experience, advice. And in particular I'm addressing to young participants of ICME, to talk about mathematics in the society, such an important constantly renewed subject.

One day, I was invited to a very broad audience, French television show. And I knew I had just one minute to talk about the essence of mathematics. And I chose to bring with me three objects to illustrate the nature of mathematical sciences.

The first one was a book — *The Elements* of Euclid (Fig. 1a). The book sounds so familiar to mathematicians. This is the most edited book in the history of mathematics and also one of the most edited books in the whole history of the world. And also for many people like me, as a child, Euclidean mathematics, Euclidean geometry was my first contact with mathematics, with mathematics of reasoning.

[1] This article is the transcript of the video record of Prof. Villany's Lecture on ICME-14, modified and approved by the lecturer.

[2] Institute Henri Poincaré, France.

(a) (b)

Fig. 1. *The Elements* of Euclid and the gömböc

The second object which I brought with me for the television show was this one, the gömböc (Fig. 1b). This Hungarian-discovered solid object, which is homogeneous, which has only one stable equilibrium and one unstable equilibrium. So if I let it, put it whatever position you want on the table, it always come back to the stable equilibrium which is this. And there is just one unstable equilibrium which is the gömböc standing on the tip. You find all the information you want on this object. It has always fascinated the audience whenever I showed it.

First thing was the book of Euclid. The second was the gömböc. And the third one was the very familiar object which is the smartphone.

And I argued that these three objects contain the diversity, the whole narrative of mathematics. Very ancient like Euclid, and very ancient because mathematics is the only science in which discoveries are made for eternity. There is a famous description by Albert Einstein saying that this is the reason why mathematics is above all other sciences. Once you establish a truth in mathematics, it remains true forever. And the theorems of Euclid are still as true nowadays as they were before.

But also Euclid is the symbol of the time when mathematics ceased to be just rules for computation and solving problems, but also became a science of reasoning, induction.

You know the fact that mathematics wants extreme care in the reasoning. Mathematics is the only field of science in which one billion clues all going in the right direction, the same direction is not sufficient to be a proof. That's the only field of mankind's knowledge, that the only field in which you need logical reasoning, and only that to establish truths.

Now on the other hand, mathematics is not just reasoning. It's also very concrete. That's the restriction with smartphones, or with the gömböc. The gömböc is an object. The smart phone is something which allows to do a lot of things. And in one case, the gömböc is something that is just for the art. There is no application which is known of the gömböc. Nobody has made money out of it, except maybe people who make the shape and can sell it to fascinated people like me. It is beautiful but does not serve any purpose except the advancement of science and knowledge.

But on the other hand, you can make fortune on smartphone, and this is a technology which is based on mathematics.

And in math, you cannot distinguish the part which is just for the sake of the art and that part which is for the sake of applications. They go together. You cannot distinguish the concrete realization and abstract reasoning. They go together. And you cannot say that there is old mathematics and the new mathematics. They all go together. And there is a stream from the ancient past to nowadays and to the future. So you have there all the diversity. Also in the problems, the problem you can ask about Euclidean geometry, about geometry of triangles which was so fascinating for me as a student. But somebody else will be fascinated by the mysteries of the complex shapes and gömböc that appear like a challenge. Some other people will be fascinated with the applications of theory of communications and cryptography and whatever. So, the essence of mathematics lies also in the extreme diversity of motivations and applications, and of ways to do this.

And whenever in the conference you insist on the beauty of mathematics, you can be sure, that somebody in the audience will tell you: “But you know, the importance is that mathematics is useful.” And whenever in the conference you insist that mathematics is useful, you can be sure that somebody will tell you that the importance is that it’s also beautiful.

Mathematics is both science and technology, and both science and art. And no other science certainly, is at the same time so deeply an art. Now of course, the status of mathematicians is very much influenced by this stage of mathematics. We have to remember it as a mathematician. The mathematicians are guardians of an art. They keep the recipes, the tricks, the theories. They passed it from one generation to another. They keep alive in their brains, the discovery, the recipes. But also the mathematicians are experts in finding, discovering new ideas, new concepts, new structures, new arguments.

And this goes with the particular mentality which is always on the side of challenging opinions. New mathematics is very often obtained by challenging points of view. And it’s something that I experienced in my career many times as a mathematician to make some progress. If you just follow the rules and advices given by your advisor, you are not making progress. You may obtain new computations, new applications. But you don’t have new ideas. You form the mathematic art, you form the reasoning. These ones come when you challenge what comes from the lessons, coming from the master.

And through the centuries, you see so many examples of mathematicians making new discoveries by challenging the theory that was known at that time, by bringing in a new whole point of view to that. There are famous histories about this, famous stories which I often tell about, for instance, about the history of the stability of the solar system. It’s one of these cases in which new theories emerged generation after generation. And the point of view changed so many times. Each time the generation of mathematicians thought with the view point that was contrary to the one of the previous generation.

Let's get started with Kepler. Kepler discovered the famous laws, named after him. He showed perfect, harmonious and simple laws, governing the solar system, an image of perfect stability. Then this was contradicted by Lagrange, Laplace and Gauss using brand new theory of arrays and perturbation theory, a masterpiece showing that stability had to occur over very large scales of time, like millions of years or something like that.

Then later it was again contradicted by Henri Poincaré. Poincaré actually thought he started to think that he could prove the long-term stability. And then he discovered, after receiving the famous prize of King Oscar of Sweden that, in fact, he could prove the possibility of instability, it was one of the famous mistakes in the history of mathematics. And after the work of Poincaré, people believe in the instability of the solar system over a very large period of time.

And then in the middle of the twenty's century, then come Kolmogorov, Arnold and Moser's beautiful work putting together classical mechanics and probability theory and Hamiltonian dynamics and new rules of probability coupled with mechanics, showing that under some assumptions (not satisfied in practice, but you could imagine applying their spirit in real life!), that had to be, with large probability, forever stability. Beautiful piece of work! And then the mood of mathematicians about the stability of the solar system had to swing again.

Then the 70's came people like Laskar and Tremaine using huge computer simulations and very clever mathematical ways of rewriting the equations showing that in practice, there should be some instability after all. So from Kepler to Laskar, you see that the mood of the dominance theory about this particular problem of solar system stability has changed many times.

Each time it comes when somebody challenges previous theory and challenges the point of view in the idea. He does not say that what the previous guys said is wrong. Remember, mathematical truths are eternal! He says "they had one point of view, but I think there is a better point of view which is this one. And this is my set of assumptions. And we try to convince you why it's the better representation of the reality and why it's better for the prediction."

This is one story. There are thousands of such stories. But this one about the stability of solar system may be the most famous because it's one of these problems in which trying to solve the problem has generated entire fields of mathematics, from matrix theory to perturbation theory, to development of probability theory, to the development of numerical computations, numerical analysis. And this is always the interplay of mathematics, the history of problems, the history of concepts. They go hand in hand.

New concepts enable to tackle new problems. New problems force you to discover new concepts. And there you go.

This story is full of adventures, full of unexpected things, full of mistakes. These are unexpected adventures. I would say, as a consequence, the mathematician always has to be on the side of freedom of thought, freedom of speech, freedom of being able to contradict the master because this is so much engraved in our field.

Mathematician is deeply rooted in democracy, and related to democracy. And the idea is that everybody is allowed to contradict and to raise an objection.

I realized this very early, when, as a high school kid, I was confronted with mistakes of my teacher. It did happen. I remembered this course in mathematics, the teacher started to prove some theorem, etc. I saw the theorem. I could not believe it. I was maybe 14 years old, At the end of the course, I went to see the teacher and I told her "Madame, I think there is a problem with the statement that you gave us because I think I can construct a counterexample". And I showed her the counterexample. She said this was strange. I explained to her etc. She said she had to think about it. The next day and at the next course, she told me "Ok, you were right, my proof was bogus". She made a correction for the whole class. So this was an example that when you were a school kid, you are not obliged to believe in what you are told by the master. You can contradict. And if the master is of good faith, good will, the master will recognize that he or she is wrong.

In all other sciences, this is impossible. In physics, they tell you about the existence of atoms, how can you contradict the existence of atoms? You have to believe what you are told about the experiments. In biology, they will tell you about the liver, about the biology of wheat, about the sugar cycle, about the climate… whatever. You are a school kid. How can you contradict that? You have no weapon to contradict. But in mathematics, you do have the power to contradict, because everything is proven by the reasoning. You have a weapon which is your brain, your capacity of reasoning, your free spirit and ability to contradict what you are told. If you give a proof, then you can contradict the authority. I told you the example which I experienced when I was a kid.

But somehow it continued. Look at my PhD thesis. Such emotion when looking at these documents in which I put all my heart. I defended my PhD when I was 25, not so young. And it was about partial differential equations of Boltzmann, and Landau in physical theory, mathematical theory of physics of gas and plasmas. There are many chapters. My PhD started a bit like a joke. I was the president of the students' union in my university at the beginning of my PhD. I was not at all motivated by mathematics. And my advisor was worried about me. And about when I was going to get to work. Once on a small card he wrote me like "You have to, It's time for you to start working." His small document, his small card I reproduced in my PhD. I had no motivation in those days. Then I started to work and work and work. I really started to work when I was promised a good position after my PhD at the École Normale Supérieure.

Anyway, I fell in love with the Boltzmann equations which was a subject in which my PhD advisor was a very well-known master. But in my PhD, the most important parts are not the questions that were asked by my PhD advisor. These were answers to the questions that were found in the course of my PhD. In some cases, questions that my advisor liked. In some other cases, questions that my advisor did not like. Some of

Fig. 2. Villani's book *Optimal Transport, Old and New*

the techniques were radically different from the techniques of my advisor. They were inspired also by other people. My advisor is Pierre-Louis Lions. But I was also very much inspired by Yann Brenier, by Michel Ledoux, by Eric Carlen.

And I developed my own techniques. At the beginning of my PhD, I thought I would do the same spirit and development of what my advisor said. But by the end of the PhD, I had switched. I'd rather use different perspectives, and I had developed some other alternative techniques. And there had to be in this PhD some element of rebellion for it to be a good PhD.

In science, as in the example which I told you, a good will, a good faith, master will always recognize the merit of the student even when the student does not comply to the instructions of the master.

Also I changed subjects. I went into questions that were unorthodox. I developed some old subjects mixing it with new subjects. You know this is a great adventure when you are a young researcher, going everywhere in the world, finding new problems, being invited here, discussing with somebody, finding out there are an interesting problem, going for another collaboration etc etc etc. And this led to a number of productions, a number of new subjects.

This is my favorite, *Optimal Transport, Old and New* (Fig. 2), 1000 pages, thick book which I wrote on the subject which I did not know at the beginning my PhD. And I started to get in the subject as I started to work. By coincidence, by accident, I dipped in the subject. I was invited to some collaborations, then to give a course. Giving a course is the best way to learn your subject. That's also one possibility in which you will grow your spirit, your free spirit, and spirit of contradiction finding for yourself which are the most important things in the subject.

2. On the Art and Science of Mathematics

You need to always remember the sentence of Cantor, the father of the set theory, the essence of mathematics lies in its freedom. It's also freedom which guided me to maybe my most famous work, on Landau damping. The work that let me clear the bar for the Fields Medal. It is quite an accident that I started to work on this problem. Nobody asked me to, of course.

But I wanted to work on another problem regularity of Boltzmann equations. Boltzmann equation is not related to Landau damping. Landau damping is related to Vlasov equations. I wanted to continue my work on the Boltzmann equations. I had a work session with my former student Clément Mouhot — with whom I would wrote the paper eventually. I told him about my ideas. He told me his ideas. He said he remembered a conversation with Yan Guo from Providence. "Maybe there is a relation to Landau damping," he said. I never thought about that. What could it be? Then I remembered another conversation with a mathematician from Princeton. This was the start of our adventure. Then for two years, Clément and I struggled with that theorem. Not knowing at the beginning if we wanted to prove this or that, not knowing which were the tools. Making hundreds of mistakes, some of them were big, some of them were tiny, and going and going on correcting them etc. It was a great story, very fragile in the sense that many times, we thought we were facing a deadend and our proof, our reasoning could not work. In the end, we did, it did work!

Landau damping is a phenomenon of stability of plasmas very important and well-known in plasmas physics and very important in showing applications of plasmas physics which are quite important. And it tells you that in the plasmas, you have some stability, even though the plasmas dynamics is reversible. Reversible in the sense that there are no collisions, no increasing entropy, no arrow of time. So you could think that there is no trend to equilibrium because going to equilibrium in Boltzmann equation is related to the increasing dynamics related to the arrow of time. But in Vlasov equation, there is such damping phenomenon for small perturbations. And genius physicist Lev Landau discovered this in the 30's. It was quite a shock, quite controversial.

Together with Clément, in this huge paper of ours, eventually, we showed, using new theory, new tools that indeed you could set the reasoning of Landau on rigorous mathematical footing provided that you are close enough to a stable equilibrium, provided that your perturbation is smooth enough, and it explains exactly how to compute the expected smoothness needed, making the link with a theory of Kolmogolov, Arnold and Moser, making the link with a famous experiment in plasmas physics called the echo experiment etc, and showing that different various physics phenomenon are related, even though this was not expected by physicists themselves.

So this work was full of adventures, full of wonders, full of miraculous events and so on. I was convinced in my heart that we would tackle and solve all the obstacles. But there was no logic about this belief. Some of my colleagues told me that "It was so difficult so many obstacles. How could you believe that you would solve it?" This is not something rational. It's not something that you learnt at school. It's something about passion that you have inside yourself. I said "Okay, I'm going to solve this mystery and fall in this so deeply that I will become part of the problem." In the sense that you want to solve the problem from within, in the sense that you are dreaming of the problem, with sometime some illuminations when you wake up at night etc. This is the kind of extremely intense state in which you will be.

I always say the three most important characteristics of mathematician are tenacity, imagination, and rigor. Rigor comes third. It's tenacity and imagination will make your mark and your career in the world of mathematics. This what we know when we are researchers in mathematics. But society at large is very much unaware of what it means to be a mathematician and what's the real nature of mathematics. How much passion there is in it. How much surprise there is in it. How much contradiction there can be.

It's very important at a time in which society very much relies on mathematics. It's very important for us to share about the work and the role of mathematics and mathematicians. And this is what I started to do after the Fields Medal in 2010.

I wrote a book to tell about the adventure of Landau damping problem solving. This is the book called "Living theorem" (*Théorème vivant*). The English title is *Birth of a Theorem* (Fig. 3). This is a book which is not written like mathematics book, because there are portraits of mathematicians and there are stories like autobiography a little bit. During a short period of time, during the two years of working on the problem, there are email exchanges, some of them very tormented you know… It's not like usual book explaining about science for broad audience because there are also formulas. There is a portrait of Carlo Cercignani and I explain what was his conjecture. What were the tools that we setup to prove it etc etc. And also I put in the book some of the big formulas that we have to fight with as mathematicians.

Fig. 3. *Théorème vivant* and its English and Chinese versions

And this was, you know, to show in the impressionist way what is the life of the mathematician. Also about cultural aspects like what is it that you do at night, how you work, what kind of the songs you listen to, etc. There is a part of book in which I describe the songs. There is a part of the book in which I describe encounter with various mathematicians etc etc. See, browsing through the pages of the book… This is about the songs… This is about some of the formulas… You know, to show in an impressionist way the life and work of mathematicians, insisting that mathematics is not a deterministic science but also a passionate art.

It's as if your kid wants to know about your work as mathematician. You don't try to simplify things. You bring your kid to work. And the kid will see what you are doing, with whom you are talking. How you are desperate sometimes, happy sometimes. What you are listening to etc. The whole life of a mathematician.

The book, precisely because of the original point of view, had quite a success. It was translated in many languages, including Chinese. An important thing to know about the book is that I was not my idea in the first place. It came by accident by encountering a famous editor in a dinner, several months before the Fields Medal. The editor was attracted by my spider. We talked to engage conversation, what you do, etc. "I was told that you are a famous mathematician."

He wanted to have me write a book for him. But all the examples of books that I could think of were of no interest for him. "I can write you a book on Boltzmann equation", "I don't care", "A book on the Entropy", "I don't care," "I can write you a book on information etc", "No". And he told me "I want to know how you work, how you think as a mathematician. What goes on in your head". I was very much embarrassed. I thought about it. Then the result was the book.

I thought I'm going to write it. It will be what is behind the curtains when you make a discovery of a theorem. And what is the process of being a mathematician. And I will tell it like an adventure. Actually, the editor thought he could even publish it as a novel.

This was the start of many years of communications of mathematics which I undertook in collaboration with various people with always the same idea that to make people understand mathematics, love mathematics. Don't just talk to them about how useful is mathematics. Tell them about the adventure of being a mathematician, about the art.

Tell it like it's a bunch of stories. And stories always mixing three traits, the stories of people, the stories of problems, the stories of concepts. And when you make a lecture, a good lecture, it has to be these three traits together. Maybe the idea of Fourier will come here, in the problem and another problem. Problem that Fourier wanted to solve. And the life of Fourier himself. How he was also in the revolution or after the revolution, the empire etc. And all this makes mathematics an art, a human activity as well as sciences.

I did this for so many projects. For instance, here is a comic strip (Fig. 4a) which I wrote with the great French comics drawer Edmond Baudoin, very famous. It talks about some very important hidden characters involved in science or innovation during

(a) (b) (c)

Fig. 4. Some "non-mathematics" cooperative projects

the Second World War who had a lot of influences through their discoveries, their mistakes, their actions. The kind of spirit they were in, the kind of crazy story that they had to live. And what is in their heads when they are afraid, when they are proud, when they are shamed, when they are full of questions, and so on. So these were Heisenberg, and Turing, and Szilard and Dowding. And telling this as an adventure as well as science in the construction.

Then there's a little bit more crazy project (Fig. 4b) made together with the great photographer Lisa Roze, very particular very special photographs. And she wanted me to write the text corresponding to the photographs. And she was attracted by collaboration with me because she thought highly of my imagination. And she thought I was ready to find some logic behind her photographs, to find some way to order them, to find some text with some kind of boutique twists etc.

This is not mathematics of course. This is contributing to the idea that mathematics comes with imagination as an art.

It's also something which I insisted on the series of standup lectures in the Maison des Métallos, a Culture hall in Paris, very much about bringing quality culture to all kinds of audience, including audience which do not usually get interested in mathematics. Look at the illustrations: You see the gömböc… this is an orrery displaying the motion of planets… the geology… this is a twin surface with negative curvature, whatever.

So in all these lectures, always, it was about the art of it, telling stories, and always stories about bringing together these three straits, story of ideas, story of people, story of concepts. My book being dedicated to a very inspiring mathematical figure that was Maryam Mirzakhani.

So this for a number of years, was the main of my activities, talking about mathematics, making collaborations of mathematicians with artists, finding ways to talk about problems, but also get involved in some projects, some associations, and so on, and being part of society. I strongly believe that we as mathematicians, have to get very much inside the society. This is also something that was one of the main characteristics of the career of my PhD advisor, Pierre-Louis Lions.

3. From Science to Society to Political Decision

Learning to do mathematical communications was not immediate. I had to work hard to find my ways to do mathematical outreach, speak about mathematics to large audience.

It was very important that for many years, I was a professor in Lyon. My neighbor was Étienne Ghys, one of the first masters of mathematical communication. At some point, he was considered the best mathematics lecturer in the world. His lectures in ICM and so on were extraordinary. And he took the job of mathematical outreach extremely seriously and I was very much influenced by that.

In Lyon, there was an atmosphere, both at the École Normale Supérieure in Lyon and in the Lyon I University, there was the atmosphere about sharing to the society, giving account to the society which is legitimate because we are part of the society, we are often funded by the society by public money. But also we need to get from the society the problem, the people, whatever. We are part of the society, we need to find a good way to underline it.

My first interview for a journalist's journal (not a science journal!) was a disaster. The journalist wanted to cancel the interview because it was so obscure, whatever. And then I worked. I went to, you know, learning sessions, master classes whatever and was passionate about that also. I wrote in a newspaper some columns. I was in the radio. I learnt a lot. And there was all these collaborations and the projects that I told you about.

Some of the most important lessons I learnt is that first to attract your audience you need to talk to the heart first, emotions. Something which looks close to you, which will bring a link between the audience and you. Something related to the culture. Culture is what brings people together. Emotion is what brings people together.

Then after you hooked your audience, with these emotions, you can go on with the concepts, with the stories, with the rationality, with the logics, you have to start with the irrational thing to speak. Never separate the concepts from human, human contact, human adventure and so on.

This was somehow in the direction, the continuation of my mathematical work. Then I did more than that and went further on. Becoming a politician and going into politics for real in 2017. Okay actually 2017 was not my first encounter with politics. As soon as 2010, right after the Fields Medal, I started to be engaged in a number of projects, associations, institutes, government, talking with people with all kind of responsibility.

I always had some faithful responsibility. This certainly goes back to the time when I was 21 years old, and I had myself elected as the head of students' office. And I likes it so much, handling the problems, finding how to try to create the cohesion.

After 2010, I was involved in political groups about the construction of Europe, federalist as they are called. I still consider myself as a federalist, name given to those people who believe all nations in Europe have to engage in the strong integration process so that Europe can become a strong unity. A political entity, an economical entity with some cohesion and some political strength. This was back in 2010. But this led me little by little to be more involved with the national politics.

In 2017, with some, you know, some complicated sequence of events, I ran for Parliament. And I was elected. It was a new life that started, new life in which the big problem was how to make sense of my scientific career within the political career. Convinced that each makes sense, to have science and politics, but it's a delicate equation to find the problems and ways in which your scientific experience can be useful. International experiences that goes within research, with the problem solving. That is quite important in politics. Also the fact that, politics nowadays raises a lot of very tricky scientific problems, related to environment, related to pandemics, related to biology, related to energy whatever.

And in these four years, from 2017 to now, on some occasions, I managed to make the better of my scientific experiences. In some other occasions, I did not manage. Whether it was a success or a failure, it was always instructive. Some of the most important things which I think I let to do is the mission on artificial intelligence. I'm showing it to you. This is the journal in which this paper in which there was the interview like "live my life of member of parliament". And it was in those days, when there were many newcomers in politics in 2017, the interviews like "How was it to be in parliament, what do you think". At first in parliament, other members of parliament would look at me as a strange beast, you know. What does this mathematician do, I'm on gas.

There was a time in history in which mathematicians were quite numerous, scientists were quite numerous in the French political life. But this was long ago. There were many examples long ago. Nowadays very few examples.

And one of the first missions that was given to me, for six months, was a mission about artificial intelligence. This is a report which I wrote after six months of work with my team. A report which tries to get a complete picture about the artificial intelligence with consequences for France and for Europe, about data policy, about the ethics of AI, about the job future, about education, about fields of applications that should have priority like health and mobility, environment and defence…

And you know, trying to make the big picture, the whole picture of what AI should be like and why it's the business of everybody. So this report was for writing a technical document, but also for addressing broad audience, going in the TV to talk about AI, going to newspapers to talk about AI, going to debates to talk about AI. Of course, it rested on my experiences of sciences as mathematician.

For instance, this is a book (Fig. 5) which I edited together with medical doctor Professor Bernard Nordlinger, about health and artificial intelligence. I'm writing this on behalf of the academy of sciences, Nordlinger on behalf of the academy of medicine. And we organize conferences, we invite lectures, whatever. So this is the scientific part.

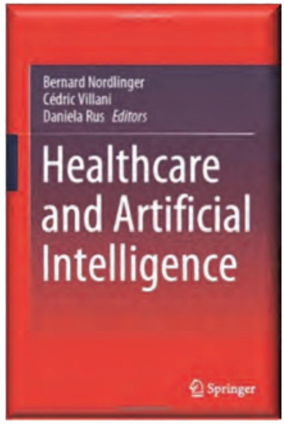

Fig. 5. A book on health and AI edited by Bernard Nordlinger, Cédric Villani et al.

Based on the scientific part, I wrote this report. Nowadays, I still get asked sometimes by members of the government, sometimes by people from the industries, sometimes by just citizens about AI. Asking what I think about this etc. Recently, there was a delegation from people from America to talk and discuss about American report and compare it to the French report and etc. So this is an example in which the scientific knowledge could be brought directly to the heart of the policy and society problem.

The plan which was deduced from this book, from this report has been implemented too, in large part, still a number remains to be done. It became the official plan of AI for the French government.

Another example which was more tricky, was a report on the teaching of mathematics in France (Fig. 6). A work I did with math teacher and inspector Charles

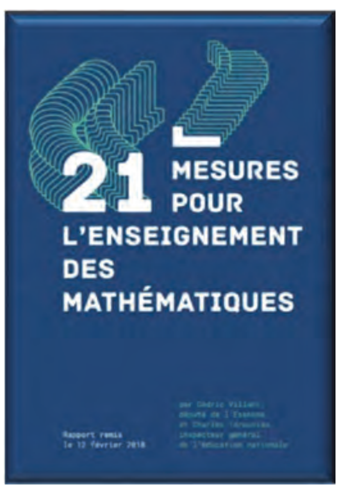

Fig. 6. The report on the teaching of mathematics in France by Villani and Torossian (https://www.vie-publique.fr/sites/default/files/rapport/pdf/184000086.pdf)

Torossian. To show and see what we had to do to repair the French system of mathematics teaching, where were the main difficulties? How to act? Training of teachers on the curriculum, on the tools, on the ways to organize things in high school, in medium high school, in elementary school, etc.

The report went very well. The report was very much praised by the mathematician community, and by the ministry of education and was started to be implemented. And then problems began. The ministry of education did not implement just our report but also a number of other things which had some constraints which were determined by this or that etc. An enormous number of difficulties arose in which I had no role and no part. I did write some warnings for the government and said "okay be careful about this, this and that", but in the end, the situation is extremely confused right now in particular among mathematicians and mathematics teachers.

It's good to write a report. But you always have to remember implementation is much more difficult. I did regret that I was not more involved in the implementation in this case. Maybe some misunderstanding could have been avoided. And currently there's a big number of things to fix still in the mathematics strategy.

Another of the things which I did and which I think was badly needed was the reform of the scientific parliamentary office. More precisely, parliamentary office of evaluation of scientific and technological choices: it is a group made of 18 members of National Assembly and 18 members of Senate. So both chambers of the Parliament working on problems which are of scientific or technological nature, important for enlightening the choice of the politics on it. Say, politicians have to make choices of nuclear energy, but this is a highly technical subject in which you need the opinions of many scientists. We need to organize some contradictory debates and also to hear the point of view from the society etc. That's the role of scientific parliamentary office, organize these debates on problems which are the interfaces of science and politics.

And it was funded in the 80's. It was just funded precisely to work on the subjects related to nuclear energy. So I became the president of this office. And I worked a lot to diversify the themes of the office, to hire scientists within this parliamentary office, to go more in the directions of humans in social sciences, to get more in association with the working groups of the Parliament, to follow more closely the base of the political event, etc. Quite a work.

What subject did we treat recently? Things such as research in polar environment, long-term Covid, or scientific integrity, or viruses used to fight bacterial diseases, or quantum computing and quantum information and quantum cryptography, or open science, or all kinds of therapeutic subjects, you name it. One of the trickiest subjects which we had to handle is the about the new breeding technologies. These new techniques of biotechnology based on editing genome techniques such as CRISPR-Cas9 to edit the genomes of plants. So there are aspects related to biology, related to economics, related to ethics. Lots and lots of debates. In this case for NBT, it was a very hard debate. The two parliament members who were responsible of the subject had conflicting opinions, could not get together. And I, as the president of the office had to step in and organize syntheses with the help of the scientific secretary. We were discussing for a long time on each subject. And we managed to formulate seven propositions, seven recommendations. The two MPs in charge agreed on six of the seven recommendations. And on just one, the seventh one, they had conflicting opinions. And we could exactly pinpoint why and what kind of different values it's corresponding to: Then we have made our job for the benefit of the Parliament. Not taken a decision because it's for the democratic decision to proceed, through the democratic procedure un Parliament. But we studied the subject and analyzed it to the point where a political decision becomes possible by analysing the possible choices. Balancing the various problems and advantages or drawbacks, balancing the natural sciences with the human sciences etc.

A common feature with all these problems that we treated, in fact, is that the most tricky parts are those related to social and human sciences, like opinion issues, bubbles of information, fake news. In science, we are used to the idea that no one a priori has the truth, we have to listen to all the contradictions. Even revered scientists can make mistakes. And there are famous examples in the history of science in which the best scientist of the world makes horrible mistakes, and in fact, some of his opponents was right. We know such examples. Eventually, all these problems get resolved in the right direction. But sometimes it takes time. But one should never a priori believe as a god given truth what somebody or some entity or some institution or some political party says. One always has to think "is this really true? Can I contradict? Where is the logical reasoning?" etc etc. That's what we do at the scientific parliamentary office organizing the political debate, which is the basis of democracy. The heart of democracy is the contradictory, open, sincere debate of ideas.

And I tell you and this would be my conclusion. In a world in which debate of ideas are extremely confused, in a world in which many political problems hugely rely on scientific and technological advances and choices, in a world in which science is hugely used by the power, we, scientists have huge responsibility to get committed in the world and to make sure, but we keep the memory of the past and everything that we can learn from the past, from the history of science, and from history of mankind. And that we get committed to making our vision of the future explicit, saying which are the consequences of the choices that we will make, consequences on our children. What we should transmit to the next generation. Currently, more than ever, and in a world which is more mathematical than ever with the advance of information, technologies, of statistics everywhere, of artificial Intelligence, you name it, all kinds of mathematical application in the world, we, mathematicians have a responsibility of being committed to the society for the future and for the sake of the future generations.

Thank you for listening.

Plenary Lecture 2

Forty-five Years: An Experiment on Mathematics Teaching Reform

Lingyuan Gu[1]

ABSTRACT This is an experimental report on mathematics teaching reform conducted in an urban-rural fringe area in the west of Shanghai. From 1977 to 2022, this experiment spanning 45 years has witnessed a change of Chinese society from bringing order out of chaos to Reform and Opening-up and eventually to educational modernization. At the early stage of the experiment, a methodological system of practical research, featuring "investigation – screening – experiment – popularization", was built up, a feasible way to improve the quality of the education under the most common educational conditions was found, and the Chinese experience of "teaching and learning promote each other", specifically, students learning with experiencing variation and teachers developing through teaching reform, was summed up. At the later stage of the experiment, the focus was shifted to the cultivation of students' all-round ability and an empirical method of "abductive reasoning through big data" was developed. Based on big data experiments and long-period sampling analysis, by way of clinical observation and evidential reasoning, the key to promote students' inquiry and innovation ability was found and, with practical effects, it exerted positive influence upon the society. This report is the result of the persistence, perseverance and the collective efforts of three generations, including the life mentors of the older generation, the backbone of the transitional generation and a large number of young talents. The experiment consists of three stages: 1. improve teaching quality generally and dramatically from a low level (1977–1992); 2. comprehend first and break through the bottleneck of high cognition (1992–2007); 3. improve teaching research and promote inquiry and innovation (2007–2022).

Keywords: Qingpu teaching reform experiment; Experiencing variation; Action education; Abduction of creative ability.

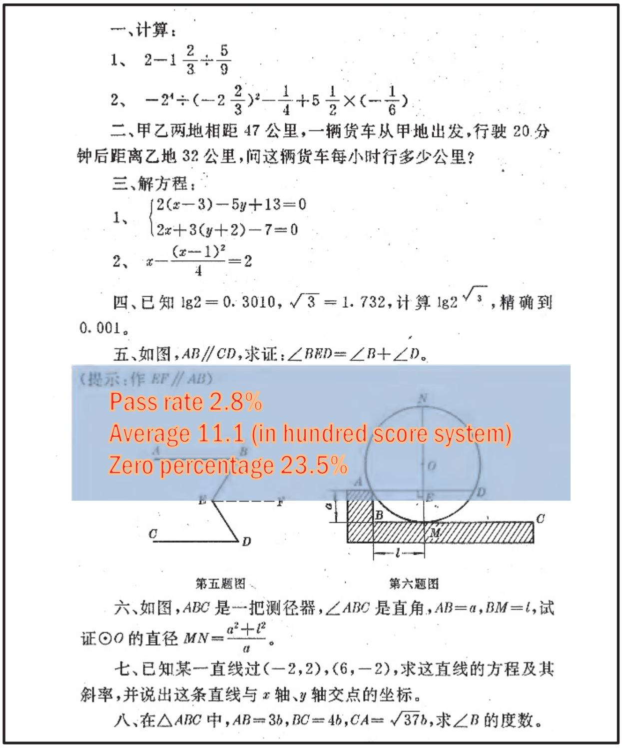
1. Improve Teaching Quality Generally and Dramatically

1.1. A reform experiment initiated by an exam paper

At the end of 1970s, the mathematics teaching quality of the primary and secondary schools in Qingpu County of Shanghai came last in the city. In 1977, we gave a diagnostic examination to 4,373 high school graduates with mathematics problems for

[1]School of Mathematical Sciences, East China Normal University, Shanghai, 200241 and Shanghai Academy of Educational Science, Shanghai, 200032

primary school and junior high school students (Fig. 1). The pass rate was only 2.8%, the average score was 11.1 out of 100, and the zero percentage was 23.5%! How should we deal with the shocking backwardness? The tension between students' low score and modern concepts bred an urgent need for teaching reform.



一、计算：

1、$2-1\frac{2}{3}\div\frac{5}{9}$

2、$-2^4\div(-2\frac{2}{3})^2-\frac{1}{4}+5\frac{1}{2}\times(-\frac{1}{6})$

二、甲乙两地相距 47 公里，一辆货车从甲地出发，行驶 20 分钟后距离乙地 32 公里，问这辆货车每小时行多少公里？

三、解方程：

第五题图 第六题图

六、如图，ABC 是一把测径器，$\angle ABC$ 是直角，$AB=a$，$BM=l$，试证⊙O 的直径 $MN=\frac{a^2+l^2}{a}$。

七、已知某一直线过 $(-2,2)$，$(6,-2)$，求这直线的方程及其斜率，并说出这条直线与 x 轴、y 轴交点的坐标。

八、在△ABC 中，$AB=3b$，$BC=4b$，$CA=\sqrt{37}b$，求 $\angle B$ 的度数。

Fig. 1. The examination[2] of 4,373 high school graduates in 1977

The backbone teachers in Qingpu pledged to the then director of the bureau of education that despite whatever hardships, they were determined to change the backwardness completely. With a strong determination to avenge the shame, they drew

[2] The English translation of the examination paper:

1. Calculate (the question items omitted).
2. The distance between Place A and Place B is 47 kilometers. A truck starts from place A, and, after 20 minutes, it is 32 kilometers away from place B. How many kilometers does this truck travel per hour?
3. Solve equation or system of equations (the question items omitted).
4. Given $\lg 2 = 0.3010$ and $\sqrt{3} = 1.732$, calculate $\lg 2^{\sqrt{3}}$, accurate to 0.001.
5. As shown in the figure, $AB /\!/ CD$, verify that $\angle BED = \angle B + \angle D$. (Hint: Draw EF with $EF /\!/ AB$.)
6. As shown in the figure, ABC is an instrument for measuring the diameter of a circle in which $\angle ABC$ is a right angle. If $AB = a$, $BM = l$, show that the diameter of $\odot\ O$ is $MN = \frac{a^2+l^2}{a}$.
7. A straight line passes through points $(-2, 2)$ and $(6, -2)$. Find its equation and slope. Find also the coordinates of the intersections of the line with the x-axis and the y-axis.
8. In ΔABC, $AB = 3b$, $BC = 4b$, and $CA = \sqrt{37}b$. Calculate the degree of $\angle B$.

up a plan consisting of three-year all-round investigation, one-year experiences screening, three-year experimental practice and eight-year promotion and application.

1.2. A reform design — "15 years to sharpen a sword"

Teaching reform was a game between change and inheritance. Our design principles for the reform were: firstly, adhere to openness and inclusiveness and absorb extensively the information from outside, including experience regeneration, theoretical progress and technology update; secondly, base our screening on practice, and, with continuous improvement and repetitive testing of teaching effect, look for appropriate path in view of the current situation.

The teaching practice was made up of four parts:

(1) Teaching investigation (three years). Conduct a comprehensive investigation into the major problems and their crux in local area, and we collected more than 160 specific experiences accordingly.

(2) Experiences screening (one and half years). Applying experiences in classroom teaching, we did 50 circular screenings repetitively, which included experiments, observation, filtering and optimizing. With a focus on the improvement of classroom teaching, we came to four key teaching behaviors: i) facilitate students to learn under urgent demand; ii) organize the sequence of teaching content; iii) guide students to attempt and explore; and iv) provide feedback and adjustment on the basis of learning results.

(3) Contrastive experiments (three years). Select 440 junior high school students from ten classes and, following the four aspects mentioned above, conduct contrastive experiments under strict control, track and compare 50 pairs of matched students closely.

(4) Popularization and reinforcement (eight years). Popularize and reinforce experiences in the entire district, and introduce the concept of communication into popularization so that popularization would lead to internalization and creativity instead of mere imitation or copy. Make a full coverage relying on multi-level teaching research groups. What we want is not tinkering with the problem, but a large-scale improvement.

These four parts make a complete methodological system of the reform experiment (Fig. 2).

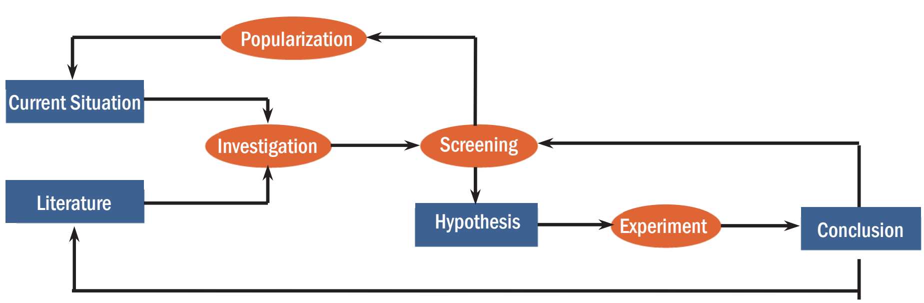

Fig. 2. Method system with circular screening as the core

This experiment always aims at the matching and mutual reflection between full-sample statistics and refined case analysis. We particularly created the method of circular screening, which filled the gap between investigation and hypothesis, and the one between conclusion and popularization & innovation as well. Given our heavy duty of solving real problems, we should avoid the traps of formalization and emptiness, or "scholars revolt" in Chinese idioms.

1.3. Give prompt feedback, make a quick change on the backward situation

The diagnostic examination given in 1977 showed that poor-grade students were all over the county and the total amount was too large to reduce. We took samples from groups with large proportions of poor-grade students, analyzed them individually, observed their homework, and eventually summed up the formation process of their poor performance (1982) (Fig. 3).

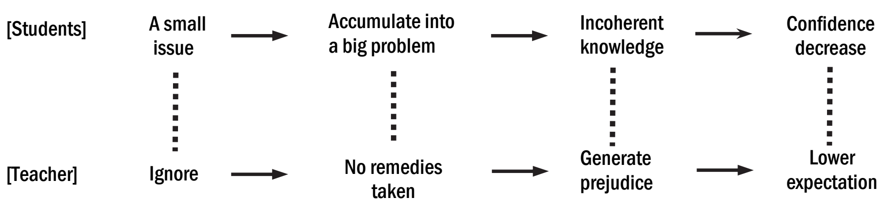

Fig. 3. The formation process of lower-scored students

The observation of students' homework showed that the cause of low score was the accumulation of both teaching and learning problems, which went all the way down to the loss of self-confidence on students' part. We should block this ill cycle promptly. Therefore, we referred to local experiences and gave feedback to students about their assignments within the day, marked their exercises face-to-face and encouraged students generously. Later, we conducted experiments in different groups in 1986, and the result showed that timely and individual guidance with targeted feedback was undoubtedly effective in improving students' score (Fig. 4).

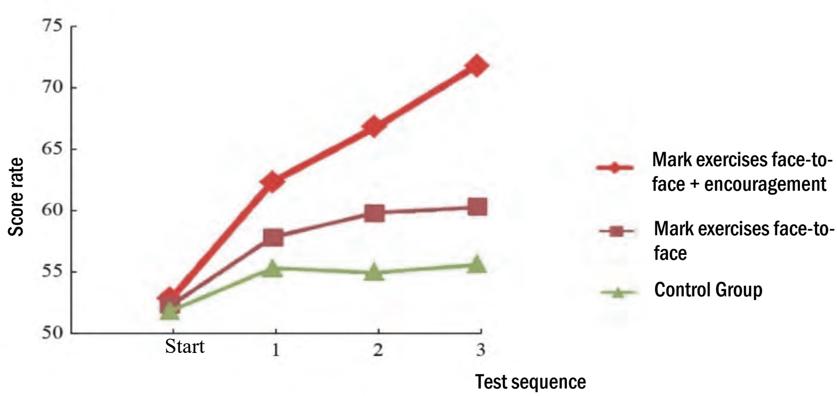

Fig. 4. Experiment results of assignment feedback

As a matter of fact, the *Book of Rites* from ancient China already described a dual-channel feedback model that goes "learn – discovers ignorance – self-reflection" and "teach – discovers difficulty – self-improvement". The module is referred to as "teaching and learning promote each other". It is a comprehensive demonstration of the charm of outstanding ancient Chinese culture (Fig. 5).

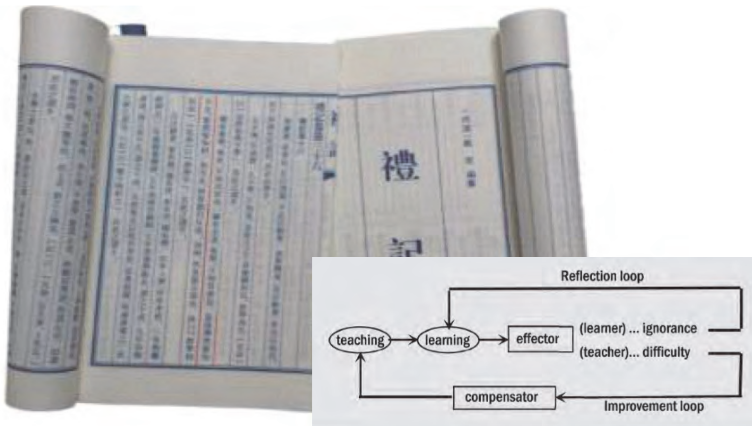

Fig. 5. The dual-channel feedback of "teaching and learning promote each other" in the *Book of Rites*

1.4. Assessment of mathematical thinking, leading to the deepening and innovation of teaching reform

In 1984, we used multi-media audio-visual technologies of "think aloud" to assess 50 pairs of students selected from control group and experimental group about their thinking process in solving a problem (Fig. 6). Individual case studies turned out that "experiencing variation" teaching was effective in improving the accuracy, agility and profundity of students' thinking, and this played a critical role in the innovation and extensive promotion at the second stage.

1.5. From experimental methods to the interpretation of teaching principles

As of 1992, the methodological characteristics of Qingpu practical educational research could be summarized as the follow:

(1) Scientific discovery models including agreement, discrepancy, covariation, deduction and induction were introduced so as to make the improvement of teaching behavior synchronize with critical thinking. As a result, the possibility and expectations of applying practical research in theoretical innovation was increased.

(2) Practice was decided as the screening method for Qingpu Experiment, by which the gap between investigation and experimental hypothesis was filled up. Taking this as the core, a comprehensive system with multiple methods complementing each

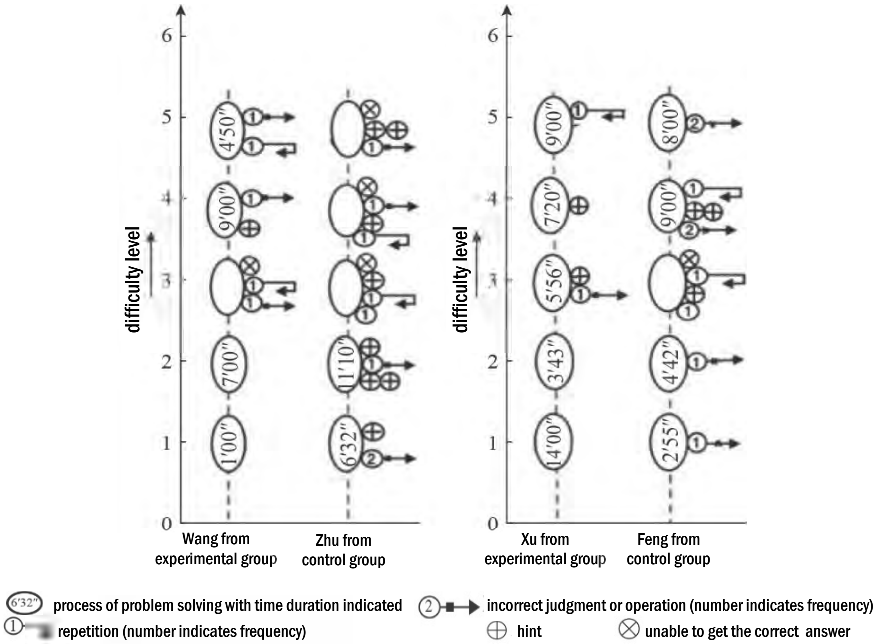

Fig. 6. The comparison of pair students on their problem-solving processes

other was constructed, increasing the ability of practical research in solving real educational problems.

(3) Make an in-depth study on the nature and form of the popularization of teaching experiences and explore the condition, form and effect of the popularization of research results in the hope of providing a reasonable basis for the application of teaching reform results in reality and guaranteeing the effectiveness of it as well.

(4) Establish a scientific research community involving researchers and teachers. Setting this community as the subject of the experiment could bring the research into the deep area of actual teaching process and increase the practical effectiveness and socialization degree of teaching reform experiments.

As a matter of fact, this is a comprehensive research based on teaching practice. It is noteworthy that Qingpu Experiment also provided interpretations for the key behaviors of teaching reform practice by having discussions, theoretically, on the process of mathematical cognition and activity, mathematical thinking and target classification, and gradually came out with a series of fundamental principles including Affection, progression, attempt, and feedback.

1.6. Win back quality

After ten years of efforts, the math score of the 9th graders in the entire Qingpu County had been increasing year by year (Fig. 7), and the pass rate went from 16% in 1979 (the lowest in the city) to 85% in 1986 (the average rate was 68%). In April, 1986,

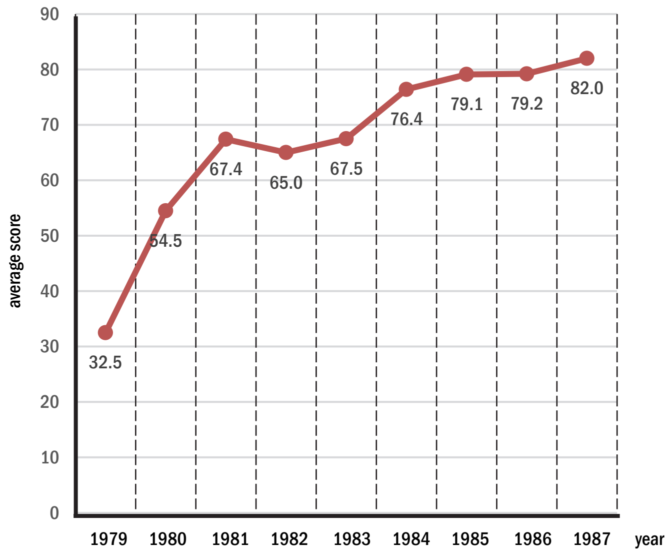

Fig. 7. Scores on the municipal tests of mathematical achievement for junior middle school graduates

Shanghai Education Committee convened a general meeting to popularize Qingpu experiences in the entire city of Shanghai. In October, 1990, the Department of Basic Education of the Ministry of Education dispatched a research group consisting of 18 experts to Qingpu and conducted a 9-day investigation on the experiences, achievements and practical effectiveness of the Experiment. In 1992, the Ministry of Education designated Qingpu experiences as a major achievement of basic education reform, and formally popularize it in the country.

Qingpu Experiment finally worked out a feasible way to improve teaching quality under the most common educational condition. The major research result of this stage are: *Learn to Teach* (1991) and *Theory of Teaching Experiments — A Study of the Methods and Pedagogical Principles of Qingpu Experiment* (1994).

2. Break through the Bottleneck of High Cognition

2.1. Attach importance to the assessment of students' math cognitive ability

The experiment at the second stage is carried out with two themes: first, the assessment of cognitive ability, and second, dig deep for outstanding experiences. With regard to the first theme, Qingpu Experiment had completed three tests and relevant studies on the math cognitive ability of local eighth graders since 1990s, conducted by professional researchers who designed the tests catering to different abilities respectively (last for 28 years with 840,000 standard statistical data).

The first test was conducted in 1990. In light of Bloom and Wilson's framework, cognitive ability objectives were classified into seven categories: computation, knowledge, comprehension, application, analysis, synthesis and evaluation, and thereafter a test with 50 test items involving 106 knowledge points was designed. The test was divided into three sections with a total of 220 minutes. Altogether 3200 8th graders took the test in paper-and-pencil format with 25 students in a group. Factor analysis technique was used for the analysis of the data. The main conclusions were:

(1) Memorizing and understanding were identified as the two most basic latent factors, and all the seven categories can be expressed through various loadings on the two factors. According to the data, the continuity and equidistance among the categories were not reasonable enough; computation and knowledge were mixed together, comprehension and application, analysis and synthesis could be merged and simplified (Fig. 8).

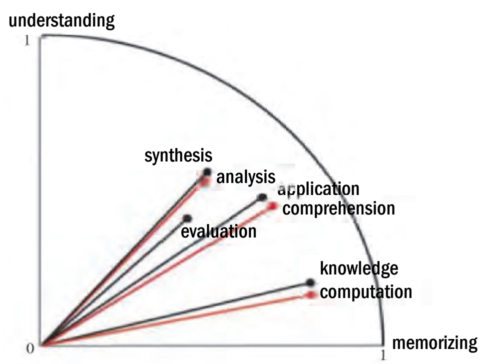

Fig. 8. Factor loadings on memorizing and understanding

(2) The distribution pattern of students' ability tendency was basically clear. Generally speaking, students had a good mastery of computation and concepts, but scored relatively low in comprehension and inquiry (Fig. 9). That is to say, in order to make students "smarter", we must get rid of rote learning and drill practice so as to break the bottleneck of crammed teaching.

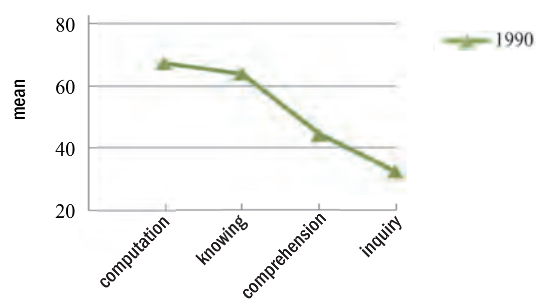

Fig. 9. Students scored relatively low in comprehension and inquiry understanding

2.2. *What if the scores are up while the students are not smart?*

The second theme was, in light of the major goal, digging deep for outstanding experiences. Having reviewed the two-way factorial design of “students attempt under the guidance of teachers + teachers provide timely feedback” (1982–1983), we primarily adopted “experiencing variation” for the practice of “students attempt under the guidance of teachers”. The follow is the result of the experiment (Fig. 10).

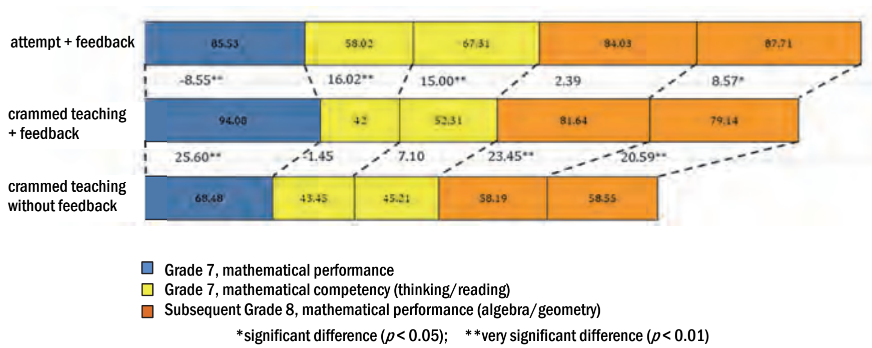

Fig. 10. Experimental results on factorial design by attempt and feedback

(1) “Mastery Learning” with timely feedback accounts for the substantial improvement of grades;

(2) “Crammed teaching + feedback” facilitates neither mathematical thinking nor reading ability and, furthermore, it even affects follow-up learning;

(3) “Attempt + feedback” could make students smarter. “It is more reasonable and helpful for students’ long-term learning than the so-called mastery learning,” Professor Fonian Liu, a former president of ECNU, said in 1985.

Therefore, “experiencing variation” became a hot topic for classroom teachers at that time. In a paper submitted to Shanghai Mathematical Society in 1981 (Fig. 11), it was clearly noted that variation has two types: conceptual variation and procedural variation, and the latter one is exactly an outstanding traditional experience in solving math problems.

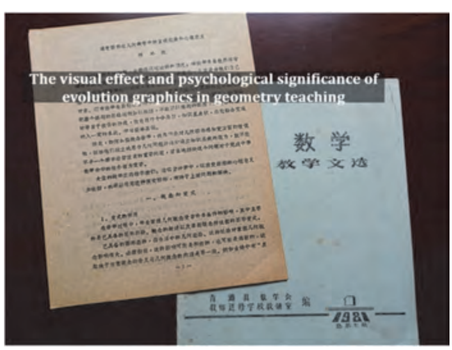

Fig. 11. Copy of a mimeograph paper on variation printed in February 1981

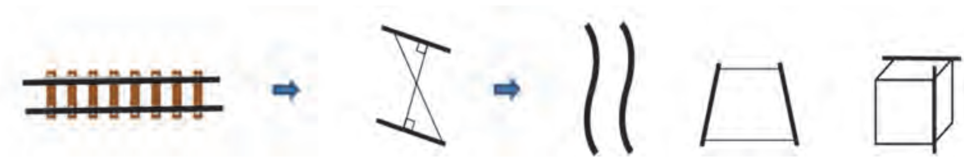
2.3. Deepen understanding in "attempt and experience" (mathematical conceptual variation)

For example, a simple concept – parallel lines. A teacher told the students that "parallel lines are straight lines that do not intersect with each other in a plane (abstract concept)". A student said, "I've memorized it". This is crammed teaching. Another teacher said, "Parallel lines are like two tracks of a train (descriptive definition)". A student asked, "Are they still parallel lines if the train makes a turn?"

Qingpu Experiment adopted another approach – experiencing variation, which includes three steps: step 1 is concrete and intuitive, they are parallel lines; step 2 is abstract and varied, they are also parallel lines; step 3 is plausible, they are not parallel lines (Fig. 12).



"is" (concrete, virsualized) "is also" (abstract, varied) "is not" (apparently "is" but actually "is not")

Fig. 12. Method of experiencing variation

Many experiments showed that: constructing mathematical concepts through the variation of material or form, from concrete to abstract, and via experiences of "is", "is also" and "is not", was able to i) reduce students' cognitive burden significantly; ii) deepen students' understanding of the key properties of mathematical concepts; and iii) improve independent identification ability in deceptive scenes.

2.4. Hold onto "core connection" while solving math problems (procedural variation)

Procedural variation involves meticulously designing "Pudian" （scaffolding） for mathematical problems to go from easy to difficult, or reducing problems from complex to simple, namely "simplification". Hence, students are guided to solve problems by themselves without mechanical practice.

In 2016, we reexamined the experimental materials of "Activity Process Analysis" and studied the connection patterns involved. For example, the application question of "a truck crossing a bridge" for 7th graders usually consists of two parts: i) When does the truck start to drive onto the bridge? ii) When does the truck start to move on the bridge? These are two critical points, which could be expressed through an "external" static line segment diagram and an "internal" one. If we make the truck move from left to right, three more questions could be asked: i) When is the truck not on the bridge yet? ii) When is the truck in the process of going onto the bridge? iii) When is the truck moving on the bridge? Holding onto the "core connection" of "moving line diagram", students could be successfully transferred to the discussion of the five kinds of relationships between two circles for 9th graders (Fig. 13).

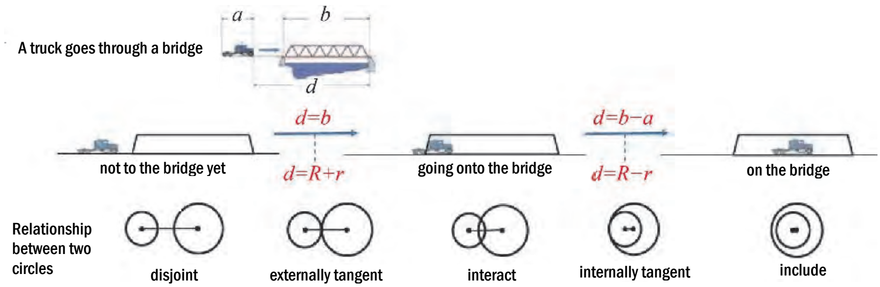


Fig. 13. Connection between truck going through the bridge and the relationship between two circles

The experiment data showed that when students applied what they had already known in solving new problems, it was important for them to find the most essential and transferrable element — the core connection. This connection could i) shorten the cognitive distance between the new problem and the anchoring point of existing knowledge; ii) significantly improve the degree of transfer in learning process; and iii) stimulate students' constructive thinking in solving math problems.

2.5. *Chinese experience of "experiencing variation"*

Teaching via "experiencing variation" focuses on students' conceptual understanding of mathematics and their constructive thinking in solving problems. Early experiments show that it can advance the transition of secondary students' mathematical thinking from visualization-based judgment to logical reasoning at least one year earlier (Fig. 14). After extensive practice, experiments and improvement, it has become a well-known Chinese experience.

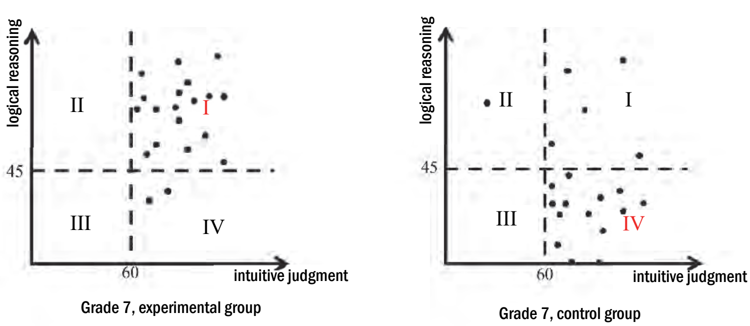

Fig. 14. Comparison of students' mathematical thinking

Variations can be applied in improving teaching via three dimensions: logical reasoning, situational application, and learning psychology. Two issues should be noted: first, that the more variations the better is not true. Rather, variations should be designed in accordance with the goals and needs of various student groups. Second, the key to variations is "experience". They are not crammed teaching in a disguised form. Instead, students should be given more opportunities to participate, attempt and express their ideas.

2.6. The change after more than ten years

The second test was conducted in 2007. With the improvement of classification of learning objectives (such as distinguishing knowledge from cognition, simplifying cognitive objectives, paying attention to creative and inquiry thinking), the test items were adjusted according to the reality of local students. The duration of the test remained unchanged, and 4349 students took the test. This time the accuracy of factor analysis improved significantly. The loadings of each cognitive objectives on the two main factors accounted for 85.15% of the total variance, which was 24% higher than that in 1990. The main conclusions are:

(1) A four-level structure, which was relatively concise and in line with the regional reality, was constructed, aiming to promote in-depth learning and teaching (Fig. 15): computation — rote memorizing; knowing — meaningful memorizing; comprehension — interpretive understanding; inquiry — discovery understanding.

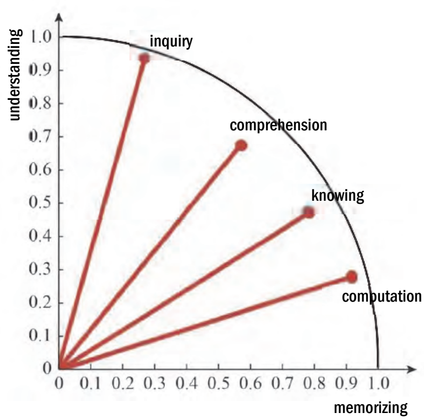

Fig. 15. A relatively simple four-level structure

(2) Compared with 1990, the scores of computation, knowing and comprehension in 2007 had greatly improved. However, the score of inquiry remained unchanged although much effort had been paid. The average score of inquiry was 28.96, which was slightly lower than 32.43 in 1990 (Fig. 16), and it became a new difficult point needed to be dealt with.

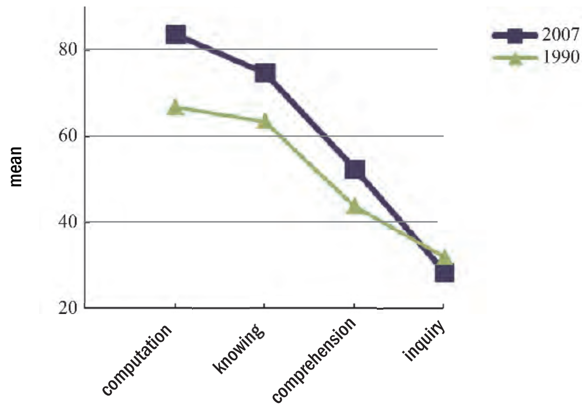

Fig. 16. The score of inquiry remaining unchanged

The major research results of this stage are: *Action and Interpretation of Teaching Reform* (2003); *A Witness of Reform — Lingyu Gu and Thirty-year Qingpu Teaching Experiment* (2008).

3. Promote Inquiry and Innovation

3.1. What if inquiry and innovation abilities remain unchanged?

Before entering the 3rd stage, we'd better take a look at the third test conducted in 2018. This test is exactly the same to the one conducted in 2007 in terms of test items and durations. A total of 3474 students took the test. The main conclusions were as follows.

(1) The average score of comprehension exceeded the passing level, and the score of inquiry was 11.31 percentage points higher. The difficulty was broken through to some extent (Fig. 17).

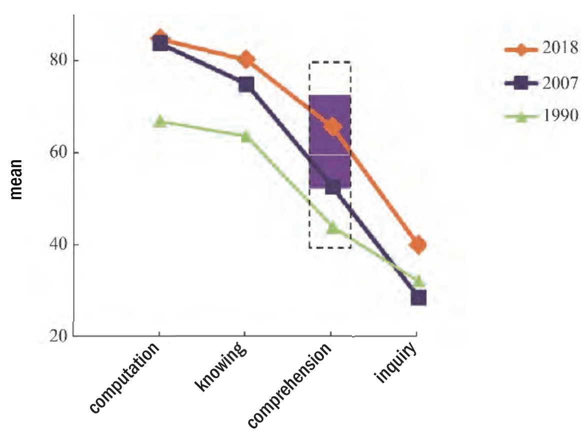

Fig. 17. Results of three tests

(2) The scatter plot showed that there was a positive correlation between comprehension and inquiry. With the improvement of students' comprehension ability, the inquiry level increased exponentially (Fig. 18).

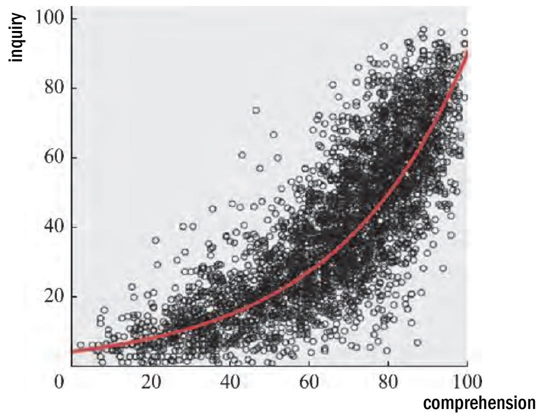

Fig. 18. A positive correlation between comprehension and inquiry

3.2. A turning point

As shown in Fig. 19, we can see the change of the correlation coefficients of comprehension and inquiry. The score of comprehension is between 45 to 95, and the graph is almost two broken lines. The turning point is in the middle. The increasing rate of correlation coefficients on both sides around the turning point shows a cliff style drop, decreasing sharply from 8.4% to 3.2%, indicating that the level of inquiry after the turning point is also affected by other factors besides comprehension.

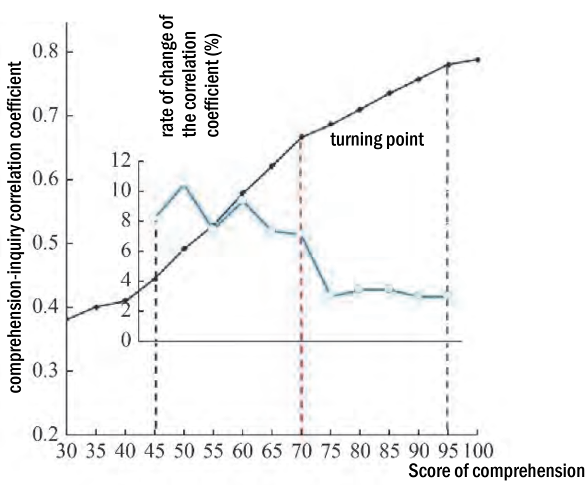

Fig. 19. Turning point of correlation coefficients appearing

Making a 2 by 2 segmentation (Tab. 1) of the average scores of comprehension and inquiry before and after the turning point, two types of students worthy of attention – type A and type B, were isolated for further analysis. The feature of type A students is that they stick to comprehension while type B students incline to inquiry. The data shows that both before and after the turning point, the number of students in groups of "double high", "double low" and "interaction" was about 1/3 whereas the ratio of type A and type B students within "Interaction" changed from 61:39 before the turning point to 46:54 after the point, indicating the significant influence of inquiry.

Tab. 1. 2 × 2 Classification of different student groups

	Low level of inquiry	**High level of inquiry**
High level of comprehension	Type A interaction: stick to comprehension	Double high
Low level of comprehension	Double low	Type B interaction: go toward inquiry

3.3. Cause-tracing empirical research based on big data

In teaching reform practice, in order to look for critical measures to improve students' inquiry ability, we designed an empirical research method named "cause-tracing". Specifically speaking, we selected typical sample groups available for comparison based on big data, and drew our conclusions through natural observations and evidential reasoning. Research flow chart is as shown in (Fig. 20). This method has the following major features: first, it demonstrates the theoretical penetration in the interpretation of phenomena and causal connections, good for the research group to exert its subjective initiative in applying background knowledge; second, it avoids subjective randomness in observations and sampling, and therefore guarantees the objective strictness in discovering logic. As a result, this method significantly increases the actual contribution of natural observations.

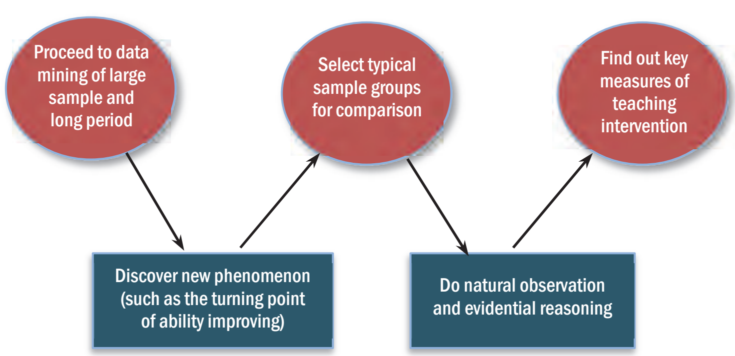

Fig. 20. Research flow chart of cause-tracing

In the research at this stage, we selected a total of 516 students consisting of both type A and B students before and after the turning point for further analysis.

(1) Elaborate data analysis reveals that the cognitive efficiency of type A & B students before and after the turning point is obviously different. They are not of much difference in knowledge understanding and regular application abilities, but type B students demonstrate overwhelming advantage in analysis, judgement, and discovery abilities (Fig. 21).

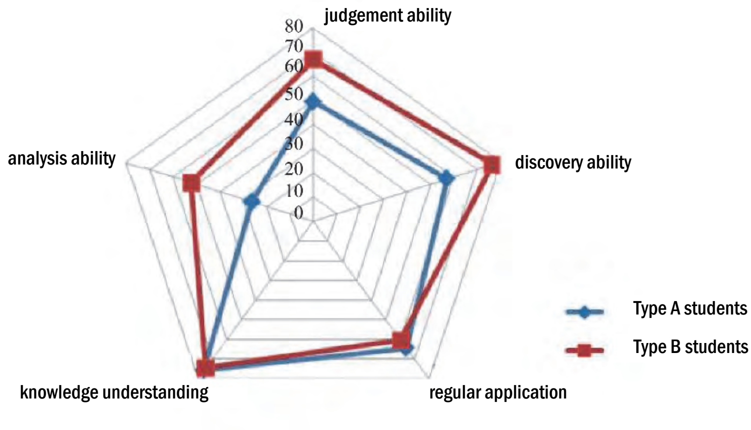

Fig. 21. Different patterns of cognitive ability of the two types of students

(2) Field research made in the schools where these students study reveals that type A students have a strong desire for high scores while type B students tend to spare energy in learning what they are interested in (Tab. 2).

Tab. 2. Characteristics of the two types of students

Type A (Have a strong pursuit for high scores)	Type B (Free up energy for independent study)
Practice common problems repeatedly; familiar with common problems and even reach the degree of “automation”; high accuracy	Dissatisfied with repeated practice; have a strong curiosity; good at asking questions and self-questioning
Good at grasping the requirement of examinations; know their own deficiency in their knowledge and skills, and try their best to make up for them; not interested in inquiry questions	Refuse to follow the majority and have their own opinions; like to solve problems by attempting; have failure experiences
Have a strong pursuit for high scores, sensitive to each single mark	Keep a grade above average; spare energy in solving problems they are interested in
Listen to teachers’ command; care for teachers’ praise	Not easy to get teachers’ attention because they do not obey rules

To conclude, there exist two different types of students, learning methods and results before and after the turning point. It is proved that excessive mechanical training is not advisable. Instead, we must look for key teaching behaviors aimed at improving inquiry ability.

3.4. In-depth clinical observations and comparisons of typical samples

Reasonable math teaching behaviors were not discovered until we went deep into the practical field in which math problems were solved. We wouldn't be able to find key teaching behaviors leading to the improvement of inquiry level until we conducted clinical analysis and comparisons of type A & B students' reaction in the tests and the teaching situations where they are in. The following are some typical teaching cases.

(1) Galileo space amphitheater design (2006)

Experimental schools, where most of type B students could be found, adhere to "activity – development" teaching scenario at a long-term basis. Fig. 22 is an assignment instruction at that time. The design of the space amphitheater is challenging: meet the technical standards and in the meanwhile, accommodate a maximum number of seats. The number of radiation lanes was decided by the designer. The less the lanes, the more the seats, but the number of seats for each row should not exceed thirty. The assignment is not difficult in terms of the knowledge required, but it is very challenging for thinking ability, and students have to deal with dilemmas before working out a solution. Obviously, this is a high-level assignment for students in training their innovative thinking ability.

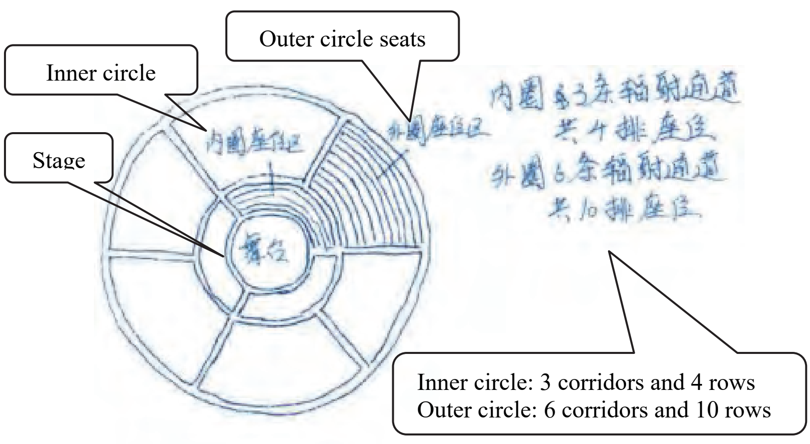

Fig. 22. Students' task: Galileo space amphitheater design

(2) Meticulous thinking ability training for unconventional travel questions (2018)

The follow is a question in inquiry section in one of the three ability tests: Ship A and Ship B set out at the same time from Island I, and shuttle between Island I and Island II. Ship A travels at 10 kilometers per hour and ship B at 8 kilometers per hour, and after 24 hours they return to Island I at the same time. Questions: 1) What is the distance between the two islands? 2) Have the two ships ever reached Island II at the same time?

Though Type A students were familiar with the formula $s = vt$ and the types of questions such as "meet" and "catch up", but they had only arrived an accuracy rate 13.8% when answering to Question 1) due to the demand of careful analysis on "round trip". For Type B students, they thought in this way: Within 24 hours, Ship A travels one more round than Ship B, so

$$s = \frac{24(v_A - v_B)}{2} = \frac{24 \times (10 - 8)}{2} = 24.$$

The accuracy hit 46.2%.

The interview after the test showed that Type B students would question the problem- solving process and further refine it. For example, they would ask, "why one more round for sure?" If we change v_B to 6 kilometers per hour, then $v_A/v_B = 10/6 = 5/3$, Ship A travels 5 rounds and Ship B 3 rounds. They return to Island I at the same time after 24 hours. As a result, ship A travels 2 more rounds than ship B. Generally speaking, the solution is:

$$s = \frac{12(v_A - v_B)}{a - b}, \text{ where } \frac{v_A}{v_B} = \frac{a}{b} \left(\text{in which } \frac{a}{b} \text{ is a reduced fraction}\right).$$

For Question 2), most students worked it out by list method. Some Type B students said, "if the two ships ever reach Island II at the same time, it must be 12 hours later, but ship B is not there at that time". This thinking is generated by counter evidence method, but the students can't explain it clearly. Under the guidance of the teacher, they came to the following result:

The time needed for ship A to reach Island II is $2.4m$ ($m = 1, 3, 5, 7, 9$);
The time needed for ship B to reach Island II is $3n$ ($n = 1, 3, 5, 7$).

Suppose the two ships ever reach Island II at the same time, then $2.4m = 3n$, that is, $4m = 5n$, both m and n are odd numbers. This is impossible. Therefore, the two ships have not reached Island II at the same time.

(3) Interdisciplinary learning and inquiry of the barycenter of a triangle (2018)

This is an in-class inquiry: the barycenter of a triangle — an interdisciplinary problem solving via mechanics and geometry. The mechanics knowledge applied here is primarily using suspension line method to find the barycenter via the balance of particles. The mechanics approach let students understand the consistence of mechanics barycenter with the geometrical conclusion that the three medians of a triangle meet at a point. Students can go further to discuss, via mechanics way, the issue that the three angular bisectors of a triangle or the three heights meet at a point, or more generally to discuss of Ceva Theorem. With closer essential connection between disciplines, there appear many creative methods for problem solving. For example, for an in-class exercise about the barycenter of an isosceles trapezoid, as shown in Fig. 23, $AD = 6$, $BC = 12$, and $EF = 9$, students came up with several solutions:

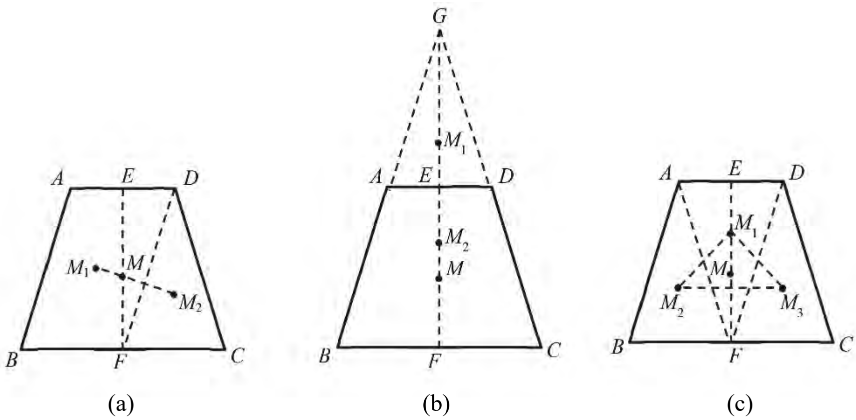

Fig. 23. Barycenter of an isosceles trapezoid

Method 1: intersection plotting

Connect D and F. Denote the barycenter of parallelogram $ABFD$ by M_1 and the barycenter of $\triangle DFC$ by M_2. Line segment M_1M_2 intersects the central axis EF at the barycenter M of the trapezoid, as shown in Fig. 23(a).

Method 2: mechanics equilibrium

Extend BA and CD respectively until they intersect at point G. Let M_1 be the barycenter of $\triangle GAD$ and M_2 the barycenter of $\triangle GBC$. Suppose the barycenter of trapezoid $ABCD$ is M. According to the balance of forces, we get equation $M_1M_2 : M_2M = 3 : 1$, then $M_2M = 2$. The location of M is worked out, as shown in Fig. 23(b).

Method 3: Equivalent reasoning

Divide the trapezoid into three congruent isosceles triangles, and their barycenters are M_1, M_2, and M_3 respectively. The barycenter of $\triangle M_1M_2M_3$ is the barycenter of the trapezoid, as shown in Fig. 23(c).

With regard to the various solutions figured out by the students, the teacher said with great emotion, “the multiple methods the students presented went way beyond my expectation!”

(4) The modeling, evaluation and revision of water hyacinth propagation (2021)

This is a real issue. An aquatic floating plant named water hyacinth grows in the water towns of Qingpu. It reproduces so quickly that it would cover a large area of water in short time and cause trouble to environment, water transportation, drinking water safety for human and livestock and fishery production. In order to discover the reproduction law of water hyacinth, the 8th graders used the knowledge they just learned, namely linear function and line chart, to create a math model of the reproduction of water hyacinth. As a result, they came up with an exponential curve:

$g = 25.01 \times 2.16^t$, where g stands for the quantity of the plant, 25.01 is the initial value, and t refers to the time at 10-day pace. After a comparison between the model data and the measured data, a big error was revealed in the 3rd month. Then they searched references and consulted professionals, trying to find the cause and make many revisions on the model. Surprisingly, some students figured out an error-trial method by themselves and minimized the sum of absolute values of the errors of each test point. This is equivalent to the thinking of so-called "least absolute deviation". With the preliminary experiences in math modeling and revising models, these middle school students acquired a significant foundation for their future study and research in math modeling.

3.5. Finding key teaching behaviors

A review of the backstepping process mentioned before: first, by refining the test data, we found the completely different cognitive abilities between type A students and type B students; through field research, we summarized the distinctive differences of the expressive characteristics between the two groups of students. Second, our research included both the case studies on the classroom teaching scenario in which type B students are in, and analysis and comparison of the two groups of students' reactions in the tests. This is clinical observations and studies under the guidance of data. In this way, we traced back gradually until we found the following key teaching behaviors that were effective for improving students' inquiry ability:

(1) High-level task-driven teaching design

- Organize challenging teaching tasks according to the internal hierarchical and sequential structure of knowledge;
- Pre-design individual targets according to different needs of students;
- Build comfortable and energetic learning environment and encourage learning with high-level concentration.

(2) An independent study process with fine processing of thinking

- With multiple strategies, activate previous experience and connect it with exploratory tasks;
- Through application, experiencing, or and knowledge assimilation, make fine processing of thinking;
- Make constant feedback and revision on reprocessing learning upon the evaluation of thinking effectiveness.

3.6. Teaching research follow up, attach importance to inquiry learning

Going from comprehension to inquiry, teaching research is indispensable. Based on the case studies of a number of master teachers from Jiangsu Province, Zhejiang Province and Shanghai, particularly Madam Yu Yi's experience of "Prepare one lesson three times, keep doing this for three years, and you're bound to be a good teacher", Qingpu Experiment proposed an in-service professional development mode called "Action Education" in 2004 (Fig. 24). It includes three focuses (focus on personal experience accumulation, focus on new ideas and experiences, and focus on the real gains of students), two reflection holders (looking for the gap between oneself and the others, looking for the gap between plan and reality), and one carrier — *Keli* (Exemplary Lesson Development). They make a cooperation platform on which all these elements repeat alternately, indicating the unique organizational culture and action route of teaching research in China.

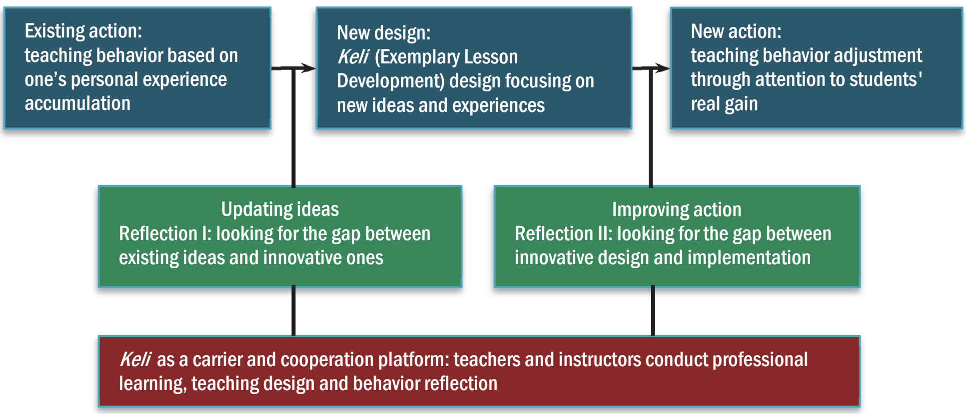

Fig. 24. The model of action research

Some scholars proposed knowledge sharing model of interpersonal learning and developed two skills: first, "expose oneself" (verbal guidance and analysis aimed at exposing real problems); second, "listen and respond" (reflective absorption and response skills). Due to the development of some high-level inquiry learning models such as discovery learning, practice learning and project learning, and so on over the years, teachers usually found themselves in an unknown area called "public issues area". Therefore, besides "knowledge sharing (knowing and not knowing)", the new concept of "create teaching behavior collaboratively (yes or no)" became particularly important. Qingpu Experiment summed up the following two key skills: first, "problem sorting" (sort out the problems about the inquiry target and create "public problems area"); second, "design and improvement" (design inquiry process and make repeated revisions based on evidences). In this way, we came up with two models of interpersonal learning (Fig. 25).

Tab. 3 is a lesson about "introduction of irrational numbers" in 2015. After three times circulation going from design to improvement, it eventually succeeded in making students learn math via "doing math". Students' learning style was successfully changed.

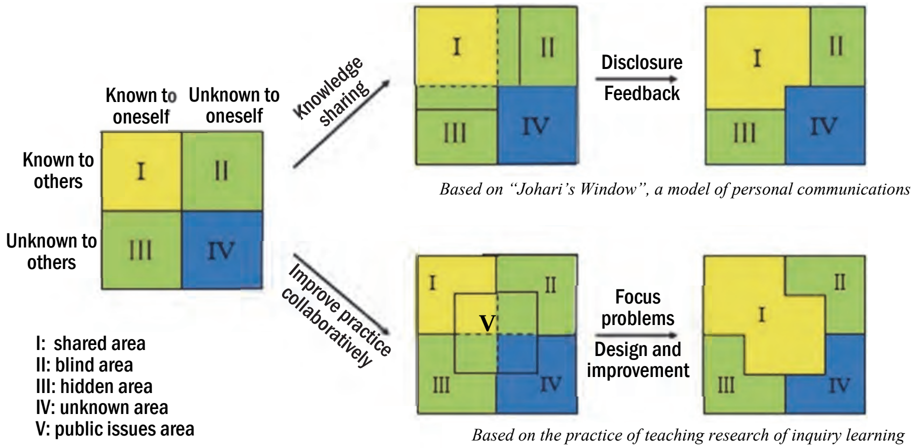

Fig. 25. Two models of interpersonal learning

Tab. 3. Lesson revision based on video analysis

Initial design	Issues during implementation	Revision
The first round — light humanistic purport		
Use historical stories about irrational numbers to arouse students' interest and experience scientific spirit.	Restricted to story plot with the mathematical discovery process left out. Have to return to the old way of passive explanation.	Stories settle in to clarify the cause of the extension of the concept of numbers. Use "$\sqrt{2} =$?" to kick off the replay of the discovery process.
The second round — attend to mathematical process		
Use decimals to approximate, and through deduction, identify the key attribute that irrational numbers cannot be represented as fractions.	Students understood the calculation and deduction. Nevertheless, they still asked: is $\sqrt{2} = 1.4142\ldots$ a definite number while it is growing all the time?	Look for the origin of the issue and choose an appropriate analogy: $\frac{10}{3} = 3.3333$. It grows all the time, but it is a definite number, implying the idea of limit.
The third round — change the learning mode		
To avoid mere deduction and explanation, design worksheets on $\frac{10}{3}$ and $\sqrt{2}$ respectively, requiring students to discuss while doing math.	Deepen the experience of "gradual approximation" in doing and discussing math. The degree of understanding varies from student to student.	The worksheets and discussion questions could be designed into a certain gradient, so as to cater to the need of different students.

"Teachers become practitioners with research ability" is the pursuit and expectation of Qingpu Experiment in educating outstanding teachers.

(1) At early stage, we required backbone teachers to sit in on the class and make observations. Not a single class should be missed. At that exact moment and inspired by what they saw, teachers thought about the advantages and disadvantages of the lesson and worked out methods for improvement. This strategy was very effective in

training teachers' teaching sensitivity. But this kind of observation was restricted by incompleteness of information and the limitation of memory.

(2) Since the end of 1990s, the introduction of information technologies, including video tapes at the beginning and CD and other video facilities later on, has witnessed breakthroughs one after another in our research. Multi-angle holographic recording made it possible to collect a great deal of data for analysis; playback, freeze and "microscopic" made it possible to study fleeting subtle behavior (including verbal expression, action and facial expression). Among these, the change of teachers' role — teachers became "both the actors and audience", was the centerpiece that provided a convenient way to educate a great quantity of good teachers.

(3) Nowadays, many teachers are becoming "cycle improvers" because the diversity of evidences has been greatly expanded by video analysis, the resource of data statistics is unprecedentedly abundant, and the materials for case analysis are much more refined. In the process of teaching research, these serve as a foundation for some people to make empirical interpretation, and for theorists to make rational deduction. Cycle improvement based on multiple evidences that prove each other pushes "Teachers become practitioners with research ability" to a higher step.

The major research results of this stage are: *Action Education – A Paradigm Innovation on Teachers' In-service Education* (2007); and *Oral Teaching Reform — Regional Experiments or Research Chronicle* (2014).

4. Concluding Remarks

Based on classroom experiments, our reform started from a low point in the hope of improving teaching quality, and gradually developed into a goal-oriented practice with different stages. We broke cramming via "experiencing variation" and promoted inquiry-based mathematics learning by designing "high-level tasks". Nevertheless, we're still on the way of reform given the big change in the current era, and therefore, negligence and mistakes are unavoidable. Criticism and suggestions are welcome.

Plenary Lecture 3

Equity in Mathematics: What Does It Mean? What Might It Look Like?

Robyn Jorgensen[1]

ABSTRACT In this plenary lecture I draw on the findings and subsequent analysis of a large 5-year project that was conducted in some of the most disadvantaged contexts in the Australian educational landscape — remote and very remote Indigenous communities. The intent of the project was to develop an understanding of the successful practices adopted in these schools that were creating success for Indigenous learners. It was a strength-based project and intentionally moved from deficit models to one that sought to document what was working in these schools. It was not interventionist but rather drew on the knowledge of those working in the field, those who experienced the contexts, the learners, the communities and sought ways to build success. It was grounded, and ethnographic in its design. This plenary, and paper, shared the outcomes of the study. The implications of the learnings from this research have application to other equity contexts.

This plenary lecture was based on the findings from the "Success in Remote Indigenous Communities" project[2]. The project sought to investigate, document and celebrate the numeracy successes of schools working in remote and very remote Indigenous communities. These communities are seen as the most disadvantaged communities in the Australian educational landscape. The project focused on the practices of those schools. Using an ethnographic case study approach, project was not evaluative since a fundamental premise of such an approach is to document what, and how, practices are contributing to the success of Indigenous learners in these contexts. The project adopted a strength-based approach, so underpinning the ethos of the project was a celebration of the work being undertaken in selected remote schools. Such successes would documented and shared with others. A website, hosted by Stem Educational Research Centre at the University of Canberra, acted as repository for the case studies and could be freely accessed by any educator or other persons interested in learning of the success of these schools. It was intended that such case studies could support others working in similarly challenging contexts and provide practical ideas to support their work A final, summative report was developed to augment the case studies so that an overarching sense of the schools, the participants and the practices could be developed. This Plenary Lecture is a synopsis of that project.

[2] This project was funded through the Australian Research Council scheme (DP130103585).

1. Equity in Mathematics Education

Foundational to this Plenary Lecture is the notion of equity as it applies to mathematics education. Many terms are used in this domain and many are rooted in particular paradigms and ideologies. When discussing equity, the domain from which I operate is critical sociology. This domain of thinking shapes the actions and patterns of thought of the researcher such that there is an assumption that in some ways schools are set up to reproduce social inequalities and the task of educators and researchers is to challenge the reproductionist agenda to bring about change. It is structuralist in its orientation so that practices that are adopted in mathematics education often reproduce social inequalities, often at a very subconscious level.

Often in mathematics education we see researchers and systems adopt practices of the past with the intent that they will bring about positive outcomes for learners. An example of such an approach is the adoption of Direct Instruction (DI) (Kinder and Carnine, 1991) in remote Indigenous contexts in Northern Australia. This is a model of pedagogy formed in the 1960s in the USA to work with disadvantaged learners. Since the 1960s there have been significant advances in research and pedagogy as to what constitutes quality learning and pedagogy yet the education systems in Australia have adopted an antiquated model of pedagogy for implementation in remote Indigenous schools. Some critical educators have been quite scathing of the rollout (and costs) of DI in remote Indigenous schools (Guenther and Osborne, 2020) while other conservative educators advocate the success of the program (Pearson, 2020). The difference between the two perspectives was the data upon which they drew to mount their cases. What is clear is that the expense of implementing DI (in excess of $20 million) in these communities has been very high while the outcomes have been limited and their sustainability has been questioned (Luke, 2014).

From an equity perspective, there is a need to do things differently as the practices of the past have reified social, cultural and linguistic differences so that such differences have been normalised and seen as part of the natural order, thus preserving the status quo. From a critical equity perspective, those who have been marginalised in their access and success in mathematics need to be treated differently so as to reduce the gap in outcomes. Treating learners the same as other learners will only help to reify social and educational differences. That is, not only in terms of mathematics scores, but also in terms of attitudes towards mathematics, continuation in the study of mathematics, application of mathematics into contexts beyond schools.

2. Method

The project was funded to undertake 32 case studies but for a number of reasons, the final project involved 39 schools. Some of the case studies, however, were not published. This was due to a range of issues including the lack of triangulation between the views of the leadership teams and the practices described or observed of the teachers, or lack of coherence in the data sets or the timelines not being met for approvals for inclusion of the case studies.

Schools were initially selected on their performance on National Assessment Plan for Literacy and Numeracy (NAPLAN). This is a national testing scheme for Years 3,5,7 and 9 across Australian schools in literacy and numeracy. Trends in school data for numeracy were used for the initial selection of schools so schools could be seen to be performing above similar schools; increasing in their performance over time suggesting that improvements were being made at the school; or through recommendation by the systems as schools that were performing well but this was not reflected on the test scores. At the outset, it is acknowledged that national testing scores are not a fair representation of success but they were the only 'objective' measure of success in numeracy. Hence, personal recommendation by systems of particular schools was a way to circumvent the narrow definition of success in NAPLAN results. Schools were required to justify their success on other measures including but not limited to other testing schemes or other measures.

The case studies were ethnographic in form and were developed through site visits to each school. Data were collected via interviews with members of the leadership team, teachers and local workers at the school; observations of classrooms; profiling of lessons, and collection of school artefacts. Collectively these were used to develop individual case studies for each site. A positive, strength-based report was generated in consultation with the school, and once approved by the leadership teams at the schools, were uploaded to a website for sharing (and celebrating) the successes of the schools. The Remote Numeracy website was hosted at the University of Canberra3 .

A meta-analysis across the schools was undertaken at the completion of data collection and coding. Trends across the data were undertaken through the application of a software package — NVivo — into which all interviews were coded and analysed using grounded theory. This enabled the identification of key trends across the data set. Two further analyses were conducted using Leximancer and a separate NVivo of the published case studies, to confirm the trends reported here were valid. Across the three analyses there was a very strong confirmation of the themes/coding. A further statistical analysis was undertaken of the classroom observations. This analysis was undertaken by a statistical expert outside the project to ensure validity of the claims being made.4 The data from the classroom observations is not included in this paper.

Schools Permissions were gained from State Government and Catholic sectors in Queensland, Western Australia (WA), New South Wales (NSW) and South Australia (SA). The Northern Territory (NT) Department of Education and Training (DET) denied access to government schools. There was only one Northern Territory Catholic school that met the criteria for inclusion but elected not to participate in the study. One NT Independent school approved access for the study. This is not to say that there is an absence of good practice in NT, as quite clearly there is some outstanding practice. Rather, it is a factor of the regulatory requirements to access schools through permission from the DET.

[4] The views expressed in this report are those of the author and not the funding authority

The distribution of schools across the states varied and were contingent upon success as defined previously. There was no attempt to seek inclusion of schools in terms of ensuring what would be typically described as a representative sample of the schools. The schools were included solely on their performance so I was incongruous to pursue a selection of schools that proportionately represented the diversity of schools in this field. However, the sample of schools did represent the diversity of schools, states and systems as a collective.

Tab. 1. Distribution of school — published case studies

	Government	Catholic	Independent	**Total**
WA	11	3	7	**21**
QLD	4			**4**
SA	4			**4**
NSW	5			**5**
NT			1	**1**
Total	**24**	**3**	**8**	**35**

The schools include the range of schools that could be expected across Australia — including primary, secondary, schools to year 10, schools to Year 12, Vocational Education and Training (VET) schools, and boarding schools. There was considerably diversity in the structure of the schools. The schools also range in size from 'one-teacher' through to schools with 50 teaching staff. Some of the schools are located in the community, while others (such as boarding) are outside the immediate community. Some schools serve the community in which they are located, while others draw students from surrounding communities. Some schools are single campus, while others are multi-campus. Some schools are boarding schools including a senior vocational college, while most are day schools. One case study is based on a system-level approach so spans many schools within that system. The project's method has endeavoured to capture the diversity of schools operating across Australia. Two schools were visited and data collected, but at the completion of the site visit there was no coherent story to be written, so no case study was developed. A further two schools were completed towards the end of the project but the principals relocated and hence the stories could not be confirmed/approved. In total, four sites were visited without case studies being published from those sites. Accordingly, of the 39 sites visited, 35 case studies were published.

3. Analysis

Two levels of analysis were undertaken in this study. At the first level was the ethnographic case study approach. Each school has had a case study produced. These draw on the key themes of the school following the site visits. The case studies were negotiated with the school so that the stories presented in the case study were validated by the school and were seen to be a fair representation of the school. The case studies were published on the project website. The second level of analysis was undertaken and will be ongoing given the enormity and breadth of the data. All interview data were entered into a qualitative database (NVivo) and coded using a grounded theory approach. This enabled trends across the data sets to be identified. The data presented in this plenary provided a summary of the key findings of the project.

A quantitative analysis was undertaken on the pedagogical profiling of the lessons and the complete dataset in NVivo which is not part of this plenary. A further macro analysis of the data sets was undertaken with Leximancer and a NVivo analysis of the case studies. These analyses were used to verify the macro trends in the data sets and to triangulate the subjective coding used in NVivo with the mechanistic (objective) coding made through Leximancer. There was strong congruence in the three systems of coding.

4. Key Findings

Unsurprisingly, there is no unifying approach across the states, or schools. However, there are some features that appear in many cases that are noteworthy. While there are examples of practices that would appear to be diametrically opposed such as problem based/investigative group work with the highly structured worksheets of 'direct instruction', there is a unifying philosophy behind the teachers' intent with the adoption of these practices. First is that they sought to identify the entry level of the students (through assessment for learning practices) and then to develop targeted strategies to meet the needs of the individual students (differentiation). Much can be said of the practices observed in schools, and these are contained in the case study reports. As the project data set was very large, some model was needed to make sense of the data across the project.

4.1. Masking Sense of Surprises in the Data

Initially the project was developed with the intent that there would be reporting on teacher practices, however as the project unfolded, there were times when teacher practice was not the key practice of the schools. Many issues beyond the practices of the teachers became critical in rethinking the initial assumptions that underpinned the project. IN the next two sections, I will share two examples (that were among many) that resulted in rethinking the macro analysis of the project.

4.1.1. Attendance

Attendance is a key issue in education, and more so in remote Indigenous education where attendance rates are notoriously problematic for teachers and systems. There are often good reasons for non-attendance from the perspectives of the families and learners.

> *Principal: I am not sure why you are here. We have not focused on maths at all so I don't know how we can help you.*

At this school, there had been a very strong focus on student welfare. Absentism was high. The principal had created a position of student welfare officer whose role was to follow up with students and why they did not come to school. Issues such as no food in the home, or no shoes for the learners so they could not come to school were often found to be the cause for non-attendance. The school then developed strategies — such a breakfast club, free lunches, a clothes stores — so that the issues being confronted by the families and learners were addressed and students could come to school without shame. Increases in attendance converted to increases in performance.

4.1.2. Attitudes Towards Schools

> *Principal: When we arrived at the school, the students (and families) would stand on the other side of the school fence and taunt us. There was clearly a strong divide between the school and community so we had to do something to redress this issue.*

At this school, the whole of school worked on developing a culture at the school where the learners were valued and welcomed to the school. Over time, more children and families started coming to school, feeling that they were valued and important. Teachers and administration staff would welcome children when they came through the gate and farewelled them when they left. Any child who had problems during the day, were especially encouraged to return the following day. The school staff conducted event outside the school gates and in the broader community, bringing the school into the community. Again, attendance translated to success.

These two examples were among many where schools had not primarily focused on teaching mathematics, but had used other strategies to bring about changes that impacted indirectly on performance in mathematics. To this end, the project needed to develop a model that accounted for these learnings.

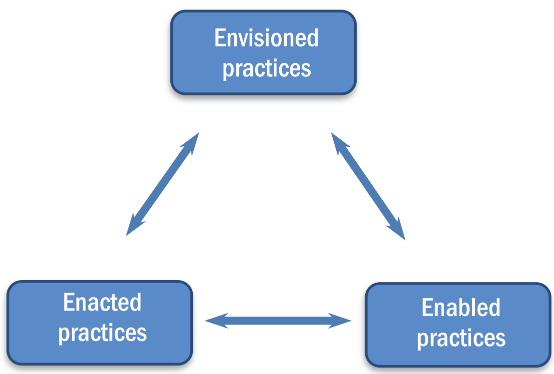
4.2. Identifying Norms

Rather than focusing on describing practices per se, the project has identified the norms that appear to underpin the practices. To make sense of the multiple levels of practice observed across the study, three levels were developed — envisioned, enabled and enacted. Schools need to have a strong and well-articulated vision. They then put practices in place to enable the vision to be enacted by the staff at the school. Different schools had different emphases in their case studies. Each of these levels of analysis and examples are provided in this report. While this is represented in a nested manner, it is the case that each of the levels of practices interact with the other, thus suggesting a much more dynamic model.

5. The Three Levels of Practice

As a result of the macro analysis and to make sense of the 'surprises' in the data, a three level model was developed. The levels are not meant to be hierarchical but rather cyclical and dynamic with each informing the other.

- ***Envisioned Practice*** — this level referred to those practices that created a vision for the school and how the leadership team worked with the school and wider communities to share and enact the vision of the school
- ***Enabled Practices*** — these were an intermediary practice that worked between the enactment of the vision and the work at the level of classroom. Two standout practices at this level were the inclusion of a numeracy (middle) leader who would support the work of the teachers to ensure that they were able to enact the vision of the school. The second type of practice was the employment (and upskilling) of local Indigenous people who could work with teachers in the area of numeracy but also around issues of culture and language as they impacted on learning.
- ***Enacted Practices*** — these were the actions of the teachers and support staff in the classroom level.



5.1. Envisioned Practices

Many of the schools in the study were very clear about the culture of the school that they sought to develop (or had developed and sought to maintain and sustain beyond the principal's time at the school). Features of these included:

• Articulating and leading the rollout of a school-wide approach to the desired culture and vision for the school.

• A supportive leadership team to work with staff to enable the effective management of the school culture — both in terms of the culture of the school, and the mathematics learning culture.

• Working relationships with community to share the visions of both the community and the school.

• Being prepared to evolve a positive culture over an extended period of time, and to ensure that the culture is embedded so that it endures changes in staff. Change needs to be slow if it is to be effective. Communities and families are often change-weary.

They were wary of new leaders coming in to make their personal mark for personal gain, rather than for the gains of students and community.

- Sharing vision and working with staff and community was an important factor for success.
- Middle leadership was a strong theme emerging from the school data — this level of leadership mediates the vision of the school and supports teachers to enact the vision of the school. Being able to see the value of middle leadership was a vision in many of the schools.

5.2. *Enabled Practices*

To ensure staff and students meet the goals of the school and thrive in the classrooms, schools employed a wide range of practices to enable teachers and support staff to enact the vision of the schools. These practices sought to implement the vision of the school and to ensure that teachers were given quality opportunities to develop as teachers while aligning with the values and approaches of the school. Some enabling practices observed included:

- Employment of quality local (Indigenous) staff to work alongside teachers. Investment of time and resources were evident. Local people took a strong role in the classroom and were an invaluable resource within the school. In some schools, their title was a co-teacher to signify their status within the class and wider community. Quality learning opportunities were provided to upskill the local people so that they felt strong and comfortable in these roles.
- Quality professional learning for teachers — most of the schools were staffed by graduate teachers who were often in their first remote position. Considerable support was made available to induct these teachers into remote education, and to provide ongoing support in their development as teachers of numeracy/mathematics.
- Numeracy Coaches were employed at some of the schools. These individual roles varied depending on the context and needs of the teachers, particularly in relation to funding the role. The role included sharing the vision of the school and supporting teachers to enact the vision of the leadership team. It also included providing in-class support for teachers, from planning lessons to providing feedback (middle leadership). Many terms were used to describe this role depending on the school.

5.3. *Enacted Practices*

At the level of the classroom, there was an extensive range of quality practices that were articulated and observed. While this was the original intent of the project, it was clear that for this role to be successful, the other levels of practice also needed to be considered. Enacted practices included:

- Being explicit about the intent of learning, how lessons were organised and what was expected of the students. There was no "hidden" agenda of lessons. Students knew teacher expectations.

- Differentiating learning to enable identification of students' learning needs through assessment for learning practices and then to build quality learning experiences that met and extended the needs of each learner.
- Recognising language as a key variable in learning, providing appropriate scaffolding in language (both home and SAE) to build bridges between the home and school, and provide entry into school mathematics.
- High expectations — of both students and staff — across social and mathematical norms. Students were provided with age-appropriate learning outcomes (e.g. algebra for secondary students) and then quality teaching practices to scaffold learners to achieve those learning intents. There was no space for deficit approaches to pedagogy and learning.
- Focus on mathematics — mathematics was a priority for learning. The mathematics that was being taught was age-appropriate so that students were being exposed to levels of mathematics that could be expected in regional settings. It became the task of the teachers to provide appropriate scaffolding for students to enable them to reach these levels of learning. High mathematical expectations were reinforced.
- Culturally responsive pedagogy was evident. Many strategies were developed to cater for culture of the students. Most obvious were strategies used to build language (of mathematics and the home language as well) and to have strategies that were cognisant of issues of "shame" within the classroom (Robyn. Jorgensen (Zevenbergen), 2019). There has only been one class to date that incorporated the more overt aspects of culture (e.g. art) but other teachers had sought to draw on the everyday activities that the students undertake (e.g. fishing, trips to town).
- Creating a sense of numeracy for life. Most communities had limited numeracy practices synonymous with urban living. Teachers have developed many strategies to create opportunities for students to see the purpose of mathematics/numeracy in their lives.
- Pacing of lessons, or parts of lessons, was often quick so as to engage learners, and prepare them emotionally as well as mathematically for the mathematics lessons. Using a quick pace engaged the learners. Humour was often part of the lesson as well, again to engage learners in a non-threatening manner.

6. Norms within the Levels of Practice

While categorising practices into these three levels provided a way of clustering the practices, a further analysis of the data produced a theorisation of these practices around the notion of norms what were aligned with the three levels. These norms provide an overarching model that describes the principles that underpin each of the levels of practice. The model gives coherence to a collection of practices at each level. Having norms to underpin and guide practice provides principles for success.

In Tab. 2 below, I have intentionally reversed the order of the levels to reinforce the non-hierarchical model of these practices. The norms provide principles to underpin the practices at each of the levels of practice.

Tab. 2. Summary of the norms identified from the project

Enacted Mathematical Norms	Enabled Mathematical Norms	Envisioned Mathematical Norms
• All students can learn mathematics — to high levels • Embedding mathematics is critical for understanding — embedding in the brain as well as embedding in contexts • Mathematics is as much about language as it is mathematical concepts • Transparency in learning and teaching mathematics enables students to access the "secret knowledge" of school mathematics • Mathematics lessons should engage learners at their levels of understanding, and then extend learning into new levels	• Teacher quality is essential for quality learning • Recruitment, development, retention of staff • Teacher support is integral to developing quality mathematical environments • A key person for mathematical support across the school enables quality teaching and environments — numeracy coach • Indigenous people are a key resource in teaching and the classroom	• Leadership is critical for developing a positive mathematics culture, supporting teachers and supporting community • Establishing a whole school approach to teaching mathematics ensures consistency and transparency — for students, teachers, and community

There is considerable literature in mathematics education on the notion of norms as they pertain to the mathematics classroom. Most notably the work of Yackel and colleagues (2000) draws on the notion of sociomathematical norms that relate to the normative understandings of the mathematical realities in classrooms. While these norms relate to the mathematical activities that are undertaken in a classroom, they are different from the mathematical content. The sociomathematical norms in a classroom provide the framework for the interactions through which mathematical meanings can be negotiated by the learners and teachers. Norms act as a means for mediating learning. Many terms are used to describe the practices that come to constitute norms in the classroom, including discourses, discursive practices, practices, and/or culture. For this project, the term "norms" has been chosen as it is well established in the mainstream mathematics education literature and dates back to the very early work of Cobb and colleagues (Yackel and Cobb, 1996) which still endures in the current context (Campbell and Yeo, 2021; Hofmann and Ruthven, 2018).

Norms can be seen as principles that underpin the practices. They provide the implicit and explicit guidelines through which the practices will evolve, and reflect what is valued within the classroom, school and/or community. They shift thinking from deficit models to strength-based models of practice. Under each of the norms, there are many sub principles and practices that need to be developed in order to embed and enact that particular norm. For example, if a school were to opt for a program that spanned across the whole school, as it was recognised that this would not only help students and community to see a common approach across the school, but there was also a need for a commitment from the staff to develop strategies that would enable this to happen. This would include staff development so that they would be familiar with the program. There may need to be consideration as to how best enable staff to undertake that staff development given that the schools are often unable to release teachers during teaching time due to the issues around isolation and inability to access to teacher relief. Considerations would also need to be made of how to ensure that the program is sustainable in the immediate context, but also how it may continue after the current staff leave the school. As such, each norm reflects various strategies (or practices) that have been shared through this research project.

7. Conclusion

While this study was conducted in some of the most disadvantaged communities in Australia, the findings have wider application. In concluding, I would like to make two key points. The first is with regard to the three levels of practice and the norms associated with those levels. The three levels of practice that arose from the study suggest that as a community, mathematics education research needs to consider the interaction of these levels. It may not be sufficient to have an interventionist program where it is not sustained by other levels of practice. While a program aimed at improving mathematics teaching and/or learning may have merit, it becomes necessary to consider the other levels of practice if success is to be enduring and long term. It became clear throughout the conduct of this research that each of the individual levels may impact on mathematics learning in and of itself, but a richer, more holistic way of working in the research domain may be at the intersections and inclusion of these levels. As argued elsewhere (Jorgensen (Zevenbergen) and Lowrie, 2015), there has been little achieved in the systemic redressing of inequities in outcomes in mathematics education. Perhaps, we have been barking up the wrong tree and may need to consider expanding research projects to include multiple levels of practice if real and deep change is to be affected.

The second point that I would like to conclude with is the focus of this study and its expansion into other equity target areas. While this study was focused on, arguably, the most disadvantaged learners in the Australian educational landscape, it is possible that the learnings from this study can be applied to other equity target areas. The levels of practices and the norms within those three levels may offer insights to support other equity target areas. This study should not be considered as relevant to only remote and very remote Indigenous learners.

Plenary Lecture 4

Mathematical Work of Teaching in Multilingual Context

Mercy Kazima[1]

ABSTRACT It is well acknowledged that teaching mathematics in multilingual classrooms where the language of teaching and learning is not the students' home language presents challenges. It is also well acknowledged that there are various knowledge demands on teaching mathematics, and that teachers face different tasks that constitute mathematical work of teaching. In this paper I explore the link between the two by conceptualising the mathematical work of teaching in multilingual contexts. I do this by drawing on lessons from studies on mathematical knowledge for teaching and mathematical work of teaching, from studies on teaching mathematics in multilingual contexts, and from my work in Malawi. My conceptualisation yields four categories, and I illustrate these using some examples from the context of Malawi.

Keywords: Multilingual contexts; mathematical work of teaching; Malawi.

1. Introduction

In this paper I discuss the mathematical work of teaching in multilingual contexts. "Mathematical work of teaching" are the tasks that teachers are regularly faced with as they teach mathematics (Ball, Thames, and Phelps, 2008). In the discussion I make reference to mathematical knowledge for teaching, and by this I use the definition by Ball et al. (2008, p. 395) to mean the "the mathematical knowledge needed to carry out the work of teaching mathematics". I will use the terms 'multilingual classroom' and 'multilingual context' to refer to all classrooms and contexts that have one or more languages besides the language of teaching and learning. While I acknowledge the differences between bilingual and multilingual that have been highlighted by many researchers, the differences are not crucial for this paper.

Discussing mathematical work of teaching in multilingual context is complex because it involves two large fields of research in mathematics education: (i) teaching mathematics in multilingual contexts and (ii) mathematical work of teaching and mathematical knowledge for teaching. Language and the teaching and learning of mathematics has been researched in different parts of the world. The emphasis and focus of the research has varied depending on the contexts and issues relevant to the situations at hand. Across the various contexts and research studies, the issues appear to be similar in general ways but also different in specific ways. For example, one

[1] Department of Curriculum and Teaching Studies, University of Malawi, Zomba, Malawi. E-mail: mkazima@cc.ac.mw

general similarity is that the various studies uncover some challenges in teaching and learning mathematics that come about because of language, while the specific nature of the challenges vary across the contexts.

When we look at mathematical work of teaching and Mathematical Knowledge for Teaching (MKT), research studies in this field generally agree that teaching mathematics requires different types of knowledge in addition to the subject matter knowledge. There are also some variations in this field in the way researchers conceptualise and name the various types of teacher knowledge. In comparison to the research on language and mathematics, in the research on MKT, there seem to be more similarities than differences. This could be because the focus is on mathematics and the mathematical knowledge demands on teaching, which can be explored in a similar manner across various contexts despite the different languages or language contexts. However, the demands on teaching might not be similar.

My work in mathematics education over the years has been mainly in these two fields and my research has mostly been in Malawi, my home country, and occasionally in other parts of south and east Africa through collaborations with other researchers. My experience, therefore, is that of multilingual classrooms where the language of teaching and learning is English, but not the home language of the students and the teachers. Malawi uses English as the language of teaching and learning from the fifth year of primary school onwards. In the first four years of primary school, local languages are used, however, textbooks for these first four years are in Chichewa only, the national language. Chichewa is also taught as a subject from the first year and throughout primary and secondary schools. Therefore the case of Malawi is often bilingual for students and teachers that have Chichewa as their home language, or trilingual (Phakeng et al., 2018) for those that have other home languages. While the classrooms as a whole can have multiple languages, thus multilingual.

My recent work in Malawi in collaboration with colleagues from University of Stavanger aims at improving the quality of mathematics education in schools through professional development of teachers and teacher educators. What has been evident in all my work and through my post graduate students' studies is that language is always an issue in such contexts even if we attempt to focus on different areas of research and not foreground language. The same is likely to be the case for others in the different multilingual contexts. Therefore it is important to discuss the work of teaching mathematics in multilingual contexts.

Researchers that have studies mathematical work of teaching include Ball and her colleagues at University of Michigan, and Adler and her colleagues at University of the Witwatersrand. Studying the mathematical work of teaching is important because "strengthening our understanding of the mathematical work of teaching … is a critical dimension of enhancing its teaching and learning" (Adler, 2010: p. 122). Ball et al. (2008) suggested 16 tasks that teachers are faced with when teaching mathematics, and Adler (2010) elaborated 4 tasks of teaching mathematics. All these tasks describe the mathematical work of teaching that is universal and apply to various contexts around the world. While these universal tasks strengthen our understanding of the mathematical work of teaching, they do not describe fully the work of teaching in specific contexts such as multilingual classrooms. It is therefore important to study the specific contexts and also strengthen our understanding of the work of teaching in such contexts.

I build from previous research to conceptualise the mathematical work of teaching in multilingual contexts. The main question I am exploring is: what is the mathematical work of teaching in multilingual contexts? I answer this question through the following three guiding questions and I relate to the context of Malawi and my work over the years.

(1) What lessons can we draw from studies on teaching and learning mathematics in multilingual contexts?

(2) What lessons can we draw from studies on mathematical work of teaching and mathematical knowledge for teaching?

(3) How can these inform conceptualisation of mathematical work of teaching in multilingual context?

My discussion is presented in four sections. First, I discuss the lessons we learn from studies on teaching in multilingual classrooms. Second, I discuss lessons from studies on mathematical knowledge for teaching. Third, I relate the discussion to the context of Malawi, the research studies in Malawi and lessons we learn. Finally, I discuss how the lessons can inform conceptualisation of mathematical tasks of teaching in multilingual classrooms.

2. Lessons from Studies on Language and Mathematics Teaching

Research on language and mathematics teaching can be grouped in a number of categories. I consider the three main categories as (a) those that focus on the mathematical language and terminology, which concerns all students even first language speakers of the language of instruction; (b) those that focus on students from minority language groups such as immigrant families into a country or community where the language of instruction is not their home language, for example Spanish language immigrants in the United States; (c) those that focus on students in countries where the language of instruction is a foreign language and not the students home language, for example previously colonised countries that use the colonial language. The third category is the case for many African countries.

I acknowledge the work by many other scholars who have focused on language and communication in mathematics and those that have discussed theoretical resources that can be used to study and understand use of language in mathematics (e.g. Sfard, 2008; Barton, 2008; Barwell, 2007). Morgan, Craig, Schutte and Wagner (2014) highlight the importance of theorising when studying language and communication in mathematics education. They point out that while there are many studies that focus on language use and how it contributes to students' learning of specific mathematics concepts, "little attention is given to the more general issue of the acquisition of mathematical ways of speaking or writing that may be applicable and acceptable in a wide range of areas of mathematics" (p. 852). Morgan et al. (2014) identify three areas of concern in this regard, one of which is "what knowledge and skills might teachers need to use in order to support the development of students' linguistic mathematical competence". This is an important concern which is relevant to this paper, and relates to questions raised by other researchers discussed later in the paper.

2.1. Lessons on mathematical language and terminology

As early as the work of Pimm (1987) and Orton (1992), we learn that some mathematical vocabulary pose problems for students, even for first language speakers. For example, words that have everyday meanings that are different from the mathematical meanings. This is difficult for all students to learn the precise mathematical meanings and use appropriately. Research and studies in this category inform us of the need to understand the complexity of mathematical vocabulary, to pay attention to words that might be difficult for students, and to plan carefully how to teach the meanings and use of such words in mathematics lessons.

2.2. Lessons from studies on classrooms with minority language groups

Examples of this work are that of Moschkovich in the US, Planas in Catalonia, and Barwell in the UK and Canada. The lessons we learn from these include that students from minority languages who are not fluent in the language of instruction need special attention to make the mathematics accessible to them. Without deliberate attempts to include these students in mathematics lessons, they will not access the mathematics and thus we will not achieve equity in mathematics education. Planas (e.g. Planas, 2019; Planas and Setati-Phakeng, 2014; Planas and Civil, 2013) and Moschkovich (e.g. Moschkovich, 2012; 2018) also caution against perceiving learners as deficit, and they suggest instead to view the learners' home languages as resources.

2.3. Lessons from studies on classrooms with foreign language as the language of teaching and learning

The context of teaching and learning in a foreign language that is not the students' home language is common in most of Sub-Sahara Africa. The foreign language is usually the colonial language, which after independence has continued to be used as official and school language. For example, English in Malawi, French in Cameroon and Portuguese in Mozambique. My review of research in this category is limited to English as a foreign language. Most of the research in sub-Sahara Africa on teaching and learning in multilingual contexts has been done in South Africa (e.g. Adler, 2001; Setati and Adler, 2000; Setati, 2008; Setati, Molefe, and Langa, 2008; Essien, 2010; Webb and Webb, 2008). There are at least seven general and related lessons that we learn from the studies:

(1) Students and parents prefer use of English as the language of teaching and learning because English is the language of power and brings "social goods" (Setati, 2008).

(2) Use of English or home language in teaching and learning should not be taken as a dichotomy where use of one completely excludes use of the other (Setati, 2008).

(3) Students' home languages should be seen as resources and not problems (Setati, 2008).

(4) Code switching can be used effectively where teachers and students share a common language (Webb and Webb, 2008).

(5) Code switching presents teachers with challenges and dilemmas (Setati and Adler, 2000; Adler, 2001; Setati, 2001)

(6) Bilingual approach where use of home language alongside English is planned and used proactively can be an effective way of teaching mathematics (Setati et al., 2008)

(7) Teacher education does not prepare teachers adequately for teaching in multilingual classrooms (Chitera, 2009; Essien, 2010)

(8) Setati, Chitera and Essien (2009) reviewed research of mathematics education in multilingual classrooms in South Africa, and raised three important questions, one of which is: "What do all teachers need to know, and what skills do they need to develop in order to be able to teach mathematics effectively in multilingual classrooms?" (p. 76). This is an important question that I will address in this paper, but with a focus on Malawi context.

3. Lessons from Studies on Mathematical Knowledge for Teaching

Since Shulman's seminal papers (Shulman, 1986, 1987) on teacher knowledge and his conceptualisation of subject matter knowledge (SMK) and pedagogical content knowledge (PCK), many researchers have based their studies on Shulman's work and elaborated on the categories of knowledge for teaching mathematics (e.g. Ball et al., 2008; Rowland, Huckstep, and Thwaites, 2005). I will focus on the work of Ball et al. (2008) that suggest six domains of teacher knowledge — three under SMK and three under PCK, which they illustrate in a figure shown in Fig. 1.

One of the lessons we learn from this work is that there are different types of knowledge that are needed for teaching mathematics. We also learn from their further work that these can be measured through carefully designed items. Review of MKT research and publications (Hoover, Mosvold, Ball, and Lai, 2016; p.9) reveals that although there have been many studies on the nature and composition of knowledge for teaching mathematics, it is difficult to draw lessons because most of these studies "do not build on each other in obvious ways and clear lessons are hard to identify". Hoover et al. (2016; p. 9) acknowledge that "the one avenue of work that represents progress for the field is the development of instruments." According to the review, there are many studies that have teacher education as a priority; these include studies

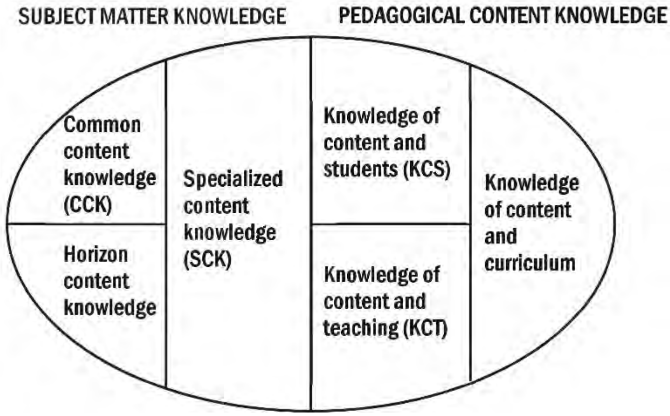

Fig. 1. Domains of MKT (Ball et al., 2008, p. 403)

on the design and evaluation of teacher education programmes. Hoover et al. (2016; p.11–12) suggest the following as what they observe as related emerging lessons from the several decades of research:

- Teaching teachers additional standard disciplinary mathematics beyond a basic threshold does not increase their knowledge in ways that impact teaching and learning.
- Providing teachers with opportunities to learn mathematics that is intertwined with teaching increases their mathematical knowledge for teaching.
- The focus of the content, tasks, and pedagogy for teaching such knowledge requires thoughtful attention to ways of maintaining a coordination of content and teaching without slipping exclusively into one domain or the other.

These are important lessons, because the main goal of studying MKT is that we understand it in ways that inform our work with teachers – both pre-service and in-service. However, I add that each of these requires careful consideration depending on the context, school curriculum and other issues surrounding teaching of mathematics in the specific context. For example, the basic threshold might vary across different school curricula, and identifying these might not be easy. Similarly designing and planning mathematics that is intertwined with teaching depends on the context: the curriculum, resources, language, and other characteristics of the context.

Hoover, Mosvold and Fauskanger (2014) shift the focus from knowledge for teaching to tasks of teaching, pointing out that there seem to be no discussion among the researchers of mathematical knowledge for teaching, about identifying common tasks of teaching that would form an international body of knowledge. They suggest that "the idea of common tasks of teaching – that represent a decomposition of the work of teaching into professionally recognizable components – constitutes a potential foundation for an internationally useful practice-based theory of MKT" (p. 8). Hoover et al. (2014; 7) call for "increased efforts to identify professionally defensible mathematical tasks of teaching that can serve as a common foundation for conceptualizing and measuring mathematical knowledge for teaching internationally"

What Hoover et al. (2014) are calling for is similar to what Adler (2010) did earlier when she elaborated on some tasks of teaching mathematics drawn from studies of mathematics classrooms in South Africa. She identified 'designing, adapting and selecting tasks', 'processes and objects', 'valuing and evaluating diverse learner productions' as interrelated mathematical tasks of teaching. These seem to be examples of "common tasks of teaching" Hoover et al. (2014) are calling for. As Adler explains, the identified tasks of teaching illustrate some of the mathematical knowledge for teaching discussed by Ball et al. (2008), thus building onto the body of knowledge.

Ball (2017; 29) also shifts focus from knowledge domains to specific mathematical work of teaching and argues that "the quest to answer the perennial question of what mathematical 'knowledge' teachers need should be based on a deep and nuanced understanding of what teachers actually do".

I respond to this shift in focus and conceptualise the mathematical work of teaching in multilingual contexts and not knowledge domains. I do this by drawing on the professional knowledge that I extract from the lessons learnt from the previous studies.

3.1. MKT studies in multilingual contexts

Studies of MKT in Africa are not many (Jakobsen and Mosvold, 2015). The available studies use the theories from University of Michigan; the earlier ones (e.g. Adler, 2005; Kazima and Adler, 2006; Kazima, Pillay and Adler, 2008) use Ball, Bass and Hill (2004) aspects of mathematical problem solving that teachers do, while the later ones (e.g. Adler, 2010; Mwadzaangati, 2018; Mamba, 2018) use Ball et al. (2008) domains of MKT. Lessons from these studies in African multilingual contexts include that the tasks of teaching as identified in the US are also identified in these contexts, furthermore there are some additions to the work of teaching that include paying attention to language; for example what is said and how it is said (Kazima and Adler, 2006). This suggests that teachers in this context are faced with additional specific tasks of teaching linked to language.

Studies of MKT in multilingual contexts outside Africa where the students are English language learners in an English-speaking country are also limited. I will focus on the work of Sorto, Wilson, and White (2018) and Wilson (2016) at Texas State University in the US. They studied specifically MKT for teaching English language learners and developed from Ball et al. (2008). Lessons we get from their studies are that there is a special kind of extra knowledge that teachers of English language learners require and that this knowledge fits within the Knowledge of Content and Students (KCS) and Knowledge of Content and Teaching (KCT) domains of MKT. They classify this knowledge as knowledge of obstacles, knowledge of resources, and knowledge of strategies. They represent these as in Fig. 2 which they call pedagogical content knowledge for teaching mathematics to English language learners (PCK-MELL).

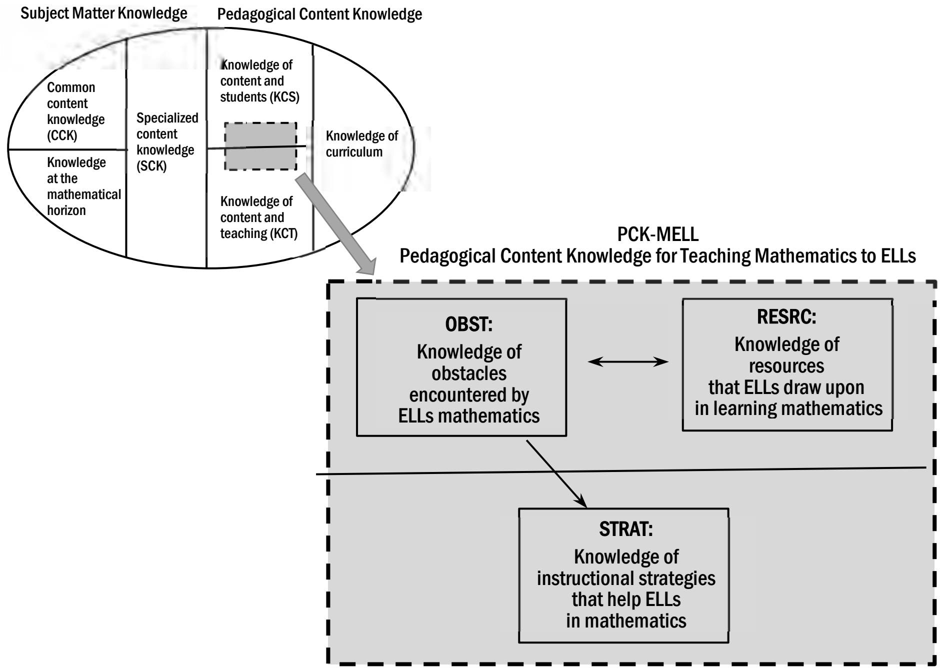

Fig. 2. PCK-MELL (Sorto et al., 2018, p. 222)

Another lesson we learn from these studies is that this knowledge can be measured using carefully designed items, similar to measuring the other knowledge of MKT domains. Sorto et al. (2018) aim was to identify domains of knowledge. My emphasis differs in that I aim to identify the mathematical work of teaching.

4. Lessons from My Work in Malawi

My work in Malawi over two decades has been about teaching mathematics in multilingual contexts, mathematical knowledge for teaching, teacher education and professional development of teacher educators and teachers. In my earlier studies I focused on language and mathematics, then later and until now on mathematical knowledge for teaching. Since 2013, my work has mostly been both research and development projects on teacher education and professional development of teachers. I am privileged to work in collaboration with colleagues from University of Stavanger. In this collaboration we have conducted two large projects, the first was from 2014 to 2018 and titled: Improving quality and capacity of mathematics teacher education in Malawi. The second project is titled: Strengthening numeracy in early years of primary education through professional development of teachers, currently in progress, started in 2017 and will end after 2021. I also work with colleagues from Malawi some of whom started as PhD students in the projects.

In Tab. 1 below, I present a summary of selected and relevant studies that I have participated in over the years.

Tab. 1. Relevant studies in Malawi

Year	Study	Researchers
2000–2002	Students understanding of probability vocabulary	Kazima
2010	Code switching in primary mathematics classrooms	Kazima and Pwele
2011	Using bilingual approach in standard 6 mathematics	Kazima, Pwele, and Kasakula,
2014–2015	Language and students' conceptions of logic in undergraduate mathematics	Levis Eneya, Mercy Kazima, Patrick Sawerengera
2014–2015	Exploring mathematical tasks of teaching in Malawi schools	Kazima and Jakobsen
2014–2018	Improving quality and capacity of mathematics teacher education in Malawi	Kazima, Jakobsen, Mosvold, Bjuland, Fauskanger, Eneya, Mwadzaangati, and Mamba
2015–2018	Measuring development of MKT in prospective primary school teachers	Kazima, Jakobsen, and Kasoka
2015–2018	Investigating MKT for teaching equations	Mamba
2015–2018	Exploring MKT for teaching geometric proofs	Mwadzaangati
2017–2021	Strengthening numeracy through professional development of mathematics teachers in Malawi	Kazima, Jakobsen, Fauskanger, Hedgevold, Mosvold, Bjuland, Eneya, Mwadzaangati, Mwale, Gobede, and Longwe
2017–2020	Investigating mediation strategies used by early years mathematics teachers in Malawi	Gobede
2017–2020	Making sense of MKT: insights from primary preservice teachers in Malawi	Jacinto
2017–2020	Exploring how primary teacher education prepares pre-service teachers to teach number concepts and operations	Longwe

4.1. Lessons from the studies on language in Malawi

Findings from these studies in Malawi supported findings reported in literature, and the lessons drawn are similar. For these studies specifically the lessons are:

(1) Students' meanings for mathematical terms can be different from the mathematical meanings, and these are influenced by their home languages (Kazima, 2007; Kazima, Eneya, and Sawerengera, 2015)

(2) Code switching can be used effectively to make mathematics accessible to students (Kazima, Pwele, and Kasakula, 2011)

(3) Bilingual approach where use of home language is planned and proactive can be effective in making mathematics accessible to learners (Kazima, Pwele, and Kasakula, 2011)

There are at least two other researchers that have studied language and mathematics in Malawi: Chitera (2009a, 2009b) and Kaphesi (2002). Chitera (2009a, 2009b) studied teacher education and the discourse practices in preservice mathematics education classrooms. She found that English is used in all lessons and there is no reference to home languages. The lesson we draw from Chitera's work is that teacher education does not prepare teachers for the teaching in multilingual contexts. Our ongoing project work with mathematics teacher educators in Malawi confirms this. Kaphesi's (2002) work analysed language practices of primary school teachers of mathematics. His findings confirm that code switching is the common practice that teachers use in teaching mathematics in Malawi. The lesson drawn from this is therefore similar to earlier lessons, that code switching between English and home language can be an effective strategy in teaching mathematics to learners that are not fluent in English.

4.2. Lessons from the studies on MKT in Malawi

It has been interesting to use theories developed in the US which is a context different from Malawi. Our use of the MKT framework was informed by many other researchers that used the framework outside the US. For example in South Africa where some of the school contexts are similar to Malawi. General findings from these studies on MKT in Malawi include:

(1) All the tasks of teaching suggested in the US were viewed as relevant by Malawi teachers but at varying levels of importance (Kazima, Jakobsen, and Kasoka, 2016).

(2) All MKT domains were observed in Malawi teaching demands (Mwadzaangati, 2018; Mamba 2018).

(3) Adapted MKT measures were appropriate to use in Malawi context (Jakobsen, Kazima and Kasoka, 2018).

Lessons from these findings are that the general tasks of teaching mathematics are the same in Malawi as elsewhere. However, language always surfaced as an issue, indicating that there are other specific demands on teaching related to language.

5. Conceptualising the Work of Teaching in Multilingual Contexts

Learning from all the discussion so far, it appears that teaching in multilingual contexts makes additional demands on teachers. I will focus on the context of Malawi and draw from the previous studies to conceptualise the mathematical work of teaching in this context. I do this by first considering the lessons drawn from studies on teaching mathematics in multilingual contexts. I take these as professional knowledge of teaching mathematics in multilingual contexts. Professional knowledge because they inform the mathematics education field and profession. From the professional knowledge, I identify the specific knowledge demands on teaching, then further identify the mathematical work of teaching that teachers face. I present this in form of a table as shown below.

As seen in Tab. 2, I propose four categories of mathematical work of teaching that teachers face: (1) identifying obstacles in home language, (2) identifying obstacles in English, (3) identifying resources in home language, and (4) identifying strategies; strategies to address the obstacles and strategies to draw from the resources in home language. I give some examples below to illustrate each of the proposed mathematical work of teaching

Tab. 2. Professional knowledge, specific knowledge demands and mathematical work of teaching in multilingual contexts

	Professional knowledge of teaching mathematics in multilingual contexts	**Specific knowledge demands on teaching**	**Mathematical work of teaching**
1	Students' meanings for mathematical terms can be different from the mathematical meanings, and these are influenced by their home languages	Knowledge of words in home language that are equivalent or closest equivalent to mathematical terms Knowledge of different meanings of the home language words that can cause difficulty. Knowledge of words in home language that students draw on to make meaning of the mathematical terms Knowledge of how to use the home language words in mathematics	Identifying resources in home language Identifying obstacles in home language Identifying strategies to draw from the resources Identifying strategies to address the obstacles
2	Code switching can be used effectively to make mathematics accessible to students	Knowledge of words in English that students find difficult Knowledge of words in home language that are equivalent or closest equivalent to the English words Knowledge of different meanings of the home language words that can cause difficulty. Knowledge of how to use the home language words in mathematics	Identifying obstacles in English Identifying resources in home language Identifying obstacles in home language Identifying strategies to draw from the resources Identifying strategies to address the obstacles
3	Code switching presents challenges and dilemmas for teachers		
4	Bilingual approach where use of home language is planned and proactive can be effective in making mathematics accessible to learners		
5	Home language should be viewed as a resource rather than a problem	Knowledge of what students can draw on in the home language to make sense of the mathematics being taught Knowledge of how to use these in mathematics	Identifying resources in home language Identifying strategies to draw from the resources

5.1. *Identifying obstacles in home language*

In drawing from home languages there are at least two types of obstacles (i) equivalent words in home language not as precise as the mathematical words and (ii) non-existence of equivalent words in home language.

5.1.1. Example of equivalent words in home language not as precise as the mathematical words

One example in Chichewa is the concept and operation of multiplication. Multiplication is translated as kuchulukitsa which literary means to increase or to make more. Being able to identifying the obstacle of using kuchulukitsa requires understanding the limitation of describing multiplication as to increase or make more. Specifically it requires understanding that it is true only for positive numbers multiplied by numbers more than 1; and that it is not only multiplication that can result in an increase, other operations on numbers can also result in an increase. For example, adding a positive number or dividing by a positive fraction. The work of teaching is to identify such obstacles and find ways of addressing them. This is mathematical work and is what teachers face for effective teaching of multiplication in this context.

Another example is the equal sign (=). In Chichewa it is translated as zikhala, which literally means will become. Thus the meaning assigned to the equal sign is that of getting a result after performing an operation. The limitation of zikhala is that it does not convey the equivalence meaning of the equal sign. For instance, showing equivalent fractions, such as $2/3 = 4/6 = 6/9 = 8/12 = \dots$, requires the equivalence meaning of the equal sign.

5.1.2. Example of non-existence of equivalent words in home language

There are some concepts such as similarity which do not exist in Chichewa and are difficult to explain. Similar is translated as kufanana literary meaning look alike, there is no word for proportional and is very difficult to explain proportionality in Chichewa. The work faced by teachers is to identify such obstacles in the home language and find other ways of explaining, such as using many examples of what are and what are not similar in mathematics, as well as the limitation of thinking of similar as only *kufanana.*

5.2. Identifying obstacles in English

There are many obstacles in English for learners that are not fluent in the language. The work for teachers is to observe closely and identify these. For example, sound alike words such as *size*, *side* and *sight* have been found to be used by learners interchangeably (Adler, 2001) and the words *probability*, *disability* and *ability* were thought to mean the same by some learners in a secondary school mathematics lesson on probability (Kazima and Adler, 2006; 53). Kazima and Adler call this “hearing disconnects” and argue that it adds to the description of mathematical knowledge for teaching. I emphasise the argument and add that it is a recurrent task that teachers face in this context. Hearing what students say and being careful in how to pronounce the words, as well as anticipating what students might hear and might mean mathematically are part of the mathematical work of teaching.

5.3. Identifying resources in home language

Resources in home language include (i) the words that teachers chose to use to provide mathematical explanations in the home language; and (ii) mathematical concepts in the home language that can be deliberately sought for use in teaching. The first case of identifying words to use mostly happens during lessons as teachers teach and code switch between English and the home language. Teachers are challenged to think fast on the spot while moving the lesson forward. For instance, looking at the two examples of multiplication and equal sign discussed above, after identifying the obstacles in home language, further work for the teacher is to identify words in home language that can be used to explain the concepts in a way that avoids the obstacles. Identifying words in home language also happens during planning where teachers have time to think and plan carefully the words to use in teaching. This is a major part of the bilingual approach where the use of home language is done proactively rather than reactively (Setati et al., 2008). The planning for this approach requires a lot of time and mathematical reasoning for teachers to provide mathematically appropriate and accurate versions of written materials for the lessons (Kazima et al., 2011).

For the case of mathematical concepts in the home language, one example is that of the number system in Chichewa. The number system has combination of base 5 and base 10, which can be drawn upon when teaching number bonds, number bases and other number concepts and operations. The counting in words is as in Tab. 3:

Tab. 3. Counting in Chichewa

Numeral	Number words in chichewa	Literal meaning in numerals
1	Chimodzi	1
2	Ziwiri	2
3	Zitatu	3
4	Zinayi	4
5	Zisanu	5
6	Zisanu ndi chimodzi	$5+1$
7	Zisanu ndi ziwiri	$5+2$
…		
10	Khumi	10
11	Khumi ndi chimodzi	$10+1$
…		
19	Khumi ndi zisanu ndi zinayi	$10+5+4$
20	Makumi awiri	10×2
…		
28	Makumi awiri ndi zisanu ndi zitatu	$(10\times 2)+5+3$
…

The mathematical work for teachers is to identify such mathematical resources and make decisions of what and when to use in teaching.

5.4. Identifying strategies

Identifying strategies is in two parts: identifying strategies to address the obstacles and identifying strategies to draw from the resources in home language. The mathematical work of identifying strategies is linked to all the other three mathematical work discussed above. For example, if a teacher decides to teach division by using some activities of equal sharing, then he or she would need to draw upon the words that the children use when sharing and find ways of using those words in teaching that would convey the mathematical concept of division. Thus as the teacher is identifying strategies to draw from the resources in home language, they are also identifying resources in home language and identifying obstacles in home language as well as identifying obstacles in English and identifying strategies to address the obstacles. Another example, if a teacher decides to use the strategy of word origins to explain meanings of mathematical terms such as polygon, triangle, or isosceles, then the teacher would need translations of the word origins into the home language. The mathematical work is therefore linked to identifying resources in home language, identifying obstacles in home language and identifying obstacles in English. One can see that the mathematical work of identifying strategies is not independent of the other mathematical work, however, it is important to acknowledge as its own category of mathematical work of teaching because it makes specific knowledge demands on teaching and requires special mathematical problem solving by the teachers to decide on the best strategy to use for effective teaching of the specific mathematics content in the multilingual context.

Comparing these identified mathematical work of teaching to the PCK-MELL knowledge domains (Sorto et al., 2018), it can be noted that the categories of mathematical work of teaching and the categories of knowledge domains are similar: they both have categories of obstacles, resources and strategy. I take this similarity as evidence of support for the findings of Sorto et al. (2018), although my focus is not knowledge domains. While there is this similarity in categories, there are some differences in the details, which appears to suggest that there is mathematical work of teaching that is common among multilingual contexts, as well as specific mathematical work of teaching for specific multilingual contexts, such as Malawi.

6. Conclusion

In this paper I have conceptualised mathematical work of teaching in multilingual contexts. I have done this by drawing from the professional knowledge of teaching in multilingual contexts that we learn from studies of teaching mathematics in these contexts. Considering the professional knowledge, I first identify specific knowledge demands on teaching then from these further identify the mathematical work of teaching entailed. I identify four categories: identifying obstacles in home language, identifying obstacles in English, identifying resources in home language, and identifying strategies. My approach is different from earlier studies on mathematical work of teaching (e.g. Ball et al. 2008; Adler, 2010) where they start from classroom practice and analyse the work faced by teachers as they teach mathematics. Some might argue that my approach, that is almost the other way round, could miss some details of what teachers are faced with when teaching mathematics. While I appreciate the limitation my approach might have, I would like to highlight that the professional knowledge I have presented is drawn from findings of classroom studies and therefore captured what goes on in practice in the multilingual context.

This identification of mathematical work of teaching in multilingual contexts is important because it informs us that there is specificity to teaching multilingual contexts. Looking at the specific case of Malawi, it appears that the specific nature of the mathematical work of teaching depends on the nature of the multilingualism. The Malawi multilingual context is similar to some that have national languages or common home languages between the students and the teachers. The context is different from others that do not have such common languages. Nevertheless, the conceptualisation of the mathematical work of teaching that I suggest can also inform those contexts.

Acknowledgement

Actors for Math Teacher Education: Joint Actions versus Conflicts

Frédéric Gourdeau[1], Despina Potari[2], Chunxia Qi[3],
Angel Ruiz[4], and Mikhail Sluch[5]

ABSTRACT We focus on the interaction of mathematicians and mathematics educators as they relate to the preparation of prospecting teachers and professional development of practicing teachers. We emphasize collaborative experiences and show how much can be gained with close collaborations. For this, we describe some examples and point out various factors that have made collaboration possible as well as potential conflicts that existed in certain institutional, cultural political and social-economic environments, and thus draw emerging issues. It is not intended to state rigid conclusions applicable in all contexts, however we consider two general perspectives and suggest some questions to guide research on this area. In general, although we did not find systematic strong research on the collaboration of mathematicians and mathematics educators in the context of teacher professional development, this does not necessarily mean that such efforts do not exist in different countries.

Keywords: Actors; Communities of practice; Conflicts; Cooperation; Mathematics educators; Mathematics teacher education; Mathematicians.

1. Introduction: Joint Actions versus Conflict — Some Key Characteristics

Various actors, with different roles and impact, interact as they participate in mathematics teacher education. These actors can be, for example: mathematicians, mathematics educator researchers, pedagogues, mathematics teacher educators, teachers, mentors, policy makers, curriculum developers, heads of schools, administrators, parents, or students. The actions of these actors and their impact on

mathematics teacher education depend on several factors such as for example the institutional and social contexts where the interaction takes place or the availability of resources.

The role of these actors and these factors have varied over time. They were not the same for example during -let's say- the "New Math" and "Going to Basics" during the sixties or seventies of the previous century, or during the recent decades where "Competencies" and "XXIst Century Skills" are promoted.

If we look at these roles today, the conditions and the actors involved in mathematics teacher education have evolved in many settings. Some of these changes are due to research in mathematics education (during the last two decades) that has focused on the mathematics teacher and has contributed to the development of teacher education practices that seem to be crucial in the education of both prospective and practicing teachers. For example, the focus on the special nature of teacher knowledge has an impact on the courses offered to prospective teachers and to the professional development of teachers (Cooper and Karsenty, 2008) where mathematics teacher educators and mathematicians play the central role. The emergence of practice-based pedagogies emphasized the importance of field experiences in teacher preparation and professional development (Solomon et al., 2017) that involves mainly mathematics teacher educators, mentors, teachers, administrators. Currently, research on large-scale studies on professional development has considered the important role of policymakers and has also developed strategies that involve a large number of teachers (Maass et al., 2019). In this setting, besides the policymakers, mathematics teacher educators, mathematicians, teachers are also key actors. This research has played an important role and attempts have been made to become available to other actors such as mathematicians (an example of this is the papers on solid findings written by the Education Committee of the European Mathematical Society (EMS) in the newsletter of EMS, see e.g. Hoyles, 2014), to teachers (teacher journals, professional development activities, conferences), to policy makers (through conferences and policy makers workshops, e.g. in the conference Educating the Educators III organised by the International Centre for STEM Education in Freiburg, Germany, https://icse.eu/educating-the-educators-iii/). Moreover, the emergence of international comparison and ranking of nations in math performance for students (PISA, TIMSS) and the last years for teachers (TEDS study) is also one aspect of the international context which has an impact on how the mathematical preparation of mathematics teachers is perceived.

The actors that we have mentioned above who play a crucial role in mathematics teacher education, as well as the underlying factors that drive their actions, have intervened and intervene in teacher education in different ways, in diverse cultural contexts (e.g. European, Asian, African) and socio-economic contexts (e.g. developed world, developing world, countries in transition).

Although each community of actors usually has its own goals and perspectives for the preparation and professional development of mathematics teachers, the collaboration between them is essential for promoting an effective way of intervention.

The attention in section 2 is given to the interaction of mathematicians and mathematics educators in connection to prospective teachers' preparation and, in section 3, to the professional development of practicing teachers. The fourth section is devoted to collaboration as a Community of Practice.

2. Mathematicians, Mathematics Educators, and Teachers in the Initial Teacher Education

2.1. Collaboration and conflicts between mathematicians and mathematics educators

The initial teacher education for prospective secondary school mathematics teachers includes several actors, and often varies according to the targeted level (grades K-12) of teaching and the presence of specialist mathematics teachers (as opposed to generalists). The level of involvement of mathematicians and mathematics educators and the potential for joint action, collaboration and conflict is dependent on context and varies greatly between countries.

In some settings, the potential for joint action appears to be lower, as mathematicians and mathematics teacher educators (MTE) participate, essentially separately. This may be the case when prospective secondary school teachers spend most of their university education in mathematics courses taught by mathematicians. In some such settings, a broad body of research has documented a disconnection between the mathematics taught and practiced at university and the mathematics required for school teaching (Zazkis and Leikin, 2010). While some mathematicians have looked at the differences between these type of mathematics in a positive light and many have acted to address this, there are tensions which can lead to conflict, as illustrated by the Math Wars (Ralston, 2004). To develop connected knowledge, numerous collaborative efforts between mathematicians and MTEs have taken place (Bass, 2005; CBMS, 2001, 2012; Ferrini-Mundy and Findell, 2001; McCallum, 2003; Wu, 2006). As a result, mathematics courses, which can be dramatically different from regular advanced courses, have been developed.

The inherent difficulties in working across institutions, faculties or departments can be a strong deterrent to joint actions. In some cases, mathematicians and mathematics teacher educators work in the same department, enabling collaborations and the emergence of educators who are experts in both domains. This creates opportunities, which are possibly reminiscent of the situation lived by earlier researchers in mathematics education. An example of research in this direction comes from Greece (Petropoulou et al., 2011; Karavi et al., 2020), where a strong expertise in mathematics and mathematics education enabled an individual to develop courses with a clearer expectation about students' difficulties, choosing representations enabling students to build a stronger understanding of advanced concepts. In this case, the MTE was both a mathematician and a mathematics education specialist.

However, it is a challenge in many cases to find how mathematics educators can support mathematicians in a study of their teaching and its impact on students' learning. As Bass points out, a fruitful collaboration with mathematics educators may not be practical for all mathematicians who wish to contribute to teacher education (Bass, 2005, p. 418). It also remains true that an important barrier is what some mathematicians expect from mathematics education research, such as the search for the effective teaching strategies, is very different from the views of mathematics education researchers (Sierpinska and Kilpatrick, 1998; Schoenfeld, 2000).

On a very positive side, in other settings, team-teaching between mathematicians and MTEs has taken place (Grassl and Mingus, 2007; Heaton and Lewis, 2011; Sultan and Artzt, 2005; Thompson et al., 2012). Research into the conditions enabling interdisciplinary collaboration in the way of team-teaching and joint work showed that shared goals, mutual trust, and open-mindedness (Goos and Bennison, 2018; Ponte et al. 2003) were key issues. It also showed that there was an initial fear of being judged by the other: mathematicians on their teaching, and mathematics educators on their mathematics.

Conditions hindering such work include cultural differences, grounded in epistemological differences between disciplines, as well as the lack of recognition, in both communities, of the value of such work (Goos and Bennison, 2018). There is also a difficulty for those working at the boundary between disciplines who can feel "like they belong to both one world and the other, or to neither one world nor the other" (Goos and Bennison, 2018, p. 272).

The emergence and the importance of brokers in such collaborative work is one of the important aspects considered in Goos and Bennison (2018): here, the collaborative work is not entirely in mathematics education or entirely in mathematics, and is done in such a way that actors from these distinct communities are engaged towards a common goal. When initiating collaborations, the presence and the emergence of brokers play a key role. They can be crucial in promoting and sustaining further work, and thus are both a product of successful collaborations and an ingredient for their ongoing success.

The presence of such brokers can also help in avoiding conflict or dealing more constructively when conflict arises. They play an important role in shaping the way one community views the other, and can help fight against ignorance and judgment, stereotypes and narrow views. This can be at the local, national and international levels, sometimes simply by sharing views about the complexity of the work done by "the other side".

As actors in different countries and institutions, many of us are in a situation where we can work towards enabling joint work by recognizing the importance of work done in collaboration in our respective communities. Despite the numerous challenges and obstacles, positive experiences show how much is to be gained from close collaborations.

2.2. Cultural aspects and their influence on the development of collaborations

Building joint actions among the actors involved in the education of prospective secondary school teachers is a long-term process and is framed by institutional, cultural, and political factors. What are some of the factors that have made this possible in different settings?

On the international level, and particularly at ICMI, several outstanding individuals have been recognized as genuine members of both communities. They were, generally, established research mathematicians who developed a very strong interest in mathematics education, in some cases leading to a career as a researcher in mathematics education: Hyman Bass and Michèle Artigue, two recent former presidents of ICMI, are prime examples of such individuals, and many other examples are found in Karp and Roberts' book (Karp and Roberts, 2014). These individuals have contributed to the development of the perspective that mathematics education is a genuine scientific endeavour, albeit very different from mathematics.

One important example motivated by ICMI has been the Capacity and Networking Project (CANP) which has conveyed the participation of mathematicians and mathematics educators in workshops held in different developing regions: Francophone Sub-Saharan African (Mali, 2011), Central America and the Caribbean (Costa Rica, 2012), Southeast Asia (Cambodia, 2013), East Africa (Tanzania, 2014), Andean Region and Paraguay (Perú, 2016).

In Norway, joint projects of mathematicians and mathematics educators have been established. The Erasmus+ European project PLATINUM (http://platinum.kubg.edu.ua/en/), which consists of seven European countries partnership between mathematicians and mathematics educators, aims to improve the teaching and learning of mathematics at the university level developing resources promoting inquiry-based learning. Mathematics education researchers and mathematicians contributed in different ways in the development of these resources and in their enactment.

In Canada, the establishment in 1978 of the Canadian Mathematics Education Study Group (CMESG) has led to annual meetings of mathematicians and mathematics educators in a highly collaborative work setting, around issues of mathematics education, particularly in mathematics teacher education. A Canadian community of mathematicians and mathematics educators was gradually formed, and numerous personal relationships forged. This enabled the development of mathematics courses for teachers influenced by mathematicians and mathematics educators (Hodgson, 2016). Initial teacher education has been an ongoing theme of working groups at these meetings, some examples are given in series proceedings of the annual meeting (Marynowski, Dufour and Liljedahl, 2017; Gourdeau and Nolan, 2016; Gourdeau, Oesterle and Stordy, 2014). The collaboration and joint involvement of mathematicians and mathematics educators in mathematics education discussion (through CMESG as well as in the Canadian Mathematics Education Fora of the Canadian Mathematical Society), and in the initial teacher education, may help explain why the Math Wars, which have affected the USA, have been much less intense in Canada.

3. Mathematicians, Mathematics Educators, Teachers and Other Actors in the Professional Development of Practicing Teachers

3.1. Joint actions in teacher professional development

Although in the initial teacher education there are research studies where mathematicians and mathematics educators collaborate, especially in designing and even team-teaching common courses (e.g. Bleiler, 2015), the research on collaboration between mathematicians, mathematics educators, and practicing mathematics teachers is rather rare. The discussion document of the ICMI-25 Study on "Teachers of mathematics working and learning in collaborative groups" (International Program Committee for ICMI-25 Study, 2019) addresses also as an important question the role of the different actors in teacher collaboration, including teachers, leaders, mathematicians, researchers in mathematics education. However, in the conference related to this Study that took place in Lisbon from the 3rd to 7th of February 2020 (http://icmistudy25.ie.ulisboa.pt/) there were no submissions reporting research in this area. Nevertheless, mathematicians and mathematics teacher educators are involved in supporting practicing mathematics secondary school teachers to develop their teaching. Mathematics educators usually organize practice-based professional development programs for teachers or act as facilitators in teacher collaborative groups (e.g. Cooper, Olsher and Yerushalmy, 2019). Mathematicians support teachers mainly by designing resources such as curriculum documents, textbooks, teacher's guides (e.g. Potari, Psycharis, Sakonidis and Zachariades, 2019).

Concerning the professional development of mathematics teachers, there is an increasing research interest on the collaboration between mathematics educators and mathematics teachers with a particular focus both on the process and the outcomes of collaboration (see the ICME international survey in (Robbuti et al., 2016)). In addition to the ICME international survey, we see several papers reporting collaborative efforts between mathematics teacher educators and mathematics teachers (Arbaugh, 2003; van Es, 2009) and a special issue in ZDM (issue 46) focusing on the collaboration addressing the importance of the joint actions, see (Jaworski and Huang, 2014). Collaboration between mathematicians/mathematics educators and teachers in the context of professional development has also been seen in offering professional development programs to teachers for revisiting advanced mathematics content that they had met during their university studies. An example of such a program concerns the teaching of linear algebra for ten practicing teachers in the US (Harel, 2017). Another example of collaboration among mathematicians, mathematics educators, prospective and practicing mathematics teachers is also reported in the study of McGraw, Lynch, Koc, Budak and Brown 2007) focusing of the use of multimedia cases as tools for teacher professional development. Through the analysis of online and face-to-face discussions, the authors show that the different backgrounds and experiences of the participants can blend in such a way that it promotes rich discussions about mathematics, teaching and learning.

In designing resources for teachers, we also see examples of collaboration between mathematicians, mathematics educators and teachers. In the study of Potari et al. (2019) that took place in Greece, different actors participated in the design of a new mathematics curriculum for the compulsory education. In that setting, tensions emerged between the different communities of participants while persons that participated in these communities (e.g. teachers who had also been involved in research in mathematics education), acted as boundary persons and facilitated the overcoming of the tensions. A similar example from China in improving teachers' teaching, university mathematics educators collaborated closely with mathematics teachers in designing and implementing lessons, and it was found that the identity of the participating teachers changed from "problem posers and solution receivers" to "collaborative problem solvers" in negotiating and finding solutions to practical problems with mathematics educators (Qi et al., 2021).

3.2. Mathematicians' efforts on teacher professional development with collaboration of other actors

The fact that there is no systematic research on the collaboration of mathematics educators and mathematicians in the context of professional development of practicing teachers does not necessarily mean that there are no such efforts in different countries. The members of the panel address collaborations that have taken place in their countries in the context of conferences and workshops, and annual conferences of the mathematics teacher associations.

More systematic collaborations are seen in China and the Russian Federation. In China, mathematicians have participated in many professional development programs for primary and middle school practicing teachers. Currently, one program is organized by the Ministry of Education (MOE) (named "Guopei" Project). It aims to improve teachers' professional skills, especially in rural areas. From the total of 45 mathematics expertise trainees in the first issued name list by MOE, 8 are mathematicians, which reveals the emphasis on the role of mathematicians from the government. In addition, mathematicians are involved in designing and planning mathematics curriculum standards and textbooks with other actors such as mathematics teacher educators and mathematics teachers. The two leaders of the current two mathematics curriculum standards (Ministry of Education [MOE], 2011, 2017) are all mathematicians. Among the six versions of current high school mathematics textbooks (Sujiao, Shanghai, Renjiao, Xiangjiao, Ejiao, BNU), two-thirds of chief editors are mathematicians who work in in-depth collaboration with other authors/actors (e.g., mathematics educators, teachers, Jiaoyanyuan, etc.).

In the Russian Federation, school textbooks and curriculum materials have been developed by working groups headed by leading mathematicians, while both mathematics educators and teachers participate in these groups. In this context, mathematicians are mainly responsible for the mathematics content while mathematics educators and teachers for the ways that the content can become accessible to the students. Moreover, mathematicians often participate in the professional development of practicing teachers, and they pay much attention to the popularization of mathematics both among students and among mathematics teachers. Mathematicians design and develop online courses for raising mathematics content knowledge of practicing teachers. For example, on http://ptlab.mccme.ru/node/5107 teachers can find a course on combinatorics and probability. Another example is the summer schools for teachers (in particular, for teachers of mathematics), organized by the top Russian universities such as the Moscow State University and the Higher School of Economics, where working scientists and educators give lectures and workshops for in-service teachers.

Another example of joint action between mathematicians and mathematics educators, in which some teachers are involved, is given by Mathematics Olympiads for secondary education in Latin America. [For example, the Brazilian Math Olympiad for Public School Students (18 million yearly participants), a nationwide educational project, includes teacher training programs.] Another such collaboration has been around mathematics modelling in Latin America and China. There is also a rich and long-time tradition of joint action of mathematicians, future math teachers and math educators in the Mathematics Olympiads for school children in Russia.

One very particular experience was developed in Costa Rica, following an unusual political decision made by a minister of education. A group of mathematics education researchers from public universities (whose initial training was in mathematics) and some practicing teachers worked as a team (Mathematics Education Reform in Costa Rica Project, https://www.reformamatematica.net) to design a new mathematics curriculum for all Primary and Secondary education (approved in 2012).

The same team with the inclusion of technology specialists have participated in the implementation of the new curriculum with a special emphasis on virtual instruments: designing, developing blended courses (with face-to-face and online dimensions) for primary and secondary teachers and pedagogical advisors (2012–2017), avant-garde MOOC and Mini-MOOC courses (since 2014) for teachers, and high school students and many other innovative virtual resources since 2019 (Ruiz, 2018, 2020). Since 2012, this team has had the support of several ministers of public education during three different national governments (Ruiz, 2020).

Here two things can be emphasized: There was a cooperation between political actors, researchers, teachers, technology specialists, pedagogical advisors within a scenario of curricular design and development. And second, during the pandemic since 2020, when virtual educational strategies gained extraordinary relevance, the multiple materials produced by this team associated with the Ministry of Public Education have constituted a non-improvised base of pedagogical support for the student population.

4. Collaboration as a Community of Practice

In the previous sections, some effective examples of collaboration between mathematicians and mathematics educators have been reported. Some of these examples share characteristics of a Community of Practice CoP (Wenger, 1998) in which mathematicians and mathematics educators are mutually engaged in an activity (e.g., co-designing, co-teaching courses), are held together by a joint enterprise (e.g., MOOC for teachers in the pandemic period), and have a shared repertoire of customs of practice (e.g., sharing views and experiences about the related resource). In this way, we can see the collaboration as forming a CoP. With consideration of seven principles of CoPs proposed by Wenger et al. (2002), we conclude three aspects:

- Achieving agreement on understanding the common objects
- Promoting equality in communication and mutual respect, and
- Facilitating transformation in identity.

To conduct the planned activities smoothly and efficiently in the collaboration, merely identifying common objects (e.g., co-designing course, co-developing curriculum, or textbooks) is usually not adequate given that mathematicians and mathematics educators/other actors may have different interpretations of them. Thus, one key factor is to ensure that every actor in the group has a common understanding of objects.

Based on the understanding of objects, promoting equality in communication and mutual respect is very crucial. A supportive atmosphere builds trust and enables mathematicians and other actors to express ideas and concerns openly (Henrick et al., 2017) without fear of others' judgment. In mathematicians' or mathematics educators' individual activity, most of them have only one fixed identity which guides their daily activities. However, during the collaboration, the objects require every member in the group to co-design the course for teachers, so that all members become co-learners and co-designers. Through their participation and collaboration, the mathematicians, mathematics educators, and other actors share and absorb each other's wisdom and sometimes act as "brokering" (Wenger, 1998) to facilitate transforming their old identities into the new ones of co-learners and co-designers. This type of benefit-sharing mechanism enables all the actors to work well with a clear understanding of the participants' identities in collaboration, performing their "delegations" from each community (mathematics content and education content respectively) and undertaking joint efforts for common development (Wenger, 1998).

Forming communities of practice in which mathematicians, mathematics educator researchers, teachers and other actors collaborate for contributing to initial teacher education and teachers' professional development is not an easy task. However, it seems that it is a promising way to offer prospective and practicing teachers learning opportunities that can have a positive impact on the mathematics education of students in schools.

5. Closing Remarks

Based on the aforementioned statements, we come to two main conclusions and propose four questions for further consideration.

Conclusion 1: *The relationships between the social agents involved in the preparation of teachers are not identical in various countries and regions due to diverse cultural or socio-economical contexts or individual or group experiences.*

For example, mathematicians may or may not participate directly in the design of curriculum materials for the school actors. Active teachers may or may not have a “say” in some teacher preparation programs.

Mathematicians can publish books on the history of mathematics or collaborate in publishing textbooks for pre-university education. In some countries there is no participation of mathematicians or even math educators in such activities.

Conflicts or tensions are not the same in all latitudes. The "Math Wars" in the USA were not a worldwide phenomenon, and in other countries the nature of conflicts may have been different.

So, it seems that it is not possible to offer a prescription for all settings.

However, we can enunciate

Conclusion 2: *It is always possible to identify internationally good practices that promote collaboration between educational agents and to manage conflict appropriately, but always with careful calibration of specific contexts.*

Even if conflict can be a problem for collaboration, they can also be an opportunity to calibrate the complexities of collaboration and to further develop these collaborations in fruitful ways. To conclude, we suggest some questions that could support research in this area as well as the emergence and development of such collaborations:

1. How to promote trust, mutual respect, and shared beliefs, values and goals, and stimulate joint practices among the several actors involved in mathematics teacher education? How can a community of practice can be developed and sustained?
2. What are the main features of institutional environments that facilitate collaborative work between the different actors?
3. What practices can help achieve convergence between the priorities and practices of universities and those of schools?
4. How to strengthen the participation of teachers in communities as a context for their professional learning? What is the role of the several actors in this process?

Plenary Panel 2

Mathematics Education Reform post 2020: Conversations towards Building Back Better

Mellony Graven[1], Marcelo Borba[2], Eva Jablonka[3], Danny Bernard Martin[4], and Kalyanasundaram (Ravi) Subramaniam[5]

ABSTRACT Our plenary panel focused on issues of mathematics education reform that have gained increasing significance since the start of the pandemic in 2020. Our panelists contributions provoked conversation about directions for mathematics education reform post 2020 with a view towards building towards ‘better’ quality and equitable mathematics teaching and learning for the future. Our topic cohered well with the 2021 International Day of Mathematics theme which was “Mathematics for a Better World”. The panel engaged with equity issues relating to two interrelated aspects of ‘building back better’ as we emerge from the crippling challenges of the pandemic. The first issue related to transitions towards remote and online teaching and learning in mathematics education which gained speed due to the massive closure of, and disruption to, schools due to Covid across the globe. The second related to the 2015 United Nations Sustainable Development Goals (SDGs), aimed at building ‘a better future’. We shared insights into emerging issues and research from across the globe and raised questions about the role of mathematics education in providing a better footing to achieve the SDGs and so build towards a more equitable future and a better world. Our paper is based on our panel contributions with voices and perspectives from diverse geographical backgrounds, research interests and expertise. The aim of the paper is to further provoke conversation about emerging and increasingly urgent issues our mathematics education community must grapple with.

Keywords: Reform; Equity; Sustainable development goals; On-line learning; Build back better.

1. Introduction (by Panel Chair Mellony Graven)

In 2020 education systems across the globe faced major challenges in finding ways to enable continued teaching and learning in the context of a global pandemic that challenged opportunities for face-to-face classroom-based learning. In our panel, with the brief of focusing on key emergent mathematics education reform issues needing attention for 'building back better' in this post 2020 period, we identified two key issues to focus and frame our panel discussion. The first issue relates to transitions towards remote and online teaching and learning in mathematics education. This transition has recently gained speed due to the massive closure of, and disruption to, schools due to Covid across the globe. While online learning opportunities bring the possibility for increased access to quality mathematics education resources there is enormous uneveness in systemic and individual preparedness to optimise these opportunities. This plays out across countries and within countries and there is concern that the digital divide could exacerbate inequities across gender/social-class/race. Recent research evidence points to this concern playing out in real time across our home countries and the globe (Oxfam India, 2021; Borba, 2021; Martin, 2021; Jablonka and Bergsten, 2021; Vale and Graven, 2021). The second relates to the United Nations Sustainable Development Goals which were established in 2015 and aim to 'build a better future' by 2030 (UN General Assembly, 2015). While most countries are signatories on the SDGs, of which the fourth focuses on quality education for all, five years on these goals are far behind in meeting these targets. The SDGs include, for example, goals such as: no poverty; zero hunger; good health and well-being; quality education; gender equality; reduced inequalities; climate action; and peace, justice and strong institutions (among others). Covid is noted to have exacerbated challenges to progress in these goals yet some argue that emerging from the pandemic provides an opportunity for using the SDGs as a 'roadmap' to 'building back better'.

The phrase 'Build Back Better' initially emerged in the context of the Sri Lankan 2004 tsunami recovery efforts with the phrase looking to capture a comprehensive approach to recovery in which building back would not recreate or exacerbate existing vulnerabilities (Khasalamwa, 2009). The phrase was taken up in the UN conference on Disaster risk reduction in 2015 (UNISDR, 2015), in the same year the SDGs were adopted. In 2020 the world became increasingly aware of other 'disasters' beyond the pandemic. Some of this increasing visibility is a result of increasing access to digital news and social media. For example, the increasing exposure of extreme systemic racial inequality gave rise to the Black Lives Matter movement that began in the United States and gained momentum across the globe. 2020 and 2021 witnessed several climate related 'natural' disasters that disproportionately impacted those with fewer resources. The increasing proliferation of fake news highlighted the urgent need for people to be able to make informed decisions about how to respond to the many disasters (health, social, political, climate, economic challenges etc.) confronting their lives. While many mathematics educators have long argued the urgency of this need, 2020 was a pivotal year in placing a spotlight on the consequences of the failure of education in general, and mathematics education in particular, in preparing learners for critical citizenship.

In the following sections our panelists focus on raising questions about how mathematics education should respond to a range of issues in the context of the rapid transitions towards remote and online teaching and learning and supporting the SDGs. We acknowledge that these are not the only issues needing urgent grappling post 2020, but we considered these important, timely, and of global relevance for providing foci for our panel.

2. What Is the Role of Media and Things in Mathematics Education Post-2020? (by Panelist Marcelo C. Borba)

The goal of my panel input was to show how the role of media and things in mathematics education. Ideas presented below can be found in a more profound way in Borba (2021), Engelbrecht et al. (2020a, 2020b) and Borba, Souto e Canedo Jr. (2022) for those that Portuguese is easier to understand than English. Artefacts have always had a role in the development of mathematics, whether we talk about writing in paper, writing in tablets in Mesopotamia, the use of compass in geometry and more recently the use of digital technology (Villarreal and Borba, 2010). In the last decades different governments have tried to implement different programs to increase the use of digital technology in (mathematics) education. However, none of these programs, when we consider countries such as Brazil, have been as effective as the pandemic in stimulating the move to digital technology, illustrating the agency of the virus SarsCov-2. Questions worth asking are: Is this true in your country? If so to what extent and how has the pandemic influenced the move towards digital technologies for mathematical learning? What are some of the consequences of this for learners, teachers, the nature of mathematics taught and the pedagogies of teaching mathematics?

Reducing inequality is one of the goals for sustainable development, a major theme of this panel. Social inequality and economic disparities are a problem around the world. The pandemic has brought the need to incorporate digital technology in mathematics education, but teachers in schools in Brazil, and I expect elsewhere, had widely differing levels of readiness for their use of digital technologies – and these unequal levels or readiness link with societal inequalities of socio-economic status.

In the references mentioned above the notion of domestication of media was developed. Domestication means using a new media without exploring its potential, using it with rules and practices of an older media. In the case of Brazil, a clear example of this is that, many textbooks were just copied and transferred to digital media in the emergency remote teaching response. Many teachers, understandably, were teaching online “in the same way”, with practices from regular classroom dominating. In this respect, most teachers, students and parents were not taking advantage of the emergence of a new medium. Instead, they simply reproduced existing teaching practices and text resources. So for example, teachers used the internet to simply record their usual chalk on board regular class instruction, followed by provision of standard school practice exercises for learners to do at home (as they would in the class). However, there were others using PowerPoint, and the camera for recording images of key ideas or representations to share with learners, and thus it is possible to think of a rainbow of domestication of digital media.

In the papers by Borba and colleagues mentioned above it is argued that teachers could (and should wherever possible) be using animation in pieces of software such as GeoGebra to do dynamic mathematics. This then would allow one to explain to a much larger public, for example, that the sigmoid is important to model the way that the pandemic is unfolding. So, at a secondary school and beyond level, teachers could teach students about the sigmoid, its derivative, and how different sigmoids, lead to different peaks of the derivative. The notion of flattening the curve then may be understood by many more citizens and in more complex ways than simply 'seeing' the shape of the curve. An illustration of the sigmoid and its derivative can be visualized at this link https://igce.rc.unesp.br/#!/pesquisa/gpimem---pesq-em-informatica-outras-midias-e-educacao-matematica/animacoes/curva-epidemica-no-geogebra/. For each red curve (sigmoid) a different peak of the derivative, the rate of change curve, that can put the health system of a given community under stress can be seen.

In all the media presentations there is little discussion of why is it important to flatten the curve? Understanding mathematically the meaning of flattening the curve and how this connects with saving lives and allowing health systems to cope with cases is important. Saving lives can be demonstrated mathematically but students need to be able to access the mathematical meaning. I have argued with my students and shown them that the sigmoid in its derivative is true of exponential functions. In this way mathematics around exponential function may become meaningful in concrete rather than only abstract ways. Similarly, exponential functions are also important to understand social inequality to understand that the rich are getting exponentially richer and the poor are getting exponentially poorer and that the social disparity is growing exponentially. During the pandemic, the large multi-national companies that dominate the lives of many (and many more in these recent pandemic times), such as Facebook, Amazon and Google made their owners exponentially richer at the same time that populations in general were becoming exponentially poorer with many more people slipping into poverty. Therefore, it might be important to teach children how to count 1-2-3-4-5-6 but also 1-2-4-8-16-32-64… and backwards 64-32-16-8....

The use of technology in mathematics education can help with the tasks mentioned above whether we use concrete material, paper and pencil and/or digital technology. Digital technology, as other types of technology, can reduce or can increase inequality. Knowledge is seen as a product of collectives of humans-with-media. Different humans, different media (orality, writing, computing, for example) different knowledge, different ways of attaching meaning. Humans-with-Geogebra in the mathematics shown in the link above is a product of humans-with-media and once it is used in someone's formal or informal teaching, the animation presented in the link is part of such a collective.

In the pandemic another non-human-actor became very prominent in a collective that constructs mathematical knowledge. The agency of the corona virus resulted in emergency remote mathematics teaching. This meant children and young adults at home became important agents in their own and their families mathematics education. Quality of the home, availability of rooms for studying, internet connection and possibility of parents, other adults or older siblings in the home as helpers and facilitators of learning became paramount for mathematics education. This was irrespective of whether technology was used in a domesticated way or not.

Collectives of humans-with-media-homes exposed the increasing social inequality compared to those without. One cannot have education for all, or thinking about “building back better” without simultaneously addressing such social inequality and inequality in access to digital technologies and learning opportunities. We must face and eradicate social inequality to open the door to mathematics education to all. We must struggle to promote change in pervasive societal and economic inequality that gives rise to extreme differences in access to digital resources, access and learning opportunities to make mathematics education for all a possibility.

Different cell phones, different video, different connection influence different knowledge construction. We cannot have extreme social difference and simultaneously have equal opportunities for mathematics education. Schools may have shadowed the differences in home, as the picture in Borba (2021) shows. The capital to have different home and the new cultural capital - that includes not only the education of the parents and the parents and the community but also includes now the quality of the internet and homes - make mathematics education different for different students. If we are back to schools, we should never be able to forget the difference of schools itself depending on the neighborhood but also on the difference of homes. These differences the corona virus has made even more visible to us.

We have used more and more videos in mathematics education during the pandemic. Mathematics videos cannot hide social issues of homes and neighborhood. With the use of subtitles you may see a sample of videos produced by students-teachers-with-mobile-phones (https://www.festivalvideomat.com/). Digital technology can contribute to make visible what may be invisible for students: different social realities of their peers. So yes, while everyone needs clean water and functioning services in today’s world they also need internet and homes that enable effective use of digital resources to be part of our collective of humans with media and things!

I end with drawing on Paulo Freire, a Brazilian educator. He has said If education alone does not transform society, neither does society change without education? We can paraphrase such a sentence! Without mathematics education for all, without understanding of exponential functions linked to the mathematics of the pandemic, can we overcome inequality? Can a collective of students and teachers with media be prepared for the next pandemic?

3. The Use of Mathematics in Communicating an Urgent Need for Action and Questions for Education (by Panelist Eva Jablonka)

3.1. Mathematics in contexts of crises

In approaching the theme of the panel on the ground of my expertise I shall focus on the role of mathematics in communicating an urgent need for action. It has been emphasised that mathematics education should address the public use of numbers, quantities, metrics or indicators – henceforth all denoted as ‘numbers’ (e.g., Fischer, 1993; Jablonka, 2003; Dowling 2009, Chronaki, 2017). In contexts of crises numbers are often used (i) to communicate the ‘reality’ behind something that happens, of which we see only some symptoms, (ii) to project what will continue to happen if no action is taken, and (iii) to predict what would happen if particular actions were taken.

Before proceeding to examine the public use of numbers, I would like to look at a fictitious situation of crisis in the story of an epidemic in a quarantined city: In the beginning of the epidemic, when regular broadcasting of the official statistics started, “[…] the reaction of the public was slower than might have been expected. Thus, the bare statement that three hundred and two deaths had taken place in the third week of plague failed to strike their imagination.” Subsequently, “[…] a new phase of the epidemic was ushered in when the radio announced no longer weekly totals, but […] deaths in a day.” When observing this practice, the fictitious chronicler comments, “The newspapers and the authorities are playing ball with the plague. They fancy they're scoring off it […].” (Camus, 1991/1947, p. 113)

Numbers still do not strike audiences’ imagination but listening to numbers via radio has become rare in 2021. The ubiquity of screens on TV, computers and mobile devices clearly has increased engagement with the visual; black-boxed mathematics in the form of visualisations of complex data and interactive tools are designed to inform non-experts (with stark differences in the quality between the so called “prestigious” and “popular” media). There has been an intensification in the use of mathematical models and speedy computations with massive data and an extended use of experts in political decision making (whose role is contingent upon the type of political system). There is a need to examine the implications for mathematics education.

3.2. An example of numbers in public discourse in Germany

The public discourse in Germany during the first epidemic wave of COVID-19 in 2020 is a useful example. Numbers featured prominently in the (changing) construction of what constitutes the crisis and in communicating an urgent need for action. The numbers were generated in a range of academic fields, such as epidemiology, infectiology, virology, demography and public health care resource statistics. Numbers included: cases, new cases, person-time incidence rate, deaths, case fatality rate, excess mortality, recovered, doubling time and effective reproduction number. In a systematic study we identified different strategies of using these numbers to defend the regulations directed to contain the spread of the virus (cf. Jablonka and Bergsten, 2021):

Rationalisation: This is the strategy one expects in a rational policy discourse that relies on experts from academic fields. It consists in the use of numbers in factual statements for providing evidence as well as in arguments and explanations, that is, elements of scientific discourse from the relevant fields. A residual strategy of rationalisation creates the impression of fact, probability and verisimilitude by means of mere repetition and compilation of numbers.

Contrast: This strategy of using numbers consists in establishing a stark contrast between numbers qualified as "high" and others described as "low", and at the same time invoking emotions on one side of the comparison, as, for example, a looming menace associated with "high" numbers. This strategy is highly adaptable in terms of supporting or opposing a particular need for action, as both the context of comparison and the selected numbers can be chosen accordingly.

Association: This strategy also appeals to imagination and fantasy, but here numbers are not compared across or within contexts; instead, particular numbers are selected and then combined with representations of concrete events, objects or behaviours seen as equivalent with overcoming the crisis or hindering this. For example, some metrics were combined with images of clubbing young people to create the association that their behaviour is responsible for "high" numbers.

Recharging: This strategy consists in presenting concrete examples of first-hand experiences, personal narratives, testimonies or individual fates "behind" the numbers. Thereby the numbers become recharged with subjectivity and materiality that have been stripped off through the mathematisation. It can be interpreted as a move towards overcoming the effect of "ethical filtration" (Skovsmose, 2006) resulting from the transformation of the handling of a complex situation into a technical problem by which moral considerations or ethical dilemmas apparently are cleared away.

These strategies of overcoming the apparent neutrality of depicting the problem by means of numbers (the kernel of rationalisation) appeared as an integral element of the public policy discourse. The discourse also included the daily presentation and production of numbers on liveblogs, infographics and interactive maps. In addition, there appeared some black-boxed mathematics, such as simulators for different epidemic scenarios or interactive tools for calculating the individual risk of infection in different environments; these fool the user into believing to be in a position of attaining definitive solutions to complex problems (cf. Gellert and Jablonka, 2009).

3.3. Examples from other contexts

Similar use of numbers that emanate into public discourse from mathematical models or simulations produced in diverse academic fields are particularly found in policy fields that relate to the United Nations Sustainable Development Goals. These often rely on complex data that can only be communicated via sophisticated visualisations designed for non-expert audiences. Space does not permit more than two examples.

The example from the German Aerospace Center (DLR) is a good illustration of a visualisation (Fig. 1) of complex data used for providing evidence (rationalisation). It relates to DLR's programme theme "earth observation" tailored "to the current and future scientific, societal, political and economic challenges posed by global processes and changes" (DLR, n.d). It shows the reduction in air pollution as an outcome of lockdown measures in 2020. Data have been adjusted for effects due to weather; one still can "see" the positive effect on air quality through comparing the images.

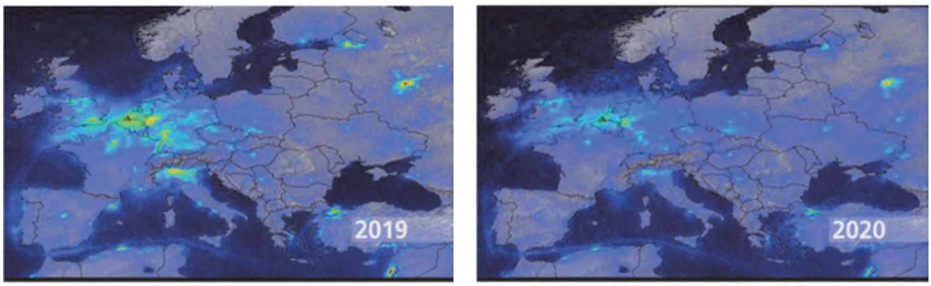

Fig. 1. DLR (2020, May 5). Comparison of nitrogen dioxide emissions over Europe between March/April 2019 and 2020, image 1(4)
Credit: DLR (CC BY-NC-ND 3.0)

The second example illustrates the use of numbers in strategies that involve appeal to affect, emotion or fantasy. In the yearly reports "Global Trends" of the United Nation's Refugee Agency with statistics on forced displacement of people that aim at enhancing public understanding, the strategy of recharging is commonly used. The reports regularly include photographs and short descriptions of individual fates. Examples in the latest report (UNHCR, 2021) include the fate of a Syrian refugee and his grandson (p. 13), an internally displaced woman in Kongoussi (p. 23); displaced people in canoes on flood water around Pibor (p. 26); the internally displaced young footballer Maria Romanchenko in Odessa (p. 28); an asylum-seeking family who fled from Honduras to Guatemala (p. 31); asylum-seekers in Congo Rive village (p. 37).

3.4. Questions for mathematics education

To summarise, in many public reports of supranational institutions, non-governmental organisations and local campaigns of policy actors who communicate the urgency of some political action we find black-boxed mathematics in form of sophisticated visualisations and strategies of communication similar to those found in the context of the pandemic. These are necessary when the data are too complex and also because numbers never speak for themselves. How should the use of numbers in communicating political priorities enter mathematics education?
Resulting from this unavoidably incomplete and inconclusive sketch of various issues related to the use of numbers, I would like to propose three questions to be asked in mathematics education as research and as practice:

(1) Where is the space in the curriculum for dealing with black-boxed mathematics in the form of visualisations?

(2) If more locally relevant topics related to Sustainable Development Goals are to be included in the teaching of mathematical modelling and statistics, how can a balance be found between simplifying the socio-political complexity of the problems and focusing on mathematically important issues?

(3) Shall mathematics still be taught as neutral tool and mathematics educators try to avoid appealing to affect, emotion and fantasy or shall it include discussions of strategies and the art of using numbers for getting a political message across?

4. Is the Future of Mathematics Education Black? (by Panelist Danny Bernard Martin)

4.1. Motivational context

My decision to frame the future of mathematics education in the United States around the question in the title of this paper is partially shaped by my positionality as a Black man in America. In this country, I belong to a group whose bottom-level status in the social hierarchy has been fortified in law, policy, practice, and reform for more than 400 years. Recurring instances of extrajudicial killings of Black people by police, the disproportionate effects of COVID-19, and efforts to disenfranchise Black voters across America serve as visible reminders of this bottom-level status. While many people across the globe may have been shocked by the recent killings of Black people by American police, or by the disproportionate impact of Covid-19 on Black people, the year 2020 was in many respects completely normal for Black people. It was not an aberration. Going back 10, 20, or even 100 years would reveal similar outcomes in many different areas of Black life.

Therefore, my thoughts about the future of mathematics education cannot ignore the realities of the past and present, and they cannot be confined to issues of teaching, learning, curriculum, and assessment. Against the backdrop of these observations, let me say a bit more about the question, Is the future of mathematics education Black? I claim that: there is no future for mathematics education in the United States if a reimagined (not reformed) mathematics education does not value the lives and humanity of Black people, contribute to their collective liberation and flourishing, and stand in opposition to white supremacy, antiblackness, and racial capitalism. if not, the future of mathematics education will continue to reflect the present and the past.

4.2. White supremacy, antiblackness, and racial capitalism

In America, the past and present reflect the fact that despite decades of curriculum and teaching reform, many Black children continue to experience dehumanizing and violent forms of mathematics education. These dehumanizing and violent experiences are rooted in systems of white supremacy, antiblackness, and racial capitalism. Invoking white supremacy, antiblackness, and racial capitalism should not be viewed as unnecessary provocation. Historical analysis shows that they are foundational to the birth of America, and they continue to undergird almost every American institution. In many ways, white supremacy is the thread that holds America together, stitching together the past, the present, and the future. Invoking antiblackness provides the necessary language to explain the particularities of Black oppression, and the willingness of American institutions to dehumanize Black people and inflict gratuitous violence. Racial capitalism helps to explain how Black pain, Black suffering, and fabrications of Black pathology continue to serve as commodities for capital accumulation. During chattel slavery, for example, the bodies of Black people were considered property and their free labor generated much of America's wealth. More than one hundred fifty years later, the marginalization of Black people in mathematics has resulted in a proliferation of 'intervention economies' focused on fixing Black learners and increasing their achievement and participation in mathematics (Martin, 2021).

The persistence of Black racial oppression in America over the past 400 years serves as a reminder that white supremacy is a self-correcting system that has resisted every attempt to dismantle it. As noted by the writer Ta'Nehisi Coates (2014), "white supremacy is… a force so fundamental to America that it is difficult to imagine the country without it. And so, we must imagine a new country." In my opinion if America cannot be reformed away from white supremacy, then the same is true for mathematics education. I can modify the Ta'Nehisi Coates from earlier to say: white supremacy is … a force so fundamental to [mathematics education] in America that it is difficult to imagine [mathematics education] without it. And so, we must imagine a new [mathematics education].

4.3. Myth of Black inclusion

Confronting the realities of white supremacy, antiblackness, and racial capitalism in mathematics education also means confronting the myths and realities of Black inclusion and the myths that are perpetuated about reform. Recent data show that after steady increases from the late 1980s to the early 1990s, the percentage of Black mathematics majors has decreased during the past 25 years and stabilized to around 5% (Bressoud, 2018). This time frame coincides with several mathematics education reforms in the United States, with many of these reforms focused on diversity and inclusion (Martin, 2019). Over the same time frame, the number of Black mathematics majors at US universities, represented by the blue curve, has remained relatively flat (Bressoud, 2018). Across these contexts, at least, Black inclusion into mathematics is a myth.

My own research and the work of several colleagues has documented other realities and material consequences of white supremacy, antiblackness, and racial capitalism for Black learners in mathematics education (Martin, 2013, 2019; Davis and Jett, 2019). In very recent work, colleagues and I discuss how Black learners encounter and negotiate various forms of violence, including epistemological, violence, systemic violence, and symbolic violence (Martin, Price, and Moore, 2019). For example, we show how knowledge production often reifies the idea of Black inferiority in mathematics by using statistics as a proxy for truth. Drawing on the work of Thomas

Teo (2010), we frame this as epistemological violence. We also show how school-based mathematical practices limit Black students' access to identities as creators and doers of mathematics, reserving these identities for white and Asian learners. We link these practices to symbolic violence.

Consider recent research by Faulkner et. al. (2014). Using data from the Early Childhood Longitudinal Study–Kindergarten Class of 1998-1999 (ECLS-K) data set, they analyzed the mathematics placement profiles of Black students and White students from late elementary school through 8th grade. In particular, the authors analyzed the impact of teacher evaluation of student performance versus student demonstrated performance on the odds of being placed into algebra in the 8th grade. Please note that in the United States, Algebra serves as an important gateway and gatekeeper course to more advanced mathematics and other prized educational opportunities. Results of the study revealed that Black students had reduced odds of being placed in algebra by the time they entered 8th grade even after controlling for performance in mathematics. The odds of placement in algebra by the eighth grade for Black students were reduced by two-thirds to two-fifths compared to their White peers. The authors concluded:

> Black students confront an untenable impediment in that their Blackness (or, as we suggest here, the teachers' implicit responses to these students' Blackness) … is an invisible… obstacle to gaining access to higher level mathematics courses, irrespective of their demonstrated performance.

In other words, meeting and exceeding standards are not enough counterbalances to antiblackness and white supremacy. Let me be clear that I am not making an argument for inclusion. If inclusion means inclusion into a system that is fundamentally anti-Black, I cannot support that. Building back better must mean more than inclusion into mathematics as it is. Rather, the focus should be on building a humane, anti-racist mathematics education free of white supremacy, antiblackness, and racial capitalism.

4.4. Racial projects and mathematics education

Why has mathematics education in the United States not stood in opposition to white supremacy, antiblackness, and racial capitalism? Let me make another claim: mathematics education reforms in the United States have always been aligned with political projects promoting white supremacy, antiblackness, and racial capitalism (along with nationalism, xenophobia, militarism, neoliberalism, etc.).

What evidence do we have for this claim? In a recent paper (Martin, 2019), I discuss how various math education reform movements in the United States have co-evolved with the prevailing political and racial projects in the larger society. For example, the new math reforms of the 1950s and 1960s unfolded while America was maintaining legalized segregation. Those new math reforms were not intended for Black Americans, and there is no historical evidence that mathematics education stood in opposition to white supremacy, antiblackness, and racial capitalism. Thirty years later, beginning in the 1980s, mathematics education was enlisted to support Reagan-Clinton-era neoliberalism and Bush-era neoconservatism focused on national security and social welfare reform. Currently, U.S. mathematics education is in the Common Core reform era and America finds itself entangled in the racial politics that led to the election of Donald Trump, the Black Lives Matter movement, COVID, white supremacist insurrection, and the transition to the Biden presidency.

Given the ongoing entanglement of racial and political projects with the project of mathematics education, what is the future of mathematics education? Rather than asking, Is the future of mathematics education Black? I suggest that the future of mathematics education in the United States must be Black. Mathematics education in the United States has no future if it does not value the lives and humanity of Black people and contribute to their collective liberation and flourishing. There must be an agenda to build Black futures and forms of mathematics education that stand in opposition to white supremacy, antiblackness, and racial capitalism.

4.5. Beyond the United States: Race and mathematics education in global contexts

Before closing this paper, I want to acknowledge that the realities of white supremacy, antiblackness, and racial capitalism in America do not map neatly onto other locations around the globe, even in those contexts where race is socially and politically significant such as South Africa and Brazil. The meanings, processes, and material consequences of race and racism are different in these three contexts. However, white supremacy, antiblackness, and racial capitalism are still very salient in all three contexts. Let me also be clear that even in those contexts where it is believed that race is not an issue because 'we have no Black people here,' critical questions can, and should, be raised. What are the implications of the existence of a far-right, conservative racial project for mathematics education in Denmark and for immigrant families and their children? How do experiences with everyday racism by Malays and Indians in Singapore, groups who occupy very different positions in the social hierarchy, play out in the context of mathematics education? How do the manifestations of caste shape mathematics education in India? What are the racialized conditions of mathematics education for Indigenous people of Australia (post White Australia policy) or the Māori in New Zealand?

5. Can Mathematics Education Help Reduce Inequality? (by Panelist K. Subramaniam)

The pandemic has caused a disruption of scholarly work and exchange that is only a shadow of the devastation it has caused in the lives of the less privileged. I will use the occasion not so much to look back on my previous work, but to interrupt it with questions that our collective experience of this disruption throws up. The question that I focus on is “Can mathematics education help reduce inequality?”. At the back of my mind is the question “What conversations do we as mathematics educators currently prioritize what conversations do we need to prioritize?" One of the sustainable development goals, SDG 10, is to reduce inequalities. The pandemic has sharpened the inequality across the world. Countries like India with deeply entrenched inequality are particularly hard hit. About 90% of the Indian workforce is in the informal economy. Many millions of Indian workers lost their jobs when the pandemic related lockdown was imposed and had to walk hundreds of kilometres to return to their home states. About 400 million Indians risk falling deeper into poverty due to the lockdown imposed in the wake of the pandemic (Oxfam India, 2021). In shocking contrast, in the period of the disaster, the wealthiest in the world leap frogged into even greater wealth. During the pandemic, the top ten billionaires in the world increased their wealth by nearly 50% over ten months (Oxfam India, 2021). In India, the top billionaires increased their wealth by 80%. Some increased their wealth multiple fold, even in comparison to their wealth before the pandemic began. Our political economic arrangements ensure that this huge suddenly acquired wealth for a rich minority bring no relief at all to those who have been impoverished by the disaster. Wealth tax is taboo and the preferred route by governments is to increase the tax on fuel further burdening those at the bottom of the pyramid. My co-panelists have already spoken about educational and social inequality. Clearly inequality, whether economic or social, will not really be overcome without democratic political struggle by those who are marginalized.

The period of the pandemic has also seen large scale protests in several countries. For example, the Black Lives Matter movement in the US, the farmers' movement in India, the movement to restore democracy in Myanmar, and other movements in several countries. Most of these movements were not related to the pandemic, but they were thrown into relief because of the extraordinary times we were living through. They served as a reminder that political movements are great opportunities for education, indeed they are opportunities for us educators to be educated. We forget easily that such movements can be occasions for mass education. How can we restore the connection between social movements and the education curriculum? What does this mean for mathematics education? In India, hundreds of thousands of protesting farmers demanded the repeal of laws that were thought to favor corporates and put farmers' futures at risk. The movement shone the torch not only on issues related to farm income, but also on issues like ecological degradation, and the control of the public discourse by media manipulation. These are important issues for education that is aimed at transforming society.

In developing countries with widespread inequality and poverty, the agenda of social transformation becomes one of the primary aims of education. Ambedkar, who came from the oppressed Dalit caste and is regarded as the architect of the modern Indian constitution, emphasized the role of education in emancipation from caste oppression: "Coming as I do from the lowest order of the Hindu society, I know what is the value of education. The problem of raising the lower order is deemed to be economic. This is a great mistake…. The problem of the lower order is… to create in them [a] consciousness of the significance of their lives for themselves, and for the country, of which they have been cruelly robbed by the existing social order" (Quoted in Velaskar, 2012).

Education, as Ambedkar says, has a great role in social transformation. But what about mathematics education? How can mathematics education help meet the goal of reducing inequality and of social transformation? Of course, mathematics opens up the pathways to highly valued jobs. To break out of the rigid occupational structures is an important aspect of social transformation and mathematics education can create pathways for such occupational mobility. Ambedkar emphasized not only material gain from education, but also gaining self-respect, and self-understanding. Critical mathematics education researchers from many different places have shown how mathematics can help sharpen our perception and understanding of inequality and the structures that underpin it (Gutstein, 2016; Rampal, 2015). However, in the existing curriculum in India and many countries, there is very little of mathematics that can illuminate social reality.

In the last round of major curriculum reform in India in 2005, efforts were made to introduce critical mathematical perspectives in the curriculum. For example, a "problem" from the Grade 5 textbook, discusses the wages paid to a couple who are farm labourers. It is mentioned that the legal minimum wage is 71 rupees per day. However, the man is only paid Rs 58 and the woman Rs 55 per day by the landlord. The problem asks students to find how much money the couple will earn for a certain number of days. More importantly for our purposes, there are two supplementary "discussion" questions in the problem. One points out that the landlord pays less than the minimum wage. Another points out that the woman is paid less than the man and asks students to discuss these observations. Firstly, even the inclusion of such questions that take a critical look at society in a mathematics textbook is remarkable and rare in the Indian context. Second, Shikha Takker found that teachers often omit discussion of such questions for various reasons (Takker, 2015). On one occasion, a teacher told Takker that she would like to focus on the mathematics and avoid the distraction that such questions entail. On another occasion, the teacher said that she did not feel equipped to deal with the discussion that might ensue if these questions were brought up. We can also imagine that there is resistance to raise questions with political undertones, which in certain situations may carry a risk for the teacher. But as mathematics education researchers, we need to ask if we can we continue to ignore these dimensions if we are serious about reducing inequality.

The mathematics involved in the examples discussed above about wealth and incomes is simple: at the most, finding and comparing percentages and ratios. Their application to understanding social reality can however be powerful. And even though the mathematics is simple, the socio economic and social political concepts involved may be sophisticated. Sometimes, the emphasis on "important mathematics", which is echoed in many curriculum reform efforts, can lead to giving less importance to the applications of mathematics which can bring about a critical focus on social reality (Noronha and Soni, 2019).

Finally, let me summarize some questions that these reflections have given rise to. Do we need to revisit our notion of what constitutes mathematics to allow for socially meaningful questions to be raised? Why does the use of mathematics to understand social reality appear as a distraction? Do our notions of "powerful mathematics" conflict with powerful uses of mathematics? Why does our curriculum not make any connection to social movements? Finally, while the mathematics curriculum typically makes at least some connections with the science curriculum, why does it make so little connection with the social science curriculum?

6. Concluding Remarks (by Panel Chair Mellony Graven)

The aim of this paper, emanating from our panel, is to continue to provoke conversation about critical issues in our current world that require urgent attention by mathematics educators. As panelists we are committed to contributing towards a more equitable world and grappling with the way in which mathematics education can contribute meaningfully to this goal.

Marcelo Borba raised the importance of placing the spotlight on the role of media ('and things') and the dangers that come with the domestication of media without maximizing the full potential of different media. Existing unequal access of different groups to increasingly essential media and technological devices need to be urgently addressed to avoid compounding inequalities. He shared a range of ways in which he and other colleagues have drawn on digital media and animations in ways that allow students to understand more deeply the emerging pandemic data (particularly exponential data) and the meaning of emerging phrases such as 'flattening the curve'. He urges mathematics educators to consider how we might prepare students and teachers with media for the next pandemic.

Eva Jablonka focused on the role mathematics plays in communicating the need for policy measures. She reveals different strategies used in public discourse to overcome the seeming neutrality of depicting with numbers and communicate the urgency for action. Since some black-boxed mathematics occurs to simplify complex data and is then used to communicate and sway public views and actions she argues that we need to ask how the use of numbers in communicating political priorities should be included in mathematics education, how we should manage simplification of socio-political complexity of problems and the mathematics involved and whether we should discuss the ways in which strategies push for action or continue to present the myth of mathematical neutrality.

Danny Martin drew on his work and experiences, positioned as a Black man in America, to argue that mathematics education cannot ignore the racist realities of the past and present that are endemic across institutions. He argues that there can be no future for mathematics education in the United States without a reimagined mathematics education that values the lives of Black people and opposes white supremacy, antiblackness and racial capitalism. He distinguishes reimagined from reformed, drawing on research to show that reforms in mathematics education have themselves contributed to entrenching inequalities and injustices in opportunities for

Black Americans. He emphasises this is not limited to the United States, arguing the myth of Black inclusion is relevant and important across first world and developing countries.

K. Subramaniam highlighted the pandemic as an opportunity to interrupt earlier assumptions about priorities in mathematics education and ask what must be prioritised now for reducing rapidly growing inequality. He notes that since the pandemic 400 million Indians are in deeper poverty while the top billionaires increased their wealth significantly (as did the top billionaires in the world). He reflects on the way in which 2005 curriculum reform in India highlighted developing a critical mathematics perspective and yet even in the few resources that include problems with data pointing to social injustices teachers tend to avoid such discussions. He argues that we cannot continue to ignore developing a critical perspective through engaging with mathematical and other data that highlights the need for prioritizing a more equitable society and world.

We hope this paper has stimulated thinking about how the issues raised relate to the contexts in which you are working. Our wish is that the questions we have asked will provoke further conversation and action in responding to the challenges to build a better future.

Plenary Panel 3

Pandemic Times: Challenges, Responsibilities and Roles for Mathematics and Mathematics Education Communities

Michèle Artigue[1], Ingrid Daubechies[2], Timothy Gowers[3],
Nelly León Gómez[4], Jean Lubuma[5], and David Wagner[6]

ABSTRACT The Plenary Panel 3 at ICME-14 was especially devoted to the COVID-19 pandemic. Its goal was to review and reflect on the challenges raised by the pandemic, the responsibilities and roles for mathematicians and mathematics educators in this context, and to draw some lessons for the future. This text begins with the presentation of the panel and the four invited panelists. Then each panelist synthesizes her/his contribution to the panel, and we end by some lessons drawn from these contributions and the exchanges between the panelists and with the audience.

Keywords: COVID-19 pandemic; Mathematics; Mathematics Education.

1. Introduction

Our lives, our educational systems and our societies have been turned upside down by the COVID-19 pandemic. The goal of Plenary Panel 3, late addition to the congress scientific activities, was to review and reflect on the challenges, responsibilities and roles for mathematicians and mathematics educators in these pandemic times, to identify possible synergies between communities that can assist them in this context, and to draw some lessons for the future. Its co-chairs, Michèle Artigue and Ingrid Daubechies, respectively former president of ICMI and IMU, invited the contributions of four panelists, two mathematicians and two mathematics educators, living and working in very different environments, with a wide range of expertise and experiences.

The mathematicians were Timothy Gowers from the Collège de France in Paris and from the University of Cambridge in the UK, and Jean Lubuma, then working at the University of Pretoria in South Africa. Gowers is a well-known mathematician, specialist of combinatorics, who was awarded the Fields Medal in 1998. He has long been interested in societal problems and popularization of mathematics, at many levels, and with respect to the Covid-19 pandemic, his writings influenced UK government decisions. Lubuma is an applied mathematician, fellow of the African Academy of Sciences and member of the Academy of Science of South Africa, who has done extensive epidemiological research in Africa, to provide a sound mathematical analysis and elaborate realistic solutions to (re-)emerging diseases such as COVID-19, Ebola, HIV/AIDS, Malaria, etc. that pose a threat to development of the continent.

The mathematics educators were Nelly León Gómez from the Universidad Pedagógica Experimental Libertador (UPEL) in Maturín, Venezuela, and David Wagner, from the University of New Brunswick in Canada. León worked for more than 40 years at UPEL as a teacher educator and researcher in mathematics education. Her responsibilities in the Inter-American Committee on Mathematics Education (IACME) and the Mathematical Education Network of Central America and the Caribbean (REDUMATE) make her especially knowledgeable about the problems generated by the pandemic in Latin America. Wagner is a researcher in mathematics education whose research especially addresses the cultural nature of mathematics and the impact of mathematics teaching practices on individuals and society. Co-editor-in-chief of Educational Studies in Mathematics, he was co-editor of the special issue "Mathematics education in a time of crisis – a viral pandemic", in preparation at the time of ICME-14.

Taking into account the diversity and complementarity of expertise and experience of the four panelists, the co-chairs prepared a specific set of questions for each of them, the exact formulation of which was discussed with them (see sections below). A collective question was added regarding the synergies observed between mathematics and mathematics education in these pandemic times. During the panel session, the co-chairs first presented the panel organization and introduced the panelists; this was followed by the videos recorded by each of the panelists in response to the specific questions asked to them. Next came an interactive phase in which the panelists exchanged views among themselves, with the co-chairs and with the participants attending the session in Shanghai.

Sections 2 to 5 are devoted to the panelists' contributions. We follow the order of their presentation at ICME-14 and each section starts with the questions especially addressed by the panelist. Section 6 draws some main lessons from this panel.

2. Teaching, Learning and Research in Mathematical Sciences in Pandemic Times. *Panelist: Jean Lubuma*

Part of your mathematical research has been focused on questions related to epidemiology. How would you describe the role of mathematicians in this field? Does the current pandemic present particular challenges? If so, how *are your colleagues and yourself dealing with them? Which of these do you find most difficult?*

We describe the role of mathematicians in disease epidemiology and highlight some challenges presented by the COVID-19 pandemic. We outline how we dealt with them at the University of Pretoria (UP), and we make a call to the international community to invest in teaching and research in mathematics in developing countries, particularly in Africa that counts the top 10 poorest countries in the world.

2.1. The role of mathematicians in disease epidemiology

The role of mathematicians in the epidemiology of human infectious diseases is to develop, analyze and simulate realistic mathematical models for gaining insight into the disease transmission dynamics and control. The use of mathematics in epidemiology goes far back to the middle of the eighteenth century, with the pioneering work of Bernouilli (1760) on modelling the effectiveness of immunization against smallpox. Two centuries later, Ross (1911), who received the Nobel Prize of Medicine in 1902, presented the first mathematical model for malaria transmission, and showed that the disease could be effectively controlled or eliminated if the malaria vector population is reduced below a certain critical threshold. In a series of seminal papers, Kermack and McKendrick (1927) and Macdonald (1957) further developed and formalized Ross' work into the theory of epidemics and laid the foundation for compartmental modelling. In recent years, there has been a strong focus on the modelling of emerging and re-emerging infectious diseases of public health significance; see Castillo-Chavez et al. (2002).

The threshold theory is expressed in terms of the basic reproduction number, $\mathcal{R}_0$, an important epidemiological threshold quantity, defined as the average number of secondary infections generated by a single infectious individual (during his or her entire infectious period) if introduced into a wholly susceptible population. The mathematical definition and the methodology for practically computing $\mathcal{R}_0$ are due to Diekmann et al. (1990) and van den Driessche and Watmough (2002): $\mathcal{R}_0$ is the spectral radius of the associated next generation matrix, K, of the model being studied. For typical models, the threshold theory is stated in the next theorem that is illustrated in Fig. 1 for $\mathcal{R}_0 = 2$; see Gumel (2021).

Theorem 1: *The disease-free equilibrium is locally asymptotically stable if* $\mathcal{R}_0 < 1$, *and unstable if* $\mathcal{R}_0 > 1$.

It follows that, for a vaccine-preventable disease, a fraction $p > 1 - 1/\mathcal{R}_0$ of susceptible individuals should be immunized (assuming a perfect vaccine) against the disease, to achieve herd immunity.

2.2. Challenges and COVID-19 modelling

Despite the rapid effort made by scientists to isolate the SARS-CoV-2 virus (the causative agent of the COVID-19 pandemic), to sequence it, to develop a diagnostic

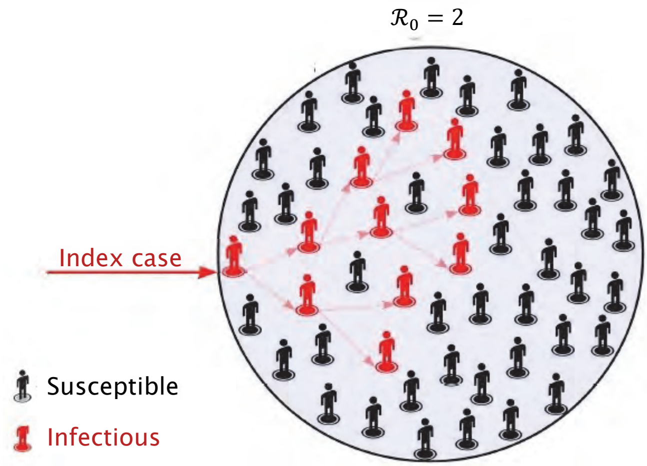

Fig. 1. If $I_{n+1} = K^n I_0$ with I the infective variables and K the (typically positive) next generation matrix, the number of secondary infectious per generation, n, is $\mathcal{R}_0$, the largest eigenvalue of $K \geq 0$. For $\mathcal{R}_0 > 1$, the final state/size of I is $I_\infty = 0$ (epidemic) or $I_\infty > 0$ (endemic).

test and to produce vaccines, numerous unknown and open questions and challenges linger around the COVID-19 pandemic. Some of the challenges are linked to the following points: social-cultural dynamics of transmission, comorbidity *vs* forgotten diseases, new variants of the virus, concerns around vaccines, and lockdown *vs* economy recovery. Regarding the lockdown, the suspension of face-to-face teaching in Africa practically means no teaching and learning since the continent is not well digitalized to offer online teaching, which is taken as granted in Europe, North America, etc. In addition to the challenge of funding research in African countries, the pandemic paralyzed collaborations between dedicated individual researchers/groups and overseas partners. Nevertheless, the pandemic brought some interesting points of contact, interactions or synergies at UP. There are ongoing weekly town hall meetings where science and mathematical communities share their experiences on issues such as staff/student mental health, online teaching, assessment, invigilation, student success, research and postgraduate supervision.

Given these challenges and the complexity of the societal problem at hand, mathematicians have adopted the transdisciplinary research approach. We developed a model for the spread of COVID-19 in South Africa, see Garba et al. (2020). It is an extension of the SEIR model, modified by adding *A, J* and *P* respective classes of asymptomatic, isolated individuals and contaminated environment, thereby considering direct and indirect transmissions. The flow diagram of the model is given in Fig. 2.

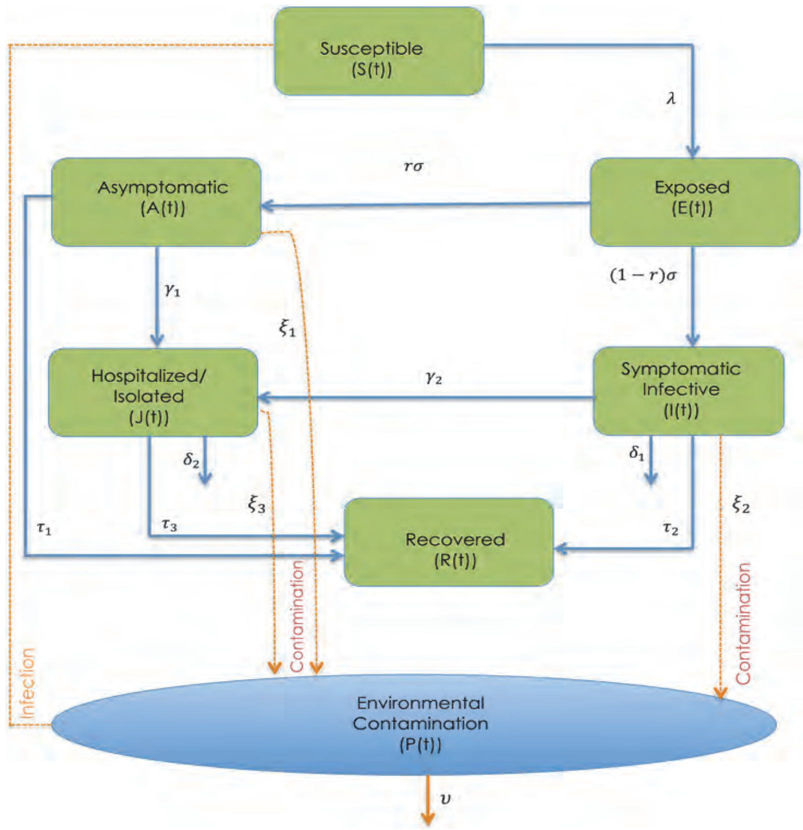

Fig. 2. Susceptible-exposed-asymptomatic-symptomatic infective-isolated-recovered & contaminated environment model

Our findings are summarized below. The model fitting with the number of deaths for the first six months of 2020 is excellent. We obtained reliable predictions in terms of peak times, numbers of cases and deaths. The continuum of disease-free equilibria is globally asymptotically stable when $\mathcal{R}_0 < 1$. Thus, the disease will eventually die out, particularly if Non-Pharmaceutical Interventions (NPIs) are implemented early and for a sustainable period of time. Further, the control reproduction number was estimated to 2.8 (3). Hence, 64 (67) % of the population should be vaccinated to achieve *herd immunity*, which is consistent with South Africa government predictions.

2.3. Conclusion

We initiated this work at the University of Pretoria. Since its emergence two years ago, COVID-19 has posed serious challenges, which led to some synergies between different mathematical communities as well as to transdisciplinary research (e.g., Google captures 36 700 000 mathematical articles). However, the challenges in teaching and research in Africa have been exacerbated by the lack of sufficient investment in this sector. These facts were echoed by the Heads of Governments at the

Summit on Financing African Economies that was held in Paris on 18 May 2021. Therefore, mathematicians should speak out, advocate and make a call to the international community to invest in education and research in mathematics in Africa. Our ongoing research includes COVID-19 models with focus on multiple strains of the virus, comorbidity issues and vaccination intervention.

3. Challenges and Lessons Concerning Mathematics Education Brought by the Pandemic in the Latin American Context. *Panelist:* Nelly León Gómez

The pandemic has forced most teachers to make a very sudden transition to remote teaching; at present, mathematics teaching is still done remotely, or at best in some hybrid mode in many countries.

What are the principal challenges this situation has brought in your country, and more generally your region? How have these challenges been met? Which lessons for the future would you distill from this experience?

3.1. Introduction

The COVID-19 pandemic has plunged the entire world into a spiral of complex unprecedented situations that have affected the lives of human beings in all their dimensions: personal, family, social, emotional, economic. In particular, education has been greatly affected, especially in the less favored regions, as Latin America.

Below I will refer to some challenges faced and lessons distilled from this crisis in the Latin American region. These are supported by reports required from the national representatives of REDUMATE (Mathematics Education Network of Central America and the Caribbean), on the impact of the epidemic in schooling in our context; the policies, limitations and innovations to face this situation and to what extent families have been able to collaborate. I also followed the results of research and experiences published in the special issue of *Journal on Research and Teachers Preparation in Mathematics Education* entitled “Mathematics Education and the pandemic in the Americas” https://revistas.ucr.ac.cr/index.php/cifem/issue/view/3099

3.2. Principal challenges and how these challenges have been met

When the COVID-19 pandemic began in March 2020, one of the first actions taken in Latin America, as in the rest of the world, was to close schools and move to a distance education modality as a way to contain the spread of the virus. This measure had to be accompanied by others to guarantee school continuation, such as supporting food, health and the biopsychosocial well-being of children and young people. By abruptly switching to distance learning, I believe the main challenge was *how to deliver the teaching of Mathematics to every student guaranteeing quality and equity of mathematics learning in non-presence contexts*. No one was prepared to deal with this challenging situation. Although each country implemented action plans to face the challenge, each according to its own social, political and economic reality, I would say that it has not been fully met in Latin America. Multiple factors have had an impact on the development of these plans. These include the following:

3.2.1. Availability of technological resources

The conditions of accessibility to technology have meant a serious limitation for remote education in Latin America. A significant number of students and teachers do not have access to a computer, smartphone and internet connection, and many of them do not even have a TV set. According to the World Bank (2021) at the beginning of the pandemic, less than 43% of primary schools and less than 62% of secondary schools in Latin America had access to the internet for educational purposes. Among the online distance learning modalities, virtual asynchronous learning platforms were the most prevalent in the region of Latin America and the Caribbean; only 4 of the 29 countries offered live classes. (CEPAL – UNESCO, 2021) In addition, other distance learning solutions were deployed to bridge the gaps between schools and learners, such as broadcast educational programs by more traditional mass media such as radio or television, audios and videos (WhatsApp, e-mail) and printed materials.

3.2.2. Teacher's preparation and their willingness to take on the challenges of non-face-to-face mathematics education

There is evidence of a lack of teacher preparation for an efficient application of technological tools in distance learning (beyond the use of these tools to maintain communication between students and teachers); in addition, artifacts and methods were used that were not entirely appropriate to the didactic transposition and the assessment of mathematics in this setting. Besides, some teachers feel that preparing a non-face-to-face Math class requires extra time, which they do not have because, in addition to teaching, they must do other tasks to supplement their low wage income.

3.2.3. Curricular adjustments

The adoption of distance or blended teaching modalities has created the need to identify key points of the curriculum on which to focus the attention of educational action. Content prioritization was necessary; consequently, the coverage of the actual mathematics curriculum is far from the expected standards, especially in public schools. This will cause the gap in mathematical skills between children from lower and higher socioeconomic background to get wider in Latin America.

3.2.4. Engagement of parents and families

Family support has been key to guaranteeing the continuity of education during the pandemic. In a depressed socio-economic context, numerous parents have faced difficulties in terms of their abilities and availability to support their children in learning mathematics and in the use of technology. Apart from family support, in some cases the children themselves have had to do informal work to help with the household economy leaving aside their studies, increasing the risk of dropout (León, 2021)

3.2.5. Motivation and emotional issues

The lack of direct interaction between students and teachers has increased the risk of disengagement especially for students who do not have access to online education. The stress of confinement, living conditions, restrictions on entertainment activities with friends, and the increase in physical abuse have greatly affected the emotional health of students. For this reason, regional government plans, such as "Every Family a School" in Venezuela, include a component of psycho-emotional care for families (MPPE, 2020).

3.3. Lessons distilled from the pandemic

The experience of facing the COVID-19 crisis has left important lessons to take into account in the new post-pandemic educational reality.

Lesson 1: The educational world has been digitized to large extent; as a result better versus worse access to digital communication channels translates into more versus less educational quality, inclusion and equity. Therefore, a strong investment in education is required in Latin America to address the technological gap. Such investment must be aimed not only at the equipment itself and at the improvement in connectivity, but also at the initial and on-service preparation of teachers to face the challenge of designing online tasks to engage students with mathematical content, while making use of such technological resources.

Lesson 2: It is important to capitalize on the technological push in education and the alternative forms of remote education developed during the pandemic. The use of digital technologies has generated new ways of thinking and representing mathematics, its teaching and assessment. The pandemic has also left us with a wide variety of innovative virtual resources created to enhance the teaching and learning of mathematics, focused not only on content but also on skills and competencies.

Lesson 3: Clear guidelines need to be established for the review of school contents and approaches in Mathematics in order to identify the mathematical knowledge and skills that will actually be required in the post-pandemic reality and to cover the knowledge gaps stemming from school closure, taking into account both the depth and variation in Math learning loss. This will take time and it will be necessary to act with prudence taking into account issues of equity and social justice in making quality mathematics education available to all.

Lesson 4: The classroom is not the only place for learning Mathematics. The closure of schools has generated interesting changes in the interaction model and has opened a range of possibilities that should be exploited to supporting students' independent and significant learning of Mathematics. Homeschooling is an experience not to be dismissed, since the new forms of relationship between school, family and community have led them to assume shared responsibilities regarding children's learning, and this must continue going on.

Lesson 5: No matter the form (in-person, remote or hybrid), teachers have to find the ways of teaching Mathematics that take into account the social and emotional needs of students, in order to maintain or to raise the expectation in their students, before launching into mathematical content.

4. Roles and Responsibilities of Mathematics Educators. *Panelist:* David Wagner

You are a researcher in mathematical education. How would you describe the role and the responsibilities of the mathematical education research community in the context of the current pandemic?

You are co-editor of a special issue of the journal Educational Studies in Mathematics centered on the pandemic and its challenges. What are the main messages you have taken away from this experience?

This pandemic has taught me that the responsibilities of mathematics educators in times of crisis should consider our complex arrays of responsibilities, from local, immediate challenges to the big questions. We need to devote time to love the people in our family and communities. We need to recognize the physical suffering, the isolation, and the compelling demands to care for others in new ways. In our teaching roles, we help students achieve their immediate needs, even when we think those needs are crazy—crazy demands from a crazy society. In our research, we study the local, immediate needs but also look at the big questions, and examine the structure beneath the crisis—the invariant things.

The coronavirus is probably not the most significant destructive force of our era. The social fabric of our world, the power structures we humans have erected and maintained, and our deep manipulation of our physical environments have been more destructive. These forces probably set the stage for the virus to be born, and certainly for the virus to multiply as it has and for the social chaos that ensued. The pandemic is an entanglement of the virus, the socio-political vectors and the environmental landscapes, all acting together. Thus, to answer the question about the responsibilities of mathematics educators in this pandemic, I step back to generalize and consider our responsibilities in crisis. We knew crisis was upon us before the pandemic. In 2013, crisis theorists Topper and Lagadec pointed to the human environmental footprint and the increasingly interconnected world and concluded: “major events are not new, but they have got denser” (p. 6). We live in a volatile world. Mandelbrot applied fractal geometry to volatile financial markets (Topper and Lagadec, 2013). Using this approach in the current crisis I see that we have to look through the massive changes and upheaval to examine what lies beneath—structures that have not changed.

When I consider the 161 articles received from our call for papers for the special issue on the pandemic in *Educational Studies in Mathematics* (Chan et al., 2021), and the thoughtful reviews of these papers, I see mathematics educators in action, responding to crisis. My co-editors, Man Ching Esther Chan and Cristina Sabena, and I saw that the pandemic has challenged usual patterns of research in our field. Many scholars were pressed with other demands and unable to focus on their research plans or on their reviewing commitments. Others found themselves with more time than before. Not surprisingly, the disparities appear to align with and magnify existing disparities such as gender disparities. This is an example of something that stays the same while we feel like everything is changing.

We saw scholars looking for accessible data that would help the field understand the pandemic. This was not easy. The pandemic makes it hard to start new studies involving participants because human interaction has been restricted. This is a major problem because we know that studies of social structures really need researchers to listen to the people most impacted by the structures. Over time, I expect that we will see more research that uses data that is harder to access, with deep engagement with the people most impacted by the crises.

Some researchers contributing to the special issue saw the pandemic as a prompt for questioning school curriculum. To identify what mathematics is needed by citizens to make sense of the crisis, researchers looked to public dialogue for analysis. We have seen governments, citizens and special interest groups disseminating graphs and statistics to explain pandemic events and inform action. Some of the research groups asked what mathematics is needed to make sense of these statistics (e.g., Kwon et al., 2021). We see that this does not exactly answer the question of what curriculum is needed. This is because the forms of statistics representation chosen by governments and others is guided by what they think citizens will understand. There is circularity when people ask what mathematics to teach based on what mathematics is being used. We need our field to identify new priorities for school mathematics based on analysis of the major challenges faced by society and individuals in the current age.

Some mathematics teachers have seen the pandemic as a prompt to re-examine their teaching. Surely, students should not accept a focus on the usual skills and knowledge when the world's habitual ways have clearly spelled catastrophe. One should expect that supposedly powerful mathematics would be used in class to address the most obvious disruption of our era. I would expect a call from students and from society, echoing the decades of injunction from Ubiratàn D'Ambrosio to examine the complicity of mathematics in the structures that allowed the virus to thrive in addition to the possibilities for using mathematics for justice in these times. However, speaking from my own experience and conversations with teachers, I see people distracted from asking deep questions—distracted by our social systems and the immediate needs of disrupted networks. Students and teachers focus on their compelling, immediate, local needs. While many are distracted, some educators are asking the bigger questions and trying to take the crisis seriously with their mathematics teaching. The special issue received articles that tell of ways mathematics teachers have addressed disease spread by studying different mathematics (Maciejewski, 2021), mathematics teachers' changing conceptualizations of their teaching due to isolation restrictions (e.g., Albano et al., 2021), and analysis of historical conversations about vaccination (Gosztonyi, 2021).

Many of the manuscripts we received studied distance teaching via digital and other technologies. This has been studied in our field for decades but now more scholars are interested. Borba (2021) reminds us that technologies of distance learning need to be seen as entangled with their contexts. One thing that is immediately clear in pandemic teaching is the inequities—unequal access to internet, unequal access to computers and tablets, unequal home infrastructure for uninterrupted time, unequal competing demands for time. Even while teachers and school systems work very hard at combatting them, these inequities persist. This is another example of something that is invariant in this time of massive change. We see that rural families have greater challenges (Yılmaz et al., 2021), and the needs of Indigenous students (Allen and Trinick, 2021), students of colour (Matthews et al., 20221) and students who have recently migrated are ignored in this crisis. The effects of poverty are magnified.

So I ask again, what are our responsibilities as mathematics educators? To answer this question, we need to answer other questions. What should every citizen know? Surely the answer is different than it was thirty years ago, considering the massive changes in interconnectivity in our world. To particularize this question, we need to identify the human and social problems of our time: What mathematics is necessary to understand interconnectivity? What mathematics is needed to understand climate? What mathematics is needed to understand biodiversity? What mathematics is needed to understand wealth distribution? With such questions I see deeper question: Should school mathematics focus on learning the useful algorithms when they can be performed instantaneously on handheld devices that are ubiquitous, or on applications to actual human problems? I know that this is an open question for many people, but I suggest that the public's evidently poor understanding of the science and mathematics of the pandemic may lead us to question the value of focusing school mathematics as we have in the past on procedural skills.

5. What Challenges Has the Pandemic Raised for Mathematics Education? *Panelist: Timothy Gowers*

The pandemic has put mathematics in the spotlight, and the media have solicited mathematicians, even those not experts in epidemiology. You have long been committed to communicating mathematical concepts to a wide audience.

Can you comment on challenges that are specific to the pandemic context?

What can we learn from initiatives realized by the mathematical community?

It is obvious that mathematics and the pandemic are closely intertwined. There is an entire academic discipline, epidemiology, devoted to the study of how diseases spread, and a significant component of that discipline is mathematical.

It is perhaps slightly less obvious that the pandemic raises challenges for mathematics education, but after a moment's reflection one can identify two important ones, at least if one takes "education" in a broad sense that moves beyond the confines of the classroom and takes in more general dissemination of mathematical ideas. The first is to improve mathematical understanding in society at large, so that people are better able to judge the reasons for and likely effects of the painful restrictions that have been imposed. The second is to improve the mathematical understanding of the principal decision makers, so that the decisions they make, which can have huge consequences, are made as rationally as possible. These two challenges are closely related, since it is much easier that politicians will make the right decisions if they can count on public support and understanding.

5.1. Public understanding of pandemic-related mathematics

Over the last two years, many people have made extraordinary sacrifices. Some have argued that these sacrifices were largely unnecessary, or at least that the benefits were outweighed by the costs. And while it is certainly right to weigh up the costs and benefits, to do so properly requires an appreciation of a few basic mathematical principles.

5.1.1. Exponential growth

To many non-mathematicians, the word "exponentially" is little more than a synonym for "quickly". So if they are told at the early stages of a pandemic that the case numbers are growing exponentially, but after two or three weeks the numbers are still small, they may wonder whether they have been misled. A more serious problem is that it is very hard to persuade people to accept significant restrictions while numbers are still small. The argument for doing so is that the earlier one imposes restrictions, the less time it takes to reduce case numbers to a level where the restrictions can be relaxed again, and the less illness and death there will be as well. But to understand this properly, one needs mathematics – not the sophisticated mathematics of a professional epidemiologist, but just the basics of exponential growth. Without such an understanding, one may be swayed by arguments such as "More people were killed by lockdowns than by Covid." In many countries that is clearly untrue, but in a country such as New Zealand, which had several lockdowns and very few COVID-19 deaths, it is almost certainly true. Does that mean that New Zealand made a big mistake? No, because the relevant comparison is between the number of deaths caused by lockdown and the number of COVID-19 deaths that there would have been without lockdown.

The point I am making here is not so much the arguments for and against lockdowns and other restrictions. Rather, I am arguing that greater public understanding of mathematics can lead to a greater willingness to accept policies that are for the good of everybody, but which are somewhat counterintuitive.

5.1.2. The role of data and modelling

Mathematical modelling is of central importance in epidemiology, but the role of modelling is not well understood by the general public. If a simulation is run on a computer, for example, it will be based on assumptions, which themselves will be based on data that is usually uncertain and incomplete, especially in the early days of the pandemic. Thus, predictions are typically conditional, but they are often presented as unconditional by journalists. Furthermore, models can be self-defeating in the following sense: if a model makes an alarming prediction, politicians may well impose restrictions that stop the alarming prediction from coming to pass.

These phenomena, which are absolutely normal and expected, have led in the UK to considerable public distrust of modelling as a discipline. This is a problem not just for managing the pandemic, but also for other areas where modelling meets public policy, an obvious example being climate change.

5.1.3. Probability and risk

Another aspect of policy making that was underappreciated by the general public was the role of uncertainty. In the early stages of a rapidly developing pandemic, decisions had to be made quickly when many facts were unknown, of which the most important was how COVID-19 spread. When one is weighing up the costs and benefits of a possible decision under these circumstances, they necessarily come with a probability attached, or more precisely a probability distribution.

A simple example of this was the question of whether mask mandates were a good idea. Early on in the pandemic, the evidence for beneficial effects of mask wearing (mainly in protecting others from the wearer) was weak. To a non-mathematician, it might seem an obvious consequence of this that there was only a weak case for encouraging the wearing of masks. However, because of the nature of exponential growth, a small reduction in the growth rate is hugely beneficial, whereas the cost of widespread mask wearing is small. So even if the reduction in the growth rate was not certain to occur, the expected net benefit of mask wearing was large.

5.2. Trust in science

One of the great potential benefits of better understanding of mathematics among the general public and politicians would be a healthier relationship with scientists. I have given several examples already of how a lack of understanding of mathematics can lead people to lose trust in science, and this has been a serious problem.

Another problem, which I have not yet mentioned, concerns the relationship between politicians and scientific advisors. A politician with a good mathematical understanding can understand not just the advice but the justification for the advice; a politician without it simply has to accept or reject the conclusion. It was extraordinary as a British person to see Angela Merkel, who has a scientific background, giving a beautifully clear explanation of exponential growth and how it informed her decisions, and to contrast that with Boris Johnson, who does not have a scientific background, simply saying in a vague way, "We are following the science," (though he said that less as the pandemic proceeded).

5.3. What can we do?

While one can see the benefits that improved mathematical understanding would have, it is less clear how any improvement can be achieved. The raising of standards of mathematical literacy is of course a central aim of mathematical education, so to call for it may seem a little pointless. However, my conclusion is a little more specific, since some parts of mathematics have a much bigger effect on the quality of public decision making than others. The basics of probability and statistics, for example, are clearly important for conducting risk-benefit analyses, whereas an understanding of polynomials, while essential for any technical uses of mathematics, is less necessary for public appreciation of political decisions.

So a potential way forward is to identify those areas of mathematics that would be most helpful for improving public discourse and decision making, and to think of creative ways of explaining them to non-expert audiences. That is still a big challenge, and maybe for many people it is simply too late to get them interested. But at the very least one could think about how best to bring up a new generation to be better educated in these aspects of mathematics than the current generations are. A natural idea to try is to design school mathematics courses that are principally aimed at people who will not be specializing in STEM subjects. Such courses could analyze current events from a mathematical perspective, giving people the tools to think about them more effectively. A well designed course of this kind would have the potential to demonstrate that mathematics is, to use words of Jordan Ellenberg (2014) "like an atomic powered prosthesis that you attach to your common sense, vastly multiplying its reach and strength". In that way, it might appeal to people who would otherwise remain unaware of its benefits to individuals and to society.

6. Reflections and Lessons

We often complain that despite their crucial role in our technological societies, mathematics remains invisible. This is no longer the case. The COVID-19 pandemic has shown the importance of mathematical models for understanding the course of the pandemic, anticipating and weighing possible consequences of different policy decisions, or managing and analyzing the very large volumes of data collected. It has shown the potential but also the limits of these models, the need to constantly adjust them due to the emergence of variants, the effect of decisions taken, etc. It has confronted the general public with science in the making, made up of questions and doubts, as opposed to the image of certainty that many had formed during their schooling. It has shown the need for a solid and shared mathematical and scientific culture within our societies, a culture that is largely lacking as shown by the permeability of the population to the incredible fake news stories that have multiplied. Furthermore, the sudden shift to distance and, at best, hybrid teaching has profoundly destabilized education systems that were totally unprepared for it. Educational inequalities have been exacerbated between countries and between pupils within the same country. The challenges are immense!

The panel has made clear that, faced with these challenges, the mathematics and mathematics education communities have mobilized strongly, each with its own expertise, means and fields of action. They have mobilized at the level of research and practical action. In addition to epidemiological mathematicians, such as Jean Lubuma, who are directly involved in research on this pandemic, many mathematicians, as Timothy Gowers has shown, have helped the general public and the media to make sense of epidemiological models, of the growth processes and probabilistic reasoning modes involved. The world of mathematics education has also reoriented its research to meet the challenges encountered, as David Wagner has shown, and beyond research, it has invested heavily in the production and sharing of online resources for teaching and training. Solidarities have been strengthened or created, as Nelly León has shown.

From this point of view, the panel also carries a message of hope. This message is all the more necessary as the current pandemic is not an isolated crisis. We will face, and are already facing, other crises, undoubtedly even more serious and lasting, such as those associated with climate change. The need for quality mathematical and scientific education for all is essential, and taking up this challenge requires the synergy of the strengths of the mathematical community at large.

Lecture of Awardee 1

Understanding the Power of Teaching and Its Role (in) Justice[1]

Deborah Loewenberg Ball[2]

1. Background

Before I begin the lecture, I'd like to say just a bit more about where I am. As I mentioned a moment ago, I am in Michigan. And here on the slide, you'll see where Michigan located in the United States as well as a map of Michigan itself. I also included a few photographs. You could get a glimpse of this diverse and beautiful land. What I really want to say is that I want to acknowledge that Michigan occupies the traditional and contemporary homelands of the three files of peoples: the Ojibwa, the Ottawa and the Potawatomi peoples. And I understand that as I stand on this land, I am part of the history of this United States that store lands from the indigenous people who are living here and remain occupied to this land to this day. I also appreciate that as I've learnt more about our history, I've come to appreciate the way in which the indigenous people on whose land I am standing, the use of the land as a teacher, from whom they've been learning since the beginning of time. The indigenous people on whose lands we stand remind us the power of the teaching from the lessons they have learnt from the land and from the water that surrounded. These powerfully shaped their past, their present and their future. I offer this landing acknowledgment here, even as I acknowledge my complexity and my white privilege. And I commit to not only give such landing acknowledgement which could be seen simply as performances but to link those to my own efforts that continue to in target to my own actions on on-going basis, learning from my mistakes, and find it useful to both my work and my personal life to contribute to dismantling oppression rather than contributing to its perpetuation. So we've often talked about the land we are standing and acknowledge whose land actually is. We also sometimes feel to acknowledge the world such as I am receiving today is actually the product of not just one person but of collective.

And I wanna pause to thank the many people who have been on this journey that I've been talking about today with me. They include former students, colleagues, mentors, teachers, my current doctoral and master students and the more than 1000 children who I have been so deeply privileged to teach over 45 years. Thank you all for your contributions to what I've been learning.

[1] This paper presents the transcription of Deborah Loewenberg Ball's Felix Klein Award Lecture at ICME-14 Congress.

[2] 2017 Felix Klein Awardee. School of Education, University of Michigan, USA. E-mail: dball@umich.edu

So, what we would begin? As I said couple of times, I am deeply honored and grateful at being awarded the Felix Klein Award for the International Commission Mathematics Instruction. The surprise I am hearing it and the humility that I was filled with when I thought about it. Let me to look back across the kind of unexpected arch of learning across the time in my professional and personal life. This lecture that I designed then is reflected to my continuing efforts to try to understand the part of society that I landed in as a brand-new teacher in an elementary school in an unusually racially culturally and linguistically diverse U.S school. I, identified as a white woman and as a Jew and I've been a daughter of a father who together with his family escaped from Nazi Germany. I later attended primary school in that country. And my identities have intersected over time in my every evolving perspective in the country I am living in the United States. Its history of enslavement of African peoples and the massacre of indigenous lands people, and the ways in which those stories are not only in the past but continue in our present in the various forms of oppression that characterized our country. This last year and half have only further highlighted the legacy of slavery and oppression that shaped my nation. My deep engagement with and wonder about teaching and how it is fundamentally tied to the role that plays in the context of systemic anti-black racism, sexism and other forms of structure of oppression characterized this arch of my learning on which I am still continuing and is expected to continue as long as I live. I took the occasion to try to look back and now and forward as I talk to you today. On this slide, here you can some pictures from my earliest years of teaching children, including a class of children who I taught at my second and third year as an elementary teacher. And some of the children I taught more recently. Give you a glimpse of this woman growing up through time through this amazing career of teaching.

And I chose to frame today's lecture to continue the journey I represented at ICME13 in Hamburg, Germany in which I was honored to give one of these invited lectures. At that Congress, I talked about something I called the Special Mathematics Work of Teaching and I reflected on how the history of my efforts to try to understand the role that teachers' mathematical understanding plays in their actual work had been both one of which I learnt a lot with my colleagues but also frustrated me in the ways in which despite of my effort to understand mathematics is dynamically part of the work of teaching. I found myself often just talking about the knowledge again or something static, and not as part of practice. And I tried to give lectures to engage all of you thinking the role of teaching, taking social cultural perspectives of that work, and trying to think that mathematics as a verb, as part of the work of teaching. Yet when I look back on that talk, I realized that there were still thing missing in my efforts to try to capture and explain how mathematics comes together with other aspects of the work in practice.

So, when I served this president of the American Education Research Association two years later, in 2018, I was still on the same journey that I had begun years earlier. I gave a lecture that year called *Just Dreams and Imperatives, the power of teaching in the struggle for public education*. And in this talk, I tried to surface the ways which teaching is powerful, both for harm and for good. And I tried to think more about this notion and its power. I tried to think about how the larger system of oppression, the systematic oppression of racism, the structures of the inequity, how those actually found their way into the everyday micro moments of teaching. I used a video to try to show the connection between larger societal pattern of racism and everyday moments of teaching. And I used particular moments in video clip to think about the ways of which marginalization of black girls easily finds its way to perpetuate in classroom teaching but also the opportunities that exist in teaching to stand and disrupt those in the moment.

In my lecture today, I am continuing this journey to try to understand what I called the "work of teaching" and today to foreground as I think about this mathematical work of teaching, how do I understand and how it intersects the power that the teaching has in the context of the society with its history of enslavement, of oppression and of racism. So, I ask three questions today. I continue my question of the work of teaching. What it is to *do* the 'work of teaching'? What does it mean to foreground the 'power' of that work and why does it even matter? And finally I will ask what are continuing challenges in trying to understand this work of teaching and why should we care? So let's begin.

2. Work of Teaching

What is it to do the 'work of teaching'? It is worth appreciating that teaching is both incredibly common and also supremely complex. Here you see images of a couple of teachers. What you can see here, although you cannot hear anything or feel anything, as you can see mathematical content, you can see body, you can see looking at one another, you can see relationships, you can see gestures, you can see mathematical ideas, you can see representations, you can see space. There are so many things even it was still a photo that help you and remind you of the commonness of teaching, the things that all of us would teach and deal with all the time, and also the complexity of it.

So you would think about how common it is. I gathered a few data to show us and remind us about how common teaching is. Here are a few countries from around the world represented at this ICME Congress. And the numbers of teachers there are in each of your lands. You can see that there are many people who work in the role of teacher. And that in fact in all of these countries, teaching is the largest occupation. There are approximately 72.5 million teachers worldwide. So the part when I said it is common, we take it for granted that in every country we have adults who are willing to commit themselves to the next generation by fulfilling this occupation we called teaching.

It's common, but it is also incredibly complex. This is the word that surfaces all the time in the literature. I think we do not always ask ourselves what does it mean when we are saying is complex. So let's take a moment to pause and try to think when any of us says that, what do we actually mean? We will take a moment to watch this short video segment from a classroom. I am showing you all this image of a classroom here. And I will just briefly explain what the children and the teacher are talking about. They are working on this mathematics problem (Fig. 1) which might be seen incredibly obvious to you. But it's worth understanding that as children begin to understand the representation we call Area Models that it is not all that simple to interpret them. Here the children are comparing two rectangles that made in fact to them look entirely the same. On the left you can see a rectangle divided into three parts and one of them is shaded to grey. And on the right, you see a rectangle that is also divided into three parts and one of them is shaded to grey. And the question asked them what fraction of each rectangle is shaded grey. If you set aside that you don't understanding, then you might realize that for children, their answers to both of these might be one third. And indeed the problem constructed to surface what it is to look at Area Models, and the importance of equal areas and the notion of the whole. As you are watching this short video clip, I would like you to notice what do you pay attention to, and what do you think of the 'complexity of teaching'. What are your eyes drawn to? What are your ears drawn to? What do you notice? Try to ask yourself — to you, from your perspective, from your expertise and experiences, what seems to you to be complex here? So I show this short clip and these two questions that I would like you to be thinking about while I play it.

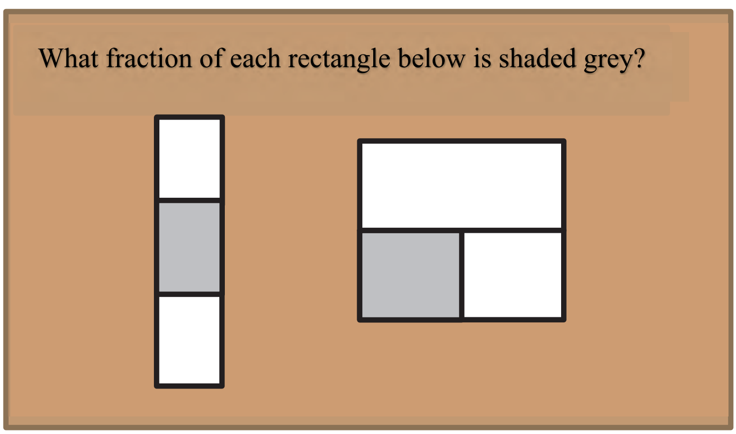

Fig. 1. The mathematics problem

(Video playing)

So take a moment and think about what is meant by "complex". What were you noticing? What were you thinking about? What were your eyes drawn? What were you hearing? What did you notice about space, about bodies, about language, about the mathematics? And what did you think about what it is meant to be called even in that very short segment "complex"? Let's think about that for a moment. Put yourself in the role of the person doing the work and being the teacher there. And you think about all the things that are to see, to understand, to sense, to think about the question like this "What does Antar mean by 'it's not a fraction'?" You might have to ask yourself

"What is the mathematical point of this of what I'm doing?" You might be worrying about "How is Antar being positioned in front of the class?" You might be watching other children saying and wonder "Are those two children over on the side following this?" You might be wondering "Whom to call on?" or "How is Antar feeling about his contribution?" or many other questions that easily can be on your mind in that moment as you make the next move. You are wondering about whether to keep the class all altogether right now. You are wondering about whether you have to do something to position both Antar and Gabi. You might wonder whether giving her the sticky line is actually a good idea. You might be thinking about your own body and where you should be. You might be thinking about what do you say and do next. So many things could be in the space of work that you are doing. And all of these have to do with try to feel, see and hear what the children are doing and what the children are thinking, because the work you are doing are with them. It is not to them. It is with them. It's about this mathematics. So keeping in mind the math, who the children are, how they positioned, their identities, what they might be feeling, all of these flowing around. And I think if that does illustrate what it means for something to be complex. I don't know what would.

So when I keep using this phrase the "work of teaching"", what do I mean by? what am I actually trying to use it for, why do I use this phrase? As reflected back, it came to me that I've been thinking about this for a very long time and struggling with what it means to talk about the work that I and so many millions of other people do every day, take it for granted and yet so complex. I found small parts of different things that I had written even 20 or 30 years ago when I saw myself beginning to think about what does it mean and try to understand that work. I see that in an article I wrote in 1996 and later some work I did with my colleague David Cohen when we talked about the role of curriculum materials. I continued to try to zoom in as I thought about what role mathematics play is in the work of teaching and what kinds of mathematical reasoning are inside and are required in that work and later with my colleagues Mark Thames and Jail Phelps, we asked ourselves questions about what makes that kind of content knowledge special when we thought again about the work for dynamic. And with my colleague Frank Forzani, we thought about how we could name some of the aspects of that work. So why I am insisting on using this phrase of "work of teaching"? I asked myself that question at my ICME-13 lecture. What I said then was that I thought it was important to focus our attention to what teachers are actually doing and to distinguish that from other features of classrooms, like different instructional formats such as small group work, or classroom culture and norms, what students are doing, how the curriculum is designed. I don't quite think about that way now, but I understand what I was asking at that point. And I do still feel that it's crucial that we honor the effortful and deliberate nature of teaching, its complexity, it's taken-for-grantedness, and not be invisible, so implicit, and taken for granted. But I am thinking I am still trying to figure out what does it mean to talk about the work and I no wonder think it is separated from what students are doing.

And so when I ask myself what do I mean by the "work of teaching", I am continuing to revisit and revise the definition. In some ways, it might be disappointing to you that I think that trying to figure out what do I mean by that is part of the ongoing inquiry of my work. I think it rests on trying to understand what is involved for teachers in their interactions with learners in context, and with more explicit learners of broader sociopolitical and historical environments in which that work takes place even in micro moments. I see this is the fundamentally both a deeply theoretical and practical question. And what I want to try to do together today is how can we better understand what I am calling the power of that work of teaching and the ways in which it either perpetuates or in fact can be used to disrupt injustice, racism, and oppression. So I am keeping in play this notion of mathematical work in the dynamic relational aspect, but I am trying to foreground more our ability to understand its power in the broader sociopolitical context of the work. And it is a hopeful question as well because in the end my dream is to begin to leverage its possibilities of that work of teaching is common, is on the presence to build a better world, a world that is more just.

3. The Power of the Work of Teaching

So my second question of this lecture is “what does it mean to foreground the ‘power’ of the work of teaching and why does that matter?” The first you could say that commonness and the complexity of teaching have powerful consequences for patterns of racism and oppression in our society.

I know that I don’t need to remind you of the many forms this takes as it taking in our current world and has taken place over time in our nation, in multiple world places around globe. I include a few images just to remind us of this larger systems of oppression, of the mass cultivation in United States and around the globe, of homeless people living in without safe shelters, the deep persistent ever brought economic inequity, the starve of indigenous lands from the people who occupied those land and occupied now by people who dominate them through oppressive ways of being, the battle of law enforcement and policing, unemployment and what the COVID-19 pandemic has reminded us this unbelievably vast deep disparities in health care and the health around the world. There are many other images that I couldn’t have given. But these seem perhaps to be large macro issues and you might be saying why we are talking about this right now? We are talking about it because I want to connect the dots between the systems of horror and hate and inequity and injustice and racism. I want to connect those to the commonness and complexity of this work we called teaching.

And to do that, I’ll try to take you zoom in from the picture I just showed to you, back into the classrooms. I’ll show you images of some adults who are themselves the people who perpetuate in the systems. It’s people who make systems. Systems are not some abstract structure out there. They are made by people and they are perpetuated by people and they could be dismantled by people. Systems and people are connected. Here is a picture of real estate agent someone who sells homes, and there is nothing could be said about how the ways in which those people’s work contributes to the ongoing and incredible racial segregation in the United States. Here is the image of a police officer. Here is a physician. Here is somebody who works in voting counting ballots in registration voters. And if you have seen some of the news from our country in the efforts, to try to deny voting rights to people who are so much deserved to be part of our electoral system. You could see the roles of these people playing in the electoral system is fundamentally important. Here is an image from the terrible day we saw in the Capital in the United States where rioters destroyed and attacked the Capital and the members of the government. And here you see a classroom. Let's pause for a moment and just remind ourselves that these adults in their various contributions to the systems in our country and in the countries all around the world. All of those adults were one time children. They were once third Graders or fourth Graders. They were in classrooms in all of our country. And in fact, even the people who teach in our countries were at one time children. So, if nothing else, if we will remember this, then when we notice hate, oppression and systems of racism, if we can remind ourselves that all the people who uphold and maintain those the systems were one time children, it might begin to illuminate how teaching is powerful.

So I make some claims here. "Teaching is powerful" I argue. And what I mean by that is when it is done carefully and sensitively, students can thrive, learners can grow, they can learn mathematics, they can develop positive identities, they can learn to value other people and work across different and work collectively. The second thing I am going to assort is that teaching involves enormous discretion. And from there, I go on to say that how that discretion is exercised can either reinforce racialized and oppressive patterns of social, personal and epistemic injustice and harm, or it can disrupt those patterns.

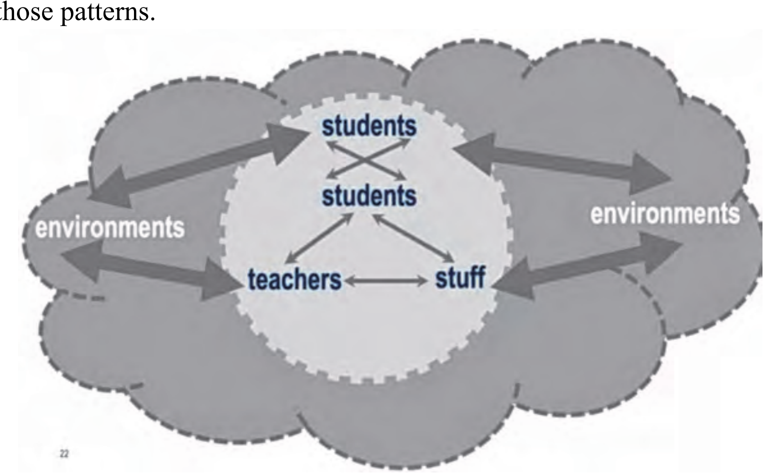

Fig. 2. The instructional diagram

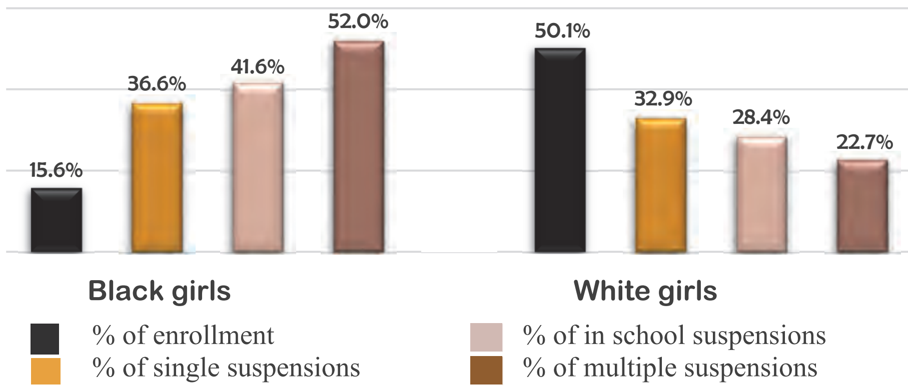
Let me explain. With this diagram (Fig. 2) that's an adaption of something that David Cohen and I and Steve Rodin originally called this instructional triangle, I modified that for my 2018 AERA Presidential address, to make some changes highlighted some features of the work of teaching and its position in environments that I thought merited highlighting. So I wanna start by looking at the environments in this picture. And remember what I am trying to represent is the analysis inside the classroom represents the inter-circle. So when I say environments, I am talking about some of the things we've already been discussing: anti-black racism, colonialism, the legacy of enslavement, Whites supremacy, housing policies of insurrection, school structure, teaching as an occupation, what families want from schools, the enormous health and wealth disparities, the curriculum, what particular committees think and believe about schooling, so many things are around the work of teaching and schools. The environment is also the arrow towards students remind us that students bring in enormous resources from their own lived experiences, from their families, from their cultures and from their communities. But they also bring bias from living and inherited from races to class and society. I am thinking about a very moving piece of research that I read over 25 years ago, by Timothy Grim Mill. He studies a classroom in which children were being helped to learn to write. And one of the things that was important in the classroom is that children could write about whatever they care about. It was deliberately in gender. They were invited to write about their ideas, their feeling to be creative. But what had not been taken account of by the teacher was all the ways in which the classroom is permeable from those outside environments. And these children lived in a various socially economically racially diverse community. What happened was the children wrote stories about other children in the class, reflecting the broad societal bias, prejudices and history of marginalization. The teacher had not realized by asking children to do what they could bring to the school, could bring inside the classroom, these forms of hate and bias. On the other hand, the ideas of cultural environment, culturally sustaining pedagogy advanced by so many scholars Gloria Ladson-Billings, Django Paris and many others required the class to be purist. So, if we want to take advantage of resources that children bring, from their own lived experiences that we don't want the classroom to be sealed off from the broader environments. So, it's a dilemma. So, the environments represent histories and present, family, community, culture and other ways of being interpreted. What were inside the classroom remind ourselves with this diagram that the students were interpreting and interacting with one another; they were interpreting and interacting with their teachers; their teachers were interpreting and interacting with them. And all of this happening around particular staff, it could be mathematics, it could be discussing something in current events, it could be discussing a world issue. But teachers and students are interacting together. And as they work, they are bringing in with them their experiences in their broader environment. The curriculum itself is influenced by the larger environment. In this country right now, there is enormous debates about the teaching of the U.S. history and the representation of White supremacy that has been raced in our history and has been targeted in our schools. So even the stuff is deeply influenced by the environments for better or for worse. So, what the diagram intends to show is that teaching, with students and teachers, is inside the classrooms that are deeply poised to the broader environments. And those broader environments include the histories, the patterns of racism, the patterns of oppression marginalization. And they also include the resources and restrains of communities and people as they come together inside the school. There is no simple answer to this, because on one hand you could argue let us constrain the classroom so that those larger patterns can't sit it inside the dynamics between teachers and students, but obviously if we want children to do things that bring forth their expertise, their experiences, their communities, their language, we cannot seal classroom out from the broader environment.

So here is where I move to talk about discretion. In the video clip that I showed you a few minutes ago, we saw a few minutes of interactions between two children and their classmates over particular set of rectangles, involving area model diagrams. I don't expect you to read what's on the slide. But basically, what I've got here is a recording in writing of the things that were set in some of the body movements that were going on in the video. And what I am arguing based on my 2018 AERA lecture is that every one of those separate lines in this representation represents some moments with the teacher has discretion to do one thing or another. It could be a decision the teacher is making, it could be the way the teacher moves, all of these are discretionary. What do I mean by discretionary, I will show you what I mean in a moment. They cannot be dictated by some outside authority. They are things happen in the complex dynamic of teaching. So, for example, at the beginning of the video, we heard the teacher say "Who'd like to answer what you think about the second rectangle? We're now only going to be able to talk about this briefly. We probably won't finish it." There are so many ways a teacher could begin that part of the lesson, and neither the textbook, nor the school leader, nor the teacher education program can tell a teacher what to say exactly in that moment. There are many different ways a teacher could begin. A teacher could have said "what is the answer to the second rectangle." which would signal something very different about the work that children are being engaged and doing together. We also see a moment when the teacher sees that many children have their hands up and responds to the question what it is that Antar just said. As a teacher has to face a moment like who is going to be called on next? Who is going to speak next? That cannot be governed or dictated by some outside force. It is a discretionary space. When Antar is done with explaining, the teacher said "Antar, do you want to stay there or do you want to sit down?" He indicated like to sit down. She says, "Okay, Thank you very much. You did a good job of explaining your thinking." How to help a child exit from the front of a room has a lot of going on in it. How Antar might feel? How might he seem to his classmates? What different things could be said and done? So many possibilities exist. It's another discretionary moment. And what I am trying to demonstrate with this diagram is that in this two-minute and twenty-one seconds of video that I showed you, there were twenty-five such moments or discretionary spaces. In order to do the work of teaching, the teacher exercises judgement, acts from patterns that she already has, says things, does things, moves, all of these are products of how she works in this discretionary space. And I hope you could see from this diagram that my argument is that teaching as I've argued elsewhere is dense with discretionary spaces. Almost like the real line is dense with numbers. Teaching is dense with discretionary spaces.

And how was this related to my argument about the power of teaching? Well, when you think about this diagram in the density of discretionary spaces, what I am saying is a discretionary space is where the interpretations, next moves, the comments or questions are not necessarily determined by the teacher-and not by a policy or a curriculum. These interpretations and actions that the teacher takes are learned by that teacher through her own firsthand experience as a child in school, through her professional training and through her experiences as a teacher in school. So, these things become absorbed by living in the broader society. They are not all highly ideally syncretic, yet they are also syncretic. They are also not all rational and planned. They are often habituated. They are often matters of habit of pattern because teaching is so complex that of course a great deal of work become routinized and it indeed a must. But what does it mean is that the use of the discretionary spaces has a lot of opening for either the dismantling in interruption of patterns of oppression that carry with us, in our bodies, in what we come to consume, or in the opportunity to disrupt these patterns of bias and oppression.

So, the question next has to do with how can we harness that power, that power of discretion in the work of teaching. So, to give you a concrete example of the way the larger systems and the micro moments interact, this is a brief diagram that I won't talk about it at length, but represents some very important research in the United States, about the disproportionate punishment of black girls compared to white girls in a nation school (Fig. 3). What the diagram basically shows is the large patterns of differential and much harsher punishment for the same infractions, committing the same offenses, or doing the same thing. You can see the black girls account for about half of the multiple suspension of the school whereas the white girls account for only one fifth for the same behaviors. So, what the researches are showing us is that these differential outcomes are related to teachers' judgements. They are the products to teachers' discretion and subjective judgements. So, you can say, so what we are going to do about that? We see these patterns. We do not want them to continue. Teacher education could work to disrupt the habits that the teachers come into teaching with, from their observations in classrooms going up, from their experiences, doing clinical works in schools. These patterns are embedded in normalized and oppressive patterns of practice. So, what could Teacher Education do? Well, here is an image of teacher screaming at the black girl. A white teacher is screaming at the black girl in a math classroom. This video showed the teacher behaving in one of the ways we see very unfortunately in the classroom. So, we can look at the Teacher Education to surface these patterns and to wipe them out through professional training. But teachers would need more than these patterns exist and more than commitment to be people who can work to combat racism and patterns of oppression in normalized practice. Teachers to do something about this



R. Epstein, J. Blake and T. Gonzalez (2017). *Girlhood Interrupted: The Erasure of Black Girls' Childhood*. Washington, DC: Georgetown Law Center on Poverty and Inequality

Fig. 3. About the disproportionate punishment of black girls compared to white girls in a nation school

would also have new habits. They would need knowledge, repertoires of possible ways of practicing and judgement. So, it's more than beliefs and knowledge, it's also changing habits of practice.

This what I am going to do today is the work of teaching: to learn and to manage that complexity and to be able to understand the broad and powerful role that it plays in justice in order to carry out that work the ways don't reproduce and perpetuate patterns of racism in oppression, patterns of anti-black racism, patterns of sexism, but to recognize these normalized practices, to see the relationships to the larger patterns in our societies and to find ways to do something different, for that we research among other things. But doing that kind of research is challenging: challenging to study the work of teaching, challenging to identify the ways that could be useful to this project of disrupting normalized patterns of racism, embedded in everyday common practice.

4. The Challenges for the Work of Teaching

So, the third question for my talk today is what are some of the continuing challenges for those of us who do research or for those of us who are practitioners in trying to understand the work of teaching? What are the challenges of trying to do that because indeed these are challenges in it? And why should we care? So, let's return to the classroom and revisit the video clip that I showed you earlier. Let's think about what are the challenges of trying to study the work that is going on in these minutes in the classroom?

(Video playing)

So this point we have one small segment of the lesson and the teacher and students are together beginning to try to figure out how best to distinguish between the first and second rectangle. Again, I am asking you this question about what are the challenges of trying to study the work of teaching here. The work of teaching that involves the mathematics, the teacher, the students, the broader environments, and the ways which children bring different identities, histories and experiences from broader societies. How all those things come together? What does it mean to study the work of that complexity? So, I wanna show you one more thing goes on a few minutes later to continue our questioning about what is it the challenging about studying the work of teaching, what it is challenging by teaching, and what is it challenging by studying it? So just as the lesson is about the end, the children are about to leave the classroom and go to lunch. A girl named Kassie raises her hand and says "Antar is right. It's not equal". And she brings upon an idea that might be something that you are not expecting. Let's watch.

(Video playing)

So, we stop there and again the class is almost over. Here is this new idea that's coming up. We have almost 30 children in this class. I think by looking at them you can see that there are overwhelming black children. You could also see it is a diverse class of people with different backgrounds and undoubtedly you could understand they bring in different intersectionality and identity. This is a math class in which they were working on this particular concept. Time is running short. And we see the teacher say many different things, for example, asking Kassie to name the child whose idea was – that was Antar; asking her to elaborate idea; not having her to come to the board at that moment. So many different things are going on. And earlier the clips we saw twice, we see the ways in which the teacher moved from Antar's contribution through Gabriella, to Gabi, and what went on. It's all those different places. We have to watch many times to appreciate the different things that might be to see, to name, to study, to analyze.

These moments that I am showing you are filled with discretionary spaces. Each of these is related to reinforcing or disrupting patterns of racism and harm. So, what are some of discretionary spaces and risks? We could name many of them in the video that I showed you. But let's just consider a few. We have Antar and things around Antar's position. We have Gabi and what she has done. And we have Kassie now as well. And we have all the other children in the class. There was the question that we want to try to understand that the researchers bring in enormous theoretical power and empirical power in studying. For example, how were these three different black children, Antar, Gabi and Kassie, positioned in front of their classmates? How were they being positioned as contributing or not as understanding or lacking understanding? Are their brilliance and their humanities be seen? Is it a hard question that yet being central? So there are especially spaces of work on the way which children experience and the work of teaching play out. Another thing we could ask and try to study is what's being signals about being and doing mathematics, both what and who? And what kinds of things are those signals? What are other children in the class besides those who are the main players in the video we saw? What are they learning about the black children about who gets to be smart in math and what does it mean to be smart? What's happening with math? What's happening to children's understanding of equal areas? There are so many different things being managed in this work of teaching and in each of these different questions I am naming and many more, there are discretionary spaces whatever gets said or done has consequences. It has matters for questions of reproducing and perpetuating patterns of how particular children get positioned, how Antar as black boy gets positioned; how Kassie gets positioned as black girl, or Gabi or the rest of the class see what's happening with the math. These are all spaces of discretion. And through them, what is the enormous power to either reproduce or to disrupt patterns of racism.

So, when we are thinking about practicing justice and practicing in justice, we have to understand more about the work of teaching which is challenging. I name now particular moments in the video clip in which these spaces arise and I invite you to think about the many kinds of questions we talked about earlier that are flowing through the work of teaching in any given moment about what to do next, where to be. Many of these are unconscious. They are habitual. They are part of striving, complex demanding interaction between the teacher and students in mathematics and in these larger settings. There is so much research that helps to drive and situate this work of teaching in the discretionary spaces. There are racial narratives about the ability and struggling learners. There are patterns of black girls. Lots of research on this. There is research about area models in fractions. There is research on what patterns are about being and do mathematics while black. I could name many other kinds of research, including misconception research, research on errors, all of these things are part of what can be studied about and is studies about the classrooms, still they could help us think about exactly what to do as you with your body do this work of interacting with children in real time. And here are lies in the power of discretionary spaces. As we begin to learn how to elaborate these discretionary spaces, they are moments and places to bring and bear the knowledge together with the practices in learning habits of action that can be powerful, for not perpetuate patterns of oppression.

So, standing back for a moment. What are the challenges in trying to do this kind of research and this kind of study of the work of teaching in justice? I will name just five and make a few comments about each of these. I hope it begins a conversation for us as a community interested in challenging, patterns of racism and oppression, in understanding the work of teaching, in finding ways to honor its complexity, and yet make its commonness able to be used in powerfully good ways for children in our countries.

So, the first challenge is combing the embodied nature of the work and the relational nature of the work with the cognitive and knowledge entailments. Some of my earlier work, I and my colleagues tried to study mathematics work, and it's super important and matters. But there's also the meaning towards the child, the use of tone and voice, the ways in which the teacher stands in the room or where children are positioned. We see children at the board and we see the teacher off camera. These are part of the body of work of teaching. And one example of our challenges our researchers, and I know many of you are working on this is finding ways to represent that work, with video, with transcript, and with so many other kinds of presentations that don't in vertically cut off parts of the work of teaching. I found myself in recent years more and more frustrated with even very imaginative use of transcript for the way in which it either goes so far away from the work or seems to translate so much about the work into language. And language is really important in the work of teaching. But so many things are also not about language, about relationships. How do you transcribe relationships? How do we move about the spaces of the room? So, there is a challenge for us: how we bring together the multi-model nature of the work of teaching and find ways to represent it and analyze it.

The second challenge is the one I won't talk about it at length, but about the importance of building theoretical and more general knowledge about teaching, and building inside while contextualizing the work and centering identities. So, for an example, I have not told you anything about the community where the classroom is, I have not told you very much about the children's identities, have not told you what time of the year it is, and yet there were some general things we've been able to talk about and think about. What does it look like to do this work with integrity where we are centered that very important contextual dimensions of the work, because it is contingent and decontextualized. We are also building theoretical knowledge. What are the responsibilities that we have to be honest about where we do this work? How are we accounting for differences? We are also looking for theories.

A third challenge is how we bring together the work that intends to be systematic, creative work on structure, racism, on macro-structures together with micro-interactions. Too often in our history on the work of teaching, we look at micro-interactions or we look at cognition, or we look at larger structures, or we look at patterns. But in fact, these things are interplaying in the work of teaching, and how can we do better to link together larger patterns of microsystems, macrosystems together with the moments and the spaces. What are the ways to do with that integrated?

A fourth challenge is how to distinguish more responsibilities between prescription and detail. There's been a kind of allergy in our field about breaking down the work of teaching in the ways that many colleagues have named decomposing practices. And it means that it has been critiqued for foreseeing to describe teaching and prescriptive ways as though one did these technical prescriptive moves that teaching would work. And yet, when we believe teaching to be vague, without ways of actually breaking it down and understanding it, we leave it to be at mercy of people doing this out of their old idiosyncrasy, their experiences of patterns in our society. We don't help with the work. It is so complex, begin to have texture, begin to have detail. How do we learn to distinguish between the should(s) and the description? A few years ago, at ICME-13, Ester Enright and I, together with other colleagues, worked on the work of questioning and teaching. And one of the things we argued is questioning is one of the most important things that teachers learn to do and yet we lack so much detail about the different ways that questions to get asked, awarded and acted. There are so many things to understand, yet we leave question asking to be very vaguely understood idea. How do we learn to look in detail and yet understand the contingent use of that detail? Analysis still remains something that has to be deliberated about with discretion.

And finally, how do we learn to represent the work of teaching in a usable discourse of practice? Some very fine work attends and is devoted to building theories and yet won't help those of us who work with teachers to help them learn to do the work. What are some of the language demands of learning to name and identify teaching in ways that are theoretically deep that are the product of analysis and yet are usable for practice? Is that an impossible goal or one to which we could aspire? And these are just some of the possible ways that we need to continue to confront challenges of work of teaching. Because when I look back across the arch of my work as a teacher, a scholar and a practitioner of teaching, I find that it is been a struggle in our field to honor the work of teaching and to represent it is not displacing work on learners or learning, or work on structures, or bias or oppression or on classroom environments, but to find ways to understand that the work of teaching is done in the context of all of that and to honor that is one form of important research that we so much need if we want to be able to leverage the work of teaching, to disrupt rather than let it simply perpetuate patterns of oppression.

And there are a few other things we need to contend more deliberately as we face challenges of studying teaching. One of those is that too often we neglect to say more about where we do this work and we need to vary that where we the work matters. We need to talk more about time of day, and time of year. All of us who have taught to know that there is a big difference between Thursday afternoon at four o'clock and Monday morning at eight. There is big difference between October and June. And these differences might look different in different parts of the world that they matter. So, in addition to thinking about whom we studying and where we are doing it, and how we blend together, some of the things I discussed in last slide, we need to think about how we don't leave out these very important parts of context of the work of teaching. Things that teachers are thinking about all the time and so rarely part of our research accounts. In fact, we very rarely, too often neglect to say anything about the identities of the children except sort of to describe them. It's not part of our analysis. And finally, and maybe most important to all, we need to diversify the research community if what we want to do is to understand how schooling is experienced, how the work is done. We need the perspectives and experiences, and expertise of broader range of people. The experience on our doctoral programs, the experience on our conferences, the experiences on so many spaces we understand that it's a matter of justice and the study of justice, to have a much more diverse research community. And all the work we can do together to understand how that would improve, not only who gets to do the work, but also what we collectively come to understand.

Because this in fact, this project is really to understand the work of teaching and its role in justice. It's a collective work. It's not a work of any one person, it not a work of somebody getting the Felix Klein Award. It's an agenda that matters for our future and the world. Teaching is powerful. It demands diversity and who 'we' is when we say 'we'. And this will necessarily broaden what we as scholars come to consider evidence, what we think of the objects of studying are, and what we value. And this would mean confronting some of the patterns of epistemology, ontology, and axiology that are shaped our research community.

Lecture of Awardee 2

The Interplay between Construction of Knowledge by Individuals and Collective Mathematical Progress in Inquiry-Oriented Classrooms[1]

Tommy Dreyfus[2]

ABSTRACT In a long-term research collaboration, the author and colleagues analyzed learning processes in inquiry-oriented classrooms in a comprehensive manner. In such classrooms, mathematical progress typically occurs in complex interplay between individuals, small groups, and the whole class. We analyzed this interplay by coordinating two theoretical frameworks, Abstraction in Context and Documenting Collective Activity, and their respective methodologies. In the present chapter, I briefly review our research.

Keywords: Classroom-based research; Inquiry-oriented classroom; Abstraction in Context; Documenting Collective Activity; Coordination.

1. Introduction

Learning in inquiry-oriented classrooms (Laursen and Rasmussen, 2019) is becoming more and more common at all levels of schooling. There is evidence from meta-analyses that student-centered approaches have advantages for learning outcomes (e.g., Theobald et al., 2020). It is important to understand why and how these advantages come about. Yet, qualitative research on classroom-based mathematics learning in inquiry-oriented classrooms is scarce. One reason for this may be the complex interplay between learning processes occurring at the different scales of social settings in such classrooms: individuals, small groups, and the class as a whole, learning processes that may strongly depend on each other. This complexity brings with it methodological questions of how to deal with learning processes at different scales. The need arises to use different theoretical frameworks, and to link between them.

I present an overview of a collaboration between Chris Rasmussen, Michal Tabach, Rina Hershkowitz, Naneh Apkarian and myself, whose aim it is to develop a methodology based on two theoretical frameworks that is designed to deal with the above complexity by networking the two previously independent frameworks. I will

give an overview over the collaboration and some of its achievement. I will refer to other publications for detailed reports on specific research studies.

2. Background

The aim of our collaboration is to investigate learning in intact inquiry-oriented classrooms. All of us had earlier experience researching aspects of mathematical progress in such classrooms, but without obtaining a comprehensive picture of such progress. Some of us have researched the construction of knowledge by individuals and small groups learning in such classrooms (see Dreyfus et al., 2015, and references therein). This research has been based on the Abstraction in Context (AiC) theoretical framework (Hershkowitz et al., 2001). This methodology did not allow for the investigation of mathematical progress of the classroom as a whole. Others have researched knowledge becoming normative and functioning-as-if-shared in the classroom as a whole (Rasmussen and Stephan, 2008). This research has been based on the Documenting Collective Activity (DCA) framework (Stephan and Rasmussen, 2002). This methodology did not allow for investigations of the constructing of mathematical knowledge at the individual and small group level. The question thus arose whether the two frameworks and their associated methodologies could be combined so as to provide a comprehensive picture of the learning processes at the different scales in a classroom and the interactions between these learning processes. In parallel, the question arose how to network the two frameworks in order to achieve this aim, and with which networking strategy (Bikner-Ahsbahs and Prediger, 2014).

After collaborating for more than a decade, we are in a position to give positive answers to both these questions. The two frameworks, AiC and DCA, can be networked, specifically they can be coordinated, and their methodologies can be used in tandem to achieve a detailed qualitative analysis of learning in inquiry-oriented classrooms. In this chapter, we give an overview of several research studies to substantiate this claim.

3. The Studies

In this main section of the chapter, I present brief reviews of four research studies. The first three studies are empirical and illustrate the coordination of the AiC and DCA frameworks to study mathematical progress in intact inquiry-oriented classrooms; the fourth study is theoretical and explains why the coordination between AiC and DCA has succeeded.

3.1. Study 1 — knowledge shifts

We analyzed mathematical progress in an early lesson of an inquiry-oriented differential equations course (Rasmussen at al., 2018). We used Abstraction in Context for analyzing the construction of knowledge by individuals and small groups; we used the Documenting Collective Activity approach for analyzing whole class discussions. We found that students in different groups seemed to be going through similar but not identical processes of knowledge construction. Indeed, it is on this basis that participants can communicate across small groups yet still have differences to debate. Our analysis provides further evidence of the importance of whole class discussions, which partially emerged from the small group work, but also were occasions for participants to develop ideas beyond what was constructed in the small groups.

In order to coordinate between the analysis of knowledge constructed by individual students and small groups of students (using the AiC methodology) and the analysis of the development of mathematical classroom knowledge and reasoning for the whole classroom community (using the DCA methodology), we looked at mathematical progress in the classroom through the two lenses in parallel. The combination of the two methodologies allowed us to follow the evolution of ideas as they flow between individuals, small groups, and the whole class. We identified the links between the constructs that emerged and the ways of reasoning that became normative. These links revealed shifts of knowledge in the classroom: up-loading ideas from a small group to the whole class, and down-loading ideas raised at the whole class level into the work of a small group.

The links also focused our attention on the students who initiated the up- and down-loading and thus assumed the role of knowledge agents. A knowledge agent is a student who initiates an idea which is later taken up by others within the classroom community. We found knowledge agents initiating up-loading of ideas, others initiating down-loading of ideas, and still others initiating new ideas within the whole class discussion itself. The instructor has a double role with respect to knowledge shifts and knowledge agents. One role is to create opportunities which afford the activity of knowledge agents in the class. The second is to help other students benefit from the actions of knowledge agents for constructing their own knowledge. We consider the notions of knowledge agent, up-loading and down-loading to be a crucial product of the methodological coordination between AiC and DCA. A detailed report on this research study has been published elsewhere (Tabach et al., 2014).

3.2. Study 2 — teacher role

In this study, we analyzed a sequence of two lessons of a probability course for eighth grade students. The students worked on purposefully designed sequences of tasks intended to afford the emergence of abstract mathematical thinking in discussion. Our overall goal was to illuminate the role played by individuals and groups in the class as well as by the class as a whole and by the teacher in the knowledge constructing process, and to learn more about shifts of knowledge between the different social settings in a mathematics classroom during the knowledge constructing process.

We used the same approach as in Study 1 — DCA, for analyzing whole class discussions, and AiC, for analyzing group work — and we found that this approach is significant in that it offers a novel methodological tool by which to document the evolution and constitution of mathematical ideas in the classroom and the processes by which these ideas move between individuals, small groups, and the whole class under the facilitation of the teacher.

The two theoretical frameworks and associated methodologies describe different but closely related aspects of the classroom learning process. The AiC analysis has a particular focus on cognitive constructing while the DCA analysis examines how ideas function at the collective classroom level. These are complementary foci and their coordination allows for tracing the growth of ideas from small groups to classroom community and vice versa. The coordination of the findings emerging from the analyses according to the two methodologies allowed us to study knowledge shifts in the classroom as one continuum, and to trace students who have a crucial role in knowledge shifts in the classroom.

The analysis also showed that the teacher adopted the role of an orchestrator by balancing between the whole class and group work in terms of time and tasks. She kept an equilibrium between the need to teach certain content on one hand, and the strategy of affording opportunities for students to construct their knowledge on the other. She assumed responsibility to provide a learning environment that affords argumentation and interaction. This enables normative ways of reasoning to be established and enables students to be active and become knowledge agents. A detailed report on this research has been published by elsewhere (Hershkowitz et al., 2014).

3.3. Study 3 — complexity

The setting for this research is a lesson from a mathematics education master's level course on Chaos and Fractals; the topic of the lesson was the area and perimeter of the Sierpiński triangle and the apparent paradox stemming from an infinite perimeter enclosing a region without area. Our focus in this study is on an enhancement of our methodology and on the insights into the complexity of mathematical progress in inquiry-oriented classrooms that the methodological enhancement reveals. The methodology of coordinating the AiC and DCA theoretical frameworks used in studies 1 and 2 was enhanced in this study as follows: not only did we analyze small group work using AiC and whole class discussions using DCA as in the previous two studies, but we also carried out DCA analyses of the small group work and AiC analyses of the whole class discussions. This enhancement allowed us to layer the explanations for the collective and individual mathematical progress in a manner that fully integrates the collective with the individual mathematical progress, thus exhibiting the complexity of the interplay between collective and individual mathematical progress in inquiry-oriented classrooms. Thus, it enabled us to make sense of the lesson as a whole.

Our analysis showed a multiplicity of ways in which knowledge developed and mathematical progress was achieved. We showed that knowledge was not only constructed by a few students in a small group but also by a large group of students collaborating and arguing together in a whole class setting. In parallel, ideas were shown to function-as-if-shared in different situations: some without a preceding constructing process, others in proximity to a relevant, prior or almost simultaneous, constructing process. In other words, our enhanced methodology allowed us to show that in an inquiry-oriented classroom, knowledge that is new to the students may be constructed not only in small groups but also in whole class discussions. This conclusion should be seen in tandem with the conclusion that ideas may begin to function-as-if-shared not only in whole class discussions but also in small group work. We believe that this complexity is not exceptional but that similarly complex interactions between processes of knowledge construction and processes of ideas becoming normative are typical for inquiry-oriented classrooms. A detailed report on this research is available from the authors (Dreyfus et al., 2022).

3.4. Study 4 — argumentative grammar

From the previous three studies, we conclude that to make sense of learning processes in inquiry-oriented classrooms, networking two or more methodologies with somewhat different foci and grain sizes is insightful. On the other hand, researchers' experience with networking (Bikner-Ahsbahs and Prediger, 2014) has shown that there are conditions for networking to succeed. In the fourth study to be summarized here, we asked ourselves what underlies the success of the coordination between AiC and DCA in the previous three studies.

In this study we identified commonalities between the two frameworks that contribute to the productivity of their networking. To start with, there are environmental commonalities: Both frameworks require classrooms in which students are routinely explaining their thinking, listening to and indicating agreement or disagreement with each other's reasoning; such classrooms typically interweave collaborative work in both small group work and whole class discussions, where the teacher adopts a role that encourages argumentation and inquiry. Both frameworks also require the intentional use of a coherent sequence of tasks that is purposefully designed to offer students opportunities for constructing new knowledge by engaging them in problem solving and reflective activities. The tasks should be designed to afford inquiry and the emergence of new constructs by vertical mathematization (Treffers, 1987) from previous constructs. While vertical mathematization appears here as component of an environmental commonality, it is also a theoretical commonality. The methodologies associated with both frameworks are based on the premise that vertical mathematization is core to mathematical progress.

The theoretical relationship between the frameworks goes much beyond vertical mathematization. The analyses of empirical data allowed us to establish a net of internal-theoretical commonalities in the form of a correspondence between the analytical constructs of AiC and those of DCA. For example, a constructing action in AiC corresponds to an argument as a whole in DCA. Another theoretical link relates to the centrality of shared knowledge. The definition of shared knowledge used in AiC relates to cognitive aspects. We find its counterpart in sociological terms in the phrase 'function-as-if-shared' used by the DCA approach. What is common between the two constructs is that each construct operationalizes when particular ideas or ways of reasoning are, from a researcher's viewpoint, "shared" or "accepted" by the participants.

These and other environmental and theoretical commonalities make AiC and DCA highly compatible. We made use of this compatibility and at the same time raised it to a higher level by articulating an argumentative grammar for our networking; that is, we were explicit about the rationale and theoretical foundation upon which the networking is based. A simplified description of our argumentative grammar is that we employ the relationships between the analytical constructs of AiC and of DCA to explicate the theoretical commonalities of the two frameworks in the empirical data we have from the classroom. The fact that the coordination of the two frameworks has succeeded in the three different studies described in the previous subsections validates this argumentative grammar. A detailed report on this research has been published elsewhere (Tabach et al., 2020).

4. Conclusion

In the research collaboration represented by the four studies reviewed in the previous section, we coordinated two theoretical frameworks, AiC and DCA, to achieve a comprehensive and at the same time detailed qualitative analysis of learning processes in intact inquiry-oriented classrooms. We explained why these two specific frameworks are compatible and allow coordination, and we described an argumentative grammar for such coordination. We found that knowledge agents play an important role in the interplay between different social settings in such classrooms, and we analyzed this role. We found that one path of mathematical progress in such classrooms is the construction of knowledge in small groups followed by a teacher-led whole class discussion in which the knowledge constructed is institutionalized. But we also found that this is but one path, and that mathematical progress in inquiry-oriented classrooms is complex and may be made in a variety of alternative ways.

We see what we achieved as just a beginning, with much research still needed in the future. For example, studies at different grade levels are in order: So far, we have neither a study at the senior high school level nor at the elementary school level. Studies in which all groups in a classroom are observed (video-recorded) would be desirable but of course present methodological challenges to deal with the large amounts of qualitative data collected. Studies with large classes, say of 30 or more students, are likely to present additional methodological demands.

In view of the promise of student-centered instruction at all levels of learning mathematics, we hope that other research teams will take up the challenge of research that aims at investigating learning in student-centered, especially inquiry-oriented classrooms in a comprehensive manner.

Acknowledgments

I would like to express deep thanks to Naneh Apkarian, Rina Hershkowitz, Chris Rasmussen and Michal Tabach for our thoroughly enjoyable and productive long-term collaboration.

Lecture of Awardee 3

From Thinking in Action to Mathematical Models — A View from Developmental Psychology

Terezinha Nunes[1]

ABSTRACT Developmental psychologists agree that intelligent action precedes language in children's development and that language transforms children's thinking. In this lecture I explore the ways in which children's thinking in action is transformed by learning to use conventional mathematical signs to represent quantities and relations between quantities. Numbers have two types of meaning: a referential meaning, which connects numbers to quantities, and an analytical meaning, which is intrinsic to the conventional systems of signs. This dual nature of numbers means that, from the psychological perspective, numbers are models of the world. The referential meaning of numbers is based on children's use of schemas of action to establish relations between quantities; it is at the core of quantitative reasoning. The analytical meaning rests of the rules that define relations between numbers in a conventional system and provides the basis for arithmetic. This paper presents research that illustrates how teaching can build a bridge between thinking in action and mathematical models by promoting the coordination of quantitative reasoning with number knowledge.

Keywords: Quantitative reasoning; Multiplicative reasoning; Action schemas; Reasoning in action; Referential meaning of number; Analytical meaning of number; Cultural systems of signs.

This paper starts from what I take to be an uncontroversial idea: mathematical modelling is a form of intelligent action. Although this idea might seem trivial, it has profound implications for thinking about how mathematics is learned and used to model the world. By examining this idea from the perspective of developmental psychology, I consider here four fundamental questions:

1. What is the origin of intelligence?
2. How does the learning of numerical signs change children's thinking about quantities?
3. What are the basic types of relations between quantities that students need to master in primary school?
4. How can schools promote students' thinking about relations between quantities?

[1] 2017 Hans Freudenthal Awardee. Department of Education, University of Oxford. E-mail: edst0248@nexus.ox.ac.uk

These four questions are examined in the context of mathematics teaching in school, but it is important to stress that mathematical reasoning develops also outside school (Nunes et al., 1993). However, an analysis of what and how people develop mathematical reasoning outside school is beyond the scope of this paper.

1. The Origin of Intelligence

For the fathers of the study of human intelligence, there was no doubt that intelligence starts to develop before language; this means that language cannot be the origin of intelligence. Gesthalt psychologists, such Wertheimer and Köhler, as well as child psychologists, such as Binet and Piaget, studied intelligent action in subjects who did not have language; Gesthalt psychologists studied monkeys and developmental psychologists studies human babies. The paradigms that were used to investigate intelligent action in the absence of language had in common the fact that the subjects could not attain the aim of their action directly: they had to use inferences that connected different aspects of the world, and by doing so they were able to attain their goal. These classical paradigms can be illustrated by detour problems and the use of tools.

In detour problems, the subject seeks to obtain an object, but is separated from the object by a barrier, as in Figure 1. Because the direct movement towards the object is obstructed, the subject must conceive of two movements as a single path: the first movement, A, away from the object, is reversed by the second one, B, towards the object, which is located in position C. Such behavior exemplifies a practical inference, which puts two different pieces of information together and leads to the conclusion of an equivalence: the movement from A to C is equivalent to the sum of the movements from A to B plus B to C.

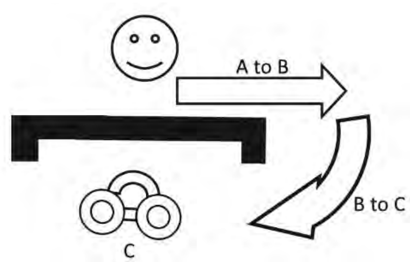

Fig. 1. The baby tries to reach the toy over a barrier but does not succeed. By thinking of a movement away from the toy as cancelled by another one, the baby can reach the toy.

A second classical paradigm in the study of intelligent action in the absence of language involves the use of tools: the subject tries to reach an object directly but the object is out of reach; by using a tool, such as a stick, the subject can move the object into reach. The use of tools also illustrates a practical inference: object A cannot be reached by the subject, but the subject can reach object B which in turn can reach object A, and B can be used to bring A within reach.

A large number of studies using the detour and tool use paradigms leaves no doubt that monkeys and babies can solve these problems and thus show intelligent action in the absence of language. Alternative theories were proposed early on in psychology to explain how detour and tool use problems were solved. The two initial hypotheses were proposed by Gesthalt psychologists and learning theorists.

Gesthalt psychologists suggested that the solution of detour and tool use problems involved a sudden re-organization of the perception of the situation, termed insight. Thus they argued that intelligence was rooted in perception, but there was no explanation for what led to this sudden perceptual re-organization. Insight provided a structure for further intelligent action: the subject became able to use previous insights to solve new problems that required the same sort of inference.

Learning theorists suggested that solution was accomplished by trial and error, also known as the law of effect, which involves a gradual approach to the solution based on the reinforcement of those actions followed by success. Such learning had no structuring role on further problem solving because learning was viewed as essentially guided by reinforcement, which is external to the learner.

Piaget criticized both theories. He argued that the Gesthaltists offered a description of structures for thinking, but no explanation for their origin, whereas the trial and error theory sought to explain the origin of the solution but provided no description of structures for thinking. Piaget proposed that the solution of problems in action was accomplished by learning to coordinate initially independent actions into structured sequences, that are repeatable and useful in different situations. Such sequences he termed schemas of action. According to Vergnaud (2009), action schemas contain theorems in action, i.e. involve a process of making inferences which are not explicitly recognized by the actor.

In summary, the existence of intelligent action in the absence of language is accepted wisdom in psychology: intelligence starts in action. Although the description of the processes by which problems are solved in action differs across theories, all theories about the development of human intelligence include a period during which babies are able to make practical inferences and to solve problems, even though they do not use language to communicate and cannot use language to represent the process of making inferences nor to represent the solution. It is also accepted wisdom in psychology that the acquisition of conventional systems of signs, such as language and number systems, changes the possibilities of human intelligent action. This idea is explored in the next section.

2. How Does the Learning of Numerical Signs Change Children's Thinking about Quantities?

All theories of cognitive development propose that the acquisition of signs transforms intelligence. Consider the case of numerical signs. Human babies can compare small quantities and distinguish two from three objects, for example; they can also compare larger quantities when the difference between the quantities is large, such as 6 versus 20 objects. But they do not succeed in distinguishing, for example, 19 from 20 objects visually, and neither do adults. Because babies do not know how to count, their ability to compare discrete quantities is restricted to what they can distinguish perceptually. Older children and adults, who are not restricted to visual comparisons and can use a counting system to compare discrete quantities, can easily tell the difference between a set with 19 and one with 20 items. They are no longer limited by their perceptual skills. Learning to count changes human's ability to compare sets.

Learning to count does not immediately transform children's ability to compare discrete quantities. Children learn how to count, but continue to try to compare quantities just by looking at them until about the age of 6 or 7 years. Many 4- and 5-year old children who can count objects up to ten do not count to compare sets with seven or eight items, for example, and do not succeed in making accurate comparisons when the perceptual arrangement of the items makes visual comparison difficult. This observation has been replicated in several countries with different counting and educational systems, such as Brazil, China, England, France, Switzerland and the US (for a review, see Nunes and Bryant, 2022 a).

The explanation for this phenomenon is a matter of controversy, which in my view boils down to the theory of number meanings upon which the different explanations are based. In this paper, I contrast two radically different explanations for how children learn the meanings of words, and in particular the meaning of number words. The general terms for these two basic explanations, associationism and representational theories, cover a variety of specific approaches that differ in their details, but still allows the theory to be classified as belonging to one of these two types. This discussion does not focus on the variations as its aim is to contrast the two general theoretical approaches.

The associationist view

According to the associationist view, which is considered the oldest theory of thought (for a review, see Mandelbaum, 2015), a word attains its meaning by being heard at the same time as its referent is perceived; i.e. by association based on contiguity in time and place, to use Hume's (1896) expression. In the same way, a number word attains its meaning by association to a perceived numerosity: the word "three", for example, becomes associated with the perceived numerosity of a group with three items.

Among the many criticisms of this view of how number words acquire meaning, I consider one the most crucial: in this theory, there is no principled connection between the meaning of the words "three" and "four", for example: each of these words acquires its meaning by association to a referent, which is a set with a specific numerosity. This problem of associationism as a theory of number meanings has been recognized by researchers, who tried to solve it by resorting to other, different processes which would be complementary to association. Carey (2004), for example, suggested that children learn the meaning of the number words "one" and "two" by association, but at the same time they distinguish each of the two items in the set with the numerosity of two. This process, termed parallel individuation, eventually allowed the child to realize that "two" means one more than one, and that "three" means one more than two. These realizations eventually would lead a child who is learning to count to generalize from the initial sequences "one, two, three" to all sequences in counting, and to infer that that each number word refers to a set that has one more item than the set represented by the number word that precedes it in the sequence. Thus, in Carey's theory, the meaning of numbers ceases to be the result of associations between words and referents and comes to rely on a new process.

Carey's theory ends up by breaking with associationism. To quote her conclusion: "We cannot just teach our children to count and expect that they will then know what 'two' or 'five' means. Learning such words, even without fully understanding them, creates a new structure, a structure that can then be filled in by mapping relations between these novel words and other, familiar concepts" (Carey, 2004, p. 68). Even though Carey does not clarify what she means by the other, familiar concepts, her explanation departs from associationism in so far as it depends on internal conceptual structures provided by the child rather than on association. It is worth noting that Carey explicitly relies on numerical comparisons as part of the internal structures when she describes the child's realization that two is one more than one. In order for this explanation to be in line with findings in mathematics education, numerical comparisons would have to be an early achievement, but research in mathematics education has shown that the mastery of numerical comparisons is a late achievement, rather than an early one (e.g. Carpenter et al., 1981; 1982; Hudson, 1983).

The representational view

The representational view offers an alternative to associationism and it is also a classical theory in psychology (von Helmholtz, 1921). I present here the synthesis to which we (Nunes and Bryant, 2015a; 2022a; 2022b) have arrived over the years. We consider numbers to be elements of a system of signs and to have two meanings.

<u>The first meaning of numbers is representational</u>, extrinsic to the number system, and connects numbers to quantities through measurement. According to Thompson (1993), a person constitutes a quantity when he/she thinks of a quality as susceptible of measurement. Measurement is the attribution of numbers to quantities according to rules (Stevens, 1946) that represent relations between quantities: thus, in the representational view, numbers are relational concepts.

When we measure extensive quantities, the measure is obtained by the addition of its units. If the quantity is discrete, the unit is often a natural unit: e.g. oranges, rabbits, pencils etc. When the child conceives of counting as the addition of each unit, as it is counted, to a set of already counted items (von Helmholtz, 1921), the child has a first insight into the representational meaning of natural numbers. The action schema of joining and its inverse, separating, are the sources for the representational meaning of natural numbers. If the quantity is continuous, a conventional unit is defined, and the total quantity is conceived as the sum of all the conventional units, such as centimeters or inches. The logic of additive relations between the units in a quantity supports counting systems in different languages, although the number words and the particular organization (e.g. base ten, mixed base ten and twenty, base 12) of counting systems differs. Understanding the connection between number and continuous quantities is a later achievement, but the logic of additive relations applies also to continuous quantities.

Measuring intensive quantities is yet a later achievement. Intensive quantities are measured by the ratio between two different extensive quantities (Tolman, 1917): e.g. speed is measured by km/hour and density is measured by mass/volume. However, a discussion of intensive quantities and rational numbers is beyond the scope of this paper, which focuses on natural numbers (for further discussion, see Nunes et al., 2022b).

In a representational theory, number meanings are not based on the association between words and referents, but rather on the ability to think logically about quantities and to make logical inferences on the basis of relations between quantities. Thus numbers are relational concepts that represent relations between the units within a quantity being measured; natural numbers can be used to determine the numerosity of groups of items, but their meaning does not result from the associations with numerosities.

The second meaning of numbers is formal, analytical, intrinsic to the system and defined by the rules of the system. Natural number systems use addition rules to define numbers: for example, 9 means $8 + 1$ because we add 1 to 8 to get to 9. In fact, any number has infinite analytical meanings: 9 means $8 + 1$, $7 + 2$, $6 + 3$, $10 - 1$, $11 - 2$ and so on. The rule of addition justifies the cardinal meaning of numbers: one can say that a set has, for example, 9 objects, because as each object is counted, it is added to the set of already counted items. Addition also justifies the ordinal meaning of numbers: 9 is more than 8 (and all its predecessors) because one gets to 9 by adding 1 to 8. In contrast, rational numbers are not based on addition, but on ratios, and thus lead to a rather different system of analytical meanings for numbers (for further discussion, see Nunes and Bryant, 2022 b).

Learning numerical signs and grasping their analytical meanings enables children to think about quantities in a new way. Whereas thinking in action depends on the quantities being present and on the child's ability to manipulate items, thinking that uses numerical representations is freed from this restriction. Steffe (1992) suggests that a simple example of this capacity to use numbers to think about quantities can be found when children are able to answer a problem such as: "There are seven marbles inside this cup; I will put four marble in; how many marbles will the in the cup?". The researcher puts the marbles in the cup as the child watches. If the child counts on from seven, saying "eight, nine, ten, eleven", the child has demonstrated that number words (in this case, seven) can now stand for a whole collection of objects; the seven marbles do not have to be seen to become part of a larger collection. Another example of this empowerment by the use of symbols is manifested in counting money: when a child can point to a single coin that has the value of 10 pence and count on from 10, in order to pay for example 13 pence using a combination of 10p and 1p coins, the child's thinking has been empowered by the use of symbols (Nunes et al., 2015 b). Neither of these tasks, in which a number word has to stand for a measure, is mastered by children immediately as they learn to count, but only later on, when they grasp the role of addition in counting.

One further example: If we tell a child that there are 12 objects in a box and 8 in another box, the child who understands the relational meaning of number words no longer needs to compare the quantities directly by looking at them and knows in which box there are more objects. Once again, this achievement cannot be taken for granted when a child has learned how to count: Davidson et al. (2012) showed that children who could count to, for example, 20 were not necessarily able to make comparisons between groups of objects inside boxes on the basis of their numerical labels. Thus, learning to count is necessary but not sufficient for grasping the analytical meaning of numbers: the analytical meaning depends on understanding the relational meaning of each number, defined as an addition of one to the previous number in a counting system.

Number meanings and mathematical skills

Each of these two types of number meaning is associated with a different mathematical skill: the representational meaning is related to quantitative reasoning and the analytical meaning is related to arithmetic (Nunes et al., 2016). Quantitative reasoning is the ability to make logical inferences on the basis of relations between quantities. One can reason about quantities without representing them with numbers: for example, if you know that I have red pencils and blue pencils, you can infer that the total number of pencils I have is greater than the number of either blue or red pencils, and that the number of red pencils is equal to the total number of pencils minus the number of blue pencils. You don't have to know the number of pencils to think about these relations, which are additive (i.e. based on addition and subtraction) and relate to part-whole reasoning. Thompson (1993) suggested that numbers are not relevant to quantitative reasoning; in fact, quantitative reasoning is the source for the representational meaning of numbers.

In contrast, arithmetic skill is the ability to analyze "the behavior of various numbers in four operations: addition, subtraction, multiplication, and division" (Guedj, 1998). Arithmetic skill is related to the analytical meaning of numbers. When students become able to coordinate quantitative reasoning and arithmetic, they are able to use mathematical models to understand the world; this is a radically new step beyond thinking in action, but originates from action schemas. The remainder of this paper does not focus on the analytical meaning of numbers and arithmetic, but on quantitative reasoning and on the relations between quantities that students need to master in primary school.

Quantitative reasoning and arithmetic are correlated, but distinct abilities, both theoretically and empirically, because each makes an independent contribution to the prediction of mathematics achievement, even after controlling for general cognitive ability (Nunes et al., 2012). Unfortunately, these two abilities have not been clearly distinguished in school nor in research: for example, word problems are designed to test students' skills in applying arithmetic to specific situations, but the focus is more often on the arithmetic operations that students have just learned to calculate than on the relations between quantities described in the word problems. With notable exceptions (e.g. Cheong et al., 2002; Kho et al., 2014; Ng et al., 2009; Nunes et al., 2015b; Thompson, 1993), teaching and research has been more concerned with arithmetic than with quantitative reasoning.

In summary, there are two different types of theory about how learning numerical signs changes intelligence in action. I suggest that the difference between the theories boils down to their explanations for how people learn number meanings. According to associationism, number signs acquire meaning by being associated with particular numerosities. In associationism, learning number signs doesn't actually change intelligent action because there is no principled connection between number words; this is a fundamental weakness of associationims. Attempts to deal with this weakness (e.g., Carey, 2004) led to a move away from associationism, because such attempts introduced the idea of change in the child's thinking structures, but the idea of thinking structures is incompatible with associationism. In our view (Nunes and Bryant, 2022a and 2022b), a representational theory of number meanings provides an alternative to associationism and a good description of how signs change intelligent action. When children realize that, as they count (i.e., use number signs) they are adding objects to the already counted group, they can explore the consequences of the action schemas of joining, separating and setting in one-to-one correspondence for relations between numbers of objects in collections.

Two distinct, even though correlated, mathematical abilities are related to each of the two meanings of number: quantitative reasoning and arithmetic. Because arithmetic has maintained such a prominent role in school mathematics, the teaching of quantitative reasoning has received comparatively little attention. In the two final sections of this paper, the focus is on quantitative reasoning and possibilities as well as obstacles to its teaching in school.

3. What are the Basic Types of Relations between Quantities that Students Need to Master in Primary School?

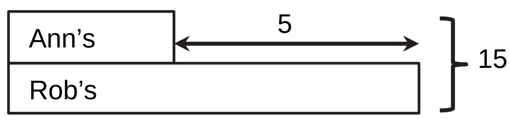
In order to think more about quantitative reasoning, it is useful to start from a classification of the types of relations between quantities that students need to master in primary school. Previous classifications by different researchers (e.g. Harel et al., 1994; Nesher, 1988; Vergnaud, 1983) have distinguished between additive and multiplicative reasoning. The distinction between these two types of relations between quantities becomes crystal clear when one considers the action schemas as well as the logical relations involved in understanding additive and multiplicative relations. Because these are the two types of relation between quantities that are crucial for learning mathematics in the first eight years in school, it is vital that research and teaching identify and promote each of these forms of reasoning. However, as Thompson et al. (2003) pointed out, there is still a school of thought that considers multiplication as repeated addition, an approach to teaching multiplication that seems to rest on the assumption that children's intuitions about multiplication is inevitably grounded in repeated addition. Teaching multiplicative reasoning as repeated addition obscures the difference between the two types of relation between quantities.

In our view (Nunes et al., 2015a), additive reasoning is grounded in the logic of part-whole relations between quantities, which in turn is anchored in the action schemas of joining, separating, and setting items in one-to-one correspondence. Multiplicative reasoning is grounded in the logic of a fixed ratio between quantities; the action schema that provides a source for understanding ratio is setting items in one-

Additive Reasoning

- Together Rob and Ann have 15 books (a sentence about a quantity)
- Ann has 5 books fewer than Rob (a sentence about a relation, which can be rephrased as Rob has 5 more books than Ann).
- How many books does each one have?

A diagram that shows part-whole relations between quantities



Multiplicative reasoning

- Together Rob and Ann have 15 books (a sentence about a quantity)
- Rob has twice as many books than Ann (a sentence about a relation, which can be rephrased as Ann has half the number of books that Rob has)
- Together they have 15 books.
- How many books does each one have?

A diagram that shows a fixed ratio relation between quantities

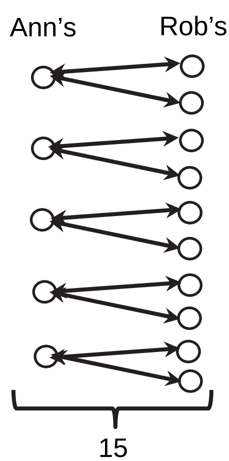


Fig. 2. The quantities in these problems are represented by the same numbers, but the relations between quantities are different. A part-whole representation of the multiplicative reasoning is possible, but conceals the fixed ratio between the two quantities.

to-many correspondence. Fig. 2 contrasts additive and multiplicative relations in problems that use the same numbers and that might seem rather similar to students, but can be solved by means of different action schemas. The diagrams used in the figure help to sharpen the contrast between the two types of relation between quantities and also illustrate how the use of a part-whole diagram is inappropriate to represent fixed ratios between quantities.

Much research has shown that 5 and 6-year old children can solve additive reasoning problems before school by using joining and separating schemas; comparison problems, which require setting items from two collections in one-to-one correspondence, are solved later (e.g. Carpenter et al, 1982; Ryley et al., 1983). Research also shows that from about the same age, children can solve multiplicative reasoning problems using the action schema of one-to-many correspondence before they have been taught about the operations of multiplication and division in school (e.g., Becker, 1993; Corea et al., 1998; Frydman et al., 1988; 1994; Kouba, 1989; Kornilaki et al., 2005; Mulligan, 1992; Mulligan et al, 1997; 2009; Nunes et al., 2008; 2010; Park et al., 2001).

Studies that analyzed children's competence in solving multiplicative reasoning problems have shown that it is critical that problem presentation fosters the use of the one-to-many correspondence schema by offering the children different types of material to represent each of the two quantities that have to be set in a fixed ratio (e.g. Ellis, 2015; Nunes et al., 2010; Piaget, 1952). In one study (Nunes et al., 2008b), children were asked to solve multiplicative reasoning problems of different types (multiplication, sharing and division in quotas) with different unit ratios (e.g., 1:2; 1:3; 1:6) using manipulatives. At the time the study was carried out, schools in England did not include the teaching of multiplicative reasoning in the curriculum until Grade 3; the children participated in this study before this teaching. The children solved three sets of problems under different problem solving conditions. For example, in one problem the children were told a boy had 2 fishbowls and that he could fit 12 tadpoles in each bowl; the task was to figure out how many tadpoles he could have altogether. In one problem solving condition, the children had different materials to represent each of the quantities mentioned in the problem: they had cut-out circles to represent the fishbowls and blocks to represent the tadpoles. In the second condition, they had materials to represent the quantity that was a unit in the ratio: in this example, they had circles to represent the fishbowls and had to imagine the tadpoles. In the third condition, they had materials to represent the second quantity in the ratio: in this example, they had blocks to represent the tadpoles and had to imagine the fishbowls.

The problems were systematically paired with each problem solving condition across children to control for problem difficulty; the order of problem solving condition varied systematically across children to control for practice effects. Fig. 3 presents the difference in mean accuracy as a function of problem solving condition.

The mean accuracy differed across the conditions: the children performed best when they had different materials to represent each of the quantities, even though they had not received instruction in solving multiplicative reasoning problems in school. This result was replicated subsequently by Ellis (2015) with younger children in their first year in school, after multiplicative reasoning problems with the support of materials became part of the English National Curriculum.

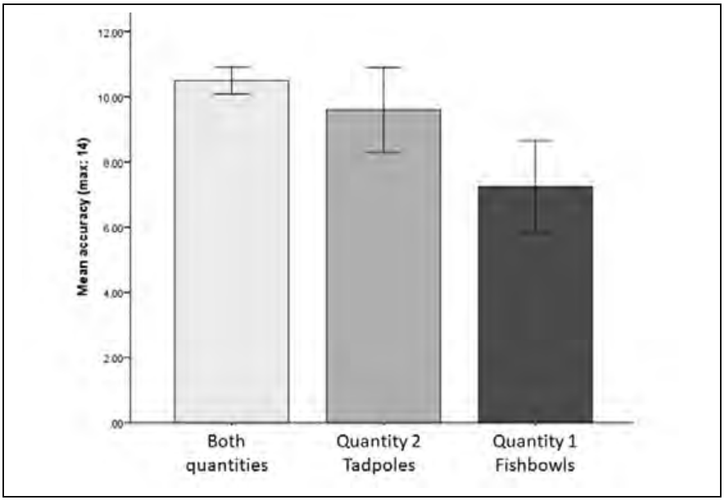

Fig. 3. Mean number of correct responses to multiplicative reasoning problems as a function of type of material that was offered to the participants to support their reasoning. Error bars represent 95% confidence interval.

In summary, even before learning about arithmetic operations in school, children can reason about relations between quantities in action. It seems common practice to encourage young children in pre-school and at the start of primary school to solve simple additive reasoning problems, but quantitative reasoning about multiplicative relations often receives little if any attention in the early years. It is possible that the belief that multiplicative reasoning stems from repeated addition is at the root of the negligence of such an important action schema in the education of young children, because it is expected that children require much practice with addition before they can start to think about multiplication. It is also possible that previous lack of awareness of the need to offer children different materials to represent the different quantities in a ratio led to the belief that young children cannot reason multiplicatively. Independently of the explanation for the neglect of teaching multiplicative reasoning in the early years, there is now plenty of research to show why it is important to include problems that involve part-whole and ratio relations in young children's mathematics education and how this can be done. I now turn to how schools can promote the use of action schemas to foster quantitative reasoning in primary school.

4. How can Schools Promote Children's Thinking about Relations between Quantities?

Even though research has shown that it is possible to cultivate students' quantitative reasoning from the time they start primary school (Nunes et al., 2007) and that this improves their learning of mathematics, quantitative reasoning has not been a traditional focus of teaching in schools (Thompson, 2011). It is now recognized that traditional mathematics curricula do not necessarily promote quantitative reasoning (Agustin, 2012; Gläser et al., 2015) and that there is an important place for quantitative reasoning in mathematics and science education (Elrod, 2014; Mayes, 2019; Panorkou et al., 2021; Smith et al., 2007). It is therefore crucial that teachers find methods to implement this new practice across the years in primary school. In this paper, some critical pointers to effective practice are presented briefly; Nunes et al. (2022a) reviewed research that documented the effectiveness of these pathways to promoting quantitative reasoning.

Encouraging the use of action schemas to solve problems: Young students aged 5-7 years can solve a variety of quantitative reasoning problems in action. Teachers can encourage students to use action schemas to solve problems by providing appropriate representations that can be manipulated (Fig. 3 for the analysis of manipulatives used in multiplicative reasoning problems). When students do not seem to know how to start, teachers can suggest a starting point: for example, they can suggest “pretend these are the … in the story” or ask “show me what happened in this story: how did it start?”

Schemas of action are characterized by being applicable in a variety of situations; thus teachers can rely on manipulatives (e.g. cut-out circles, rectangles, blocks, tokens) as representations for different objects (e.g. fishbowls, cars, children, balloons) mentioned in different problems. Students become more confident when they use the same action schema, such as one-to-many correspondence, in the context of different activities (e.g. arranging children in cars to go to the zoo; placing balloons in correspondence with children who are going to a party; paying the same amount of money for each chocolate bar; sharing pencils fairly among children; figuring out how many children can sit in a hall where there is a fixed number of chairs around a table). They have the opportunity to explore the action schema from different perspectives and to start to represent it in words, which leads to a greater awareness of the action schema’s organization and utility.

Reflecting about the consequences of actions in situations and using the action schemas forwards and backwards: Joining and separating are schemas of action; addition and subtraction are arithmetic operations. In order to take the step from thinking through action schemas to using thinking based on arithmetic operations, students need to understand addition as the inverse of subtraction and vice versa. The research literature has documented the difficulty of thinking of operations as the inverse of each other in problem solving (e.g., Brown, 1981; Booth, 1981) and it has also shown that there are effective approaches to support students to reflect about the inverse relations between operations (e.g., Fong et al., 2009; Nunes et al. 2008; 2009; Schneider et al., 2009; Squire et al., 2003).

Reflection about solutions obtained through action is facilitated by discussion, which requires the students to describe what they did in language and to articulate their thinking in words. Metacognition, i.e., thinking about one’s own thinking, plays an important role in promoting students’ thinking about relations between quantities (e.g.

Garofalo et al., 1985; Kramarski et al., 2002; Lamon, 1993; Lee et al., 2014; Schoenfeld, 1987).

From actions to drawings and diagrams: It is vital that schools promote thinking in action and it is just as essential that they help students to take the step from active to iconic (i.e. using drawings and diagrams) representation and then to symbolic representations. The step from action to drawing might seem very small to an adult, but it has an impact on students' problem solving performance. In one study carried out in London schools (Kornilaki, 1999), 5- and 6- year old children were shown rectangles that represented hutches and told that there 4 rabbits in each hutch; the students' task was to take the right number of food pellets (represented by tokens) from a box so that each rabbit could have one food pellet. Students' performance was quite good: 68% of the 5-year olds and all the 6-year olds took out the right number of tokens from the box. In another study carried out in the same schools (Watanabe et al., 2000), 6 and 7-year olds were presented with a similar problem, but this time there were no manipulatives: the students were presented the problem by means of drawings and asked to present their answers in drawing. Fig. 4 shows the item presentation and a students' response.

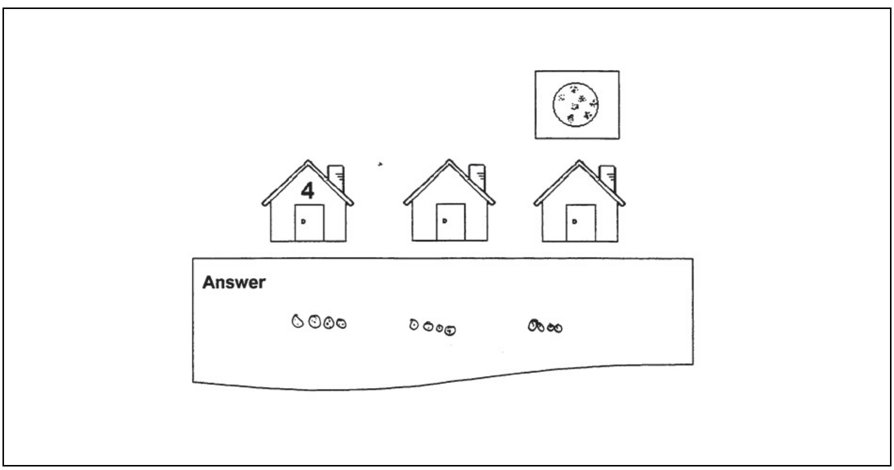

Fig. 4. The problem: In each house live 4 rabbits. They like carrot biscuits, like the one in the top box. Draw the right number of carrot biscuits so that each rabbit can have one biscuit.

In spite of the similarity in the problem, in the task presented by means of drawing the students' performance was much lower than in the task with manipulatives: 52% of the 6-year olds and 68% of the 7-year olds answer correctly. Thus it is important that schools support students in the transition from solving problems in action to solving problems using drawings and diagrams.

Drawings and diagrams are arguably a means towards abstractions of relations between quantities (Gravemeijer, 1997) and have been used widely to support quantitative reasoning in problem solving (e.g., Brooks, 2009; Csíkos et al., 2012;

Gravemeijer et al, 1990; Streefland, 1997). It is a central hypothesis in the Singapore Model Method Ang, 2001;2015; Kho et al., 2014; Ng, 2009; Yoong et al., 2009) and of the Tape Method used in Japan (Murata, 2008; She et al., 2022). There is much research about the use of drawings and diagrams, but relatively little emphasis on the distance between solving problems in action and using drawings and diagrams.

Drawings and diagrams can be used to extend students' reasoning to novel and rather problems. Cartesian or product of measures problems have been found to be significantly more difficult than the type of multiplicative reasoning problems presented earlier on in the paper (Brown, 1981; Vergnaud, 1982). However, they can be solved by the same action schema of one-to-many correspondence with some support. Figure 5 shows an example of a diagram used to encourage students aged 10–11 years to extend their multiplicative reasoning to Cartesian problems (left). Students who participated in this program initially had cut-out shapes to solve Cartesian problems and were later encouraged to use drawings and diagrams. At the end of the program, they used the same approach to describe the sample space in probability problems (Nunes et al., 2014).

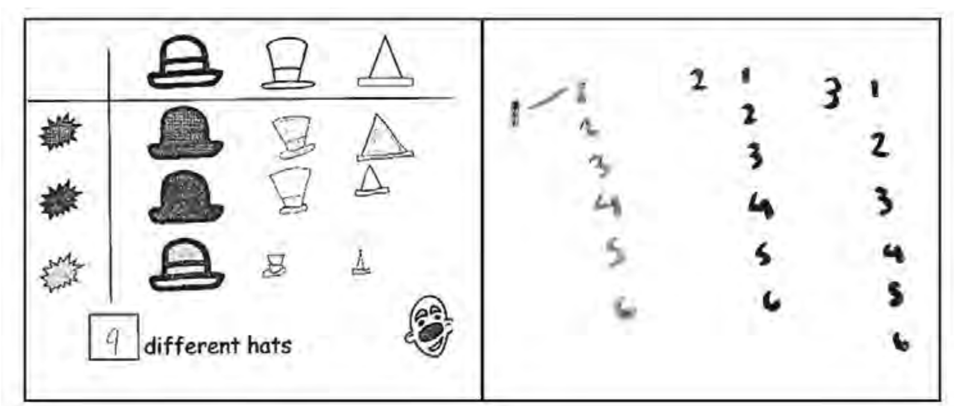

Fig. 5. Left - the problem and a student's production: A shop that sells hats lets the client choose from three different materials and three different shapes of hats. How many options does the clown have to choose from? Right – the problem and a student's production: When you throw two dice and add the numbers, is there one total that is more likely to come up than all the others?

5. Summary and Conclusions

This paper starts from the recognition that mathematical modeling is a form of intelligent action grounded in cultural mathematical practices. The aim of the paper is to explore what this assumption means for learning mathematical modeling from the perspective of developmental psychology. This aim was pursued by considering four fundamental questions. In this final section, I address these questions briefly, without contrasting the theoretical options adopted here with other possible views.

1. What is the origin of intelligence?

The origin of intelligence is in action. Psychological research about intelligent action has documented problem solving by babies before they have learned language. There is little controversy in psychology about the idea that intelligence precedes language. Piaget studied in detail how instincts and reflexes change as they are used and give rise to intelligent action. He adopted the concept of action schema to describe actions that are organized and applicable in a variety of situations and to a variety of objects, allowing the child to think in terms of relations between classes of objects and positions in space. Relational thinking is the essence of intelligent action.

2. How does the learning of numerical signs change children's thinking about quantities?

What happens to children's thinking when language is learned has proven to be hugely controversial amongst psychologists. The controversy starts with how children learn the meanings of words. In this paper, the theory adopted is the one held by eminent developmental psychologists, such as Piaget and Vygotsky, which proposes that word meanings are concepts rather than associations between two stimuli, words and objects. Therefore, children's conceptual development is intimately related to the meanings that they attribute to words. When children learn conventional systems of signs, such as natural language and number systems, they need to master two types of meaning: a representational meaning, that connects the signs to something external to the system of signs, and an analytical meaning, that is defined by the system. In the context of natural numbers, children must learn that, as they count, they are adding: the meaning of each number is based on a relation to the previous number $(+1)$ and also based on a relation to its successor (-1). This relational conception of number meanings implies that any number has an infinite number of analytical meanings (e.g. 8 means $7+1$, $6+2$, $5+3$, $9-1$, $10-2$ and so on).

Mastery of the relational meaning of numbers transforms counting. For example, children become able to count on from the number that represents a hidden group of objects and to count on from the value of a coin; learning the relational meaning of natural numbers means that children no longer need to see the items in order to account for them when trying to find the cardinal of a collection or the total amount of money that someone has. Additive relations between units are represented by natural numbers and ratios are represented by rational numbers. Learning conventional numerical systems empowers children's thinking.

3. What are the basic types of relations between quantities that students need to master in primary school?

In primary school, students need to master two types of relations between quantities: part-whole and ratio. Part-whole relations are additive and rely on students' action schemas of joining, separating and setting items in one-to-one correspondence. Ratio relations are multiplicative and rely on the action schema of one-to-many correspondence. Additive and multiplicative reasoning have distinct origins and students can be helped to recognize their difference from an early age by solving both additive and multiplicative reasoning problems in action.

4. How can schools promote students' thinking about relations between quantities?

Research has shown several ways in which schools can promote students' thinking about relations between quantities. The first step is to engage students in thinking in action: modeling a variety of story problems with manipulatives is an important pathway to develop their reasoning about relations between quantities. The next step is to support students' thinking about their problem solving in action. Talking about processes of solving problems enhances metacognition, which in turn promotes further understanding of the problem solving processes. The use of drawings and diagrams is also a pathway towards abstraction. Diagrams aim to capture the essential relations between elements rather than the particularities and support talking about ideas by pointing to aspects of the diagram.

To conclude, it is important to bear in mind that the development of intelligent action based on cultural tools, such as number systems and arithmetic operations, is not an instantaneous process: it takes time and nurturing. Schools are assigned the task and awarded the privilege of promoting students' development, from thinking in action to mathematical models.

Lecture of Awardee 4

Developing the Research Programme on History of Mathematics Teaching and Learning

Gert Schubring[1]

ABSTRACT Having been distinguished by ICMI with the Hans Freudenthal medal for having established the research programme on the history of mathematics education, and this area being relatively new within mathematics education, I thought it adapted to expose in my awardee lecture, in a somewhat autobiographical manner, the development of this research programme, to show its rationales, its methodological challenges and approaches and the relations to mathematics education at large.

Keywords: Mathematics history; Relation to teaching; Research methodology.

1. My Multiple Contacts with Hans Freudenthal

I should like to express my profound gratitude to ICMI for honouring me with its Hans Freudenthal medal. I might use this occasion to mention that I am probably – among the Hans Freudenthal medal awardees — the one who had the most differentiated types of contacts with him.

- My very first contact with him was on mathematics, by studying his results in the theory of Lie algebras, when I was working at the Mathematics Institute of Bonn University for a PhD thesis in mathematics.
- The next contact was a review he had written about the first paper published in 1974 by the group around Michael Otte at the just created *Institut für Didaktik der Mathematik* of Bielefeld University, severely criticising this contribution to the emerging of mathematics education as a scientific discipline. Freudenthal had qualified it as a product of an alleged Bielefeld *Zauberberg* – magic mountain (Freudenthal 1974, p. 124).
- Thereafter, I met him eventually personally at various mathematics education meetings, in particular those organised by Hans-Georg Steiner at Ohrbeck, a conference centre between Bielefeld and Osnabrück.
- At one of these meetings at Ohrbeck, in one of the usual getting together in the evening, I was instigated by him to my research about the history of negative numbers: he had claimed that the conception of negative numbers

[1] 2019 Hans Freudenthal Awardee. Faculty of Mathematics, Bielefeld University, Bielefeld, 33501, Germany. E-mail: gert.schubring@uni-bielefeld.de

had already become settled since the 16th century – a remark which arose my doubts about traditional lore of mathematics history.

- And more recently, I was remarking the lasting influence of his conceptions for realistic mathematics education and its international impact via, in particular, the PISA testing machine (see Schubring 2021).

1.1. How to reach from mathematics to the history of its teaching?

As a first issue of my development I should like to comment upon how one can reach from studying mathematics to research on the history of mathematics education. Let me first report about my studies. I began studying mathematics and physics in 1963, at the University of Mainz (Federal Republic of Germany). In 1965, after having obtained the *Vordiplom* in mathematics and the *Vordiplom* in physics (a kind of intermediate exam), I moved to Bonn University, then a leading German research centre in mathematics. Finishing my studies there in 1969, I obtained the *Diplom* in mathematics — before the deconstruction of the German university structures by the Bologna process, from 1999, a highly valued degree in mathematics. I dare say that I never heard something about the history of mathematics or its teaching.

Shortly later, in 1973, I became a member of the just created *Institut für Didaktik der Mathematik* (IDM), a part of the also recently founded University of Bielefeld – aspiring to revive the research ethos of Wilhelm von Humboldt. There, I worked at first in the group led by Michael Otte — a group constituted of newcomers to mathematics education and thus not prejudiced by traditional conceptions of mathematics education, challenging traditional views and establishing new theoretical perspectives (see Schubring 2018). This group conceived of these perspectives from a strong interest in philosophy and epistemology of mathematics. Thus, there was always an interest present in the history of mathematics, though without any experiences in pertinent research.

The first publication of the group was the study *Zu einigen Hauptaspekten der Mathematik-Didaktik* (Otte et al., 1974). As a theoretical outline, it met an unprepared and rather shocked public. Freudenthal was one who voiced this strangeness (Freudenthal 1974).

My PhD thesis of 1977, on the genetic principle in mathematics education, had already searched historical roots of this prescriptive conception, with its great number of differing representatives, back until the 17th century (Schubring, 1978).

1.2. From ingenious approaches towards research standards

Focussing after finishing the PhD thesis upon historical research, I became aware that I did need professional formation in standards of such research. Happily enough, Bielefeld University itself provided an excellent context for such an extension of my formation. It constituted a highly propitious atmosphere for interdisciplinary research and for new approaches:

- there was the new branch of social history, established within historiography by Hans-Ulrich Wehler (1931–2014);
- there was a proper institute for science studies: the *Universitätsschwerpunkt Wissenschaftsforschung*: with the sociologists Peter Weingart and Wolfgang Krohn, and in particular Peter Lundgreen (1936–2015), a historian of science and technology, who would become an important partner of cooperation;
- their focus of research was the social function of the sciences, history of disciplines, and institutional history of science. All these approaches should become basic elements in my research;
- another sociological theory, which should become important for my understanding of the social functions of science and of education was the systems theory just developed in Bielefeld by the sociologist Niklas Luhmann (1927–1998) (see more below);
- cooperation with my friend Hartmut Titze, professor of history of education, specialised in research about quantitative data of the development of the German educational system.

Thanks to this broad net of connections, communications and cooperation, I had been introduced to methodological approaches for historical research understanding history of science not as a history of ideas, but as a complex system, of interacting sub-systems, which one can call social history of science, focussing in particular on:

- the conceptual development of science;
- processes of discipline-building and professionalisation;
- social supports for science: institutionalisation and career structures in related labour markets;
- priority of access to sources;
- use of quantitative and qualitative methods.

1.3. The first research project

Based on this autodidactic formation for interdisciplinary research, I chose independently, after the PhD, my first research project. It was on history of mathematics, but soon proved to evoke questions needing research into the history of mathematics teaching.

Background was the focus of some research into the history of mathematics in my group at the IDM: this focus was on the interrelation between the poles of research and education. According to my new methodological orientations, I understood the relations between development and application of science as missing and set out to search a subject for a pertinent case study.

In 1978, I chose as subject for such a case study: the projects for creating a Polytechnic Institute in Berlin, in Prussia (between 1817 and 1845), in the context of pure mathematics then there dominating — thus confronting two quite opposed patterns for the practice of mathematics.

Although there had been four phases to create the Institute, all of them had failed. There were several publications about these attempts, but none gave satisfactory reasons for the failures.

Upon searching for the reasons more effectively, it became clear that I should have to analyse the sources intensely and extensively. And for identifying the pertinent sources and for getting access, I am owing very much to the advice by Wolfgang Eccarius (born 1935), who had done important research on the history of mathematics — and he, already too, on the history of its teaching! Meanwhile he turned to studying orchids ...

His paper on the projects was the nearest one to the analysis of sources (Eccarius, 1977), and I learned from it that the major archival document was the volume with the deliberations within the Prussian Ministry of Education. And the archive of this Ministry was preserved, not in Berlin, but due to the last stages of World War II in Merseburg, in the *Deusches Zentralarchiv* of the GDR.

Using an archive in the other German state was rather adventurous at that time. I visited therefore Eccarius, living in Eisenach, in the GDR, in a not really legal manner during a trip to the Leipzig fair, and was generously received and perfectly informed about how to access and how to use files there. Therefore, I became first confronted and then familiar with the reality of working in archives exploring old documents.

The first challenge there was to decipher handwritten manuscripts. This turned out to be really challenging: German people used another script in the 19th century, no longer in use today — I had to learn to decipher texts written in this script unknown to me. The problem became worsened by understanding the practice that the officials wrote their drafts of documents in a type of shorthand script, known to the staff in the bureau who had to transform this into a fair copy which would be sent to the addressee while the draft remained in the ministerial files. See here an example, the last lines of a draft by Johannes Schulze, the powerful official of the Prussian Education Ministry, of 1828 (Fig. 1).

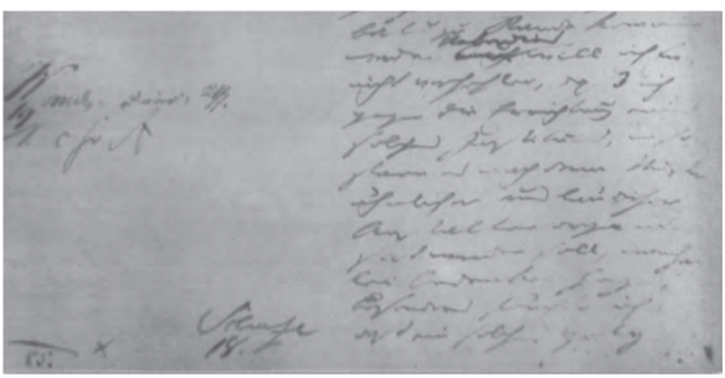

Fig. 1. Example of manuscript draft writing, by Johannes Schulze, in the Prussian Ministry's file on the Plans for the Polytechnic Institute, fol. 2v (Schubring, 1981)

My approach for analysing documents can be called “holistic”: not just searching a few documents in the files, supposedly being the decisive ones, but to assess the files in their entirety. Although it had been quite difficult at that time, I had asked the archive in Merseburg for complete copies of the entire volume regarding the Polytechnic Institute, and of the related volumes in the archives of the War Ministry, and the Commerce Ministry — for not missing any possibly relevant detail. Clearly there did not yet exist the technique to obtain digitalised copies; the standard form were microfilm copies. And paying invoices from the FRG to the GDR implied then quite intricate procedures.

Eventually, I obtained significant results. The major result was to succeed in revealing why all the four attempts for creating a polytechnic institute had failed and, at the same time, why the accounts of the projects given so far had failed, too, in understanding the reasons: August Leopold Crelle (1780–1855), the mathematics advisor of the Ministry, had planned the Institute to promote *pure* mathematics:

> So it is also important that pure mathematics should be explained in the first instance without regard to its applications and without being interrupted by them. It should develop purely from within itself and for itself. For only in this way can it be free to move and evolve in all directions. In teaching the applications of mathematics it is results in particular that people look for. They will be extremely easy for the person who is trained in the science itself and who has adopted its spirit (quoted from Schubring, 1989a, pp. 180f.).

Crelle explained his radical transformation of the nature of a polytechnic institution by a peculiar re-interpretation of the Paris model, claiming it to be: “an institution having as its essential task the training of mathematics teachers” (ibid.).

Thus, the projects eventually were not realised because one became aware that one had already an institution for training mathematics teachers: the universities, reformed in Prussia according to neohumanism!

This principal result led me to a new challenge: Researching the history of mathematics in Prussia, but also in Germany, afforded to investigate the history of the training of mathematics teachers! This led me to then to my second research focus, to the history of mathematics teaching and learning.

1.4. Entering the scientific community

Before addressing this second focus, let me first tell about publishing research results and entering the scientific communities. In fact, there occurred happy sequels of my research upon the never realised Polytechnic Institute: thanks to a circulating first version of my research results, I was invited to the first congress on social history of mathematics, in Berlin, July 1979, organised by three key researchers in mathematics history: Henk Bos, Herbert Mehrtens and Ivo Schneider. There, I had the chance to meet and get in contact with leading researchers in the area, thus establishing communication with the community.

As a result, already a second paper was published, in the Proceedings of this congress, on the conception of pure mathematics, then dominating in Prussia (Schubring 1981a). Moreover, there occurred another happy instance, regarding the publication of my first research. In fact, I was faced with the problem: how to publish as a youngster, without any international publication experience, a paper in good idiomatic English and in a scholarly style? I enjoyed an incredibly strong assistance by the two historians of science Roy Steven Turner and Lewis Pyenson, for the important international journal: *Historical Studies in the Physical Sciences.* There my paper was published in 1981 (Schubring, 1981b).

In continuing now research, I consolidated my research approaches. It proved as essential to have as a clear priority to get access as much as possible to primary sources; and especially for history of science the focus was on using the *Nachlass* of scientists. Actually, it proved that searching the *Nachlässe* had not been so far a major concern of historiography. I dedicated therefore much energy to search and localise *Nachlässe*, either already organised, kept in a library, archive or an Academy, or kept without an inventory, or even being preserved in the hands of some descendant.

1.5. Two major research strands

Based on the methodologies developed and meanwhile improved, and based on the research experiences made, I focused since now on two major research strands. The fist became:

- Analysis of the development of mathematical concepts.

A major issue for this research strand became, instigated by Freudenthal's remark, the history of negative numbers. And this research led me to a new pattern of conceptual research, to "social history of ideas", since the results made me understand that national communities, based on the specific structures of the social systems in their country, proved to practice proper epistemologies.

This conceptual research kept me occupied for over 20 years and resulted eventually in a voluminous book, revealing conceptual development as a contextualised history: *Conflicts between Generalization, Rigor and Intuition. Number Concepts Underlying the Development of Analysis in 17th-19th Century France and Germany* (Schubring, 2005).

2. The Second Research Strand

This second strand became the History of the Teaching and Learning Mathematics. It was based on methodological approaches and on various key results of the first research strand. I should name in particular:

Understanding the history of a school discipline as quite more complex than a scientific discipline, requiring even more an interdisciplinary approach:

- regarding methodology, modern society is structured, according to Luhmann's system theory, as a net of interacting functional sub-system;

- the education system, the labour market with its professional sub-systems, the system of the sciences with its institutions.

Origins: due to my results of research on pure mathematics in Prussia, the basis of pure mathematics practice had proved to be the profession of mathematics teachers in the *Gymnasien* (college) of Prussia.

This origin provoked the question: how did this profession come about? This profession of mathematics teacher turned out to constitute a historical novelty. I led a two-year postdoc project for these researches, 1981 to 1983. Of these two years, summing the days of research in the various institutions, I had spent six months in archives and libraries. The results of this quantitative and qualitative research resulted in the book: *Die Entstehung des Mathematiklehrerberufs im 19. Jahrhundert. Studien und Materialien zum Prozeß der Professionalisierung in Preußen (1810–1870)* (Schubring, 1983, second edition 1991).

Besides studies on the practices of mathematics teaching at Prussian Gymnasia during this period and searching for all kind of documents about mathematics teachers, a major dimension of the project was the evaluation of the teacher examination introduced in Prussia in 1810: to assess, firstly, whether the intention was to have encyclopaedic-qualified and multi-disciplinary practicing teachers or to provide disciplinary-specialised teachers. In the archive of the Prussian Education Ministry, it was preserved the collection of the files of the at first three examination boards (wissenschafliche Deputation), as well as from 1817 the six, and later seven, boards (wissenschaftliche Prüfungskommission) in the university towns. The second assessment was for identifying those who were declared qualified to teach mathematics. The revealing results were that the intention was to provide scientifically trained teachers, and not to continue with the earlier practice of encyclopaedic formation and practice. And it became documented that the — at first abstract — conception of a mathematics teacher was accepted by young people who began to study mathematics in a specialised manner and who qualified as a teacher in an impressively growing manner, thus constituting mathematics teaching as a profession (Schubring, 1991, pp. 126 ff.).

This quantitative analysis was complemented by a qualitative analysis, using the method of prosopography: having identified to "new" mathematics teachers, graduates of specialised studies and the teacher examinations from 1810, and having found also those who had taught mathematics before the reform period, thanks to histories of the older Gymnasia, I undertook it to systematise the profiles of their teaching activities. These profiles allowed it to group the teachers into three subsequent generations:

- those who taught already before the reforms of 1810: in general, without academic studies or with not specialised ones (encyclopaedic), and recruited without an exam;
- recruited since the beginning of the reforms, frequently without an exam, often just with autodidact studies — and frequently with weak teaching success;

- generation (since about 1820) with specialised academic studies and qualified with an exam (ibid., pp. 156).

A last stage of quantitative-qualitative analysis was devoted to the question about school teaching reality, namely whether the teaching of those who taught in the school reality mathematics corresponded to the qualifications attested to them in their exam. I undertook it to assess this question for the Gymnasia in three of the seven Prussian states, in distances of five years for these schools. The results showed a remarkable degree of correspondence between the attested teaching competence and the attributed classroom disciplines (ibid., pp. 147 ff. and especially p. 157).

2.1. Extending the research programme internationally

While my research into history of mathematics and of mathematics teaching at first had been confined to one of the great German states, to Prussia, I extended its reach rapidly, from Germany to an international scope.

A first extension had been to the history of teaching the sciences, in Prussia, too, and then to the other German states. This was due to an invitation to participate at the great project on the German history of education: the *Handbuch der deutschen Bildungsgeschichte,* editors Karl-Ernst Jeismann and Peter Lundgreen. For its volume III, for the period 1800 to 1870, I had been invited to write the chapter on the history of teaching mathematics and the sciences in Germany (Schubring, 1987a).

The first instance to extend the research programme internationally was the invitation by Roland Stowasser, colleague at the IDM, to update an earlier entry in *The International Encyclopedia of Education*, edited by Torsten Husen and T. Neville Postlethwaite, on the history of mathematics teaching. This entry was written together with Christine Keitel and Roland Stowasser (Keitel et al., 1985). The extension to an international vision entailed new methodological problems and approaches.

My aim became increasingly to investigate structural patterns determining general characteristics in order to differentiate them from patterns characteristic for one (or more than one) country.

Thus, I embarked on studying such patterns from the Antiquity, and focussed at first upon comparing France and Germany where the developments in the 19th century had been very different (Schubring, 1984). Thereafter, Italy presented for me a highly revealing case for confronting global patterns with local ones. I had become aware at first of Italy presenting a challenge when I learned that Legendre's geometry textbook had been refused there, since 1860, together with Euclid's *Elements* having been prescribed as a textbook in 1867. The refusal of Legendre's book, having been translated into Italian already various times and praised in all other countries for its rigour, was legitimised by its condemnation due to alleged lack of rigour (Schubring, 1994).

The surprise about Legendre's refusal and the adoption of Euclid was reinforced when I remarked as a problem for conceptualising history of mathematics teaching: all publications by Italians until then on their proper history of mathematics teaching had shared this denunciation of Legendre's textbook (see Vita, 1986, p. 7).

This peculiarity of the Italian case afforded to abandon to be kept within the educational system of one's own country, being no more bound to accept all characteristics of this country as evident and natural, and to be able to rather questioning all what constitutes matters of course of this system and to thus detect them as historical *variables*.

The Italian case made thus even more imperative to reveal social determinants of mathematics teaching: secondary schools in Italy were still functioning according to classicist values. This dominant classical education induced mathematicians to adapting the mathematics taught to the values of classicism.

It proved to be likewise imperative to consider epistemological determinants of the views of mathematics as a school subject. Mathematics was understood in Italy as also rooted in classicist values: geometry should be taught according to the values attributed to the Greeks: geometry as strictly separated from algebra, while Legendre's approach was: mutual support between geometry and algebra (Schubring, 2004).

The cases of the various German states, of France and of Italy led to conceive of research into the history of mathematics teaching and learning, on the one hand, as an interdisciplinary programme and, on the other hand, as an internationally and transversal comparative programme — to unravel, over periods and epochs, structural patterns for the functions of mathematics teaching. As one such rather universal pattern, the two-polar-relation between general education and professional functions had proved to provide an effectively structuring characteristic. My paper delivered at the so-called Fifth day of ICME 6 at Budapest in 1988, which had introduced to consider broader contextual research agendas in mathematics education within the issues of ICME, presented a first conceptualisation of this research programme (Schubring, 1988).

2.2. The traditional research focus analysing textbooks

The traditional practices of studying the history of mathematics teaching was to understand it as collecting facts, easily accessible, conceiving of the history of mathematics instruction as a series of administrative decisions, which supposedly were transformed into classroom practice. According to this perspective, the history basically is a history of the curriculum, of the syllabus, managed by centralist authorities — and transformed into schoolbooks.

The analysis of mathematics schoolbooks used to be restricted to just one book, assuming this should already reveal its meaning within the history of school mathematics. There, I developed a methodology for connecting textual analysis with *con*textual analysis; a first elaboration, with great overall reception is the paper (Schubring, 1987b).

This approach, which thus means a hermeneutical one, was established at first for one author, Sylvestre-François Lacroix (1765–1843), in his time the dominant French textbook entrepreneur, where I proposed to investigate the production along three dimensions, for contextualising the respective schoolbook — already understood not as an isolated document, but as an element in a series of editions, which indicate already changes requiring understanding:

- the first dimension consists in analysing the changes within the various editions of one textbook chosen as a starting-point, say an algebra textbook or an arithmetic one;
- the next dimension consists in finding corresponding changes in other textbooks belonging to the same *œuvre,* by studying those parts dealing with related conceptual fields, say geometrical algebra, trigonometry, etc.,
- the third dimension relates the changes in the textbooks to changes in the context: changes in the syllabus, ministerial decrees, didactical debates, evolution of mathematics, changes in epistemology, etc. (Schubring, 1987b, p. 45).

I developed this methodology, further — as of hermeneutical textual analysis, being contextualised in the respective educational system and the development of the mathematical knowledge, related to its respective elementarisations.[2] This proved to become a general approach, practiced in my endeavour of a first historical analysis of mathematics textbooks, from Antiquity, over periods and cultures (Schubring, 2003).

2.3. International establishment of the research programme

The systematic development of this research programme for international, comparative analyses, well disseminated and received by books, chapters and papers in journals, turned into a broad international area of research.

A decisive step for this new degree was enhanced at ICME-10, in Copenhagen, in 2004. Its president, Mogens Niss, proposed a new Topic Study Group, on the history of mathematics teaching and learning. I was called as one of the co-chairs. The TSG worked very successfully, and became a permanent TSG, realised at each ICME since then. As a thematic issue of the journal *Paedagogica Historica*, the main contributions of the TSG at ICME 10 were published, in 2006.

This first international event meant the take-off for the research programme. Already in 2006, the first international journal dedicated to it was launched: the *International Journal for the History of Mathematics Education*, IJHME (Fig. 2).

[2] This can be called the objective hermeneutics following its founder in philology, Friedrich August Wolf, and in philosophy Friedrich Daniel Schleiermacher; it should not be confounded with what one call subjective hermeneutics — from Wilhelm Dilthey to Hans-Georg Gadamer, aspiring only a personal sense-making and empathy (see Schubring, 2005, pp. 4).

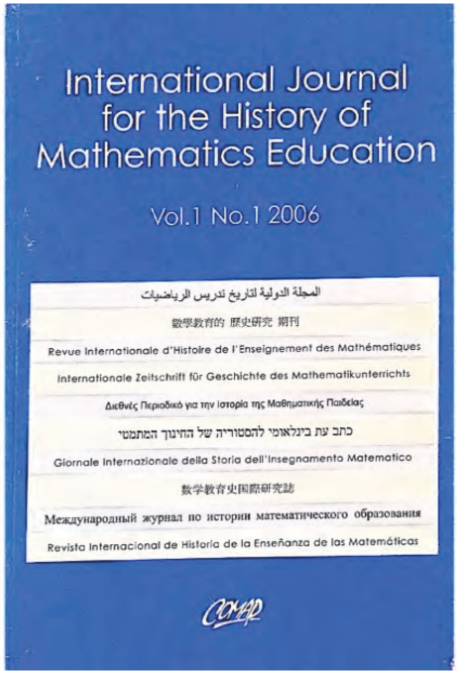

Fig. 2. Cover of the first issue of IJHME

And in 2009, Fulvia Furinghetti and Kristín Bjarnadottir launched the first *International Conference on the History of Mathematics Education*, ICHME. It took place in June 2009 in Reykjavik, Iceland. ICHME became a series, realised bi-annually. So far, there have been six ICHMEs:

- ICHME 2: Lisbon, Portugal 2011,
- ICHME 3: Uppsala, Sweden 2013,
- ICHME 4: Torino, Italy 2015,
- ICHME 5: Utrecht, The Netherlands 2017,
- ICHME 6: Luminy, France 2019

ICHME 7 is planned, due to the pandemics, for September 2022, in Mainz, Germany. Proceedings were published for each of the ICHMEs, with the recurring title *Dig where you stand*.

The most significant sign for the consolidation of the research programme was the publication of the *Handbook on the History of Mathematics Education*, edited by Alexander Karp and Gert Schubring. It presents the history from Antiquity till the end of the 20th century, according to cultures and periods, in 35 chapters, resp. sub-chapters.

The latest development in this international research area is the establishment of the series, in 2018: *International Studies in the History of Mathematics and its teaching*. So far, the following volumes were published in the series:

- Gert Schubring (ed.), Interfaces between Mathematical Practices and Mathematical Education. Cham: Springer, 2019.
- Alexander Karp (ed.). National Subcommissions of ICMI and their Role in the Reform of Mathematics Education (Cham: Springer, 2019).
- Évelyne Barbin, Marta Menghini and Klaus Volkert (eds.), Descriptive Geometry, The Spread of a Polytechnic Art (Cham: Springer, 2019).
- Alexander Karp (ed.), Eastern European Mathematics Education in the Decades of Change (Cham: Springer, 2020).

2.4. Recent dimension: relations between coloniality and decoloniality

This new aspect is instigated by a major break in the history of mathematics teaching: the ex-colonies reflecting which mathematics teaching did their colonial powers import and which are they needing? In this decolonialising movement, there has been a conviction, as a complement to the usual assumption of a universality of mathematics, a likewise universality of Western school mathematics was assumed, despite relating that each colony had to follow its respective metropolis, while not being aware of the significant differences between the educational systems of the metropoles and thus also of their conceptions of mathematics teaching:

> During the colonial period, the school system was patterned exactly after that of the colonising country. The norms of fit between school and society were quite precise: the school system was to come as close as possible to that of the mother country. It should produce graduates that would fit into the civil service and who would do well in universities in the mother country. With independence the above norms of fit between school and society were seen with mixed feelings. Leaders became conscious that a school system developed according to such norms would, among other things, simply contribute to the brain drain. They also became conscious that the school system had to respond to different cultures and classes in the country: a westernized elite, a growing lower middle class, urban workers, a traditional rural sector (Bienvenido Nebre, 1988).

Despite not being aware of the metropoles' decisive differences regarding social strata and hence regarding mathematics curricula, this was a first document calling for the necessity of decolonialising the teaching conceptions in the former colonies of the imperialist powers. It should be mentioned that there is also a widespread conviction of a global uniformity of the mathematics curriculum. The Finnish mathematics educator George Malaty is maintaining this:

> Till the end of the school year 1957/1958 school mathematics was quite the same everywhere. Primary school mathematics mostly consisted of arithmetic. Secondary school mathematics was mostly algebra and plane Euclidean geometry, and in the upper grades algebra, analytic geometry, solid Euclidean geometry and

trigonometry. In the 1950s calculus teaching spread in upper secondary school (Malaty, 1999, p. 231).

According to Malaty, diversity began as a consequence of the Sputnik shock and the ensuing modern mathematics movement launched by the Royaumont Seminar in 1959. There is likewise a widespread opinion that modern mathematics affected all countries in the same way.

There are examples of decoloniality practices in former colonies. For a certain time, after independence in 1975, schoolbooks in Mozambique evidence these approaches (Fig. 3). Yet, these achievements need not to persist. Pressures by the World Bank and International Monetary Fund are exerted on developing countries for "liberating" their national schoolbook market to international publishers, in order to obtain grant development aid funds (Schubring, 2017).

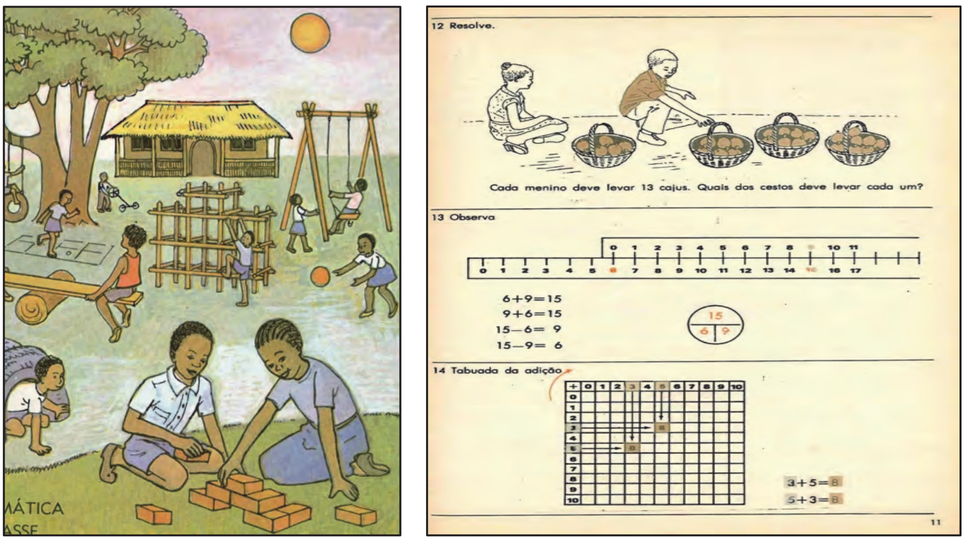

Fig. 3. Left: Cover of Draisma et al., *Eu gusto de Matemática*. Classe 2. 1984; right: ibid., p. 11.

And there are even rather global new coloniality pressures. they are exerted by the Organisation for Economic Cooperation and Development, OECD. This organisation, created by the USA after World War II to reconstruct the "West" as a fortress against the "East", and thus practicing politico-economic agendas also for the international education sector, is acting decisively for homogenising the mathematics curriculum globally, via pressures to the member governments to achieve good results in the international ranking established by the PISA test achievements (see Schubring, 2021).

I should like to mention here an excellent research project upon coloniality and decoloniality: a research into the history of mathematics teaching in French colonial times and in Khmer post-colonial times in Cambodia, by Sethikar SamAn (2018).

Fig. 4. Cover of Ramus's 1569 book

3. Closing Remarks

I should tell you that I have a dream: to edit the first book ever published on teaching of mathematics. This was the book published by the French Petrus Ramus in 1569: *Scholarum Mathematicarum Libri Unus et Triginta*, distinguished by the methodical critique of Euclid's *Elements*, as not suited as a textbook for teaching (Fig. 4). It inaugurated the special French way of conceiving of teaching geometry, differing from other European countries. The voluminous book, with 320 pages, written in Latin, but with many Greek terms inserted, is difficult to read due to the many abbreviations used then by printers to economise casting letters.

Lecture of Awardee 5

Advocating for High Quality Mathematical Access for Each and Every Child: Our Collective Work, Our Passion, and Our Future

Trena Wilkerson[1]

ABSTRACT It is imperative that we advocate for the highest quality mathematics for each and every student across the world. All students must have access to mathematical learning experiences that will prepare them for success not only in the classroom but also to lead our world in the future. While we have seen much progress in mathematics education over the last 30 years, we continue to face significant challenges related to access. Disparities in learning opportunities based on race, ethnicities, class, language, gender, and perceived mathematics ability are far too prevalent in school mathematics—this has been made more evident during the COVID-19 pandemic. We must address these disparities to ensure equitable mathematical opportunities for each and every student. The National Council of Teachers of Mathematics identifies four key recommendations that serve as a catalyst for change to launch each and every student on a successful journey with mathematics. These are discussed in this paper.

Keywords: Advocacy; Teaching practices; Mathematical understanding

1. Introduction

The National Council of Teachers of Mathematics (NCTM) is honored to receive the International Commission on Mathematical Instruction (ICMI) Emma Castelnuovo Award for Excellence in the Practice of Mathematics Education. It is an honor to receive such a prestigious award that was named after Emma Castelnuovo, an Italian mathematics educator, to honor her pioneering work in mathematics education. Her work aimed at a way of teaching that actively engaged students, marked a key point in history for teaching and learning mathematics that fostered a discovery learning environment for all students from elementary through university. NCTM is honored to continue to build on this legacy so that each and every student has an engaging, high-quality experience in learning mathematics.

[1] The 2020 Emma Castelnuovo Awardee: National Council of Teachers of Mathematics (Trena Wilkerson as the President). Council of Teachers of Mathematics. Reston, Virginia USA; Department of Curriculum & Instruction, Baylor University, Waco, Texas 76798, USA. E-mails: twilkerson@nctm.org; Trena_Wilkerson@Baylor.edu

As President of the National Council of Teachers of Mathematics, I would like to thank The United States Commission on Mathematics Instruction, chaired by John W. Staley for submitting the nomination of NCTM for this award. The U.S. Commission includes Solomon Friedberg, James Roznowski, James Barta, Marta Civil, Robert Gould, Maria Hernandez, Ilana S. Horn, Chris Rasmussen, Padmanabban (Padu) Seshiyer and April Strom. In their nomination they highlighted four continuing priorities in NCTM's work:

- NCTM has served the mathematics education community (nationally and internationally) for 100 years by providing leadership, publications and resources, professional development, and networking opportunities.
- NCTM has served its membership by supporting and growing educators and involving them in many of the organization's initiatives and projects, and providing various opportunities to develop members' leadership skills.
- NCTM continues to advocate for high-quality mathematics teaching and learning for each and every student. This advocacy extends to the work that helps educators who choose to advocate with their elected officials and policymakers. And
- NCTM continues to build and value collaborative relationships with educators throughout the world.

The U.S. Commission noted that the National Council of Teachers of Mathematics is the public voice of mathematics education, supporting teachers to ensure equitable mathematics learning of the highest quality for each and every student through vision, leadership, professional development, and research. We also are grateful for the multiple letters of support that were included in the nomination.

Our thanks also goes to the International Commission on Mathematical Instruction for awarding the 2020 Emma Castelnuovo Award to the National Council of Teachers of Mathematics. I would like to thank Dr. Jill Adler, President of the International Commission on Mathematical Instruction. It was an honor for NCTM to receive notification of the 2020 Emma Castelnuovo Award from Dr. Adler in October of 2019. I also thank Professor Konrad Krainer, Chair of the Emma Castelnuovo Awards Committee and the entire committee for their work in reviewing nominations. We are honored.

NCTM's work in mathematics education is consistent with International Commission on Mathematical Instruction's principles:

- The development of mathematical education at all levels; and
- The promotion of reflection, collaboration, exchange, and dissemination of ideas on the teaching and learning of mathematics from the primary to the university level.

NCTM's mission is to advocate for high-quality mathematics teaching and learning for each and every student from early childhood through secondary school and beyond. NCTM includes mathematics educators from preschool, elementary, middle grades, high school, universities and colleges across the United States and

Canada and 171 other countries across the world with over 30,000 members and more than 230 Affiliates. NCTM also established the International Corresponding Societies (currently 19 organizations with representatives from South and Central America, Europe, Asia, Africa and Australia) to build ties with professional associations of mathematics education in other countries. In addition, NCTM has supported several initiatives with educators in Latin, Central, and South America.

I would like to take this opportunity to recognize Ken Krehbiel as Executive Director of NCTM. He has provided professional leadership for the organization for over 20 years. He has guided NCTM in multiple efforts to further the mission and vision of the organization. I also want to acknowledge the work and leadership of Dr. Robert Q. Berry, III who was NCTM President at the time of the nomination and continues as Past President. Dr. Berry is an accomplished writer, researcher, presenter, and leader in mathematics education. It was in his role as president-elect that NCTM's Catalyzing Change initiative for high school was launched under the leadership of then NCTM President Matt Larson. Dr. Berry has expanded the initiative to address early childhood, elementary and middle school levels. I was fortunate to be in the position of president-elect at that time to work with him and the other outstanding writers on the Catalyzing Change position and series of publications. It is this initiative, *Catalyzing Change in Mathematics* to which I would like to devote the remainder of this paper.

2. Advocating for High-Quality Mathematics Teaching and Learning

Let us consider our role and responsibility in advocacy for high quality mathematics teaching and learning. It is imperative for our profession that we advocate for the highest quality mathematics for each and every student across the world. All students must have access to mathematical learning experiences that will prepare them for success not only in the classroom but also prepares them to lead our world in the future. While we have seen much progress in mathematics education over the last 30 years, we continue to face significant challenges related to access. Disparities in learning opportunities based on race, ethnicities, class, language, gender, and perceived mathematics ability are far too prevalent in school mathematics — this has been made more evident during the COVID-19 pandemic. We must address these disparities to ensure equitable mathematical opportunities for each and every student. How can we do that? To that end, NCTM gathered writing groups to examine how we can address the issues we face today and move forward in the teaching and learning of mathematics for all. *Catalyzing Change* moves this conversation forward by focusing on structural policies, engaging in conversations on the purposes of school mathematics, and sustaining a focus on sense-making and reasoning.

2.1. Catalyzing change in early childhood and elementary mathematics

Why do we need Cata*lyzing Change* in early childhood (NCTM, 2020a)? We know that children's growth in mathematical knowledge in kindergarten and first grade is a strong predictor of later mathematics success. Mathematics instruction in early childhood and elementary school often places too much emphasis on memorizing basic number facts and following procedures at the expense of developing deep conceptual understanding. And mathematically powerful instruction in early childhood and elementary school is reaching too few children, particularly those most marginalized in our society. This leads to differential and unjust mathematics learning environments and outcomes (Adair 2015).

2.2. Catalyzing change in middle school mathematics

Why do we need *Catalyzing Change* at the middle grades level? At the middle grades level structures and traditions in mathematics education are deeply rooted. We must reconsider legacy practices and structures impacting students' mathematical identities and sense of mathematical agency (NCTM, 2020b). Instructional practices must be examined in order to systemically support, enhance, and adopt practices that are equitable and provide high-quality learning opportunities to motivate and engage students in learning. The evidence is compelling that students who are identified as marginalized learners based on certain ethnicities, Indigenous populations, language learners, poor, or those with disabilities do not have the same access to a high-quality mathematics program as their peers.

2.3. Catalyzing change in high school mathematics

Why do we need *Catalyzing Change* at the high school level? We are finding that in the United States the percentage of high school students enrolling in upper-level mathematics courses over the last three decades has increased (Dossey, McCrone, and Halvorsen, 2016). This is good, but there are major gaps on who has access to those courses and who does not. There is a concern over opportunity gaps and actions that are needed to support each and every high school student. It is an issue of access. There are times that the sheer amount of content expected to be addressed in high school is seen as a deterrent to addressing the desired level of rigor that is needed. Further, it is imperative that we have a high school mathematics experience for our students that prepares them for future college and career opportunities, particularly related to STEM fields, that is the fields of Science, Technology Engineering, and Mathematics. Thus, it was important to consider what changes were needed and how these might be addressed (NCTM, 2018).

3. Recommendations Serving as a Catalyst for Change in Mathematics

It is important to initiate these critical conversations and consider next steps and actions that are needed. As noted previously, NCTM began in 2018 with *Catalyzing Change in High School Mathematics: Initiating Critical Conversations* and followed in 2020 with the publication of *Catalyzing Change for Early Childhood and Elementary Mathematics* and then *Catalyzing Change for Middle School Mathematics.* Together these outline four key recommendations that serve as a catalyst for change to launch each and every student on a successful journey with mathematics. They are

(1) Broaden the Purposes of Learning Mathematics;
(2) Create Equitable Structures in Mathematics;
(3) Implement Equitable Mathematics instruction; and
(4) Develop Deep Mathematical Understanding.

While the four recommendations span the grade bands, they vary slightly in focus depending on the grade band. Let's unpack these four recommendations and consider what critical conversations we need to have that will lead to actions to address these recommendations. Consider who we should engage in those conversations. Who are our partners and stakeholders in mathematics education?

3.1. Recommendation #1: broaden the purposes of learning mathematics

For all grade levels there are three major areas of focus: develop a deep understanding of mathematics, understand and critique the world through mathematics, and experience the wonder, joy and beauty of mathematics with developing as confident and capable learners and contributing to a positive mathematics identity as central.

The early childhood and elementary authors note that "The power of the multiple purposes occurs when the purposes converge in ways that foster positive relationships between children and mathematics. The goal is for children to see themselves in the world of mathematics, not looking in from the perimeter or looking for the nearest exit door" (NCTM, 2020a, p. 23). We should also note that the mathematics students learn during middle school includes many of the most useful mathematics concepts that students will use as adults. "Middle school mathematics programs must challenge students to reason, and, most important, they must be respectful of students' distinctive cultural and developmental needs and interests" (Gutstein, 2003; Liptstitz and West, 2006; Lounsbury, 2015 as cited in NCTM, 2020b, p. 7). The purposes have to do with empowerment. Preparing learners for their future education and employment-opening and expanding opportunities. As students transition to high school, we need to remember that "A multipurpose high school mathematics curriculum plays a critical role in the cultivation of students who become fully engaged members of society, who contribute to society in positive ways and who become human beings capable of achieving their full potential, personally and professional, through the intellectual experiences of their mathematics education" (NCTM, 2018, p. 12–13).

Each and every learner should develop deep mathematical understanding, be able to use mathematics to understand and critique the world, and experience the wonder, joy, and beauty of mathematics. I challenge us to consider what short- and long-term work needs to be done toward achieving this vision of broadening the purposes of learning mathematics. That is, what can we do now and what can be done over time? This is an important, critical conversation to have.

3.2. Recommendation #2: create equitable structures in mathematics

Across grade levels we need to dismantle and attend to inequitable structures such as ability grouping and tracking of students and teachers, and challenge spaces of marginality and privilege that exclude many students from high-quality learning opportunities in mathematics. These may vary or look different across our countries, but we all need to carefully examine our structures that support or may be deterring the teaching and learning of mathematics. We need to position students as competent, confident, and capable learners and doers of mathematics affirming their strengths every day in ways that cultivate positive mathematical identities and a sense of agency.

As students move from early grades to middle school, they continue to build their mathematics identity. We need to continue to support their positive mathematics identity as they develop in their mathematical thinking and explore their world through mathematics. One's mathematical identity continues to develop from adolescence to adulthood. Our continual affirmation of students' positive mathematical identities through their learning experiences, building on their strengths will support them in developing strong and resilient positive identities (NCTM, 2018, 2020a, and 2020b).

We need to examine our own deficit-based beliefs about students or their families and communities and ensure that we truly believe that all students can and should do mathematics. Are there ways that we are grouping students that limit their access to high quality mathematics instruction and opportunities for deep understanding of mathematics? Are there historical, cultural or social beliefs about our students' mathematical abilities contributing to inequitable practices and opportunities in mathematics. Are structures in place that inhibit student learning in mathematics?

I encourage us to ask ourselves: What supports are needed in schools, districts, states/provinces, or our countries to discontinue inequitable practices such as ability grouping, tracking, and dead-end course pathways where students' opportunities for learning mathematics are limited and not always of high quality and inclusive? Have we considered our curriculum, instructional resources, assessment practices and professional development and support for our teachers? What work is needed to make sure all students — and specifically those often traditionally marginalized — have equitable structures in place to support their mathematics learning? Actions might include identifying, analyzing, and evaluating policies and practices to assess the impact of tracking; providing each and every student access to grade-appropriate intellectually challenging curriculum; providing ongoing professional development and support for our teachers; and providing time and space for educators to collaborate (Berry, 2018).

3.3. Recommendation #3: implement equitable mathematics instruction

"Teachers and their instructional practices have strong influences, often far greater than one realizes, on children as they learn mathematics" (NCTM, 2020a, p. 45). Equitable mathematics instruction requires that teachers take direct action stemming from intentional planning and reflection informed by data from their students (NCTM, 202b). We should approach through asset, strengths-based perspectives and not deficit views of students and their learning. Our instructional practices should be dedicated to implementing equitable instruction that engages all students in learning mathematics. Students bring multiple strengths to the mathematics learning experience. They begin formal school eager and ready to learn, and with multiple strengths from their daily learning experiences. These strengths continue to grow if nurtured in both formal and informal learning environments. We need to identify, foster and value these strengths, support students as thinkers and doers of mathematics, and leverage students' experiences, cultural perspectives, backgrounds, languages, and interests. This strengths-based approach will facilitate deepening mathematical understanding, helping students make sense of their world through mathematics.

In 2014 NCTM published *Principles to Actions: Ensuring Mathematical Success for All,* which identified eight effective mathematics teaching practices.

(1) Establish mathematical goals to focus learning
(2) Implement tasks that promote reasoning and problem solving
(3) Use and connect mathematical representations
(4) Facilitate meaningful mathematical discourse
(5) Pose purposeful questions
(6) Support productive struggle
(7) Build procedural fluency from conceptual understanding
(8) Elicit and use evidence of student thinking

These eight, taken together, provide research-informed mathematics teaching practices to create a classroom learning environment that supports ambitious, effective, and equitable mathematics instruction and nurtures children's positive mathematical identities and strong sense of agency with shared authority in learning mathematics.

Focusing on implementing equitable, effective mathematics instruction helps us to consider the quality of mathematics learning experiences rather than quantity of problems and provides a space for student voice, student interest, and student concerns. This focus supports mathematics as a collaborative endeavor and one in which problems may be solved in multiple ways, and it encourages students to share their mathematical thinking and not just solutions. All learners are viewed as thinkers and doers of mathematics across all grade levels (NCTM 2014, 2018, 2020a, and 202b). I challenge us to consider the question: Do our student see themselves as mathematically capable? Do all teachers see all students as *doers* of mathematics? Do we see ourselves as a *doer of mathematics*? Implementing equitable instructional practices positions all students for success. "effective teaching is the nonnegotiable core that ensures that all students learn mathematics at high levels and that such teaching requires a range of actions ….[at all]….levels" (NCTM , 2014, p. 4).

Let's consider this question: In what ways can and should we engage in discussions with multiple stakeholders to create shared experiences and a collective understanding of equitable mathematics instruction? Who are our partners and stakeholders? Are we inclusive of voices and supportive?

3.4. Recommendation #4: develop deep mathematical understanding

Considering broadening the purposes of mathematics, implementing equitable structures and equitable, effective mathematics teaching practices leads us to the last recommendation — develop deep mathematical understanding. “When mathematics instruction goes deep, children are empowered to explore the richness of the mathematical landscape” (NCTM, 2020a, p. 77). *Catalyzing Change* underscores the importance of engaging children — beginning in early childhood and elementary grades—as active doers of mathematics who author and generate strategies and share their mathematical insights. Doing mathematics involves engaging in the norms, routines, and habits that are central to the work of mathematicians (NCTM, 2018, 2020a, 2020b). These include representing and connecting mathematical ideas and concepts, explaining and justifying mathematical thinking, and noticing, using and understanding mathematical structures.

Moving to middle grades mathematics students need to engage “as active participants in their and their peers’ mathematics learning” (NCTM, 2020b, p. 67). They need to engage in mathematics that is relevant — often about sensitive or controversial topics — and requires careful attention and thoughtful implementation, but it needs to be a part of students’ middle school mathematical learning experiences. Across all grade levels to support students in developing a deep mathematical understanding there are multiple mathematical proficiencies to address as noted by the National Research Council (2001). They include conceptual understanding, procedural fluency, strategic competence, adaptive reasoning, and productive disposition. Further, we need to include mathematical experiences and course or curricular pathways that support students’ development of key mathematical practices such ss those identified in the Common Core State Standards in the United States (National Governors Association Center for Best Practices [NGA Center)] and Council of Chief State School Officers [CCSSO], 2010). These include making sense of problems, persevering in solving problems, reasoning both abstractly and qualitatively, being able to construct viable arguments, model with mathematics, use appropriate tools strategically, attend to precision, along with recognize and use mathematical structures. We need to consider mathematical and statistical modeling and thinking threaded throughout all grades. *Catalyzing Change* calls for disrupting the cycle of rote learning of mathematics. Each and every learner deserves mathematically powerful learning spaces that emphasize reasoning and sense making on a daily basis (NCTM 202a).

Often in the United States in the high school grades we see a segmented approach to the curriculum that includes a course sequence of an Algebra I, Geometry, and Algebra II pathway with a rush to calculus. This is often to the detriment of deep understanding of major key mathematical concepts and connections, and it avoids addressing other essential mathematical topics such as statistics, quantitative literacy, and modeling which are essential in today's world and to our future. This is not necessarily the case in other parts of the world but there may be other challenges that exist when thinking about mathematical experiences across all grade levels in developing a deep understanding of mathematics. Important questions for us to consider are: What is the essential mathematics needed? What are varied possible pathways for students to pursue rich mathematical experiences? And do all students have access to those essential robust pathways?

4. Conclusion

In considering these four recommendations it is essential that we engage in critical conversations to move to actions that will provide and support powerful mathematical learning spaces to support access and equity for all. Currently there are many marginalized students who are not receiving equitable learning experiences and thus their education is limiting their future opportunities. We have an opportunity to change this by working together in mathematics education. To be effective and impactful we must advocate both individually and collectively across local, national, and international levels. The gathering at the 14th International Congress of Mathematical Education was a unique opportunity to engage in reflection, discussions and collaboration to address advocacy efforts in mathematics education.

In my April 2021 NCTM President's message, *Advocacy as a Mathematics Education Community-The Time is Now*, I shared that we have much we can engage in as an advocate in mathematics education. We need to be called to action to advocate for high-quality mathematics teaching and learning for all students (Wilkerson, 2021).

Advocating for high-quality mathematics teaching and learning for each and every student must be more than words. To be effective advocacy must include thoughtful actions both individually and collectively across local, national, and international levels. Advocacy should raise awareness and influence decision makers and the public on issues to expand high-quality mathematics teaching and learning and provide access to every student, school, and community. Why should we advocate? What are effective ways to advocate in mathematics education? These are just some of the questions to consider as we examine our role in advocacy in mathematics education.

Every voice matters in mathematics education. Just think what we can do working together on this journey advocating for high-quality mathematics teaching and learning for each and every student and supporting each and every teacher! We must challenge existing inequities in structures and practices related to teaching and learning mathematics. Together we can do this.

On behalf of the National Council of Teachers of Mathematics, I want to again thank the International Commission on Mathematical Instruction for honoring NCTM with the Emma Castelnuovo Award for Excellence in the Practice of Mathematics Education. It's been an honor to accept the award and to have this opportunity to offer this address. I look forward to our continued dialogue.

Survey Team 1

Research in University Mathematics Education

Marianna Bosch[1], Reinhard Hochmuth[2], Oh Nam Kwon[3], Birgit Loch[4], Chris Rasmussen[5], Mike O. J. Thomas[6], and Maria Trigueros[7]

ABSTRACT In this report we highlight significant advances in university mathematics education research as well as areas that are in need for additional research insights. We add here to the rich set of literature reviews within the last several years. A novel aspect of this literature review is the fact that the areas of accomplishment and areas for growth were identified based on thematic analysis of survey responses from 119 experts in the field. The review provides a useful overview for both seasoned scholars and those new to research in university mathematics education.

Keywords: University mathematics; Advances; Gaps.

1. Introduction

It is an exciting time for research in university mathematics education (RUME). There are now several major conferences every year across the globe, as well as the fairly new *International Journal of Research in Undergraduate Mathematics Education*, now in its seventh year. With the significant growth in the number of researchers focused on university mathematics education has come the development of research groups and the consolidation of a diverse academic community; RUME is coming to age as a field of research that is beginning to coalesce and develop an identity.

To explore this identity we first surveyed 218 RUME scholars across the world, both well-established scholars and rising stars. We invited these scholars to respond to the following prompt:

What do you see as the most significant advances, changes, and/or gaps in the field of research in university mathematics education? These advances, changes, or gaps might relate to theory, methodology, classroom practices, curricular changes, digital environments, purposes and roles of universities, social policies, preparation of

university teachers, etc. Please elaborate on just **one or two advances, changes, or gaps** most relevant to your experience and expertise. If possible, please include a few key references.

We received 119 responses. Our next step was to conduct a thematic analysis, which led to the identification of five areas in which there has been considerable progress (advances) and seven areas that are less well-researched (gaps)[8]. Our next step was to conduct a literature review, guided by the identified themes. Perhaps not surprisingly, these two areas are not entirely disjoint.

2. Advances

2.1. Theoretical perspectives

One of the field's major advances considered by several respondents is that we now have a plethora of theoretical perspectives and hence tensions among them can sharpen their constructs and methodologies, and also open the possibility to find commonalities among some of them previously considered to be incompatible. This diversification has contributed to the development of new methods, research topics, and the development and research on theory-based teaching experiences. In particular, the growth of the networking of theories is a recent advance that has added power and depth for analyzing complex learning and teaching phenomenon (Bikner-Ahsbahs and Prediger, 2014; Prediger, et al., 2008)

Related to the networking of theories, recent years have seen the emergence of an interdisciplinary group of scholars interested in using a variety of approaches (logical, cognitive, historical, philosophical, etc.) to address questions which have always been of interest to RUME. This also has increased connections with other disciplines in mathematics and science education and in funding agencies supporting interdisciplinary projects.

Another theoretical advance that is of growing interest is the use of theories that enable insights into issues of equity and social justice. Adiredja and Andrews-Larson (2017) lay out a research agenda for this emerging domain that speaks to the interrelatedness of knowledge, identity, power, and social discourses. While there is still much research that is needed here, we see this new direction as an important advance for the field of university mathematics education research.

2.2. Instructional practices

The research of instructional practices at university level is a rapidly developing area of research. Much of the research on this topic relates to active or inquiry based mathematics education (Artigue, M. and Blomhøj, 2013; Laursen and Rasmussen, 2019). Given the myriad calls for instructional reform in university mathematics

[8] Special thanks to Antonio Martinez and Talia LaTona-Tequida, graduate students at San Diego State University, for their help in this analysis.

classrooms, researchers and educators have challenged traditional lecture-based instruction by conducting studies that have provided evidence for the positive effects of innovative student-centered instructions on students' cognitive and affective development.

Active learning, broadly defined as classroom practices that engage students in activities, such as reading, writing, discussion, or problem solving, that promote higher-order thinking, has repeatedly shown to improve student success and to reduce the equity gap for women and underrepresented students (Freeman et al., 2014; Laursen et al., 2014; Theobald et al., 2020). For example, Freeman et al. conducted a meta-analysis of 225 studies that compared student success in traditional lecture versus active learning in postsecondary science, technology, engineering, and mathematics (STEM) courses and found that average examination scores improved by about 6% in active learning sections, and that students in classes with traditional lecturing were 1.5 times more likely to fail than were students in classes with active learning and the effectiveness of active learning was found across all class sizes. On the other hand, RUME has only begun to deeply explore the culture, experiences, and gendered/racialized interactions in these classes — and how those social factors may be mitigating the students' opportunities to learn (Johnson et al., 2020).

2.3. Professional development of university teachers

Just over a decade ago, Speer et al. (2010) described tertiary level professional development as virtually non-existent and an unexamined practice. Since then there has been considerable progress in this area. In their review of recent research, Winsløw et al., (2021) characterise the literature as comprising primarily small-scale studies of lecturer preparation for teaching. Examples include the effect of backgrounds on teaching (Hernandes-Gomes and González-Martín, 2016; Mathieu-Soucy et al., 2018) and the knowledge used in teaching (Musgrave and Carlson, 2017). An inquiry-based experience can be found in (Florensa et al., 2017).

Another advance is the growing collaborative research that builds links between mathematics educators and university mathematicians, links that can increase the pedagogical awareness of the latter group through reflection on teaching practice and provide pedagogical tools (Bardini et al., 2021; Nardi, 2016). However, in order for mathematics educators and mathematicians to collaborate on professional development initiatives, the two groups need to build mutual understanding and trust. Some positive and productive examples of such collaborations are detailed in Jaworksi's (2020) overview of the professional development of university mathematics teachers.

Another very successful collaboration between a group of mathematics educators and mathematicians is detailed in Barton et al. (2014). This collaboration sought to open a two-way channel of communication between the two groups, with the aim to close the ideological perspective gap (Thomas, in press) by understanding the other group's thinking. In this manner, the theoretical and pedagogical knowledge of mathematics education could be conveyed to mathematicians in a manner that focused on their orientations and goals (Schoenfeld, 2010). In turn the mathematician's focus on the crucial elements of mathematics and its learning, along with the role of rigour, was conveyed to the mathematics educators.

2.4. Digital technology

As the review by Clark-Wilson et al. (2020, p. 1223) notes, "in the last two decades the range of digital technology (DT) available has expanded considerably and their facilities and power have also greatly increased. In the light of these changes, the research focus of many has moved from how computers can help with learning to how teachers can make practical use of different types of digital technology to provide students with activities that will enhance their mathematical learning." In addition to new digital technologies, new theoretical perspectives may be applied to the study of technology use at the tertiary level. There have been advances in this area that have emerged. For example, the notion of *Instrumental Orchestration* that arose to consider the collective knowledge building of teachers and students when a technology is appropriated for some mathematical pedagogical purpose (Trouche and Drijvers, 2010). This has recently been developed into the *Documentational Approach to Didactics* (Trouche et al., 2020). The latter combines theoretical elements related to the (instrumental) use of technology, resources, curriculum design, and teachers' professional learning and development to document meaning resource use in a given context with a pedagogical intention.

There have been many advances in terms of DT tools in recent years, such as an ever-expanding internet, clickers, pen-enabled tablets, powerful mobile technology, and interactive retinal screens on smartphones. Several recent studies (e.g., Loch et al., 2014; Maclaren et al., 2018) have demonstrated a very positive feedback from the students on the use of pen-enabled tablets in teaching mathematics, in particular showing a strong preference for this delivery mode compared to other delivery modes.

2.5. Service-courses in university mathematics education

Service-Courses in mathematics are courses provided by mathematicians for students who study engineering, natural sciences, economics, social sciences, psychology, medicine or life sciences, etc. The importance of mathematics for university education is reflected in institutionalized discipline specific mathematics working groups. For example, the European Society for Engineering Education has developed a competence orientated framework for mathematics curricula in engineering education. Research on mathematical service courses also plays an increasing prominent role at national and international conferences in university mathematics education.

Workplace studies figuring out the specific relevance of mathematics for vocational demands have so far mainly considered engineering. For example, considering structural engineers, Gainsburg (2007) has shown that reflections on mathematical concepts become mainly important and more explicit in situations where usual routine procedures do not lead to sufficient results. For this kind of situation Kent and Noss (2003) coined the notion of "breakdown situations".

There are many endeavors making service courses more helpful and relevant to students by implementing or strengthen the discipline related perspective, which intend both to improve the motivation for learning mathematics and the ability to transfer mathematics to discipline (mostly engineering) contexts (Czocher, 2017; Schmidt and Winsløw, 2021). To realize a better connection among service mathematics and other disciplines, a collaboration of mathematics lecturers and lecturers from the other discipline seems to be crucial. Jaworski and Matthews (2011) demonstrate how such a collaboration could be achieved where the lecturers involved conjointly design materials and plan teaching activities. Also related to an inquiry based perspective is the recently started design of so called study-and-research-paths (see for example Barquero et al., 2020) intending to support students in the integration and validation of mathematical practices from different institutional settings.

3. Gaps

3.1. Theories and methods

The development of novel research questions can contribute to the exploration of cogent theories of teaching and learning and the development of sound and innovative methodologies to answer them. As for existing coherent theories there may be a need to develop and extend them further to capture the complexities of the studied phenomena. Studies aiming at developing theory or to test and revise theories using empirical data, and their corresponding methodologies can help in making existing theories more robust and move the field forward. The lack of a shared discourse on meta-level learning is also reflected in the abundance of conceptual and theoretical frameworks suggested by the research literature, which are not necessarily compatible or even commensurable. Developing a shared and explicit discourse for the informal/meta-level content of university mathematics education is a crucial component in any effort to improve pedagogy at this level. While the networking of theories has made some progress on this front, more is needed.

There is in particular a need for frameworks for conducting evaluation research in realistic university settings for testing innovations integrating insights from broader educational research and from university mathematics teachers. Moreover, small-scale qualitative studies are still predominant (Artigue, 2021) or typically only one cycle of research is reported whereas reliability is often associated with multiple rounds of principled research. Also, knowledge of the process of scaling research-based innovations, including effective ways to navigate the political obstacles to shifting undergraduate mathematics courses to be more meaningful, coherent and mathematically engaging for students, is needed.

3.2. Linking research and practice

Some research results have been introduced into university mathematics curriculum, particularly through widely available textbooks for introductory courses. This is, however, not enough. Research results need to inform the teaching of all the mathematics courses through their introduction in the curriculum to significantly improve teaching practices. An important gap that impedes reaching this goal is the lack of research results in advanced university mathematics courses and in the possibility to introduce advanced mathematical ideas in introductory courses. This kind of research can illuminate new ways to motivate students through the teaching of both the usefulness and beauty of mathematics using interesting examples related to students' areas of interest, using what has been found in research about modelling and applications or by introducing new theory-based didactical approaches such as "training using challenges" and paradigms such as "questioning the world" (Chevallard, 2015).

Mathematics teachers and mathematicians need, on the one hand, to have access to different means of communication that go further than research published papers. Mathematicians often find it difficult to read and make sense of the theoretical points of view and the vocabulary used by researchers in mathematics education. Research results need to be made accessible to these other communities, and evidence based instructional practices in ways that are convincing to them. To make this possible not only through professional development programs but other types of media must be used and it is important to offer instructors and mathematicians incentives that can be financial or cultural together with longitudinal support through coaching and mentoring. These incentives and initiatives should clearly be to transform the university culture, which means researchers, teachers and students' transformation, and to support improvements in education. This change is considered fundamental because it is about the culture of mathematics departments, but we know very little about how to affect change (see Reinholz et al., (2019) for a research agenda centered on institutional change).

3.3. Professional development of university teachers

As reviewed in the previous section, there has been some progress in the professional development of university teachers, but much more is still needed. Research could consider the professional needs that university mathematics teachers have, in addition to completing a PhD and possibly a short course in general pedagogy (Winsløw, et al., 2021). How can university mathematics research be developed to contribute to filling those needs, and what measures are needed to engage university mathematics teachers in doing or learning from such research?

The development of programs to achieve strong teaching competence, along with study of their implementation, analysis and improvement comprise an important area for research in university mathematics education. While there have been a number of small studies in this area, the question of how to develop these further and extend them to scale is a topic for research. As Winsløw et al. note, there is a lack of large-scale international studies on teaching practice and its development in university mathematics teacher education.

One aspect to consider in the design of professional development programs is whether there is a role for technology in its design and implementation. For example, could use be made of recent online courses, such as MOOCs designed for in-service mathematics teachers where the aim has been to increase teachers' professional competencies and improve their practices? One advantage of this is the use of online mathematical communication in an open forum. Exchanges from such online mathematical forums have found fruitful use in similar research (Kontorovich, 2018).

There is still room for investigation of the orientations (Schoenfeld, 2010) of mathematics lecturers with respect to their pedagogy. For example, in what manner is mathematics taught by teachers and what do they believe about students who do not do as well as expected in their courses? Do they develop a "deficiency discourse" about their students (e.g., they can't do mathematics because of a lack of ability, are unprepared, unmotivated)? Is their practice influenced by their beliefs about students and is this discourse in any way related to their positive professional identity?

Another issue related to institutional factors that needs attention is to the culture of mathematics teaching and learning at tertiary institutions and how and why this culture continues to result in under-representative participation levels of women and historically marginalized groups (such as those from indigenous cultures and persons of color), particularly at higher levels, where retention rates are extremely low.

3.4. Digital technology

In many schools around the world there has been increased use of digital technology in mathematics learning. Discussing the transition from school to university, Gueudet (2008, p. 252) noted "the question of the effective and possible uses of technology in the secondary–tertiary transition has not been researched yet, as far as I know. Are the abilities with technology built at secondary school exploited at university?" (p. 252). Thus the possible disjoint between school and tertiary use of technology means that issues related to school-university transition may be in need of further research. One interesting question could be, how does a shift from a technological to a non-technological environment influence students' perceptions/interest/attitudes about/for/towards mathematics?

There is now a wealth of sources of mathematical information available to students, who have almost instant access to them, both at home and at their institution. There has been some research related to how they use these sources, such as how engineering students make use of mobile devices and the Internet (Puga and Aguilar, 2015), however, serious questions remain about how and what tertiary mathematics students access and the factors that influence and shape their help-seeking behaviors in the digital era. Examples include research that would systematically analyze how university students use the Internet and mobile devices as a source of mathematical help: What sites do they consult? Why do they consult them? Do they use online real-time support? What makes students trust or prefer one source of information over another one? And how are their mathematical reasoning processes affected by immersing themselves in the use of these digital resources?

Finally, due to the pandemic, courses have increasingly been converting to an online or hybrid format, and when this is pedagogically desirable or not is a topic for research. The research on DT as it relates to the pandemic is only just beginning, detailing both what the field has learned and what open questions remain. We trust that the next ICME survey on RUME will provide substantive insights on this topic.

3.5. Curriculum

Curriculum is an entity present but rarely taken as a unit of analysis in research in university mathematics education. Curricular questions are obviously at the center of all study and examination regulations of mathematics degree programs. However, their treatment rarely relies on specific research, except some empirical studies about students' difficulties or perceptions that are rarely published. At the same time, and at least in the case of mathematics undergraduate degrees, topics, contents, and the structure of study, programs appear surprisingly stable. In the case of mathematics subjects in other types of degrees (engineering, natural sciences, economics and business, etc.), the situation seems more evolving thanks to the introduction of new technologies (especially in the case of statistics subjects), but it is still stable in calculus and linear algebra subjects.

A comparative description of curricula across universities and countries, as well as the processes of external didactic transposition, i.e. the process of selecting and transforming scholarly knowledge into knowledge to be taught, have surprisingly seen little systematic investigation. This is possibly also due to the fact that in mathematics degree programs the knowledge to be taught is rarely questioned. According to (Bosch et al., 2021) for the case of mathematics degrees, there are some differences, for example, between Canada and the USA on the one hand, and Europe on the other, or between types of higher education institutions, such as classical universities and universities of applied sciences. Nevertheless, within each type, the knowledge to be taught has not strongly evolved. This also applies to the external framework conditions, as well as the various dynamics of decision-making processes for changing the curricula or processes of maintaining curricular orders.

3.6. Higher years

Didactic research on learning and teaching in advanced mathematics studies is significantly under-represented. The focus has so far been clearly on the transition from school to university and in the first year of study. This reflects the relevance of the transition and study entry problem, e.g. with regard to dropout rates.

Historically, Felix Klein should of course be mentioned here. Core parts of his "Elementary Mathematics from a Higher Standpoint" actually refer to mathematics that many of today's student teachers do not even get to know in their academic studies. This applies, for example, to knowledge of Fourier analysis that goes beyond the basics, but especially also to knowledge of function theory, e.g. Riemann surfaces and value assignment theorems. Even when students hear about function theory, for example, they usually do not get as far as understanding what Felix Klein considered appropriate knowledge for prospective teachers more than a century ago. Klein considered this knowledge appropriate because it explains why, for example, certain elementary operations have to be restricted in certain ways for mathematical reasons (and not just for didactic reasons of reduction!), and related curricular decisions.

3.7. Interdisciplinarity

Survey responses addressed gaps on many different levels. The most general level concerns research itself. On the one hand, this involves cooperation with mathematicians, engineers, economists, psychologists, etc. For many years, there have been many different kinds of cooperation, for example, agreements between faculties with regard to teaching. What does not seem to exist so far is, among other things, systematic research on these cooperations. What are the benefits of these? How do they take shape? How do they function? Possibilities, limits, etc.? On the other hand, it is about cooperation with researchers from other disciplines in our own research in the narrower sense, i.e. besides mathematicians, with psychologists, university teachers, pedagogues, sociologists, political scientists, historians, anthropologists. In the context of empirical research into learning processes, cooperation with psychologists and educationalists has now been established in many places and, with a view to professionalizing teaching, also with university didacticians. And of course there are also isolated cooperations with other academics. What seems to be missing, however, is a more systematic description and conceptualization of the links. This could be formulated as goals.

The relationship of mathematics to other sciences or the use of mathematics in other sciences also is an area that needs to be addressed. There are several places, such as philosophy or the history of science, in which such connections are examined and the question of what distinguishes mathematics itself and its respective role in other sciences is explored. Research on this is dependent on the respective ideological assumptions and accordingly there are no unambiguous and generally accepted answers here in depth. From the point of view of didactics, however, clarifications in this regard could certainly be regarded as desirable, since they would be of great help in answering the question with which goals, which and how mathematicians, but especially engineers, economists, psychologists, etc., are to be taught.

Last but not least, although in a slightly different way, this also concerns mathematics in itself. It, too, changes its inherent orientation and, to some extent, its character over time. New fields are emerging, such as Big Data and Data Science. Correspondingly, there are new fields of application in other sciences, such as discrete mathematics in electrical engineering, numerical methods also in psychology, etc. This leads directly to questions of teaching: the question of what should be taught in service courses and how is manifold but certainly not sufficient.

4. Conclusion

Grounded in the responses from our RUME scholar survey, we identified five areas in which the field has made significant progress (Theoretical Perspectives, Instructional Practices, Professional Development of University Teachers, Digital Technology, and Service-Courses in University Mathematics Education) and seven areas are in need or further development (Theories and Methods, Linking Research and Practice, Professional Development of University Teachers, Digital Technology, Curriculum, Higher Years, and Interdisciplinarity). These gap areas represent exciting opportunities for the mathematics education research community to conduct scholarly work and help advance the field at large. So while there is now much research-based wisdom, there are also exciting opportunities for new research.

Acknowledgements

The authors thank all those who took the time to respond to the survey.

Survey Team 2

A Survey of Recent Research on Early Childhood Mathematics Education

Iliada Elia[1], Anna E. Baccaglini-Frank[2], Esther Levenson[3], Nanae Matsuo[4], and Nosisi Feza[5]

ABSTRACT This is a summary report of the ICME-14 survey on Early Childhood Mathematics Education, which was conducted by the authors of this paper, with the aim to establish a review of the state-of-the-art of the most important developments, and of current tendencies, new perspectives and emerging challenges in the particular field. The survey was based on an analysis of the research literature published between 2012 and 2020.

Keywords: Literature review; Early mathematics learning, Early mathematics teaching; Technology; Early childhood teachers.

1. Introduction

In the past few years there has been an internationally growing interest in early childhood mathematics education (ECME). The interest in this field is induced firstly by the strong emphasis given on early childhood education in many countries. This is evident by the increase of their expenses and investments on early childhood education and of their access to pre-primary education (Kagan and Roth, 2017). The well documented, positive relation between children's early mathematical knowledge and their later success in mathematics learning is another factor for the growing research in this field (Dunkan et al., 2007).

This survey has been designed to establish an in-depth and comprehensive review of the state-of-the-art of the most important developments and contributions between 2012 and 2020, and of new perspectives and emerging challenges in ECME.

In the survey we identified six major research themes in recent literature on ECME. Three of these themes are content-oriented: number sense and whole number development, geometry education and children's competences in other content domains. Another theme that is systematically reviewed deals with the role of technologies in early mathematics teaching and learning. A cognition-oriented theme

[5] Research and Postgraduate Studies, University of Venda, Thohoyandou, South Africa. E-mail: nosisi.piyose@gmail.com

focuses on cognitive skills associated with mathematics learning and special education and comprises two parts: Abilities predictive of or associated with mathematical performance and special education. Finally, the sixth theme focuses on developments and trends in teacher-related issues, particularly on early childhood teachers' knowledge, education and affective issues in mathematics.

To identify relevant research for the survey, we drew from a broad range of sources, focusing on publications since 2012. For each identified theme we searched for relevant peer-reviewed papers in journals in two fields, that is, Mathematics Education and Early Childhood Education, for relevant chapters in prominent research books on Mathematics Education (such as PME Handbook, POEM, ICME-13 monographs), international peer-reviewed conference proceedings, including ICME, PME and CERME. Moreover, we used publications found in search engines using strings with relevant keywords for each theme.

After eliminating double records, we produced annotated bibliography with summaries of the papers that have been identified as relevant for each theme, leading to a comprehensive analysis of the issues raised by this research literature and to a qualitative synthesis of the pertinent findings. This led to the production of a written overview of the research in each theme. A summary of the key findings for each theme of the review and a final section with our concluding remarks are presented below.

2. Number Sense and Whole Number Development

Number sense development is globally recognized as the fundamental foundational knowledge for children's mathematical growth. Hence, literature argues for children's stimulation of numerosity as early as their toddler stage for future benefits. The complexities brought forward by diverse backgrounds of children as well as diverse provisions of stimulation enriches strategies and seek more conceptualization. Children's diverse numerical abilities reflect children's varied experiences from home and their immediate environment (Ramani and Siegler, 2011). These abilities are foundational blocks for children's development of numerical fluency, on the other hand low performance is proven to be associated with limited numerical experiences prior to kindergarten and inability to catch up with peers (Aunio et al., 2015).

Innate abilities of young children have been identified to be observable as early as six months. New-borns of 7 to 94 hours demonstrated that they could map space, number and time including brightness, and loudness (de Hevis et al., 2014). Robertson, Shi and Melancon (2012) discovered that 24 months babies were able to match objects with the defining number. Also, Norwegian toddlers demonstrated competencies using number words, however reciting lower competencies than previous literature (Reikerås, Løge, and Knivsberg, 2012).

Sella et al. (2017) explored numerosity and spatial mapping to three groups, preschool children, 4-year-olds, 1st Grade and 3rd Grade, to discover that spatial mapping favored high numerical abilities in all groups studied. Benz (2014) revealed that 4- to 6-year-olds were able to explain structures in quantities and why they used to compose or decompose, while a more recent study with the use of eye tracking by Schöner and Benz (2018) showed that children built structures in the collection of objects but could not explain their approaches and resort to counting as a strategy.

Strategies that are revealed to enhance numerical abilities are linear board games (Ramani and Siegler, 2011), numerical acuity and inhibitory control, tablet-based non-symbolic approximate arithmetic game, conceptual subitising (Sayers et al., 2016), fine motor skills (Asakawa et al., 2017), story problems (Jordan et al., 2012), catch up numeracy (Holmes and Dowker, 2013) differentiated approach in using games (Bay-Williams and Kling, 2014). Children who get exposed to numeracy stimulation before school demonstrate a positive gain in early schooling (Clerking and Gilligan, 2018; Segers et al., 2015). Particularly, benefits are observed in play-based approach for numeracy development at home, allowing children to learn through play and give opportunity to adults to pose challenging questions and listen to children illustrating their action and adding meaning to them (Magnusson and Pramling, 2018). Furthermore, mediation of patterns and structure influences children numerical fluency positively especially those who are low performers (Lüken and Kampmann, 2018). Problem solving was found to boost four basic operations with an effect size of 0.60 (Bicknell et al., 2016).

Dynamic assessment is one of the strong predictors for problem solving of word problems development (Seethaler et al., 2012). Polotskaia and Savard (2018) used Relational Paradigm in facilitating problem solving and this led to improved problem-solving skills and enabled students to solve problems demanding rational thinking. A longitudinal study favored students who begin to use derived fact strategies during mid-year than those using counting strategies (Gaidoschik, 2012). White and Szucs (2012) promoted modelling methods to increase understanding and developing mental representation through estimation tactics.

Although children's mathematical development through technology is systematically analyzed in a distinct theme of this review, it is worthwhile here to present a number of technology-based interventions that were found to support the numeracy abilities of children with diverse backgrounds. A Math Shelf intervention using a tablet was designed for at risk 4-year-old pre-schoolers with results that show significant improvement performance (Schacter et al., 2016). Also, an adaptive computer game "Number Race" yielded similar findings as Math Shelf intervention for disadvantaged children (Sella et al., 2016). Lady Bug Count and Fingu apps allow children to develop own mathematical concepts such as subitizing, estimation and finger motor-skills (Ladeland Kortenkamp, 2014).

Generally, this literature addresses vital concepts within number sense that need attention and recognition. Our findings indicate a need to understand or unpack children's language as some studies assert that children were able to articulate their strategies and reasons behind their selection, while others report that children were limited to counting in describing their strategies. Furthermore, there is too little literature on transitioning from informal numerosity to formal numerosity and how mediation should be structured to achieve the transitioning.

3. Geometry Education

The literature review about geometry education in early childhood focused on the following major threads: Spatial skills and their relation to mathematics and geometry learning, shape knowledge and understanding, embodied, dynamic and semiotic approaches in geometrical thinking and learning and enhancing and assessing geometry learning.

Regarding the first thread of the review, strong relations have been found between spatial skills and quantitative competences, including, number-line estimation, counting and arithmetic (addition and subtraction) in children already from age 3 up to 7 years (e.g., Verdine et al., 2017). The potential significance of young children's spatial training or learning in their mathematics performance is also highlighted (e.g., Hawes et al., 2015). The relationships between spatial skills and geometry learning are scarcely investigated and research on this issue suggests that the associations between geometry learning and teaching and spatial reasoning are quite complex (e.g., Dindyal, 2015). However, spatial knowledge is found to be the basis for building geometrical knowledge and understandings in problem solving (Soury-Lavergne and Maschietto, 2015).

Our findings on shape knowledge and understanding (second thread) suggest that a great deal of studies focused on plane shapes, taking a rather static perspective, e.g., studying children's shape recognition and sorting abilities, definitions/descriptions of shapes (e.g., Olkun et al., 2017). A major finding, revealed also by previous literature, is that children develop visual prototypes and they use these prototypes to compare shapes they are asked to identify or to draw (e.g., Dağlı et al., 2014).

A few studies adopted a more spatial perspective in investigating children's competences in geometry. Research on children's competences with 3D shapes has shown that children encounter difficulties when reasoning about plane and solid shapes across various kinds of geometric representations (Hallowell et al., 2015) and also in reconstructing a 3D figure with building blocks and in using the regularities of this geometrical object when needed (Maj-Tatsis and Swoboda, 2017).

A large part of research on embodied, dynamic and semiotic approaches in geometrical thinking and learning (third thread) investigated the role of body and gestures in children's learning of geometry. A major finding is that children's body and gestures reflect implicit knowledge and have a crucial and fundamental role in the development of geometrical reasoning, in solving geometrical problems and argumentation and in communicating geometrical/spatial relationships (e.g., Calero et al., 2019; Elia, 2018). The multimodality of children's learning, and specifically the synergy between talk, gesture, and material environment is regarded as a critical characteristic of children's development in geometry by many research studies (e.g., Thom, 2018). A number of studies on dynamic learning environments (DLE) in early geometry provided evidence for the potential of DLE to support children's developing understanding, and reasoning about, different geometry concepts, including the properties of specific shapes, angles and reflective symmetry (e.g., Ng and Sinclair, 2015).

Research on enhancing early geometry learning (fourth thread) suggested play as a significant learning approach. Using children's play as starting point to teach mathematical content supported children's explorations of shapes (Bäckman, 2016), while guided play also enhanced children's shape knowledge (Fisher et al., 2013). In addition, using picture book reading with or without the inclusion of additional mathematical activities was found to be a promising avenue to contribute to the development of children's understanding of shapes and spatial relationships (McGuire et al., 2021). Regarding the assessment of children's geometrical thinking and learning, a study by Thom and McGarvey (2015) showed that drawing serves as a means to access, assess, and attend to children's understanding. Tirosh et al. (2013) highlighted the need to use a combination of tasks to assess strengths and weaknesses of children's geometric knowledge, as not all children take advantage of the opportunities afforded by a given task.

The findings of the review on early geometry education indicate the need for further research on the body's role in children's geometrical learning (regarding both plane and 3D shapes), so as to deepen and enrich current knowledge about how children think and build geometrical understandings, on teaching strategies in geometry and spatial reasoning (e.g., picture books, DLE) to support children move into more abstract ways of thinking and, finally, on how early geometrical knowledge and understanding affect children's future mathematical performance.

4. Children's Competencies in Other Content Domains

Compared to the domains of number and geometry, other content domains have received less attention within ECME research. The major content domains within ECME that are studied in the reviewed literature are patterns and structures, measurement, statistical reasoning and early algebraic reasoning. A common focus of the reviewed studies across the different content domains is twofold: Firstly, offering insights into young children's competences and development and secondly, proposing and investigating the effectiveness of programs or interventions on children's learning. Research on patterns had increased rapidly since 2013, when Mulligan and Mitchelmore (2013) proposed Early Awareness of Mathematical Pattern and Structure showing that it generalizes across early mathematical concepts. In this study, not only can students' abilities of structural development be reliably categorized through particular levels, but students who show a superior level of development on one task also operate at a similar level on other tasks.

Besides this, research has investigated children's recognition of the unit of repeat and the structure of the repeating patterns and the relations with other mathematical contents, such as number and arithmetic, algebra, calculation, or geometrical thinking. It is shown that effective patterning instruction included instruction on symmetrical patterns, patterns with increasing numbers of elements, and patterns involving the rotation of an object through 6 or 8 positions. Moreover, the abilities to ascertain the structure of patterns and understand mathematical language were found as strong predictors of mathematical success, with the latter making a more significant contribution.

Concerning measurement, a significant number of studies in this theme have focused on general measurement, length, area, mass, and time. However, few research papers are about bulk, or volume. Regarding length measurement, which has received greater attention than measurement of other properties, research has provided evidence for the effects of different pedagogical approaches on kindergarten children's learning and evaluated and elaborated the developmental progression or levels of thinking on length measurement (e.g., Szilágyi, etc., 2013). A few pieces of literature are about area measurement. Clements et al. (2018) investigated the effects of instructional interventions through different levels of a learning trajectory designed to support young children's understanding of area measurement as a structuring process.

The literature on data modeling includes research on statistical reasoning, statistical learning, quantitative modeling, and probabilistic thinking. English and Crevensten (2013) explored data modeling with a specific focus on structuring and representing data, including the use of conceptual and meta-representation competence, informal inference, and the role of context through the longitudinal study of data modeling in grades one to three.

Kieran, Pang, Schifter and Ng (2016) investigated the nature of the research carried out in early algebra and how it has shaped the field's growth for the younger students, aged from about six years to 12 years. This study found that mathematical relations, patterns, and arithmetical structures lie at the heart of early algebraic activity, with noticing, conjecturing, generalizing, representing, justifying, and communicating central to students' engagement.

Based on the strengths that have been identified in this current research body about mathematics learning in other content domains in early childhood contexts, we consider important for future research pathways to investigate the connections of the development of early knowledge and skills in content domains beyond number, e.g., pattern and structure, data modeling and early algebra with future mathematical performance of students. Further research could be carried out about the nature of classroom culture and the role of the teacher, the curriculum, instructional strategies and new technologies on the learning in the above mathematical content domains, as well as on the relationship between children's competences in these content domains and their cognitive skills and affective characteristics.

5. The Role of Technology in Mathematics Teaching and Learning

A large body of research on this theme focused on design features of different technological tools used in ECME, such as spreadsheets, Interactive Whiteboards

(IWBs), dynamic geometry software and programmable toy robots, but the vast majority of the technological tools described are interactive applets for tablets.

An issue raised in many papers is the need for designing new apps for learning mathematics in order to create constructive opportunities to represent mathematical objects so that they can be manipulated. A second issue raised is the importance of well-founded guidelines at the basis of this design.

A number of studies focused on multi-touch devices, in which environments are designed supporting embodied and multi-player interactions. Among the most referenced and studied is the app TouchCounts, which takes advantage of the multi-touch and gestures functionalities of the device and provides multimodal visual and auditory feedback for every touch or gesture (e.g., De Freitas and Sinclair, 2017). Other studies have focused on activities with programmable toy robots designed to ameliorate preschool children's visuospatial reasoning, engaging them in a playful and tangible way (e.g., Di Lieto et al., 2017).

Frameworks used in this domain or developed from design research include the Theory of Semiotic Mediation (e.g., Bartolini Bussi and Baccaglini-Frank, 2015), the discursive approach, and a framework that makes a distinction between instructive, manipulable, and constructive multimedia (Goodwin and Highfield, 2013), through which a review of educational apps was conducted. An important conclusion was the value of open-ended tasks, also expressed in other studies.

An important area of research is that of computer assisted interventions. Various studies focused on educational software centered around specific topics, such as number sense. This research aimed at highlighting the educational potential (in terms of students' improvements in mathematical achievement) offered by certain apps that exploit affordances of multi-touch devices for fostering preschoolers' development of number-sense (e.g., Baccaglini et al., 2020).

Studies suggested that well-planned integration of apps in the classroom, with clear learning objectives and appropriate feedback could motivate children, enhance concentration, and support independent learning and communication (e.g., De Freitas and Sinclair, 2017; Kaur and Sinclair, 2014). Some studies showed that children make sense of the digital tools and are able to apply the tools purposefully as long as they also interact with an adult, within their zone of proximal development. Findings also suggest that when technology integration is accomplished successfully in early childhood education settings, children tend to interact more with one another and exchange information related to computer tasks as well as to the overall classroom on-going curriculum themes. Research on using dynamic geometry environments with young children suggested that gestures and motion play an important role in children's developing the mathematical conceptions at stake (e.g., Kaur and Sinclair, 2014).

Many of the studies in this theme explored the roles that preschool teachers give to technologies in mathematics education and the ways in which they structure their mathematics learning activities when using technological artefacts. As far as the teachers are concerned, having a negative attitude towards technological artefacts like an IWB led to a decrease in the likelihood to enrich the learning environment and lead to pedagogical change. The IWB does not seem to pose pedagogical challenges to teachers as its stable location offers the opportunity of using it in traditional teaching ways. Instead, tablets seem to pose a problem for some teachers because of their mobility and the need to reconfigure the organization and, to some extent, the roles of teacher and students.

Many semiotic resources were used with different mediating roles in different teaching-learning processes. However, an emerging challenge is that teachers frequently do not seem to be confident about their ability to teach mathematics using computers. These studies suggested providing effective professional learning and development programs so that teachers can employ a wider range of pedagogical strategies to support the children's use of ICT (e.g., Dong, 2018).

Overall, the findings on preschoolers' interactions with touch-screen-based virtual manipulative mathematics apps confirm the hypothesis that multi-touch technology has the potential to foster important aspects of children's development of number-sense, however such research is still in its infancy. A few studies have pointed to relationships between children's strategies used when interacting with certain apps that afford multi-touch inputs and their development of number sense abilities (e.g., Holgersson et al., 2016).

6. Cognitive Skills and Special Education of Young Children

6.1. Abilities predictive of or associated with mathematical performance

In this area of research, a distinction is made between domain general abilities (e.g., executive functions (EF), working memory (WM), long term memory, visuo-spatial abilities, inhibition), domain specific abilities (neurocognitive trend) and abilities related to the socio-cultural dimension and language.

Studies on domain general abilities highlighted the correlations between children's executive functions and their numerical abilities. Also, non-verbal number sense and working memory are central for early mathematical achievement in preschool. Both visuo-spatial working memory and the phonological loop have been associated to mathematical achievement as well as to the children's development of language, and linguistic competence, is also correlated with mathematical achievement (e.g., Fuchs et al., 2019)

Low visuo-spatial abilities do not seem to change the nature of the mental number line, but they can lead to a decrease in its accuracy. On the other hand, visualizing spatial arrangements is a key ability in the development of number sense.

Regarding domain specific abilities, studies have found that the nature and time needed for the development of children's mapping of the new symbolic representations of numbers they learn onto pre-existing non-symbolic representations are not yet clear. Moreover, there seems to be a tendency within neurocognitive research to support the development of cardinality before ordinality. However, some studies have suggested the importance of early focus also on ordinality (e.g., Coles and Sinclair, 2017).

The approximate number system (ANS) plays a key role in the development of basic numerical abilities, and it is thought to help children achieve cardinality. However, an important role is also played by children's spontaneous focus on numerosity (SFON) (e.g., Verschaffel et al., 2016). Research has widely recognized the importance of using fingers, suggesting that explicit teaching of finger counting in early primary school practices should be promoted to help weaker children overcome their difficulties in arithmetic.

The literature on the abilities related to the socio-cultural dimension and language indicated that the role of language is quite controversial. All of the studies analyzed suggested that there are links between early mathematical achievement and phonological competence. Moreover, the use of narration enhances mathematical learning.

Difficulties with mathematical language can also become obstacles in the development of mathematical meanings. This line of research highlighted the key role played by the teacher. Research converged on the main objective of developing multimodal approaches to mathematics education, within which language is a resource that involves various elements (signs, gestures, etc.) combining mathematical symbols (including formal ones) and images to promote the development of mathematical meanings.

Different ways of pronouncing numbers in different languages can support or hinder the development of number sense itself; for example, using languages with more transparent ways of denominating numbers has a long-lasting benefit on children and it places them at an advantage (e.g., Dunbar et al., 2017).

A number of studies emphasized how a deprived socio-economical-cultural environment has a significant negative influence on the development of number sense.

6.2. Special education

The reviewed research in special education within ECME involves two major directions: The first direction is focused on mathematical capabilities and their development in young students with special needs and the second one refers on ways to support and improve mathematics learning of young students with special needs. For both directions, the findings from the literature review reveal a greater emphasis on researching low-attaining children than high-achieving children. Considering the first direction, a large part of research in low performing students focused on students with mathematical learning disabilities (MLD) mainly with respect to numeracy. Several studies have investigated the relations between MLD and cognitive skills (e.g., working memory), language skills, other learning difficulties (e.g., dyslexia, non-verbal learning disabilities) or pathological disabilities. Regarding the second direction, a significant number of studies developed remedial numeracy programs or examined the effectiveness of interventions for young children at risk for mathematics difficulties or low-attaining children in mathematics (e.g., van Garderen et al., 2020). However, the remediation of MLD in educational contexts is a field that needs further improvement. There is also growing research that takes place on the use and effects of evidence-based instructional tools, ICT, teacher professional development, family-centered practices and parent involvement/ training on the mathematical development of children at risk for mathematics difficulties which could contribute to this endeavor.

7. Early Childhood Teachers' Knowledge, Education and Affective Issues in Mathematics

For preschool teachers, subject matter knowledge (SMK) often refers to the concepts and skills learned before first grade, such as number and operation, measurement, geometry, data representations, and patterns. Several studies presented models and frameworks for investigating teachers' knowledge and competencies for teaching early childhood mathematics (Gasteiger and Benz, 2018; Tsamir, et al., 2014). In addition to content, studies included elements of pedagogical content knowledge (PCK) such as knowledge of early mathematics development, ability to observe mathematical situations and to take appropriate pedagogical actions. Lindmeier et al. (2016) added reflective competence and action-related competence. Most studies of preschool teachers' SMK reported on general scores, (e.g., Opperman et al., 2016), with a few focusing on specific domains, such as patterns (e.g.,Tirosh et al., 2017) and geometry (e.g., Tsamir et al., 2015; Ulusoy, 2020). Investigation of teachers' content knowledge in areas such as measurement and data representation is scarce.

Studies that concern teachers' PCK are more frequent than studies of teachers' content knowledge, focusing on teachers' knowledge of students as mathematics learners (Tanase and Wang, 2013) and teachers' knowledge of task orchestration (Hundeland et al., 2017). Several studies focused on teachers' abilities to recognize mathematical situations that occur during children's natural play (e.g., Benz, 2016) or during play-based scenarios (Lee, 2017). In general, teachers note concepts related to classification, number sense, and measurement.

Teachers' attitudes towards teaching mathematics improved through professional development (e.g., Sumpter, 2020). Some teachers claim that mathematics in kindergarten is important because children need to be prepared for first grade (Schuler et al., 2013). Teachers mostly consider counting, rather than geometry, as relevant and important (Schuler et al., 2013).

Concerning pedagogical mathematical beliefs, teachers stress children's need to use their bodies as tools for learning mathematics, for example by climbing up and down to feel differences in height (Franzén, 2014). Most teachers believe that it is essential for children to be active learners (Li et al., 2019) and that the teachers' roles are to ask questions (Cross Francis, 2015), instill curiosity (Schuler et al., 2013), and encourage children to think and draw conclusions by themselves (Li et al., 2019).

Self-beliefs, such as anxiety, confidence, and self-efficacy were found to be linked to various contextual factors (e.g., Thiel and Jenssen, 2018). Gasteiger and Benz (2018) pointed out that teachers' attitudes and motivation influence how they use their knowledge and skills. Higher knowledge is associated with higher levels of student-centered beliefs (Ren and Smith, 2018). Tirosh et al. (2017) investigated the links between pattern knowledge and corresponding self-efficacy.

Few studies investigated the preparation of prospective teachers to teach mathematics in preschool. Instead, programs aimed at promoting practicing teachers' knowledge of their young students' mathematical thinking, and helping teachers develop and use tools to better understand children's engagement with mathematics. Several programs used video as a tool for reflection (e.g., Cross Francis, 2015). Other programs encouraged teachers to use clinical interviews (e.g., Polly et al., 2018).

In conclusion, although this section is about teachers, the common thread running through most studies is an emphasis on children. More studies focused on teachers' PCK than their SMK, and within PCK, research has focused on coming to know young students as mathematics learners. Studies of teachers' beliefs investigated the relevance of mathematics for young children, and what is appropriate mathematics for children. Finally, many professional development programs focused on enhancing teachers' knowledge of children's mathematical reasoning. Further research might focus on teachers' knowledge and beliefs related to the use of technology in preschool mathematics and interventions specifically for prospective preschool teachers.

8. Concluding Remarks

Our work on this survey has shown that there is a plethora of research work of a broad scope on ECME and that there will be continued growth and important progress in this field in the years to come. In the past few years we gained considerable amount of relevant knowledge about what mathematics children know and (can) learn before or at the beginning of formal education, how they learn mathematics and develop their mathematics skills, how early mathematics learning can be stimulated and enhanced and also on teachers' knowledge, acts and beliefs related to early years mathematics. We expect to see further development in the aforementioned areas with greater research attention on the following aspects: assessing and developing children's competences in content strands beyond number sense and also children's cognitive abilities that are strongly associated with mathematics performance (e.g., SFON, ANS), toddlers' mathematical development and learning opportunities, the use of digital tools to support children's learning and opportunities offered to children to engage in embodied ways of mathematical thinking and learning. The development of early childhood teachers' knowledge and skills on the above aspects would be another major challenge in the field.

Acknowledgments

We wish to thank Giulia Lisarelli and Alessandro Ramploud for their help in reviewing a part of the literature for the survey.

Survey Team 3

Teachers' Collective Work as Regular School Practice for Teacher Professional Development and Learning

Birgit Pepin[1], Zeger-jan Kock[1,2], Hiro Ninomiya[3], Yudong Yang[4],
Bill Atweh[5], Gerard Sensevy[6], and Jehad Alshwaikh[7]

ABSTRACT In this report we present the results from an extensive search of the literature regarding mathematics teachers' collective work in schools, in the Eastern and Western literature. In particular, we try to answer the research questions related to the following themes: (1) the nature of mathematics teachers' collective work as regular school practice; (2) the participants of such school-based collective work and their roles; and (3) the professional development and learning that can be observed in school-based teacher collective work. In terms of theoretical frames, results show that different variations of Lesson Study have been the main frame for teachers' collective work at school level, in particular of course in Japan and China, but also increasingly in Western countries such as the UK, the Netherlands, Portugal and Spain. The choice of this frame also impacted on the nature of the collective work: working in cycles of lesson (and learning progression) planning, enactment, and evaluation, leading to the re-design of lessons. Whilst in Western countries participants comprised a mix of teachers and researchers, in most Eastern countries, teachers would also work on their own (as a group of teachers) or with so-called expert teachers in their collective groups. Teacher learning resulting from collective work was reported in terms of: (a) lesson planning and preparation; (b) pedagogical content knowledge(c) classroom practices; (d) general pedagogy; (e) social and personal issues in the mathematics classroom. The findings have implications for the conceptualization of school-based teacher collective work, for the support and facilitation of such work, and for research, in particular in terms of teacher agency.

Keywords: Teacher collaborative work; Regular school practice; Teacher professional development; Teacher learning; Lesson Study.

1. Introduction

During the past decades, teacher collaboration has received increasing attention from both the research and the practice fields. It has been claimed that teacher collaboration can positively influences the whole school community. DuFour et al. (2005) contend

that collaborative learning communities "hold out immense, unprecedented hope for schools and the improvement of teaching" (p. 128). Amongst others, teacher self-efficacy has been found to have improved (e.g., Puchner and Taylor, 2006), increased teaching effectiveness (e.g., Graham, 2007), and improvement of instructional quality (e.g., Jackson and Bruegmann, 2009; Hochweber et al., 2012). These positive effects will improve their quality as professionals and as Hattie (2003) suggests, teacher quality alone accounts for 30% of the variance in student performance. Hattie (2015) also claims that teacher collaborative working communities will enhance teacher effectiveness and expertise. Moreover, selected research has shown that the positive influence of teacher collaboration transcends the teacher community, and it has been suggested that professional collaborative activities might have a positive effect on student achievement (e.g., Dumay et al. 2013; Goddard et al. 2010).

Whilst in many (Western) countries previously teacher professional development activities were mainly conducted at and by universities and teacher education institutions, nowadays they are often run by local or regional school boards and agencies at school level. This trend goes hand-in-hand with proposals that teachers become partners in the design of their curriculum, rather than "simply" implementing the curriculum, supported by (government) approved textbooks. Moreover, due to the availability of an enormous amount of free educational resources on the web, teachers ask for guidance and support for choosing and appropriating those resources for their classroom, and the closest support lies at school level, with their colleagues (in their or neighbouring schools). However, this trend also asks for teacher agency, their professional agency: e.g., their decisions to participate in or withdraw from the teacher collective; which resources to ask for and use; which foci to choose in the collective; how to collaborate with colleagues/peers; which role to take in the collective.

At the same time teachers' collective work as regular school practice has a long history in many (mainly Eastern) countries: Lesson Study in Japan and Teaching Research Groups in China are well known examples. However, varying forms of such practice exist in many countries and in varying educational contexts. Over time, and particularly in more recent years, these practices have been shared and researched leading to the evolution of a wide, yet dispersed, knowledge base.

In this paper, we present the results from our international survey of the literature regarding mathematics teachers' collective work in schools. In particular, we try to answer the following research question:

> ***What can be learnt from an examination of common features of mathematics teachers' collective work as regular school practice as well as from variations in practices and their rationales in different national contexts?***

We ask the following sub-questions:

1) *What is the nature of mathematics teachers' collective work as regular school practice, and how does this relate to situation, culture and context?*
2) *Who is engaged in such school-based collective work, what are the roles*

of those people involved, and how do they relate to each other in the different communities?

3) *What kinds of learning can be observed in school-based teacher collective work? (How does teacher collective learning happen in teacher collectives at school, what is the evidence for their learning?)*

In the following (second) section, we present the background to the present study. This will be followed, in the third section, by the methods we used to conduct the literature review. In the fourth section, we explain the theoretical frames. In the fifth section we present the results relating to the research sub-questions, and in last section (section six) we refer to the main research question with our conclusions.

2. Background

In the previous section we have provided a rationale for conducting the survey we did, as we contend that teacher collaborative work is an important area for study. In earlier and recent ICME- related studies this has been acknowledged by: e.g. Borko and Potari 2020 (ICMI-25 Study); Robutti et al. 2016 (ICME Survey 13); Jaworski et al. 2016; Adler et al. 2005 (ICME 2004 survey). We build on this body of work, and attempt to establish in which ways teachers' collaborative work at school level has developed and how it varies across contexts.

3. Methods

To identify the relevant literature to answer our research questions, we conducted a systematic literature review. This review mainly relied on the procedures of a thematic synthesis (Xiao and Watson, 2019) with the overarching aim to build on the current body of literature, to summarize what is known about teachers' collective work at school level. Since research on teachers' collective work has enormously increased over recent years, we reduced our literature review to publications that were published since 2015. We went through all titles and abstracts from the following list of journals, conference proceedings and books in order to identify the papers comprising recent research on mathematics teachers' collaborative work at school level:

- Journals:
  - ✓ Educational Studies in Mathematics
  - ✓ International Journal of Science and Mathematics Education
  - ✓ Journal of Mathematics Teacher Education, Research in Mathematics Education
  - ✓ ZDM — Mathematics Education; Mathematics Teacher Education and Development;
  - ✓ Professional Development in Education
  - ✓ Mathematics Education Research Journal
  - ✓ Journal of Science and Mathematics Education in South-East Asia
  - ✓ Mathematics Teacher Education and Development; Mathematics Teacher
  - ✓ The Montana Mathematics Enthusiast

  - ✓ The Mathematics Educator
  - ✓ International Journal of Lesson and Learning Study
  - ✓ Teaching and Teacher Education
  - ✓ South African Journal of Education
  - ✓ Journal of Research in Mathematics Education
  - ✓ Teacher Education Quarterly
  - ✓ Professional Development in Education
- Conference Proceedings:
  - ✓ Congress of the European Society for Research in Mathematics Education (CERME),
  - ✓ Conference of the International Group for the Psychology of Mathematics Education (PME)
  - ✓ Mathematics Education Research Group of Australasia (MERGA)
- Books:
  - ✓ The International Handbook of Mathematics Teacher Education (Vol. 3, Participants in mathematics teacher education- individuals, teams, communities and networks; Krainer and Wood (eds.) 2008)
  - ✓ The Resource Approach to Mathematics Education (Trouche et al., 2019)
  - ✓ Mathematics lesson study around the world (Quaresma et al. 2018)
  - ✓ Lesson study research and practice in mathematics education (Hart et al. 2011)
- National/regional publications (in the respective languages) in the following countries: Japan, China, Netherlands, Lebanon, Australia
- Reports by researchers from particular countries (based on selected questions): Italy, Denmark, Singapore, Israel.

Altogether we searched through 21 journals and 4 different conference proceedings between 2015 and 2021, to collect about 200 articles (including national publications in the native languages), in addition to reports from four countries. After identifying a corpus of the relevant literature, we went through the literature identifying results on mathematics teacher collective work at school level that related to the three research questions.

4. Theoretical Frames

The following theoretical frames are explained below:

(1) teacher collective work (at school level);

(2) Lesson Study;

(3) teacher agency.

4.1. Teacher collective work at school level

Within mathematics teachers' collective work, we can basically distinguish between two types: (1) Lesson study (please see section 4.2) with its three distinct features: planning a research lesson collaboratively; conducting and observing the planned lesson; jointly reflecting on the lesson based on observations of student activity (Murata, 2011); and (2) teachers' collective work on a proposed (or agreed, e.g., by a project) theme: e.g., reasoning and proof in commonly used textbooks. This would not necessarily include lesson preparation or indeed the enactment of a planned lesson.

Another distinction of teachers' collective work relates to **the place of the collective work**: e.g., in school, at a distance (online), or at university. Clearly, we refer here only to work that is school-based. However, school-based teacher collective work can also be online, that is at a distance. The latter have enormously increased, possibly due to COVID-19 pandemic related measures.

It can be said that most of the collective work at school level includes planning and enacting lessons, as this is the main part of teachers' daily work. Hence, we can say that most of mathematics teachers' collective work at school level relates to Lesson Study, one way or another, and this is the reason why we have emphasized this way of working in our theoretical frames.

In order to conceptualize lesson study adaptations (also in their home Danish context), Skott and Moeller (2020) have used the notion of *figured worlds* (Holland et al., 1998), asking 'What characterizes the dominant figured worlds when groups of teachers engage in lesson study in a Danish context?'. Their results and insights stress

> the importance of working on adaptations of approaches such as lesson study in order to transform issues of culture and power in the teachers' local setting. This applies in particular to those related to the three characteristics of a Danish teaching culture identified earlier …: teacher methodological autonomy (as interpreted from a teaming perspective), teacher collaboration characterized by functionality of teaching and a family culture, and the tendency to shake off macro-level demands. (p. 8/9)

This importance was supported by parts of their data showing that some teachers occupying senior-teacher positions would alternate between "old-hand" and "development-oriented" positions. Hence, they conclude that in their (Danish context) "it is necessary to address these broader issues of culture and power in order to adapt lesson study in a Danish context" (p.9). From this study (and others), we conclude that it is indeed necessary to distinguish between (research on) **lesson study adaptations within and outside the East Asian region.**

In terms of Lesson Study adaptations, Ding and Jones (2020) compared three such adaptations/models, each designed for supporting (and studying) in-service teacher collaboration and learning: (1) The Action-Education Model (AE) (Gu and Gu, 2016), a combination of Keli study (exemplary lesson development) practiced by researchers and teachers in schools in China and action research; (2) Learning Study (LS) (Lo and Marton, 2012), a combination of Lesson Study and design study originally conducted in Hong Kong SAR, China; (3) The Community-Centered (CC) model for teacher learning (Borko et al., 2005), a university-based summer institute program for supporting mathematics teacher collaboration (and learning) in the United States. The authors note that both Lesson Study and Learning Study (LS) address simultaneously lesson plan design and implementation as a whole teacher learning process, and (referring to Huang and Shimizu, 2016) how theory can be used to guide teaching and how teaching experiments can further refine theory (p.115). Interestingly, the western design studies (e.g., Cobb et al. 2017) share this view: whilst practically supporting teachers in improving specific aspects of their instructional practice, theoretically, they aim at designing and evaluating (and possibly re-designing) learning progressions (in association with instructional practices) and the teacher learning that goes with it.

4.2. Lesson study

Lesson Study is a complex professional learning approach. Several researchers have used the metaphor of an iceberg to capture the unseen features of lesson study with respect to the task for exposing student thinking and impacting student learning. Their metaphor is useful, in as much as the iceberg has much beneath the surface, many of the features (or essentials) of lesson study are not immediately obvious, and exposing them is said to assure fidelity of implementation of those essential features (Hart et al. 2011).

Historically, Lesson study is a collaboration-based teacher professional development approach that originated in Japan (e.g., Fernandez and Yoshida 2004) and also in China. Over the past decade it has attracted the attention of an international audience: e.g., in 2002 it was one of the foci for the Ninth Conference of the International Congress on Mathematics Education (ICME).

Lesson study incorporates many characteristics of effective professional development programs identified in prior research: e.g., it is site-based, practice-oriented, focused on student learning, collaboration-based, and research-oriented (e.g., Borko 2004; Cochran-Smith and Lytle 2001; Darling-Hammond 1994). Lesson study places teachers at the center of the professional activity with their interests and a desire to better understand student learning based on their own teaching experiences. The idea is straight forward and authentic: teachers share a question/goal regarding their students' learning and they come together based on that question; they plan a lesson to make student learning visible, and examine and discuss what they observe. Through multiple iterations of the lesson design, refinement, enactment and collection of data on student learning, reflection on lesson, and re-design process, teachers have many opportunities to discuss student learning and how their teaching affects it. Lesson study typically has a research lesson (live lesson observation) as the centerpiece of the study process (e.g., Fernandez and Yoshida 2004; Wang-Iverson and Yoshida 2005). The main purpose of this step is not to plan a perfect lesson but to test a teaching approach (or investigate a question about teaching) in a live context to study how students learn. During lesson planning, teachers also have an opportunity to study curricular materials, which may help teachers' content knowledge development. During the lesson, teachers attend to student thinking and take notes on different student approaches. In the discussion after the lesson, teachers discuss student learning based on the data they have collected during the observation (Murata 2011).

There are other professional development programs that incorporate many of the characteristics of lesson study (e.g., action research). For example, in China, the concept of Lesson Design Study has been known to work well in the Teaching Research Groups in China (Ding et al. 2019). And there are also many adaptations to Lesson Study, in particular in the United States (e.g., Amador and Carter, 2018) and in Europe (e.g. Manolino, 2020) However, what is typically different in Lesson Study is the *live* research lesson. This is said to create a unique learning opportunity for teachers. Shared classroom experiences, such as teacher noticing of certain aspects of teaching and learning, might not otherwise be shared.

4.3. Teacher agency

From the work on agency, agency is known to be related to social systems or individual characteristics: e.g., making choices among alternatives, taking initiative or being able to influence oneself and others; and is both constrained and afforded by social relations and structures, particularly power relations (e.g., Mercer 2011). Mercer (2011, p. 428) argues:

> humans as agents [are] able to influence their contexts, rather than just react to them, in a relationship of ongoing reciprocal causality in which the emphasis is on the complex, dynamic interaction between the two elements.

At the same time, Etelapelto and her colleagues (2013) argue for a subject-centered, sociocultural view of professional agency, which takes the individual and social contexts of agency to be analytically separate but mutually constitutive (2013, p. 45). In understanding agency from this perspective, they say, we need to investigate:

> how agency is practiced and how it is resourced, constrained and bounded by contextual factors, including power relations and discourses, and further by the material conditions and cultures of social interaction (2013, p. 61).

The same group of researchers also argue that agency has a temporal aspect, in that people's life histories and prior experiences influence their agency in relation to their contexts (Etelapelto et al. 2013). Biesta et al. (2015) argue that agency is an emergent phenomenon of actor–situation relations and is something that people do, rather than have, i.e. agency is enacted in context and denotes the 'quality of engagement of actors with temporal-relational contexts-for-action' rather than a property, capacity or competence of the person (2015, p. 626). This means that agents act 'by means of their environment rather than simply in their environment' (2015, p. 626).

5. Results

In this section we answer the research sub-questions with data and examples from the literature review.

5.1. What is the nature of mathematics teachers' collective work as regular school practice, and how does this relate to situation, culture and context?

We now summarize insights from studies and reports of mathematics teacher collective work at school-level (1) within and (2) outside the Austral-Asian region, and (3) at school and (4) school-based but at a distance (online).

5.1.1 Austral-Asia

Starting with **Japan**, one of the major characteristics, or the nature, of Japanese mathematics teachers is their **voluntary in-service training**. Baba et al. (2018) discusses the background of "mathematics education Lesson Study in Japan" from four perspectives; Historical, Community, Institutional, and Development Assistance. In the Community perspective, the following facts are highlighted. Some schoolteachers, who usually are excellent teachers, have had a chance to get long-term in-service training under the supervision of university researcher. After their training, these teachers returned to their school and became "Leader Teachers" in the school. They also play an important role in their district teachers' communities. School teachers often have voluntary workshop in their district communities, in which teachers discuss about mathematics materials (Kyozaikenkyu, or material research), preparations for their Lesson Study in their school, writing papers about the results of their in-service trainings, and so on. Such community or workshop is called **"Kenkyukai", or math teacher circles**.

At the same time, schools sometimes have opportunities to get funding for their in-school teacher trainings. Such projects are assigned by district education office, by prefectural education office, or sometimes by ministry of education, and usually done by the strong leadership of "Leader Teachers", who are not only the teachers who have had long-term in-service training, but also the teachers who actively attend to "Kenkyukai", or math teacher circle activities. In this sense, Japanese Teachers' Collective Work as a Regular School Practice is done with strong implicit support of "Kenkyukai", or math teacher circles.

Another major characteristic in Japanese education is the existence of "Fuzoku schools", which are attached schools to university. Especially, Fuzoku schools attached to faculty of education (or university of education) have had special role in Japanese education. It is said that the major role of Fuzoku school are: 1) education to students just as regular school, 2) preservice teacher training, 3) practical study. Regarding (1), Fuzoku teachers are also schoolteachers who do the same work as other schoolteachers. Concerning (2), Fuzoku schools are the place for prospective teachers to do their student teaching. Regarding (3), each Fuzoku school usually has its own "research or study topics", and play an important role to serve practical information about education. Mathematics teachers who are working for Fuzoku schools are usually the "Leader Teachers" in their math education communities. Obviously, they have more opportunities to write reports about their practical work in mathematics education. The number of Fuzoku schools attached to faculty of education is very small. There are about 70 Fuzoku within 20,300 elementary schools, 71 Fuzoku within 11,000 Jr. high schools, and 15 Fuzoku within 5000 senior high schools.

In a paper by Isoda (2020), the author reports on the historical development of Japanese Lesson Study. The author briefly sketches the Japanese theories for designing and reproducing better lessons to share and transfer the challenges and experiments of lesson study. Whilst Lesson study was initiated in 1873, it developed over more than a century, whilst "the major theories of mathematics education for designing and reproducing sciences were developed on the elaboration of theories proposed by various lesson study groups." (p.15) At the time of the author's writing, these can be summarized as the theories for: "clarify the objectives; distinguish teaching concept; establish the task sequence; and teaching approaches which includes assessments" (p. 15).

One of the differences of Lesson Study in Japan as compared to Western practices is that the importance of lesson preparation is largely underestimated in the West, and the collaborative work among teachers that goes into creating that lesson plan is largely under-appreciated by non-Japanese adopters of Lesson Study. This might be due to the effort involved being largely invisible to outsiders, with attention going to its most visible part, the live research lesson. The paper by Fujii (2016) makes visible "the process of lesson planning and the role and function of the lesson plan in Lesson Study" (p. 411). The paper identifies key features of the planning process in Lesson Study, including its focus on task design and the flow of the research lesson, and offers suggestions for educators seeking to improve Lesson Study outside Japan.

In **China**, mathematics teachers' collective work as regular school practice has been guaranteed by the teaching research system, because each mathematics teacher is "naturally" (by default, as part of the job as a teacher)) a member of the mathematics TRG (Teaching Research Group) and LPGs (Lesson Preparation Group) in each school in Chinese mainland. In *Secondary School Teaching Research Group Rule-book* issued by MOE in 1957, the duty of TRG was emphasized:

A Teaching Research Group is an organization to study teaching. It is not an administrative department. Its task is to organize teachers to do teaching research in order to improve the quality of education, but not to deal with administrative affairs (MOE, 1957).

Chinese Lesson Study (CLS) is just one of the forms of collective learning based on school-level TRG activities.

Not only mathematics teachers, every subject teacher belongs to a specific subject TRG for the reason of the teaching research system as the fundamental context in Chinese mainland. Because most of the Chinese teachers who teach just one subject two or three times a day, the same subject teachers are easily organized into subject-specific TRGs. This multi-tiered teaching research system is a network where province-level TRO oversee city-level TRO (see figure below), and city-level TRO oversee county-level TRO which oversee school-level TRGs (Yang, 2009; Yang and Ricks, 2013). The TRG is the basic unit in this network; its main responsibility is conducting research on teaching to solve the practical problems from teachers. So, mathematics teachers' collective work rooted deeply in the school-level TRG activities, which linked the lessons and the studies in their daily work (Fig. 1).

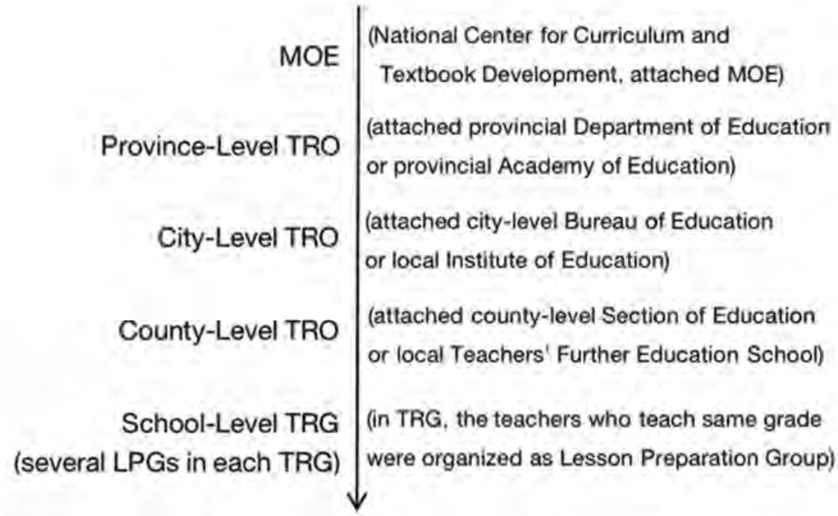

Fig. 1. The top to down guiding structure in Teaching Research System

In terms of content in such CLSs, a study by Huang et al. (2016) reports on student learning being studied by teachers, to improve teaching that promotes students' understanding. Interestingly, this CLS included didacticians (practice-based teaching research specialist and University-based mathematics educators) and mathematics teachers in China, who explored and documented how teacher participants "shifted their attention to students' learning by incorporating two notions of teaching: learning trajectory (LT) and variation pedagogy (VP)" (p.425). The former describes conjectured routes of children's thinking and learning with pertinent tasks to move towards the learning goals along the route, while the latter suggests strategies for using systematic tasks progressively. The concepts of LT and VP were used to guide planning, teaching, and debriefing throughout the LS process. Results revealed that "by building on the learning trajectory and by strategically using variation tasks, the lesson has been improved in terms of students' understanding, proficiency, and mathematical reasoning" (p.425). It was claimed that (and how) "theory-driven Lesson Study could help teachers improve their teaching and develop the linkage between theory and practice." (p.425)

In **Australia**, there has also been a particular interest in Japanese Lesson Study, as a vehicle to improve mathematics teaching practice. In their paper Groves et al. (2016) report on a small-scale research project, implementing structured problem-solving mathematics lessons through lesson study. The two major aims of the project were to investigate critical factors in the adaptation and effective implementation of (1) structured problem-solving mathematics lessons, and (2) Japanese Lesson Study as a model for teacher professional learning in the Australian context. Critical factors of Lesson Study were identified by the teachers as contributing to the success of the project. These included “the opportunities for in-depth lesson planning, the presence of large numbers of observers at the research lessons and the post-lesson discussions, and the insight provided by the knowledgeable other” (p. 501). Major constraints included the difficulty in finding suitable problem-solving tasks to match the Australian curriculum, and the teaching culture that emphasizes small-group rather than whole-class teaching.

Reporting on Lesson Study in **Korea**, Pang et al. (2016) describe how a lesson study using five practices for mathematics discussion was implemented in the Korean context. They contend that Lesson Study has had an effect on improving the quality of mathematics instruction and supporting teachers’ professional development, in the sense that “the lessons were changed to specify learning goals for students, to devise mathematical tasks in a rigorous and meaningful way, and to design the lesson structure to maximize students’ engagement” (p. 471).

5.1.2 Europe and Middle-East

During the past two decades, in Europe and Western countries (including North America) professional learning communities (PLCs) have been established, as they are seen as levers for teacher professional development. PLCs are generally defined as groups of teachers who come together to engage in regular, systematic and sustained cycles of inquiry-based learning, with the intention to develop their individual and collective capacity for teaching to improve student outcomes (Brodie 2021). PLCs are said to create spaces for ongoing, sustained professional development, in particular at school level, different from the often-fragmented professional development programs that many teachers are exposed to (Borko 2004, Cobb et al. 2018). PLCs can be seen as a special case of communities of practice (Wenger 1998), where members engage in professional learning (see section 5.3). One of the main intentions for PLCs is to deliberately position teachers as professional agents in their own professional development, through their making professional decisions as to what they need to do to enhance their teaching, in particular based on their understandings of their learners’ needs. While much of the work on PLCs argues for teacher agency as a key driver of PLCs, it is not yet known what it means to develop teachers as agents and what teacher agency actually entails (Brodie 2021; Horn et al. 2018). However, the literature on PLCs converges on five key characteristics of successful PLCs (e.g., Brodie 2021): focus, long-term inquiry, collaboration, leadership support and trust. How these characteristics play out in PLCs is central to their sustainability as spaces for professional development.

In Europe, these PLCs meet, for example, at school or at university, or in other commonly agreed spaces. In many European countries (e.g., UK) it is common to meet in school, on a voluntary basis. However, there is typically no institutionalized system of PLCs, as we see in China and Japan. Often, the PLCs are initiated by (European) projects and conducted by university academics in regional schools. In selected countries (e.g., NL), the PLCs (sometimes called DOTs- design teaching teams; see articles by Verhoef 2013, 2015) are initiated by national institutions to implement curriculum changes at school level. In recent years, Lesson Study in various forms (see earlier discussion; Skott and Moeller 2020; Ding and Jones 2021) has been promulgated as a suitable vehicle for professional development.

In Israel, Karsenty et al.'s (2019) team explored how secondary mathematics teachers, participating in a school-based video club (Sherin, et al. 2009) communicated with each other and with the facilitator along the different sessions of the club. Whilst there are different forms of video clubs, in this context a group of teachers met on a regular basis, usually under the guidance of a facilitator, to watch and discuss classroom video selected according to a certain aim. Analyzing their evaluative comments (with respect to the non- judgmental norms that this club aimed to nurture), three types of evaluative comments were identified, "reflecting varying degrees of teachers' capability to interpret and discuss observed teaching moves while attributing possible rationalizations to the filmed teacher's decisions." (p.3400) They found that as the club proceeded the communication became more productive.

In the UK, we found an example of Lesson Study in the context of the introduction of a New National Curriculum for Mathematics in England; this was not supported by a mathematics teacher educator (Warwick et al. 2016). They claim that Lesson Study is "rapidly becoming one of the most adopted models of teacher professional development worldwide" (p.555). They examined the teachers' discussions that were an integral part of the Lesson Study research cycle. In particular, they investigated "the 'dialogic mechanisms' that enable teachers' pedagogical intentions to be developed within the context of discussions that stem from observations of students as they address mathematical problems" (p.555). Findings suggested that a focus on student outcomes enabled teachers to collaborate effectively on developing pedagogical intentions to directly address student need.

Leaning on teacher collaboration for lesson planning, the paper by Pepin et al. (2017) reports on mathematics teachers re-designing their lessons due to curriculum changes in selected countries in Europe. Whilst the goal of this paper was to develop enhanced understandings of mathematics teacher design and design capacity when interacting with digital curriculum resources, it also offered new understandings of teacher collaboration in different context: e.g., France and Norway; small group collaboration (France) vs large group of teachers (Norway). Drawing on two different collective environments and two individual teacher cases working within these environments, the authors investigated and illustrated teachers' design processes (and design capacity building) across a range of contexts and curriculum formations, with the focus on how digital resources can help to develop teacher design capacity.

In terms of teacher collaboration at the distance, we found several papers, all using different ways of communicating at a distance. One of these ways were MOOCs (e.g. Taranto et al. 2020). In this project the authors used two theoretical lenses (Meta-Didactical Transposition, Connectivism) to investigate teachers' learning processes (see also section 5.3). Results showed two different teachers' learning processes: one that evolved dramatically because of the interventions — they called it an 'explosion'; the other less proactively — they called it 'linear'. In the Danish context, as another example, Tamborg (2021) investigated how a national platform brought teachers together for professional development and how it affected teachers' work. The platform was the main tool to implement at scale "an evidence-based, objective-oriented approach to teaching". He concluded that the design of platforms conflicted with the needs of mathematics teachers.

5.1.3 Americas

Over the past decade, Lesson Study has become very popular, in particular in North America. Stigler and Hiebert (2016) reported that lesson study is gradually spreading around the globe, and that the Western community has "much to learn from how it is implemented in a variety of cultural contexts". (p. 581) They reflect on the goals of lesson study, the organizational supports required to sustain the practice in various contexts, and "the benefits that may be derived from making more explicit the connections between lesson study and the wider field of improvement science" (p.581). They claim that both research and practice can benefit from learning about and from such different practices.

To provide an example of such 'borrowing', Lewis (2016) presents a theoretical model of lesson study's impact on instruction by impacting on teachers' beliefs and their learning community, amongst others. She also describes four different types of lesson study in Japan: (1) incorporation of high-quality tasks and materials; (2) attention to processes that illuminate student thinking; (3) attention to system features; and (4) models for scale-up. (p.581) She points out their "synergies in producing a system where local teachers "demand" knowledge for their lesson study work and lesson study provides a collaborative, practice-based venue to try out recent innovations in curriculum and instruction" (p. 581).

In several Western countries (e.g., USA, France) we found teacher collaboration being established around how to make sense of new academic standards and how teachers may shape the implementation of those standards. In the US context, Johnson et al. (2016) reported on a study where professional development was organized around the analysis of mathematical tasks, to support teachers to prepare for standards implementation by helping them develop common understandings of standards and how to help students meet ambitious new learning goals. However, in reality designers and teachers brought different goals to the professional development context, which became evident when teachers engaged in task analysis. Using a particular 'design tensions framework', they analyzed tensions within a research–practice partnership comprised of university researchers, district curriculum leaders, mathematics teachers, and Web engineers. Results showed the need for designers of professional development focusing on standards implementation, to be 'adaptive and willing to evolve activities to satisfy multiple stakeholders' goals for participation'.

In terms of distance learning in collectives, we found many ways of collaborating 'at school level'. For example, Larsen and Liljedahl (2017) used Twitter posts to analyze stimulating sustainable mathematics teacher collaboration in a 'distant professional development context'. To their surprise, an unprompted, unfunded, unmandated, and largely unstudied mathematics teacher community emerged where the mathematics teachers use social media to communicate about the teaching and learning of mathematics. Results indicated that enough redundancy and diversity among members is necessary to make conversations productive.

In summary, it can be said that the contexts and cultural education traditions influence the professional learning communities: their set-up, their practices, the tools used, and the expected outcomes. In the Western countries, many communities are driven by a desire to innovate or renew the curriculum and the pedagogy or to come to a meaningful integration of technology. These communities tend to be part of projects with a limited time frame. In the Eastern countries professional learning activities are more connected to the everyday teaching activities and focus on values and perceptions of 'good mathematics teaching' and 'good lesson planning'. In particular, countries like Japan and China have established a 'tradition' of teacher professional learning communities at school level.

5.2. Who is engaged in such school-based collective work, what are the roles of those people involved, and how do they relate to each other in the different communities?

Depending on the context (e.g., research project in Europe, Lesson Study in Japan, Learning Study in China), there are often different people involved in the collective work of teachers. As explained earlier, in the European context, teachers often work with teacher educators on Lesson Study or similar project that is most of the time financed by outside (school) funding bodies (e.g., EU financing), whilst in the Japanese and Chinese lesson study collaborations, classroom teachers (e.g., of the same grade) work together, sometimes with the support of expert teachers (Pepin et al. 2017). Despite these differences, a common thread running throughout the surveyed articles is the need for learning to be situated in collaboration with others. However, the collaboration can take on very different structures in supporting teachers' professional learning due to the different purposes and roles of the teachers, expert teachers or teacher educators in the studies (see 5.3).

Professional learning communities with mathematics teachers and teacher educators and/or expert teachers working and learning in collaborative groups show a huge diversity of roles, identities and interactions. This makes it difficult to get an insightful overview of this diversity, to compare initiatives or to grasp the specificity of individual initiatives. In their article Krainer and Spreitzer (2020) selected seven recent articles (covering all continents) and analyzed them along the following dimensions: relevant actors, relevant targets, and relevant environments of the collaboration (RATE). In terms of 'relevant actors', they claim that (using the RATE scheme) apart from mathematics teachers, the seven articles show “a variety of actors”, including teacher educators (6 initiatives), mathematicians (4), and policy makers (2). As social entities they found (video) “clubs”, different “communities”, (lesson study) “groups”, (project) “partners” and (design and project) “teams” (p. 34).

Regarding Lesson/Learning Study in China, Gu et al. (2016) reported on the roles of experts and other participants. The team investigated how “mathematics teaching research specialists” mentor practicing teachers during post-lesson debriefs of a lesson study in China. Results of fine-grained analysis of post-lesson study debriefing revealed that the “Chinese teaching research specialists (expert teachers, see Pepin et al. 2017) pay a great deal of attention to practical knowledge, which consists of setting students’ learning goals, designing instructional tasks, formative assessment of students’ learning and improving instructional behaviors” and that “less attention is paid to mathematics content knowledge and general pedagogical knowledge” (p. 441). The teaching research specialists apparently also pay less attention to address issues raised by the teachers or to engage in dynamic dialogue with them. Using a purposefully-developed framework for analyzing mentoring activities emerges, the strengths and weaknesses of the teaching research specialists’ mentoring strategies were identified.

It has been noted that in the USA, it is rare that teachers work with university colleagues in their school settings even though this collaboration often improves classroom instruction (Herrenkohl et al. 2010). Overall, university partnerships with teachers for professional development has been considered beneficial because of the potential of collaborative work in the teacher’s own classroom to be relevant to practice. From this perspective, both teachers and researchers can draw on their own expertise and work as authentic partners. In a study by Jung and Brady (2016) in the USA, they investigated how a teacher and a researcher performed their roles when collaboratively implementing mathematical modeling tasks within a context of in situ professional development. The researcher–teacher partnership shown in this study demonstrated how such collaboration can be supported by sharing knowledge and resources (Lau and Stille 2014). Through this in situ professional development focusing on mathematical modeling tasks, “several teacher and researcher roles were highlighted: (1) the researcher’s ways of opening the discussions and addressing the teacher’s concerns, (2) the researcher’s approaches to acknowledging the teacher’s expertise, (3) the teacher’s strategies for overcoming difficulties, and (4) the teacher’s process of reflecting on the factors that helped student development” (p.291). While the teacher learned about the new mathematical modeling tasks and related research, she helped the researcher recognize classroom realities and implement modeling tasks in these realistic settings. They also shifted roles at different stages of instructional practice (e.g., the researcher led classroom instruction or the teacher analyzed student work), which ensured that both teacher and researcher took ‘‘the role of expert’’ depending on the classroom situation (Lau and Stille 2014). The study supports the value and viability of this form of in situ professional development, indicating that significant changes in teachers' thinking (in this case about their students' mathematical model development) can occur in relatively short periods of time.

To summarize this section, it can be said that the different forms of professional learning communities include different actors. From the Chinese and Japanese cases of Lesson/Learning study, we learnt that these either include teachers (e.g., teaching the same grade) working on their own or with an expert, in a collaborative community. In these set-ups, the expert teachers (who can also be university teacher educators) are greatly appreciated, due to their seniority, their experience and expertise (e.g., Pepin et al., 2017). Teachers are expected to learn from the expert, perhaps even by 'imitating' the expert. In the European settings, university teacher educators often work with classroom teachers, not because of their seniority or teaching experience, but due to their knowledge about mathematics didactical theory — this is expected to 're-source' the teachers. However, in these settings teachers are expected to become involved in curriculum design (to take agency), including planning lessons and learning progressions, often according to newly implemented curriculum guidelines.

5.3. What kinds of learning can be observed in school-based teacher collective work?

In the studies we reviewed, teacher professionalization often has taken place in several dimensions. For example, teachers have gained content related insights, and have also changed their teaching practice based on the new insights and collectively designed lessons. We have categorized the kinds of learning reported in the studies, while we are aware that the categories can be distinguished, but in teacher learning processes they can often not be separated. We distinguish the following categories of teacher learning: (a) Lesson planning and preparation (including design capacity); (b) Pedagogical Content Knowledge (PCK); (c) Classroom practices; (d) General pedagogy; (e) Social issues and teacher identity in the mathematics classroom (e.g. teaching for equity, identity development). In the following paragraphs we describe each category in more detail.

(a) Lesson planning and preparation (including design capacity)

The focus on lesson planning and preparation appears typical for Lesson study approaches. Participation in Lesson Studies has helped teachers in a Korean and Chinese context to realize the importance of creating detailed lesson plans to accomplish mathematical learning goals. Teachers reported that, in several rounds of lesson study, they learned to anticipate student reasoning and to design tasks that evoked this reasoning (Huang, Gong, and Han, 2016; Pang, 2016). Also in an Australian study on structured problem-solving primary-school mathematics teachers reported that they had learned to appreciate the value of creating a detailed lesson plan in Japanese lesson study (Groves, Doig, Vale, and Widjaja, 2016). It had made the teachers realize "just how much there is to the teaching and learning when you step back from the actual lesson or class itself" (ibid, pp508). Enacting the lessons and receiving feedback from observers in post-lessons discussions were driving forces for their learning, which had led to changes in their classroom pedagogy. However, the teachers also noted that the Japanese approach was difficult to implement in an Australian classroom due to the different classroom cultures: in the Australian context, small-group rather than whole-class teaching was emphasized.

(b) PCK

Several studies reported PCK-related learning gains, which typically depended on the mathematical topic of the professional development project described in the study. This learning was even relevant for teachers at pre-school level. Thouless and Gifford (2019) studied the learning of UK teachers from 6 schools who participated in a two-year professional development project. The teachers formed a community of practice, in which also researchers were involved. The teachers developed their knowledge of patterns and changed their teaching of this topic by jointly developing pedagogical approaches. Other examples of PCK-related learning gains in teacher collective work at different school levels include: proportional reasoning in the primary school curriculum (Hilton and Hilton, 2019), exploring the functions between two variables by students at middle school level (Wilkie, 2016), implementation of mathematical modeling tasks in middle school (Jung and Brady, 2016), meaningfully integrating the concepts of functions and graphs in combined science / mathematics tasks in upper secondary school (Potari et al., 2016).

Involvement in the design of educational technology can contribute to the development of teachers' technological pedagogical content knowledge. This was demonstrated in a study by Hansen, Mavrikis, and Geraniou (2016) with a group of primary school mathematics specialists in the UK, who co-designed virtual manipulative on fractions and used it in their classrooms. A promising to develop teachers' technological pedagogical content knowledge was described by Misfeldt and Zacho (2016): in their project teachers developed digital learning environments, using GeoGebra and Google sites to create open-ended projects for students, based on the concepts of educational scenarios and games. More research was needed to overcome among others the steep technological learning curve for some participants.

(c) Classroom practices

Some studies on PD projects including teacher collective work aimed at a change of classroom practices, generally with the purpose to move away from mathematics focused on procedures, towards student conceptual understanding and mathematical reasoning. In lesson study projects, classroom practices change as a result of enacting the collectively developed lesson. For example, a Chilean lesson study project focused on primary teachers developing classroom practices to maintain high cognitive demand (as opposed to procedural or routine efforts) in the implementation of statistic lessons (Estrella, Zakaryan, Olfos, and Espinoza, 2020). In types of PD programs other than lesson studies, teacher collective work was included as an effective way for teachers to learn (e.g. see Wiliam, Lee, Harrison, and Black, 2004). Veldhuis and van den Heuvel-Panhuizen (2020) took this approach when developing PD workshops for primary school teachers in the Netherlands to help them develop classroom assessment techniques, methods that allow the teacher to get a quick overview of students' skills and knowledge of relevant mathematical content, so as to provide meaningful formative feedback. In the workshops, teachers and researchers collaboratively developed classroom assessment techniques, based on mathematical and pedagogical analysis of the mathematical content. Significant increases in student achievement scores on standardized mathematics tests were found. A change of classroom practices was also the purpose of a design research project in New Zealand in which teachers and researchers collaboratively aimed to improve statistics lessons for Pasifika students whose home language was not English (Sharma, 2019).

In Sweden, a large scale professional development program took place in which more than 33,000 mathematics teachers participated (Bergqvist, Liljekvist, van Bommel, and Österholm, 2017). Purpose of the program was, among others, to develop the teaching culture at the schools towards teaching for the development of mathematical competencies in line with a new national curriculum (e.g. problem solving, conceptual understanding, mathematical reasoning, and modelling). The program consisted to a large extent of supervised teacher collaboration and discussions, including the use of web-based support modules. An evaluation study in 35 schools, based on observations and interviews before, during and after the program showed that significant and sustained changes took place in teachers' classroom practices towards the development of mathematical competences. The researchers argue that the program was successful, because "the teachers were given organized possibilities to develop their knowledge and abilities to teach in line with the new curriculum documents" (pp160).

(d) General pedagogy

In several studies, teacher learning was reported that took place in the context of teaching mathematics, but was not typical for mathematics teaching. This learning typically consisted of an increased ability to notice, to reflect on teaching and learning, and to take the perspective of the student. For example, Tan and Lim (2017) studied in Malaysia how the primary teachers' reflections on lessons developed by participating in several rounds of lesson study. They found that with increasing experience in the reflection process, teachers reflected in more detail on student learning, shifted their perspective from the teacher to the students, changed perspective during their reflections and were able to anticipate student responses when refining lesson plans and student tasks. Such a shift took also place in a one year PD program studied by Haßler et al. (2015) with primary school teachers in Zambia, in schools serving disadvantaged communities. This study aimed to promote interactive forms of subject teaching in conjunction with Open Educational Resources (OER) and technology. An increasing ability to reflect and the development of a reflective language that supports deep discussions about core issues was found in a study on PD project in which Israeli mathematics teachers watched and discussed videotaped lessons of unknown teachers (Karsenty and Arvaci, 2017). Another study on the use of video, a video club for rural mathematics teachers in the USA, reported an increasing ability to notice student thinking, and to use it for instructional decisions (Wallin and Amador, 2019).

Collective work of teachers in PD is not a guarantee for effective teacher learning. Dalby (2021) studied a design research project in which groups of secondary school mathematics teachers in the UK designed lessons to explore the use of iPads for formative assessment. Findings show that teachers made progress towards this aim, both technically and pedagogically. However, comparing two groups, she found that they did not develop as equally effective professional learning communities. Group leadership, how often communication between members took place, and the extent to which group members felt ownership of the aims had an impact on the effectiveness. For individual members, also their prior technical knowledge influenced their learning.

(e) Social issues and teacher identity in the mathematics classroom

Several studies reported teacher learning in terms of in terms of doing justice to students of mathematics and developing their own professional identities as mathematics teachers. In New Zealand, professional development focusing on the collective redesign and enactment of classroom practices in schools serving disadvantaged communities helped mathematics teachers to see more and different mathematical capacities in their students (Hunter et al., 2020). Such developments of supporting student engagement may result in a shift of mathematics teachers' professional identity from knowledge providers to "'facilitators', 'learners' and 'co-creators' of knowledge" (Bobis et al.). Others (e.g. Nicol et al., 2017) used discussion and reflection as to explore possibilities and challenges of teaching mathematics for justice. The process was described as complex, with dialogue, contradictions and discomfort playing a role.

6. Conclusions

In this section we analyze the findings from the previous three sections and link them to our earlier conceptualizations of the theoretical frames (see section 4).

First, we ask 'what means school-based teacher collective work', because we have seen that teacher collective work can happen in person, or at a distance (whether teachers sit at home or in school). Different initiatives for distance collaboration can be activated through MOOCs (e.g., Italy), through platforms (e.g., Denmark, France, Netherlands), or through websites (e.g., Israel). These initiatives ask for a more nuanced description and conceptualization of school-based teacher collaborative work.

Second, this re-conceptualization of teacher learning communities also needs to include the ways these communities are supported: e.g., are teachers given time, as a matter of course, to collaborate at school (or at a distance), or do they have to ask the head teacher to carve out time for such activities? Do teachers have opportunities to meet and discuss their lesson planning? If teachers are expected to participate in such communities (that provide opportunities for discussions with colleague professionals), a culture of collaboration is needed. This is particularly needed, so the literature argues (e.g., Lamb and Visnovska 2012), in rural communities and small schools, where there is a smaller number of mathematics teachers who can support greater collegial collaboration. Leaning on Millet and Bibby's (2004) 'zone of enactment', school-based teacher collective work needs to be supported, for example with low-cost digital resources that allow for video conferencing from different sites. They can also be supported by teachers' working condition: e.g., where the professional learning in school -based communities is counted as a 'normal' daily task of a teacher (as it is in China and Japan). Or they can be supported by individual projects (e.g., as in Europe by EU projects); however, the sustainability of such initiatives is not ensured, and often the learning community 'disconnects' when the project finishes.

Third, we have seen that Lesson Study (albeit in different forms) exists all across the world. However, and according to local or regional or national practices, they are differently 'lived' in different cultures.

Fourth, we have seen that different forms and participation of professional learning communities provide different forms of agency for teachers. It seems that teachers always enact agency, even when they seemingly accept practices from others. These enactments have to be seen in relation to particular social and material conditions in their environment (and often relations of power). More research is needed to understand how teachers enact agency in school, and more particularly in school based collaborative communities.

Fifth, we have seen that teacher learning in collective work takes place in many domains. Teachers may gain competence in preparing their lessons, in mathematical classroom practices, in general pedagogy and in helping their students learn mathematics in more equitable ways. They gain PCK and develop their professional identities as a result of their activities. A common element of many studies is that teachers learn from enacting new practices in the classroom, collectively reflecting on these practices, and developing them further. In many cases knowledgeable others, experts or researchers facilitate the learning processes (and may be the initiators of the professional development programs in which teachers participate). The Lesson Studies in Japan and China are, indeed, part of teachers' regular school practice. However, such initiatives do not exist in all countries and other studies we examined were set up as projects with a limited duration. It can be expected that many mathematics teachers do not take part in these projects, but do participate in collective activity as part of their regular practice. Hence, there is a need to do further research on how these teachers learn and develop professionally.

Survey Team 4

Interdisciplinary Aspects of the Teaching and Learning of Mathematical Modelling in Mathematics Education Including Relations to the Real World and STEM[1]

Gloria Ann Stillman[2], Toshikazu Ikeda[3], Stanislaw Schukajlow[4], Jussara de Loiola Araújo[5], and Jonas B. Ärlebäck[6]

ABSTRACT This report presents preliminary results from a survey commissioned for ICME-14 on *teaching and learning of mathematical modelling and interdisciplinary mathematics educations.* The systematic literature review focusses on how a well-understood relation between mathematics and the real world underpins interdisciplinary work, interdisciplinarity in research and teaching teams, issues and challenges in the relationships among mathematical modelling, mathematics, the real world and interdisciplinarity, and mathematical modelling and a well-understood relation to the real world ensuring mathematical depth in STEM integration.

Keywords: Interdisciplinary; Mathematics; Mathematical modelling; Relations to the real world; STEM.

1. Background

1.1. The survey team's terms of reference

This paper reports preliminary findings from Survey Team 4, commissioned for ICME-14, focusing on the topic, *The teaching and learning of mathematical modelling and interdisciplinary mathematics educations,* expanding on aspects presented by the authors during the congress in July 2021. The terms of reference of Survey Team 4 were the teaching and learning of mathematical modelling and interdisciplinary mathematics education with a focus on relations to the real world and connections and implications for Science, Technology, Engineering and Mathematics (STEM) education.

The importance of mathematical modelling and mathematical applications to real world context has been growing in mathematics education over recent decades supported by regular activities on applications and modelling at the ICME's and through the series of International Conferences on the Teaching of Mathematical Modelling and Applications (ICTMAs), held biennially since 1983 (except for the recent interruption due to the COVID-19 pandemic). ICME Proceedings and Survey Lectures indicate the most recent developments at the relevant time and contain many studies, conceptual contributions, and resources addressing the relation between the real world and mathematics, as do the ICTMA Series books (e.g., Leung et al., 2021). Additionally, ICMI study 14 on *Modelling and Applications in Mathematics Education* (Blum et al., 2007) addressed a variety of topics related to modelling bringing together international perspectives. An increasing number of empirical research projects which focus on special aspects of mathematical modelling and applications, as well as national and international comparative studies, generate further interest.

In 1989, D'Ambrosio proposed that mathematical modelling is the thread by which individual disciplines in the curriculum can be interconnected to promote curricular integration. English has long argued (e.g., English 2007, 2008; English et al., 2016) for mathematical modelling becoming an enabler of interdisciplinary practices in schools, as the means by which "creative and flexible use of mathematical ideas within an interdisciplinary context where students solve substantive, authentic problems that address multiple core learnings" is promoted (2007, p. 275). The survey therefore reviews the current state-of-the-art on the teaching and learning of mathematical modelling under the specific consideration of interdisciplinary aspects. For this reason, a well understood relation between mathematics and the real world is an important focus. This is particularly relevant in the context of STEM, which has recently come to political prominence (Kelley and Knowles, 2016; Moore et al., 2020) in several educational jurisdictions around the world.

1.2. Interdisciplinary approaches to education and research

The construct, *interdisciplinarity*, entered the literature in 1972 (Miller, 2020) in an Organization for Economic Cooperation and Development report (Apostel, 1972), although the idea was well known in education long before this. Like most constructs, interdisciplinarity has morphed to have several meanings. In our survey, we were guided by the USA National Academies definition for *interdisciplinary research*:

> a mode of research by teams or individuals that integrates information, data, techniques, tools, perspectives, concepts, and/or theories from two or more disciplines or bodies of specialized knowledge to advance fundamental understanding or to solve problems whose solutions are beyond the scope of a single discipline or area of research practice. (National Academy of Sciences, 2005, p. 39)

In actual teaching and learning situations in classrooms, different approaches to integration can be seen as *isolated* into separate disciplines, or *connected* deliberately relating separate disciplines to show connections, or *nested/fused* where content from one or more other disciplines is taught in a discipline to enrich it, or *multidisciplinary* incorporating two or more disciplines around the same theme or topic but the disciplines keep their identity, or *interdisciplinary* when two or more disciplines interact to become something new such as mathematical ecology, or *transdisciplinary* where there is a transcendence of the disciplines and the focus becomes the field of knowledge as exemplified in the real world (Gresnigt et al., 2014, p. 52). Gresnigt et al. use the metaphor of a staircase of increasing complexity where more elements of teaching are shared between disciplines rather than assuming the higher up the ladder the better the integration. Instead, they characterise these steps as different ways to integrate. Others such as Williams and Roth (2014) include *meta-disciplinarity* where there is awareness of the nature of the disciplines involved in their relation and the differences within an inquiry or problem solving. As Roehrig et al. (2021) point out, “It is the multidisciplinary nature of real-world problems, as opposed to the disciplinary structure within formal schooling, that grounds arguments for curricular integration” (p. 2).

1.3. Mathematical modelling and interdisciplinarity

Mathematical modelling can be understood as real-world problem solving, although we acknowledge it does not have to be. Mathematical modelling in this interpretation is then the process of applying mathematics to a real-world problem or situation with the goal of understanding it (Niss et al., 2007). It is more than applying mathematics in a closed situation where nothing needs to be assumed or estimated — just a known mathematical technique applied. Thus, multiple interpretations of the situation being modelled are possible. “The modelling enterprise involves identifying and addressing open-ended questions, creating, refining and validating models, and arguing the case for implementation of model informed outcomes” (Niss et al., 2007, p. 17).

In addition, from an epistemological perspective, “essential characterisations of modelling… involve posing and solving problems located in the real-world, which for our purposes includes other discipline areas such as engineering or medicine, and general contexts of living as they impact on individuals, groups, and communities” (Niss et al. 2007, p. 17). Researchers have therefore developed or proposed theoretical views on the interplay between mathematical modelling and interdisciplinarity in mathematics education (e.g., Borromeo Ferri and Mousoulides, 2017; English, 2013; Michelsen, 2006, 2015).

English (2013), for example, argues that there is a need to build a stronger foundation in the mathematical sciences through future-oriented learning experiences to equip students for the challenges of the 21st century. She lists core competencies that are key elements of productive and innovative workplace practices to ensure such a foundation. To achieve this aim, she recommends an increased focus on interdisciplinary problem solving that engages students in complex modelling with challenging, life-based scenarios. In such learning experiences, knowledge and skills from at least two disciplines are applied to real-world scenarios with the aim of shaping the total learning experience. English sees such mathematical modelling having applicability in primary and middle schooling where the focus is on engaging students in the kinds of mathematical and scientific thinking needed for challenges beyond the classroom. She supports her argument from two design-based studies, a data modelling study in Year 1 and engineering-based modelling experiences in Year 7.

1.4. Mathematical modelling and a well understood relation to the real-world

Relations between mathematics and the real world have existed since the very beginnings of mathematics (see, e.g., Joseph, 2011). If mathematical modelling is conceived as real-world problem solving, a well understood relation between mathematics and the real world is essential. When such a relationship is in play, the real-world situation encourages a deeper understanding and processing of mathematics; but simultaneously use of mathematics encourages deeper understanding and processing of the real world. Each enriches the other.

The example of water falling from two gates on a dam wall into the spillway below illustrates our point and is a context to design modelling materials for a secondary school classroom. From a mathematical point of view, the maintaining of a well-understood relation of any in-class modelling to the real world is an issue for teaching mathematics in school. The situation to be modelled is derived from the observation that the water from the gate that is lower in the dam wall appears to have stronger momentum than that from the higher gate; however, the horizontal distances from the dam wall to the impact point on the spillway seem to be similar. We pose the real-world problem: What is the relation between the location of a gate and the horizontal distance of where the water lands? This situation is concerned with mathematics and physics. (See Stillman et al., submitted, for a full solution to this problem.)

From a mathematics perspective, students realise the importance of generating and selecting variables, setting up a simplified situation and validating the solution derived from the model by experiment. During their modelling, students have opportunity to appreciate the utility of mathematics to understand (represent, explain, predict) parts of the world. From a real-world perspective, knowledge of physics is enriched. Students learn that the velocity of the spilling water is proportional to the square root of the distance of the gate from the top and that the horizontal distance of the landing site of the spilling water becomes a maximum when the gate is located at the mid-point of the height (depth) of the water in the dam at the wall where the gates are located.

Two questions are crucial in both solving an authentic real-world task like this and in planning its implementation and management in class. Firstly, what type of mathematics can be applied and secondly, how can the real-world situation be conceptualised. Interaction between these two leads to a well-understood relation between mathematics and the real world *when they enrich each other*.

2. Focuses and Research Questions

It is timely for the international mathematics education community to survey, synthesise, and propose new directions for research that is focused on interdisciplinary aspects of research and teaching in mathematical modelling. The survey team has been addressing the specific scope and foci of relevant work that has been developing in these areas over the last decade in different educational systems around the world. The interdisciplinarity aspects that have been focused on are (a) interdisciplinarity in research teams as well as research focussed on interdisciplinarity and (b) interdisciplinarity in teaching and teaching design teams through all levels of schooling and into tertiary education.

Broad research questions, guiding the analysis the survey team has conducted for this paper are:

- How does a well-understood relation between mathematics and the real world underpin interdisciplinary work in mathematics education?
- How have interdisciplinary teams contributed to knowledge about mathematical modelling and the relation of mathematics to the real world?
- What issues and challenges are there in the relationships among mathematical modelling, mathematics, the real world and inter-disciplinarity in both teaching and research?
- How could contributions from research and teaching on mathematical modelling and relations of mathematics to the real world contribute to ensuring mathematical depth in STEM integration?

3. Methodology

The team started collection and collation of potential sources for the survey by calling for contributions on several online list serves which resulted in contributions by individuals of lists of publications, including projected future publications, and chapters about research and teaching projects with interdisciplinary connections of mathematics as well as mathematical modelling. An initial surveying of literature (including English, German, Japanese, Portuguese and Swedish) from selected geographical regions was conducted by different team members. This established a basis for what we might expect to locate in the time period and the likely fruitfulness of potential sources, so a systematic survey of sources began in preparation for a systematic analytical review of literature (Newman and Gough, 2020). Synopses of all selected sources were collated in one database where they were coded by reading the original source and the synopsis, re-reading the source and adding to the synopsis when necessary. Sources that did not appear to be within the remit of the terms of reference were starred for potential culling following cross checking. This was carried out by two team members independently. Our initial focus was on the period 2012–2020 but then we conducted a more in-depth search of 2016–2021, once the date of the conference and reporting was extended. Our sources included refereed journals, edited books (especially in relevant book series in mathematics education and other fields such as STEM), conference proceedings, and theses (see Tab. 1). Our database extends beyond this because of the initial cross geographical regions search and individual contributions. As well as major mathematics education journals, we have read and collated articles from other journals to augment understanding of the breadth and depth of research and teaching in other fields such as science education and to gain insight into the STEM field, especially in relation to mathematical modelling outside of what is usually cited in mathematics education. We, thus, examined articles from the *International Journal of STEM Education*, amongst other journals.

Research projects
Funded research 2011–2021 projects in mathematics education in the Nordic countries also involving interdisciplinarity and STEM
Theses and dissertations
Craig (2017); Gibbs (2019)

In the grey literature we examined outputs in recent years in several conference series in different parts of the world and added those where there was no similar literature in other scholarly sources. Research projects, both by established researchers and teams and by early career researchers in theses and dissertations, were also surveyed. For example, when Prof. Arleback joined our team at the end of 2020, he began by surveying funded research projects in mathematics education in the Nordic countries which also involved interdisciplinarity and STEM to gain an understanding of what was happening in the time period of the survey. It was expected this would lead to published literature on the earlier projects but most likely not on the recent ones, given COVID-19 had restricted conference travel and possibly the research proceeding.

A coding scheme was developed, and the codes for this paper were structured around our research questions according to four overarching categories: (a) relations between mathematics and the real world (RQ 1), (b) interdisciplinary team contributions (RQ2), (c) issues and challenges in relationships (RQ3), and (d) mathematical depth in STEM integration (RQ4). Tab. 2 provides an example of our coding scheme for a selection of the reviewed literature for the interdisciplinary team contributions category. Similar coding schemes were developed for the other three categories. Initial and final coding was carried out by the first author. Another member of the team checked the first coding and sent all queries to the initial coder who then carried out a second coding. Subsequently a third re-coding round was conducted 6 months later to check coding reliability. A configurative synthesis (Newman and Gough, 2020) of the different literature sources was then conducted to answer our research questions, focusing on the research questions and problems or topics the selected literature addressed, noting confirmatory and contradictory findings and rival explanations of such findings.

Tab. 2. Example coding scheme for interdisciplinary team contributions category

Code	Brief Description	Examples of Literature
CoA	Co-authorship from other domain(s) other than mathematics education	Sala et al. (2017); Sawatzki et al. (2019); Viirman and Nardi (2021)

4. Findings

We present our findings in four threads to address our four research questions where overall trends, issues and challenges will be illustrated and exemplified.

4.1. Relation between mathematics and the real world underpinning interdisciplinary work in mathematics education

As seen in subsection 1.4, to try to understand the relation between mathematics and the real world, we think about two worlds, the real world and mathematics. On the one hand, the real world encourages deeper understanding and processing of mathematics. On the other hand, mathematics encourages deeper understanding and processing of the real-world situation. If both are satisfied, enriching each other, we say the relation between mathematics and the real world is well-understood and this is what we see as ideal to underpin interdisciplinary work in mathematics education.

Mathematical modelling is sometimes described as a transformation of a real-world problem to a mathematical problem and back again, so the real-world and mathematical world appear distinct. Czocher (2018) raises and considers a critical issue in the modelling process related to a deep understanding of the *relation of mathematics to the real world*: "How do modellers determine if the transformation from the real world to mathematics was conducted well?"

From a study of the modelling activity of four engineering students, Czocher (2018) presents an empirically derived typology of five validating activities to explain how validating functions to ensure a mathematical model will yield a reasonably accurate prediction. To capture the complexity of modelling due to validating, she offers an empirically grounded schematic adapted from the modelling cycle diagram of Blum and Leiß (2007). Two circular regions show the real world and the mathematical world, respectively; however, a honeycomb-patterned annulus surrounds the mathematical world representing reasoning that is mathematically structured but constrained by real-world conditions. Triangles and circles are used to indicate the model construction stages (e.g., situation model) with solid arrowed arcs showing the transitions between these. Dotted arrowed arcs show validating actions which lead to, or from, the mathematically structured real world. The schematic shows that most of the observable reasoning occurs in the annulus as a blend of the real-world and the mathematical world, thus validating ensures the real world and mathematical world stay intertwined. Czocher (2018) proffers this model because she found no evidence of a separation into purely mathematical thinking and purely real-world thinking and switching between the two in her study.

The four validating activities that perform this function are comparing the mathematical expression, its constituent components or relationships, to the interpretation of the problem setting; comparing the mathematical expression, its constituent components or relationships, to the idealized version of the problem setting; comparing the real results to empirical, or based-on-empirical, expectations (predicted by theory); and comparing real results against physical principles accounted-for in the real model. The fifth validating action she identified occurred purely in the mathematical world. "The nuances of validating suggest that creating and maintaining relationships between reality and mathematics [are] more complex than a transformation" (p. 137). As a consequence, Czocher (2018) suggests a more prominent role should be afforded to validation in the modelling process. Czocher et al. (2018) argue that in order to foster learners who are confident and capable in STEM fields, it is necessary to revisit how verifying and validating activities are conceptualised and developed across the years of schooling and in different subject areas. (See also Jensen, 2018.)

Another issue in teaching modelling is how to facilitate students' conceptualisation of the real-world situation. Bearing this in mind, Wernet (2017) focused on the interaction between teachers and students about contextual features in written tasks. During whole class discussions, teachers and students discussed context of written problems in multiple ways, and these interactions often led to higher authenticity (Palm 2008) being enacted in discussions, than was written in the task descriptions. In a similar vein, Chang et al. (2020) focused on making assumptions to conceptualise a real-world situation. Such conceptualisation necessarily involves both realistic considerations and non-mathematical knowledge. Inadequate assumption making leads to an inadequate situation model and to an inadequate mathematical model for the problem situation.

4.2. Contributions from interdisciplinary teams to knowledge about teaching and learning mathematical modelling and relations to real-world

With respect to contributions from interdisciplinary teams, there were some limitations with respect to determining disciplines of researchers and team composition from published work and how, and to what extent, a researcher contributed to a study. At times this information was available in the biographies of authors or in acknowledgements but at other times information had to be sought from project and university staff personal webpages. In many cases, many experts who contributed to a project are not visible (e.g., curriculum designers, methodology experts). Despite these limitations, there was evidence of contributions of several interdisciplinary research teams and interdisciplinary teaching and curriculum design teams and combinations of these to knowledge about teaching and learning of mathematical modelling and relations to the real-world. Some of the interdisciplinary teams were multi-national, whereas others addressed topics in which interdisciplinary teams are essential. The latter included international comparative studies where both culture and language had to be taken into account, knowledge transfer from one country to others, and validation of results of a study across countries and cultures.

The study by Chang et al. (2020), for example, involved a team of four mathematics educators, two from Chinese Taiwan and two from Germany. The aim was to compare Year 8 Chinese Taiwan students and Year 9 German secondary school students' knowledge use in solving structured modelling problems set in familiar contexts. In this study, the researchers intentionally designed two types of assumptions in two modelling tasks, namely, one requiring only non-numerical assumptions and another requiring both non-numerical and numerical assumptions. As few current studies comparing modelling performance between Western and non-Western students have considered the differences in students' knowledge, students' relative performance was investigated when students' mathematical knowledge in solving modelling problems was matched. The results showed that the Chinese Taiwan students had significantly higher mathematical knowledge than did the German students, whether conceptual or procedural. However, when students had the same level of mathematical knowledge, the German students showed higher modelling performance on the same modelling problems, no matter what type of assumptions were necessary. Chang et al. suggest that their findings imply that Western mathematics education may be more effective in improving students' ability to solve holistic modelling problems. It should be noted, though, that the German school mathematics curriculum provided opportunities for students to learn modelling, whereas the Chinese Taiwan students did not, so the findings could also be reflecting opportunity to learn.

Viirman and Nardi (2021) report on the work of an interdisciplinary research team comprised of three tertiary mathematics education researchers and one research mathematician with extensive experience of mathematical modelling and teaching applied mathematics. Mathematical modelling was being used as a vehicle to integrate mathematics and biology to improve tertiary biology students' engagement with mathematics and their competencies in both mathematics and biology. Viirman and Nardi traced the students' meta-level learning about mathematical modelling, particularly as they fluctuated between deploying graphs for mere illustration of data and as sense-making tools. Some students, however, used graphing only for illustration of work done and not to make meaning from data in their modelling. Previous mathematical experiences with graphing were relied on and the necessity to maintain a good relation, between mathematics and the real or extra-mathematical worlds in the situations they were modelling, was not noticed. Hankeln (2020) noted similar results from a comparative study of upper secondary school students' modelling processes in Germany and France. Although French students were more unfamiliar than German students with real-world context being of more importance than as a mere motivation to engage in mathematics, German students often just exposed the mathematical content as they had accepted socio-mathematical norms that a deep understanding of the real-world context was not the focus of mathematical tasks and could even be a hinderance. These findings in both studies highlight the importance of teachers at the secondary and tertiary levels making students aware of the depth of engagement with real-world aspects of tasks that are needed to be productive in adjusting modelling methods and models used previously to fit a new situation when constructing, interpreting, and validating models or the modelling used.

4.3. Issues and challenges in the relationships among mathematical modelling, mathematics, the real world and interdisciplinarity

Several issues and challenges in the relationships among mathematical modelling, mathematics, the real world and interdisciplinarity in teaching and research were raised in the literature reviewed. We have space to raise only a few.

As Carreira and Baioa (2015) point out, it is rare in mathematics classes for secondary students to engage in examining material objects and artefacts of the real world to generate mathematical ways of viewing reality. However, such experiences enable the making of connections between students' everyday life, mathematics, and the real world. Carreira and Baioa designed and implemented a mathematical modelling learning activity where students collected data about staircases in their neighbourhood. This allowed students to come to the realisation that linearization was the key to designing the best staircase for a house despite finding slight variations from the ideal in reality. A linear model came from mathematical notions such as average step to compensate for variability in tread and riser measurements in producing a staircase of constant slope. As Diego-Mantecón, Haro et al. (2021) note, in teaching activities such as this, there is a need for contextualised knowledge that is not taught in school but, as Carreira and Baioa (2015) have demonstrated, there are ways to gain some of this such as going out into the locality where students live.

In other work, Diego-Mantecón, Prodromou et al. (2021) found that in-field mathematics teachers avoided using transdisciplinary projects where school mathematics content was difficult to address, whereas out-of-field mathematics teachers tended to overlook the mathematics in interdisciplinary projects, oversimplified it, or used basic mathematics below curriculum standards. In-field mathematics teachers promoted high cognitive demand and productive dispositions towards mathematics in projects. Some students, however, did not want to invest time into such projects, being more examination oriented. Students also contributed to projects where their strengths were (e.g., practical skills) rather than use the opportunity to improve areas where they were less confident (e.g., mathematical analysis).

4.4. Ensuring mathematical depth in STEM integration

STEM integration can foreground mathematics teaching, learning and use in two ways: *intra-mathematical* providing opportunities to engage with mathematics in the development and application of mathematical ideas, concepts and skills in the context of meeting curriculum obligations in mathematics or *extra-mathematical* as a unique mathematical viewpoint and its practice contributing to understanding and development of ideas, concepts and skills in other STEM disciplines. According to several authors, the optimisation of these ways of foregrounding mathematics so there is a noticeable effect on mathematical achievement and learning is yet to be realised as mathematics is seen as benefiting least from STEM integration (English, 2016; Fitzallen, 2015; Maass et al., 2019). A study by Li et al. (2020) of publicly funded STEM projects in the USA from 2003-2019 perplexingly showed that the majority of projects focused on single disciplines, especially mathematics. However, these projects showed a strong emphasis on mathematics, particularly before 2012.

To address the rather shallow treatment of mathematics in STEM education, several sources (e.g., Ärlebäck and Albarracin, 2019; English et al., 2016; Gonçalves and Pires, 2014; Leung, 2018; Turner et al., 2019) expressed the expectation that mathematical modelling would be an enabler of interdisciplinary practices and integrating professional disciplines with secondary school subjects and also in primary/elementary school (e.g., Baker and Galanti, 2015). However, from a literature survey of STEM integration practices 2013-2016, Bajuri et al. (2018) identified mathematical modelling as the least focused on integrative practice. They proposed using metacognition and social interaction development to promote these abilities in a mathematical modelling approach to STEM. Such a proposal would seem eminently sensible given the nature of mathematical modelling as conducted by professional modellers and in school classrooms and the fact modelling is included in each of the STEM disciplines and is "an opportunity to express and to develop disciplinary knowledge and ways of thinking" (Hjalmarson et al., 2020, p. 229).

5. Closing

As our preliminary findings from our systematic analysis of relevant literature show, all four threads we have explored have not been exhausted. These areas represent opportunities for the mathematics education research community to conduct further scholarly work and help advance the field at large. Our final report will also contribute to this.

Topic Study Group 1

Mathematics Education at Preschool Level

Marja van den Heuvel-Panhuizen[1], Angelika Kullberg[2], Ineta Helmane[3], and Xin Zhou[4]

1. Aims of the TSG

TSG-1 is about the foundations of learning mathematics and the contexts in which the first steps are taken towards achieving mathematical understanding. The aim is to share and discuss contemporary research on early childhood mathematics learning and teaching and their theoretical and methodological frameworks. TSG-1 involves research on children's mathematical development from birth until entering formal schooling in first grade (children up to 6). The nurturing of this development can take place in care centers, preschool, and kindergarten, and at home.

Although it is currently widely accepted that the development of mathematical skills in the early years is essential for later mathematics learning, it is not so obvious what mathematics should be fostered in young children. Mathematics as a subject has traditionally been considered above the preschool and kindergarten levels. Moreover, researching young children's mathematical understanding has for a long time been a privilege of psychology and pedagogy. These sciences have provided much knowledge about conditions and variables that influence children's mathematical development but do often not consider very deeply the mathematics that is, or has to be, developed by young children and generally do not cogitate about why certain mathematical competences are important or what activities are crucial to stimulate the development of these competences. To gain a better insight in this what aspect of mathematics education at preschool level, we invited contributions from the didactics of mathematics, but also for example from (neuro-) cognitive, developmental, socio-cultural and other approaches to the learning and fostering of young children's mathematical understanding. TSG-1 intends, from multiple perspectives, to contribute to the improvement of knowledge and understanding of issues that early childhood mathematics education encounters in different contexts and come eventually with

proposals for advancing research, development and practice in mathematics education at preschool level.

To achieve this TSG-1 we invited submissions of substantial research-based theoretical or empirical contributions within the following four subthemes:

1. Unpacking early childhood mathematics. Opening up the thinking about the mathematics content (broadly interpreted as knowledge, skills, conceptual understanding, mathematical reasoning and attitude) to be fostered in young children. What mathematics is worth to be developed? What mathematics anticipates future learning and opens the road to future learning?
2. Pedagogical and didactical approaches in early childhood mathematics education. What are meaningful learning environments for young children in a school setting or home environment? What tools, including manipulatives and technology, supports early mathematics learning? How can play and story reading be used? In what way can learning environments for young children be improved by embodiment theories on learning?
3. Assessing mathematical understanding in early childhood. How to get a better understanding of young children's mathematical development?
4. Preparing early childhood educators to foster children's mathematical development. How can professional development provide appropriate support and flexibility to allow teachers, care-givers and parents to develop new knowledge and understanding about mathematics education for young children?

1.1. Submissions

The 2021 round of submissions ended up in 17 accepted papers from 14 countries (North America: 3; Asia: 5; Europe: 9; Australia: 2).

1.2. Sessions

The TSG met during three days. In the first session, the TSG chair Marja van den Heuvel-Panhuizen, and the rest of the organizing team, described the organization of the sessions. Before the conference all papers and one power point slide for each paper were sent to the participants. The sessions were organized around two themes. The first session was on the theme Investigations of children's learning, whereas the two last session was on the theme Investigations of children's learning environment. Each paper was presented and discussed during 10 minutes. At the end of each session there was a joint discussion for 25 minutes on topics related to the papers as a whole and developments in the field. The list of papers and order of presentation are shown in Tab. 1.

Tab. 1. List of papers presented

Paper and author(s)	
[1]	Application of number line estimation strategy for 5–6 years old children: Effect of reference point marking. ***Xiaoting Zhao*** *and Xiaohui Xu* (China).
[2]	Unraveling the quantitative competence of kindergartners. ***Marja van den Heuvel-Panhuizen*** (Norway) *and Iliada Elia* (Cyprus).
[3]	Insights about constructing symmetry with 5-year-old children in an artistic context, ***Yuly Vanegas***. *Carla Rosell and Joaquin Giménez* (Spain).
[4]	Kindergartners' use of symmetry and mathematical structure in representing SELF-portraits. ***Joanne Mulligan*** *and Gabrielle Oslington* (Australia).
[5]	Investigating evidence of girls' and boys' early symmetry knowledge through multiple modes of assessment. ***Nicole Fletcher***, *Diego Luna Bazaldúa, and Herbert P. Ginsburg* (USA).
[6]	4-Year-olds children's understanding of repeating patterns: A report from China. ***Fang Tian*** *and Jin Huang* (China).
[7]	Investigating how kindergartners represent data with early numeracy and literacy skills through a performance task. ***Insook Chung*** (USA).
[8]	Counting activities for young children: Adults' perspectives. *Dina Tirosh, Pessia Tsamir,* ***Ruthi Barkai****, and Esther S. Levenson* (Israel).
[9]	Asking early childhood teachers about their use of finger patterns. ***Miriam M. Lüken*** *and Anna Lehmann* (Germany).
[10]	Performance expectations in the area of "Shapes and Spaces" of early childhood educators in an international comparison. ***Catherine Walter-Laager*** (Austria), ***Manfred R. Pfiffner*** (Switzerland), *Xin Zhou* (Chian), *Douglas H. Clements* (USA), *Julie Sarama* (USA), *Linh Nguyen Ngoc* (Vietnam), *Lars Eichen* (Austria), *and Karoline Rettenbacher* (Austria).
[11]	Mathematics in play. ***Ronald Keijzer***, *Marjolijn Peltenburg, Martine van Schaik, Annerieke Boland, and Eefje van der Zalm* (Netherlands).
[12]	Does preservice teacher training change prospective preschool teachers' emotions about mathematics? ***Oliver Thiel*** (Norway).
[13]	Bishop's (1988, 1991) mathematical activities reframed for pre-verbal young children's actions. ***Audrey Cooke*** *and Jenny Jay* (Australia).
[14]	When math meets games — The active construction of children's core mathematics experience in games. ***Jianqing Wen*** (China).
[15]	Analysing a Danish kindergarten class teacher's instructional support in mathematics with the tool Class. ***Birgitte Henriksen*** (Denmark).
[16]	Mathematical learning environments in Norwegian ECEC child groups. ***Øyvind Jacobsen Bjørkås***, *Dag Oskar Madsen, Anne Grethe Baustad, and Elisabeth Bjørnestad* (Norway).
[17]	"More Gooder": children evaluate early numeracy apps. ***Ann LeSage*** *and Robyn Ruttenberg-Rozen* (Canada).

2. Conference Themes

The studies discussed in TSG-1 involve mainly research on children's mathematical development in the years before they enter in formal schooling in first grade. The nurturing of this development can take place in various environments: care centers, preschool, kindergarten, and at home. The 17 submitted papers to TSG-1 was divided in the categories: "Investigations of children's learning" (papers [1]–[7]) and "Investigations of children's learning environment" (papers [8]–[17]).

The papers in the first category are all based on data collected from children. For several mathematical content areas and competences it is investigated what children are capable of. The papers of the second category are based on data collected through observing classrooms and interviewing early childhood teachers and educators, prospective preschool teachers, and other adults. Interestingly, in one study the learning environment was also investigated by interviewing children themselves. In this second category are also two papers which have a more theoretical stance. One is proposing a revision of a framework for mathematical activities and the other is recommending the use of mathematical games in kindergarten.

2.1. Investigations of children's learning

The collection of papers in this section addresses mathematical competences in the domain of early number, symmetry, patterns, and representation of data.

With respect to early number, one of the Zhao and Xu[1] investigated children's competence in making estimations on the number line. This is a topic that is not everyday dealt with in kindergarten classes. By eye-tracking technology the study showed that the ability of kindergarten children (aged five to six) of making estimations on a 0–10 number line can be effectively improved by using a midpoint marker instead of a marker at every quartile.

Heuvel-Panhuizen and Elia[2] aimed to unravel the composition of the quantitative competence of kindergartners. By analysing data from a collection of paper-and-pencil items it was revealed that in addition to counting, subitizing, and additive reasoning, also multiplicative reasoning belongs to this early number ability. Furthermore, an implicative analysis at item level showed that in general, multiplicative reasoning and conceptual subitizing items were found at the top of the implicative chain, counting and perceptual subitizing items at the end, and additional reasoning items in the middle.

Three studies investigated the development of the notion of symmetry in kindergartners. In the study[3] of Vanegas et al. a sequence of 16 symmetry-related activities was developed in the context of art work. In these activities kindergartners had to work with various axes of symmetry. The authors found that the designed sequence can constitute a hypothetical path by which children in early childhood education can progress in their learning of symmetry.

Mulligan and Oslington[4] contributed the second study on kindergartners' competence in symmetry, which looked for an alternative for the often used "butterfly" pictures. To make the context more meaningful for the children they had to work with drawings of their portraits which they had to analyse for features of line symmetry and mathematical structure. The authors found that over thirty percent of children represented explicit structural features such as equal spacing, congruence, partitioning and alignment of facial features. The third symmetry study[5] by Fletcher et al. explored the assessment of early symmetry knowledge. In the study an intervention with symmetry software took place in which first and second grade children were taught reflection, translation and rotation. After the intervention the children were assessed by a paper-and-pencil test and by interviewing them. The authors found that children who reached higher scores on reflection and translation tasks, in the interviews also provided explanations indicating conceptual understanding of the symmetric transformations. The similar relationship was reported for girls and boys.

Recognizing and being able to work with patterns is considered a vital element of young children's mathematical development. To know more about children's understanding of patterns, Tian and Huang[6] investigated in a sample of 134 four-year-olds preschool children how able they are in solving tasks on repeating patterns. The results showed that the children could fill and expand repeating patterns, but also difficulties came to the fore in the abstraction of the pattern, especially in identifying the unit of a repeating pattern.

The last content domain that is reported in this section is the representation of data. Chung[7] describes a study in which it was investigated whether kindergartners (aged five-six) can sort and group objects, identify the quantity of each group of objects, and then can draw pictures or write names and numbers to organize and present the data. One of the results of the study is that half of the 35 children involved failed to represent the quantities using numerals and pictures.

2.2. Investigations of children's learning environment

The papers in this section lift in different ways the veil of the conditions and circumstances in which the early learning of mathematics can come about. To gain knowledge about this, in most studies data were collected by interviewing early childhood teachers. In the study[8] by Tirosh et al. a broader response group was surveyed and adults (not being preschool teachers but including grade school and high school teachers, psychologists, occupational therapists, engineers, municipal workers, and accountants) were asked what types of activities they perceive as the ones that can promote numerical skills. Many participants suggested counting objects. Sub-skills such as counting forward from some number other than one or focusing on one-to-one correspondence, were less mentioned.

In Lüken and Lehmann's study[9], when 23 early childhood teachers were asked about their use of finger patterns in their daily interaction with children it was found that they all use finger patterns in a variety of everyday (such as age/birthday, finger games, board games) and mathematical contexts (verbal counting, object counting, referring to quantities or number signs, and when calculating). The frequency and type of used finger patterns varied among the teachers. Only four teachers used finger patterns doing calculations. Two of them used the fingers in a dynamic way and two in a static way. No more then ten teachers used finger patterns as a visualization to help children develop an understanding of numbers.

Because what early childhood educators think about the mathematical abilities of their children may influence the learning environment they offer to them, an international study[10] by Walter-Laager et al. was set to investigate the performance expectations of early childhood educators in five countries. The focus was on shapes and space. The data of 1343 early childhood educators revealed that the expectations for this content area were more accurate in Austria and Switzerland than in China, Vietnam and the USA. Also, the estimations for 3–6-year-old children were more appropriate than those for the 1–3 year olds.

In addition to learning through focused activities, young children's learning of mathematics also takes place to a large extent through free play. In Keijzer et al.'s report[11], to figure out what interactions between preschool/kindergarten teachers and preschoolers (2 to 6 years) can be considered as useful for stimulating young children's language and mathematical development a professional learning community (PLC) was set up consisting of preschool and kindergarten professionals and researchers. Based on discussions held within PLC-meetings and the analysis of the mentioned interaction characteristics three guidelines for interactions were identified that can stimulate children's mathematical development during children's spontaneous play: observing (understand the child's interest and feelings), connecting (confirm what the child is playing) and enriching (cooperatively construct mathematical meaning).

Preschool teachers' positive feeling about mathematics is a determining factor of the quality of the early childhood learning environment. Therefore, in Thiel's longitudinal study[12] with an experimental pre-test post-test control group design, it was investigated whether and how a preservice teacher training can change prospective early childhood teachers' emotions about mathematics. The study was carried out with full-time and part-time teacher students. Only the part-time students showed after the training an increase in mathematics enjoyment and a reduction of mathematics anxiety. For almost all the part-time students the lessons at the university were the most important reason of this change. For only half of the full-time students this was the case, while 35% indicated that it was the five-weeks practical period they spent in an early childhood institution.

In the two following papers, instead of an empirical approach, the learning environment is considered from a theoretical point of view. Cooke and Jay[13] discussed with what mathematics young, pre-verbal children might be engaged. The authors used for this Bishop's framework of the six mathematical activities which are fundamentally mathematical: counting, locating, measuring, designing, playing, and explaining. By reframing each of these activities by putting the focus rather on actions than on language, the framework is made appropriate for pre-verbal children and may provide assistance in identifying the mathematical thinking that is evident in pre-verbal children's actions. Wen[14] focuses on games as the basic form of activity for preschool children and describes the mathematics that children can meet in games and through which they can achieve the ability to think mathematically. Questions to be answered are how the gameplay and the core mathematics experience are related and how the fun of games can be combined with the effectiveness. The paper continues by giving examples of teachers playing games with children and children playing alone or cooperatively.

A tool to measure the quality of the early childhood learning environment in a standardized way is the Classroom Assessment Scoring System (CLASS). With this tool, among other things, the given instructural support can be investigated with respect to three dimensions: the development of concepts, the quality of the feedback and the language modelling. Henriksen[15] used this tool in a kindergarten class and analyzing the classroom interaction in an observed lesson. It was revealed that there was a low score on Instructional Support: the teacher did not prompt children to explain their strategy, did only focus the feedback on the correctness of the answers, and asked mostly close-ended questions. By proving this information, the tool can give indications in what way the teacher may develop.

In a large national study[16] by Bjørkås et al., the quality of the learning environments in the child groups of Early Childhood Education and Care centers were investigated by means of data based on observations with the Infant/Toddler Environment Rating Scale —Revised and the Early Childhood Environment Rating Scale — Revised. The focus in these observations was on the learning area “Number, Spaces and Shapes”. In addition, questionnaires were used to collect from directors of ECEC centers. A comparison of the results with a study done some seven years ago showed that the centers worked more systematically on this learning area. However, the quality of the learning environments as measured through the observations varies greatly and are to a large extent qualified as inadequate. For example, most of the centers only provided one kind of blocks on a daily basis, giving little opportunity for children to investigate different kinds of properties of space and shape.

In the final paper[17] by LeSage and Ruttenberg-Rozenan an alternative research perspective was chosen. In this study children themselves was given a voice when investigating the quality of the early childhood learning environment. The focus was on the quality of educational software. In particular five early numeracy apps were investigated, which were uploaded onto the classroom iPads. Data from 12 children (4 to 6-year-olds) were collected through multiple sources, including observations, interviews and videotaped child-led ‘tours’ of their favorite apps. As criteria for good apps were identified the quality of the game experience (frequent positive verbal reinforcement and earning rewards) and the autonomy in making choices.

Topic Study Group 2

Mathematics Education at Tertiary Level

Ghislaine Gueudet[1] and Irene Biza[2]

ABSTRACT In this report we summarize the activities and the studies presented at the TSG-2: Mathematics education at tertiary level of the 14th International Congress on Mathematics Education (ICME-14) that took place online and in Shanghai, China on July 11 to 18, 2021. The activities of the group spanned across four themes: mathematics teaching; students' practices and experiences in mathematics; transitions to, across and from studies of mathematics at tertiary level; and, mathematics for other disciplines. New themes and emerging theoretical directions are amongst the suggestions of the group.

Keywords: Mathematics for other disciplines; Secondary-tertiary transition; Students' practices and experiences; Teaching at tertiary level.

1. Introducing TSG-2 at ICME-14

1.1. Scientific scope of TSG-2

Topic Study Group 2 (TSG-2) at ICME-14 aimed to share and discuss the recent results of research and practice on learning and teaching mathematics at tertiary level, and to identify perspectives for future research. The works in the group drew on findings discussed at ICME-13 related to themes such as: mathematical practices; teaching, professional and curriculum development; connections to engineering; transition to university; preservice teachers; student thinking; and, research related to specific courses such as calculus, differential equations, and linear algebra — see Topical Survey on Research on Teaching and Learning Mathematics at the Tertiary Level (Biza et al., 2016).

The scope of TSG-2 was described in the call for papers as follows:

The questions studied can concern "traditional" courses, such as "chalk and talk" lectures in relations to teachers' practices and students' difficulties or achievements. They can also relate to "innovative approaches", such as design, implementation and evaluation of experimental courses. The contributions can address particular mathematical domains or mathematical practices. They can also concern teaching and learning practices such as assessment, use of technologies or resources; or university teachers' professional knowledge and professional development. Also, we expect submitted proposals to address the variety of tertiary programs that include

[1] University Paris-Saclay, UR Etudes sur les Sciences et les Techniques, Orsay, 91400, France, E-mail: ghislaine.gueudet@universite-paris-saclay.fr

[2] School of Education and Lifelong Learning, University of East Anglia, Norwich, NR47TJ, United Kingdom, E-mail: i.biza@uea.ac.uk

mathematics, such as pure mathematics, engineering, teacher education, etc. Contributions can engage explicitly with theory (e.g., cognitive, socio-cultural, institutional, discursive, etc.) and certain methodological approach or can share a systematic reflection on teaching and learning practices."

More precisely, TSG-2 initially proposed the following five themes:

- Mathematics Teaching at the Tertiary Level;
- Students' Practices and Experiences in Mathematics at the Tertiary Level;
- Mathematical Topics Teaching and Learning at Tertiary level;
- Transitions to, across and from Studies of Mathematics at Tertiary Level;
- Mathematics for Other Disciplines at the Tertiary Level.

All these themes were covered by the submissions we received. Nevertheless, the "mathematical topics" (e.g., Linear Algebra, Calculus, Arithmetics etc.) theme was discussed in studies which could be also categorized in one of the other themes. As a result, the Sections 2 to 5 below address the four other themes with attention to the specific mathematical topics under consideration. Finally, Section 6 addresses emerging perspectives for further research that were discussed in the group.

1.2. TSG-2 at ICME-14: Organization and participants

The work in TSG-2 at ICME-14 was prepared by a team including the authors of this report, as chair and co-chair of the group; Rongrong Cao (Qingdao University, China); Victor Giraldo (Universidade Federal do Rio de Janeiro, Brazil); and, Azimeh Khakbaz (Bu-Ali Sina University, Iran). The IPC Liaison person was Frode Rønning (Norwegian University of Science and Technology, Norway). During the hybrid conference, TSG-2 welcomed 1 invited talk (30 minutes); 8 long presentations (15 minutes); 16 short presentations (10 minutes) and 3 posters (brief 'teaser' presentation before the poster sessions). The authors came from more than 20 countries, representing all the different parts of the world (Brazil, Canada, Chile, China, Colombia, Finland, France, Germany, India, Iran, Israel, Netherland, Philippines, Russia, Spain, South Africa, Sweden, Thailand, Uganda, UK, USA, etc.). Tab. 1 (on the next page) lists the titles and the authors of the papers and posters presented.

2. Mathematics Teaching at the Tertiary Level

The communications in TSG-2 highlighted the ever-growing interest in mathematics teaching at the tertiary level. Different complementary aspects were considered by the participants of TSG-2. Watkins et al.[22] studied university teachers' mathematical knowledge for teaching algebra. Analyzing videos of lessons, they evidenced that for instructors with high MKT for teaching algebra, much more segments without errors or imprecisions can be observed. Chen and Niu[26] studied the impact on class size, in the context of an evolution in Chinese universities to reduce this size. While it did not directly impact students' achievement, the class size influenced teaching practices.

[26]	Study of the influence of class size on the teaching effect of college mathematics. ***Chaodong Chen*** *and Dunbiao Niu* (China). (Poster)
[27]	The relationship between conceptual and procedural knowledge. ***Janine Hechter*** (South Africa). (Poster)
[28]	Meaning of good mathematics teaching from the university students' point of view. ***Seyed Hadi Afzali Borujeni*** *and Azimehsadat Khakbaz* (Iran). (Poster)

Nevertheless, some teachers did not adapt their practices for small classes (50–60 students).

Other studies focused on the development of teacher practices, and the support needed, in particular towards more student-centered approaches. Mammo and Kastberg[12] observed a teacher improving his practice especially for underperforming students, in a setting where peer-tutors were helping these students. The teacher developed their awareness of factors that favor or hinder the efficiency of peer-tutoring. Salinas Layana et al.[19] studied the development of teaching practices on long term, towards more student-centered practices. Through interviews with two teachers, they evidenced that the support of the institution and the agency of teachers were both crucial for this development. Indeed, promoting student-centered practices requires specific teacher support and education. Sandefur et al.[21] investigated the impact of an intensive mentoring experience. Two teachers were involved in a course using a flipped approach and more active learning strategies, new to both of them. Teachers were supported by experienced mentors, and used videos and other material prepared by their mentors. The authors observed evolutions of the two teachers' practices, and of their awareness of students' learning processes. Rogers et al.[18] analyzed the teaching practices of novice collegiate mathematics instructors, also supported by mentors for implementing student-centered techniques. The analyses evidenced discrepancies between the declarations of the novice instructors (who consider that they actually used students-centered techniques), and those of the students and of the mentors. Even with the support of mentors, implementing students-centered techniques remains challenging.

Some studies also presented successful interventions. Kumar and Kumaresan[10] presented a program called: "Mathematics Training and Talent Search (MTTS)", and emphasized some of its aspects, such as personal attention and collective work. This four-week summer school for university students in India has convinced many students to go further with their mathematical studies. Pokhrel and Laosinchai[16] presented an innovative hands-on activity for the learning of group of symmetries in undergraduate level. Working on this activity, students developed an inquiry stance and explore groups of symmetries. Xue and Nanna[25] presented a flipped course about modeling with elementary functions. They evidenced that students learned better with this course than with a traditional lecture-based course, and that the classes were more active and dynamic. Some of the interventions concerned the assessment practices. Häsä et al.[5] study the impact of students' self-assessment on their learning practices. Comparing two models of self-assessment, they show that the assessment of their own skills seems to promote deep learning, more than the assessment of coursework. Morgan and King[13] studied alternative scoring practices and how they impact the students' learning experience. They evidenced the importance of feedback, allowing the students to improve their scores; and the positive effect of non-numerical scores.

3. Students' Practices and Experiences in Mathematics at the Tertiary Level

Students' practices and perceptions at tertiary level were also an important theme in TSG-2. Several theoretical evolutions have been proposed, and new themes emerged.

Williams et al.[24] investigated students' engagement during collective mathematical activity. They proposed a specific theoretical construct about students' engagement in the context of collective activity, linked with the interpretive framework introduced by Cobb and Yackel (1996). They observed that participating in argumentation is not sufficient for high engagement, while participation leading to collective progress and further understanding corresponded to higher engagement. The theoretical construct they proposed evidences that sociomathematical norms influence associations between engagement and mathematical activity. Levin et al.[11] proposed a conceptualization of students' agency and autonomous actions. Through interviews with students, they observed that agency and autonomy should not be described as qualities that participants either had or did not have. Agency and autonomy depend on the context, and exist on a continuum. Another theoretical and methodological construct was proposed by Göller[4] to investigate students' goals and strategies. Drawing on self-regulated learning theory, Göller introduced three overarching categories of strategies and associated goals. Learning strategies aimed to understand and remember new content, problem-solving strategies aimed to solve mathematical problems; nevertheless, students also used coping strategies to deal with institutional requirements. An empirical study confirmed the relevance of this theoretical construct. Gildehaus and Liebendörfer[3] also investigated students' strategies, searching for gendered patterns in the choice of strategies. They observed that, across different courses, female students reported a higher use of organization, time investment and peer learning strategies. This confirmed the view of female students being diligent and social, and can explain gender differences in the learning of university mathematics.

Other studies considered students' perceptions. Khakbaz and Afzali Borujeni[28] investigated what "good mathematics teaching" means for students. They observed different meaning, linked with the students' specializations. For example, for engineering students a good teaching of mathematics emphasizes on applications. Kock et al.[9] study concerned students' perception of the usefulness of different kinds of resources to study mathematics. Analyzing students' answers to a survey, they observed three different groups of students, those who see more importance (a) to lecturer explanations; (b) to the textbook; and, (c) to other curriculum resources (e.g., worked examples, materials prepared by the teacher). Nevertheless, these groups were depended on the courses as the resources proposed by the teachers and the institution vary across courses, and can influence students' practices.

4. School and Tertiary Mathematics Education, Transitions

The secondary-tertiary transition was, not surprisingly, one of the issues addressed in TSG-2. Pinto et al.[15] conducted an international survey about this transition, collecting the views of 310 university mathematics teachers in 30 countries. Exploring the discourses of the respondents, they noted that the concerns about the secondary-tertiary transition were aggravated during the last decades; many universities have organized concrete measures to face the difficulties, but communication between university teachers, secondary school teachers and mathematics education researchers still seems to be lacking. Several other papers addressed issues pertaining to teacher education at university, in different countries: Uganda (Kabuye Batiibwe[8]), Colombia (Sanabria[20]), Brazil (Ripoll and Doering[17]) and Germany (Hoffmann and Biehler[6]). Future teachers experience indeed "double discontinuity" as identified by Klein (1908): from secondary school mathematics to university mathematics, and then back to secondary school mathematics. The content of the teacher education programs has to acknowledge this double discontinuity, for example, by connecting university and school mathematics (see Hoffmann and Biehler[6], for an example in geometry).

5. Mathematics for Other Disciplines at the Tertiary Level

Research about mathematics and non-mathematics disciplines has developed internationally in the last five years; communications within TSG-2 at ICME-14 reflect this development. Wawro et al.[23] investigate students' meanings for mathematics (namely eigentheory) when solving quantum physics tasks. Using the theoretical framework of Knowledge-in-Pieces (diSessa 1993), they analyzed students' discourses and evidenced in some cases synergies between the mathematical and physical meaning of the same concept, but also incompatible interpretations. Other studies related to this theme concern mathematics in engineering education. In this context, the combination of theoretical and procedural aspects is a complex issue. Hechter[27] evidenced that conceptual understanding and procedural fluency are intertwined and should not be separated in the mathematics courses for future engineers. Cárcamo and Fuentealba[1] studied the difficulties encountered by engineering students working on linear algebra tasks, and observed difficulties related to proof and definitions. Johansson et al.[7] studied the learning practices of engineering students in a differential calculus course and their consequences in terms of students' achievement. While regular personal work across the semester had positive effects on exam results, some students worked with mathematics in the preparation for the exams only.

6. New Themes and Emerging Theoretical Directions

Studies in TSG-2 evidenced new themes and emerging directions for research. We note that Inquiry-Oriented practices in mathematics at tertiary level seem to be now well developed in the USA. Which kind of teacher support (including teacher education programs) can promote these new practices? This question is not only considered in the USA, for example, *Study and Research Paths* (SRPs, Bosch, 2018) are Inquiry-Based courses that have been increasingly developing in Europe and South America.

SRPs are also linked to emerging theoretical and methodological development we identified at TSG-2's works. The studies about SRPs are grounded in the

Anthropological Theory of the Didactics (ATD, Chevallard, 2015), which is increasingly used in studies at tertiary level. Moreover, these studies introduce new methodological approaches: Question-Answer maps, essential for the epistemological analysis needed before designing an SRP, and also allowing a collective work of researchers in mathematics educations and university teachers (Florensa and Bosch[2]). Related to emerging theoretical approaches, we also would like to mention the increasing number of studies using discursive approaches. Such studies consider the teaching and learning phenomena as discursive phenomena, and use methods for analyzing discourses. In TSG-2, Nardi[14] raised the potential of the commognitive approach (Sfard, 2008) to observe discursive shifts in university mathematics, beyond the micro-level of a student working on a precise task. She claimed that this approach can inform a reform agenda. Besides the aforementioned frameworks, some studies proposed innovative conceptualization to address particular aspects of students' practices at tertiary level. Williams et al.[24] proposed a conceptualization of students' engagement in collective mathematical activity. Göller[4] proposed categories for the analysis of students' goals and strategies. Levin et al.[11] introduced a conceptualization of students' agency and autonomy in the context of mathematics teaching and learning at tertiary level. This conceptualization leads to consider that students' agency and autonomy can change in response to context and over time. We really look forward to seeing further advances to research in tertiary mathematics in the next ICME conference and in other events such as INDRUM, CERME, RUME or DELTA conferences.

Topic Study Group 3

Mathematics Education for Gifted Students

Florence Mihaela Singer[1], Joseph Li[2], and Viktor Freiman[3]

1. Aims of the TSG

The goal of TSG-3 was to promote research and practice in the field of mathematical ability, mathematical potential, and giftedness in different cultures and contexts. The topic study group involved educational researchers, research mathematicians, mathematics teachers, teacher educators, curriculum designers, doctoral students, and others in a forum for exchanging insights related to the research and practice in mathematics education. The main purpose was to contribute to the development of our understanding of the nature and nurture of high mathematical ability in individuals.

1.1. Submissions

We received 28 submissions from 16 countries: Austria, Canada, China, Germany, Israel, Japan, Peru, Romania, Russia, Singapore, Slovenia, South Africa, USA, Sweden, Thailand, and The Netherlands, thus reaching our goal of diverse cultural representation. Of the submissions, five were accepted as long-paper presentations, seventeen were accepted as short-oral presentations, and six as posters. Among these, 21 papers have been presented.

1.2. Sessions

Throughout the three days of the TSG sessions, participants' dialogue and networking were focused on identifying emerging research themes, potential interdisciplinary approaches, and future research opportunities. To create a diversity of approaches and interactions, chairing the sessions was distributed among the TSG-3 organizers. Thus, first day: Florence Singer and Joseph Li, second day: Viktor Freiman, Florence Singer, Joseph Li, and third day: Joseph Li, Viktor Freiman, Florence Singer alternatively chaired the respective sessions. During the third day, we succeeded to have an interesting ad-hoc interaction between the online community and the participants in situ, in Shanghai, thanks to the excellent translation provided by Joseph Li. This online — offline interaction has shown the large interest of our TSG topic and the desire to extend the discussions concerning important issues related to high achievement and giftedness in mathematics.

1.3. Paper topics

As mentioned above, of the 28 accepted papers, 21 papers have been presented during the online conference. A list of these papers and authors, organized in Tab. 1 in the order of presentation, is next included.

Tab. 1. List of the presented papers

Papers and author(s)
[1] Student perceptions of support provided by a summer math camp. *Michael Hicks,* ***Hiroko Kawaguchi Warshauer****, and Max Warshauer* (USA).
[2] Derivation of regression equations predicting Japan mathematical olympiad preliminary qualifiers from within arbitrary groups. ***Atsushi Tamura*** (Japan).
[3] How do math students use informal representations? A comparison between gifted and not gifted. ***Florence Mihaela Singer****, Cristian Voica* (Romania).
[4] School stages of educating the mathematician-investigator. ***Aleksandr Vasilevich Yastrebov*** (Russia).
[5] Problem solving and creativity among talented students from a multi-age perspective. ***Odelya Uziel****, Miriam Amit* (Israel).
[6] Educating prospective teachers in the field of mathematical giftedness - comparing experiences. ***Matthias Simon Brandl****, Attila Szabo, Elisabeth Mellroth, and Ralf Benölken* (Germany).
[7] Questions about the identification of mathematically gifted students. ***Marianne Nolte*** (Germany).
[8] What do prospective teachers express as to mathematical giftedness? An exploratory study. *Daniela Assmus and* ***Ralf Benoelken*** (Germany)
[9] Mathematical thematic content and didactic skills for the teaching of mathematics of students of the primary education career of the Catholic University Sedes Sapientiae, Peru. *Norma Fuentes Supanta De Fukunaga and* ***Patricia Edith Guillen Aparicio*** (Peru).
[10] Role of peer and teacher recognition for students' talents in STEM projects. ***Viktor Freiman*** *and Jacques Kamba* (Canada).
[11] Egalitarianism in inclusivity: thwarting the intellectual growth of mathematically gifted students in South African schools. ***Michael Kainose Mhlolo*** (South Africa).
[12] Activities for the mathematically gifted and their evaluation in Slovenia. ***Bostjan Kuzman****, Mojca Juriševič, and Urška Žerak* (Slovenia).
[13] Using interdisciplinary problem posing to promote gifted students in the regular classroom. ***Sara Hinterplattner****, Zsolt Lavicza, and Marca Wolfensberger* (Austria).
[14] Mathematically gifted students: challenges and opportunities in the primary years. ***Ban Har Yeap*** (Singapore).
[15] Discovering and educating the gifted students with excellent problems. ***Xiangrui Chan*** (China).
[16] Mathematical culture and teaching of equation. ***Yanchun Liu****, Lili Gao, and Peng Zhao* (China).
[17] Study of construction by quadratic curve addition method. ***Hideyo Makishita*** (Japan).
[18] Intuitive sense constructions of children with mathematical giftedness. ***Alena Witte****, Franziska Strübbe* (Germany).
[19] LEMAS — a joint initiative of Germany's Federal Government and Germany's Federal States to foster high-achieving and potentially gifted pupils. *Friedhelm Käpnick, Philipp Guillaume Girard, Julia Kaiser, Yannick Ohmann,* ***Lea Martina Schreiber****, and Wiebke Auhagen* (Germany).
[20] University students self-evaluation: digital solutions for identifying highly motivated students. ***Mirela Vinerean Bernhoff****, Yvonne Liljekvist, and Elisabet Mellroth* (Sweden).
[21] Experimental study on intellectual development in elementary school students. ***Yuwen Li*** (China).

2. Conference Themes

The congress papers can be summarized across five main themes:

- analysis of high-achieving students' skills and perceptions,
- identification and prediction of mathematical giftedness,
- informal training programs for the gifted and talented students in mathematics,
- adequate training for teachers and prospective teachers dealing with mathematically gifted students, and
- educational policies related to mathematical giftedness in different countries.

Concerning the *analysis of high-achieving students' skills and perceptions*, Uziel and Amit[5] explored the problem-solving capacities of 118 talented students in grades 5–12 who took part in the enrichment program known as "Kidumatica", examining the students' solutions from a multi-age perspective. Data was gathered from students' products and teacher observations during a series of workshops devoted to 10 non-routine problems with multiple solution paths. Their findings revealed a troubling phenomenon: as the age of students rises, they are less prone to looking for creative and holistic solutions when solving problems, and more likely to be "held hostage" by their habitual use of algebra. Somehow strengthening this conclusion, Witte and Strübbe[18] noticed that very young mathematically gifted children show a strong fascination for mathematical questions, and they develop intuitive conceptual constructions regarding various mathematical relationships. For older students, in a qualitative case study, Hicks, Warshauer and Warshauer[1] examined the perceived support as described by three female African American students enrolled in a summer camp for high achievers with an interest in STEM. The students' perceptions on the given support for developing their mathematical competence and sense of belonging to a community of mathematics learners highlighted that the key solution for progress in learning is adequately addressing individual needs at the right time. From another perspective, Singer and Voica[3] investigated students' representations of abstract mathematical concepts beyond reproducing definitions and theorems. They exposed 51 undergraduate university students to tasks that required the association of mathematical concepts as limits or convergence to as many as possible images that potentially generate suggestive mental representations in school students. The researchers found that high-performing university students have focused on mathematical properties of concepts, for which they found meaningful images that revealed deep mathematical meanings, compared to low performers who only pointed some surface characteristics of the mathematical concepts involved.

Identification and prediction of mathematical giftedness was a topic of high interest in the TSG-3 community, as the discussions have shown. Thus, in her review article, Nolte[7] gave an overview of the questions on diagnostics and procedures of high mathematical talent. Various methods such as intelligence tests, school achievement tests and checklists were presented and discussed. The conclusions favored multidimensional approaches with a focus on specially designed mathematical tests. Identification of the gifted students is important when we talk about Mathematical Olympiads. Thus, Tamura[2] developed a model based on derivation of regression equations that could predict Japan Mathematical Olympiad preliminary qualifiers from within arbitrary groups. Within the presentation, he explained how his mathematical talent checklist was used to identify preliminary qualifiers among a group of average high school students and Mathematical Olympiad preliminary qualifiers at a true discriminant ratio of over .. % and how this tool was refined through a logistic based on regression analysis to improve the result. As he pointed out, an analysis of the characteristics found in the sample of students with advanced mathematical abilities are indispensable in the development of "math for excellence" educational materials. Beyond complex mathematical tools for the identification of talented students, Bernhoff, Liljekvist, and Mellroth[20] found that it is possible to identify highly motivated individuals among engineering students by exposing them to the use of Learning Management System (LMS) to self-evaluate their work on recommended tasks, which then provided the lecturer with some statistical data. The research is just at the beginning, we wait for the next steps of it.

Some of the TSG-3 papers were focused on the presentation of *informal training programs for the gifted and talented students* in mathematics, giving the audience some concrete hints and procedures. Thus, Li[21] described a training organized for students who participated on a voluntary basis from first to fifth grade at Changhe Elementary School in Dezhou, China, and compared their mathematics achievement with students who did not participate in the training. Through comparison studies on all participated students and prospective longitudinal studies on randomly selected students from both the experimental group and control group, he found that students who participated in the training had significantly better mathematical achievement and abilities in geometry, logic, and innovation than their comparable peers. Some relevant tasks for talented students could come also from history and traditions. Makishita[17] refered to a traditional Japanese mathematics from the Edo period described in Wasan books, showing that people learned mathematics for fun to solve quizzes, puzzles, and other entertainment problems, as well as for monetary exchange, and other everyday work activities. The author has used Wasan contents and applications in modern mathematics education, recording success with various types of mathematics classes. Diverse and substantially rich examples of working with mathematically gifted students exist in many countries. Kuzman, Jurišević, and Žerak[12] from Slovenia presented activities such as mathcamps, research projects, competitions provided by different parties (schoolteachers, educational institutions, expert groups, learning societies), concluding that often the success of these activities largely depended on the enthusiasm and competencies of the involved individuals. These activities were evaluated within the PROGA project (2017–2020), and a support system for high school students with special talents in mathematics was established. While in many countries, alternative programs are searched to improve students' mathematical abilities at higher levels, Yastrebov[4] made a three-folded plea: 1) Shaping of skills and habits of the future mathematician can be started at the early stages of his/her education and upbringing within school; 2) Educating the mathematician-investigator at the early stages of education contributes to the implementation of general goals of school education, regardless of the student's future profession; and 3) Experience of the pedagogical society is sufficient for shaping the uniform, integral system of educating the mathematician-investigator at the school level.

The issue of *adequate training for teachers and prospective teachers dealing with mathematically gifted students* was also one of high interest for the TSG-3 community. Brandl, Szabo, Mellroth and Benölken[6] focused on how prospective teachers can be trained in the field of mathematical giftedness. By comparing three independently developed concepts to deduce cornerstones of appropriate seminar concepts, they concluded that a combination of theoretical and practical parts is particularly important for a sustainable education in the context of giftedness. As Freiman and Kamba[10] have stressed, over the past decades, novel integrated STEM learning spaces have emerged in K-12 schools providing students with new interdisciplinary enrichment opportunities to express their gifts and talents. Based on the study of provincial makerspaces and maker projects they have conducted since 2016, they identified a clear trend related to an increasing role of an expertise of some students who became recognized by their peers and was essential for the collective success of the projects they developed. Therefore, enhancing the monitoring role of high achieving students among their peers can promote better learning in the whole class. Within a study investigating prospective teachers' perceptions regarding mathematical giftedness, Assmus and Benölken[8] found that future teachers' ideas and knowledge are rather shadowy compared to the state of research on the modeling of mathematical giftedness. Yeap[14] has proposed a model of professional development of teachers comprising three phases. In the first phase, teachers learn by experiencing the doing of challenging mathematics. In the second phase, they observe students engaging in mathematically challenging tasks. In the third phase, they teach lessons that include such tasks. Following this strategy, three categories of opportunities emerged: for the mathematically students the teachers teach, for the other students who are also taught by these teachers, and the final category includes opportunities for the teachers, their colleagues, and the school culture. De Fukunaga and Aparicio[9] analyzed the mathematical thematic content and the didactic skills of prospective primary education teachers from Universidad Católica Sedes Sapientia, Lima-Peru. Their results show that student-teachers require training in mathematical content and personalized pedagogical help, as well as the necessary didactic material for their children to achieve meaningful learning and develop their mathematical potential applied to daily life and society. Still, mathematical culture is the treasure of human culture, and its contents, ideas, methods, and language are important components of modern civilization; following this assumption, Liu et al.[16] insisted on the fact that teachers in the new era should think deeply about how to integrate mathematics culture into the teaching practice, so that students can be influenced by the mathematics culture in the process of learning. They provided an example of introducing mathematical culture into equation teaching for students in different grades. They explored ways to maximize the charm of cultural acquisitions to stimulate students' interest in learning, and their passion for mathematics and mathematical culture.

The topic of *educational policies related to mathematical giftedness* in different countries inevitably goes into the eternal debate between egalitarianism and the promotion of giftedness — how this two can be approached and complemented. As Mhlolo[11] has stressed, since 1994 the focus moved from separate and specialized education for gifted learners to inclusive education with all learners being educated in regular classrooms. Although inclusive education policy initiatives in theory aimed at ensuring quality education for all, current empirical evidence shows that in many African countries including South Africa, excellence and egalitarianism have become out of balance as gifted students from previously disadvantaged communities do not reach their full potential in regular classrooms. Similarly, Hinterplattner et al.[13] noticed that meeting the needs of all students in an inclusive classroom is a rather challenging task. Gifted students often need more or different tasks and activities than teachers in regular classes can or are willing to offer. In such situations, it may happen that gifted students face boredom, which may lead to various behaviors driven by unsatisfaction. To prevent boredom and misbehavior, an experiment with 10 gifted secondary school students was carried out based on findings from neuro-didactics, to ensure a good learning experience. The students were taken out from one of their three regular mathematics classes per week for 9 weeks and challenged with an interdisciplinary problem that was based on STEAM ideas. To solve this problem, a combination of problem-posing abilities, the capacity of gathering knowledge from various fields, and their applied interdisciplinary ideas were necessary. After this experiment, students were asked about their experiences concerning the project itself, and its impact on their regular classes. Results show that the project was described as quite challenging and motivating. Also, its impacts on their regular classes were described as highly positive. Students reported that they used the time they were usually waiting in the regular classrooms for solving the problems they found in their project. Educational policies addressing strategies to foster high-achieving and potentially gifted students might not be only developed from a research perspective, but also from a systemic one. Käpnick et al.[19] presented a joint initiative of Germany's federal government and Germany's federal states for an interdisciplinary network of scientists from 16 universities, together with 300 schools, under the name of "LEMAS" to develop guiding principles and adaptive concepts to support gifted and talented students. This long-term program has just started, and the entire community is expecting relevant results.

3. Future Directions for Research and Practice

The participants agreed that they will continue the international exchange of ideas related to research on the identification of mathematical talent, didactics of teaching highly able students, as well as the promotion of mathematical challenge and enrichment for all. The focal topics will continue to include empirical, theoretical, and methodological issues related to students' excellency in mathematics. Discussions and research within community will aim at better understanding of: useful tools for identifying and assessing mathematically gifted students; the educational approaches and organizational settings more effective for training gifted individual students or groups of students of various ages; the nature of mathematical tasks and activities that are challenging, free of routine, inquiry-based, and rich in authentic mathematical problem solving and posing; the relationship between exceptional mathematical abilities, motivation and mathematical creativity; the relationship between mathematics education for the gifted and equity of education for all students; teacher education aimed at mathematics teaching that encourages and promotes mathematical talents, and the development of interdisciplinary programs (STEAM included), for gifted students. New areas of research will be opened towards the relationship between mathematics education for gifted students and the talent development in the areas that are important in the future, such as artificial intelligence, genetic technology, computational thinking, big data, cryptocurrencies, etc. We hope that the network of professionals in the field will continue to increase, for the benefit of the students around the world.

Topic Study Group 4

Mathematics Education for Students with Special Needs

Michelle Stephan,[1] Yan Ping Xin,[2] Anette Bagger,[3] and Juuso Nieminen[4]

1. Aims of the TSG

In TSG-4, we focused on a variety of theoretical and practical topics related to supporting the mathematical development of students with special needs as well as teachers' support of students. Throughout the presentations we actively searched for connections both in regards of methodology, theory and the possible impact of the presented research. We aimed to explore five related themes: 1) how do we define "special needs", 2) what are the benefits of differing instructional contexts (e.g., 1-1 teaching as opposed to inclusive settings), 3) how do we reconcile the variety of frameworks that originate from two different fields, special education and mathematics education, 4) what are the characteristics of effective professional development programs that aim to support teachers of students with special needs, and 5) what are the pros and cons of different research methodologies within our context (e.g., single case design and classroom teaching experiments)? We encouraged submissions that offered theoretical and/or empirical contributions and sought to include research from a variety of cultural contexts to enhance our discussions.

1.1. Submissions

We received 35 submissions from 21 countries (South America: 3; North America: 8; Asia: 3; Europe: 17; Africa: 2; Australia: 1; Eurasia: 1), thus reaching our goal of diverse cultural representation. Of those 35 submissions, twenty-seven were accepted as paper presentations, seven as posters, and 1 was rejected.

1.2. Sessions

There were so many high-quality submissions, the ICMI organizing committee granted our TSG one more time slot for presentations. In our first 90-minute session, the TSG Chair, Michelle Stephan, introduced the rest of the Team and described the format of the sessions. Generally, all four-time sessions led with a 25 minutes long oral presentation and discussion and two to three short oral presentations with a 10-minute collective discussion. Throughout the four days, we attempted to facilitate participant dialogue in order to collective identify emerging research themes, potential

interdisciplinary approaches and future research opportunities. Discussion time was critical for fostering participant networking as well as countering "virtual conference" fatigue. At the end of our last session, we built in 50 minutes for whole group reflection, discussion and suggestions for needed research trajectories.

1.3. Paper Topics

Of the 27 accepted papers, only 18 papers were able to be presented during the online conference. A list of these papers and authors are included in order of presentation and are organized in Tab. 1.

Tab. 1. List of papers presented

Paper and author(s)
[1] Mathematics learning difficulties? The impact of a constructivist oriented approach to intervention for young learners who struggle the most. ***Ann Gervasoni*** *and Anne Roche* (Australia).
[2] Conceptual model-based problem-solving computer tutor for elementary students struggling in mathematics. ***Yan Ping Xin****, Soo Jung Kim, Bingyu Liu, Qingli Lei, Shuang Wei, Wudong Wang, Sue Richardson, Signe Kastberg, and Yingjie Chen* (USA).
[3] Interventions in micro-spaces for learners with mathematics difficulties. ***Robyn Ruttenberg-Rozen*** *and Ann LeSage* (Canada).
[4] An inclusive child's enactment to a task in dynamic geometry environment. ***Shajahan Haja-Becker*** (Germany).
[5] The effect of schema-based instruction on the resolution of addition problems by a student with autism spectrum disorder. ***Irene Polo-Blanco****, Steven Van Vaerenbergh, Maria González, and Alicia Bruno* (Spain).
[6] Emergent technological practices of middle year students with mathematical learning disabilities. ***Alayne Armstrong*** (Canada).
[7] Introduction to probability in an inclusive setting — insights by a student with learning difficulties. ***Nadine da Costa Silva*** (Germany).
[8] Preparing teachers for mathematics and special education consultations. A collaboration across four continents. ***Sarah Van Ingen*** (USA), *Samuel Eskelson, David Allsopp, Steffen Siegemund, Anna-Sophia Bock, Vera Lúcia Messias, Fialho Capellini, Ana Paula Pacheco Moraes Maturana, and Di Liu* (China).
[9] Criteria used by teachers to identify students with difficulties in learning mathematics. ***Shemunyenge Hamukwaya*** (Namibia).
[10] Becoming a mathematician: The role of learning environments in the identity narratives of mathematics students with learning disabilities. ***Juuso Nieminen*** (Finland).
[11] Tactile drawings and 3-D objects: Two keys to geometry for a blind student in an inclusion university course for preservice K-8 teachers. ***Patricia Baggett*** (USA).
[12] Arithmetical achievements of children with Trisomy 21 supported on geometrical basis. *José Ignacio Cogolludo-Agustín,* ***Elena Gil-Clemente****, and Ana Millán Gasca* (Spain).
[13] Beyond ability rankings: Educational assessment as relational rigor and accountability. ***Anette Bagger****, Alexis Padilla, and Paulo Tan* (Sweden).
[14] Mathematics and blind students: The problem of representations. *Elisabete Marcon Mello* (Brazil).
[15] Mathematics difficulty of students with special needs from the perspective of memory theories. ***Chi To Lui*** *and Ida Ah Chee Mok* (Hong Kong Sar, China).
[16] A teacher's attitude and approaches to high and low achieving students. *Julie Vangsøe Færch, Signe Gottschau Malm, and* ***Steffen Overgaard*** (Demark).
[17] Intervention based on mathematical thinking improves student outcomes: Math disabilities and difficulties. ***Jessica Hunt*** *and Kristi Martin* (USA).
[18] The variety of mathematical braille notations and their underlying principles. ***Annemiek van Leendert****, Michel Doorman, Johan Pel, and Johannes van der Steen* (The Netherlands).

2. Themes

Although there was a large variety in research topics presented during the sessions, the majority of the work can be summarized across four themes. First, a few research teams focused on supporting students who are visually impaired as they learn to symbolize in geometry, probability and other mathematical areas. For example, van Leendert's group[18] analyzed a variety of braille readers to see how they read and express mathematical notations and images. The results show that most of their ways of representing mathematics are very close to the graphical notation used by people who are not visually impaired or to the notation used in Excel or LaTeX. Baggett[11] shared a variety of manipulatives that were used to support a university student who is visually impaired as she learned geometry. And Marcon Mello[14] found that having students who are visually impaired draw their mental image of a mathematical object can reveal much more about their understanding than simply having them describe an already-drawn object.

A second theme that arose across the sessions involved advocating for a strengths-based, critical approach to both teaching and research with students with special needs. In particular, Bagger's group[13] argued that local and national assessments have been used to marginalize students with disabilities and make a compelling case for disrupting that deficit narrative. Hamukwaya[9] explored the criterion that teachers use to determine if a student has mathematics difficulties, while Færch's team[16] showed how a teacher's knowledge that a student was either high or low achieving impacted the quality of instruction given to them. Finally, Nieminen[10] interviewed university mathematics students to explore their social and cultural identities as mathematics majors and what experiences led to those identity formations.

In a related theme on identity and asset-based approaches to teaching mathematics to students with special needs, many participants argued that traditional research and teaching that focuses solely on developing students' procedural knowledge is inequitable to students with disabilities. Rather, students with disabilities should be engaged in mathematical sense making, like their regular education peers. Hunt and Martin developed an instructional unit for fractions that builds on constructivist learning progressions as did Gervasoni and Roche[1] for elementary students. Ruttenberg-Rozen and LeSage[3] introduced the term *microspace* and argued that students with disabilities should engage in these small, micro instances of sense making that, over time, build conceptual understanding. Cogolludo-Agustín's group[12] and Polo-Blanco's group[5] each showed how instructional units focusing on students' sense making in elementary concepts can improve students' with special needs mathematical understanding.

Finally, several research teams explored the use of manipulatives and technologies with students with disabilities. Xin and colleagues[2] created a computer tutor program to help students with learning disabilities/difficulties make sense of additive word problem solving after priming their early number concepts while Haja-Becker[4] found that students only partially used the provided technology when given the choice.

Similarly, Armstrong interviewed middle school students with disabilities to learn what types of mathematics technologies they regularly use besides calculators and found that students do not utilize assistive technologies much outside of the classroom.

3. Areas for Future Research

On the final day of the conference, the participants discussed three potential future research topics. First, we wondered what kinds of assistive or instructional technology are widely available to *simultaneously* support a particular need a student might have and would also engage them in mathematical sense making. Many technology programs facilitate procedural fluency but are not as strong in developing deep conceptual understanding (an exception is the computer tutor developed by Xin and colleagues[2]). How can we attend to both when designing technology for students with special needs and for inclusive purposes (i.e., technologies that are accessible to all students)? What kind of design principles are needed to strengthen such technologies and what research needs to be conducted in order to better understand their impact?

Participants also noted that there continue to be a relatively small number of research studies conducted in classroom settings. With the exception of da Costa Silvas' findings[7] regarding a student's learning of probability in an inclusion classroom, there were no other studies that explored students' learning in the context of a classroom with a teacher with multiple students learning together, such as in an inclusion setting.

Another research strand that was under-represented at the conference concerned supporting teachers in their work as both regular and special educators. Van Ingen and colleagues[8] presented a framework to describe the complex knowledge necessary for teachers to support their students with mathematics difficulties. Their singular work suggests that much more research is needed to determine the types of professional development and university preparation that is needed to support the work that teachers do with students who are struggling in mathematics.

Topic Study Group 5

Teaching and Learning of Number and Arithmetic

Andrea Peter-Koop[1], Arthur Powell[2], and Rui Ding[3]

1. Aims of the TSG

The purpose of this TSG was to gather congress participants who were interested in research and development in the teaching and the learning of number systems and arithmetic through activities in and out of school. The mathematical domains include whole numbers, integers, ratio and proportion, and rational numbers as well as representations and problem-solving using numbers related to each of these domains:

- *research-based specifications of domain-specific goals,*
- *analysis of learning processes and learning outcomes in domain-specific learning environments*
- *and classroom cultures,*
- *new approaches to the design of meaningful and rich learning environments and assessments.*

We encouraged submissions that offered theoretical or empirical contributions and sought to include research from a variety of cultural contexts to enhance our discussions.

1.1. Submissions

We received 37 submissions from 18 countries (US: 5; Canada: 2; Brazil: 6; China: 1; Japan: 1; UK: 2; Germany: 3; Mexico: 3; South Africa: 4; Spain: 1; France: 1; Australia: 1; Sweden: 2; Isrel:1; Italy: 1; Nigeria: 1; Bruni: 1; Chile: 1), thus reaching our goal of diverse cultural representation. Of those 37 submissions, twenty-nine were accepted as paper presentations, six as posters, and two was rejected.

1.2. Sessions

There were so many high-quality submissions the ICMI organizing committee granted our TSG one more time slot for presentations. In our first 120-minute session, the TSG Chair, Arthur Powell, introduced the rest of the Team and described the format of the sessions. Generally, there are four 20 minutes long oral presentations and discussions and 13 short oral presentations, and after every 2 or 3 presentations, there were 10 minutes of collective discussions. Throughout the four days, we attempted to facilitate participant dialogue in order to collectively identify emerging research themes,

[1] University of Oldenburg, German. E-mail: andrea.peter-koop@uni-bielefeld.de
[2] Rutgers University-Newark, USA. E-mail: powellab@newark.rutgers.edu
[3] Northeast Normal University, China. E-mail: dingr919@nenu.edu.cn

potential interdisciplinary approaches, and future research opportunities. Discussion time was critical for fostering participant networking as well as countering “virtual conference” fatigue. At the end of our last session, we scheduled 50 minutes for whole group reflection, discussions, and suggestions for needed research trajectories.

1.3. Paper topics

Of the 29 accepted papers, only 18 were able to be presented during the online conference. In Tab. 1 below is a list of these papers and authors in order of presentation.

Tab. 1. List of papers presented

Paper and author(s)	
[1]	Representational flexibility linked to higher attainment in early number learning. ***Samantha Morrison*** (South Africa).
[2]	Conceptual and procedural understanding on addition of fractions among Year 5 primary children. ***Nor’Arifahwati Abbas****, Masitah Shahrill, Mohd Khairul Amilin Tengah, Nor Azura Abdullah* (Brunei).
[3]	South African learner’s patterns of performance on additive word problems. ***Herman M. Tshesane*** (South Africa).
[4]	The case against coherence in mathematics instruction. ***Ola Helenius*** *and Linda Marie Ahl* (Sweden).
[5]	Identifying South African primary learners doubling and halving reasoning through a written assessment. ***Sameera Hansa*** *and Hamsa Venkat* (South Africa).
[6]	The use of arrays in solving multiplication word problems in Grade 4. ***Mayamiko Malola*** (Australia).
[7]	Toward a universal cognitive core: A cross-cultures (USA, China) progression in multiplicative reasoning. ***Ron Tzur*** (invited speaker, USA) *and Rui Ding* (China).
[8]	Flexible mental calculation: A study with 2nd and 4th Grade Brazilian students. ***Luciana Vellinho Corso****, Sula Cristina Teixeira Nunes, and Évelin Fulginiti de Assis* (Brazil).
[9]	The flexibility in mental calculation: Characterizing the profiles of a group of Brazilian Elementary Students. ***Évelin Fulginiti de Assis****, Sula Cristina Teixeira Nunes, and Luciana Vellinho Corso* (Brazil).
[10]	Precursors of problem-solving in two Brazilian cities: the role of social and economic differences. ***Beatriz Vargas Dorneles****, Camila Peres Nogues, and Elielson Magalhães Lima* (Brazil).
[11]	The performance in domain-specific cognitive abilities among low and typical mathematical achievers. ***Camila Peres Nogues****, Elielson Magalhães Lima, and Beatriz Vargas Dorneles* (Brazil).
[12]	Improving student knowledge of fraction magnitude in the early grades. ***Arthur Belford Powell*** *and Candell V. Ali* (Israel).
[13]	Elementary teacher professional learning to explore and extend nuanced meaning of number. ***Krista Francis****,* ***Sharon Friesen****, Miwa Takeuchi, Armando Paulino Preciado Babb, and Barb Brown* (Canada).
[14]	Difficulties of learning the decimal positional numeration (DPN) system: The principle of exchange. ***Daniela Fernandes*** *and Jeanne Koudogbo* (Canada).
[15]	Decimal number system in Quebec Mathematics Program and in textbooks: What Knowledge and for which mathematical education. ***Jeanne Koudogbo*** *and Daniela Fernandes* (Canada).
[16]	Errors in ratio and proportion: A framework for analysis. ***Özdemir Tiflis*** *and Gwen Ireson* (UK).
[17]	School-readiness in mathematics: Development of a screening test for children starting school. ***Andrea Peter-Koop*** (Germany).
[18]	Students performance when solving word problems involving fractions. ***Maria T. Sanz****, Carlos Valenzuleza, Olimpia Figueras, and Bernardo Gómez* (Spain).

2. Conference Themes

Although there was a large variety of research topics presented during the sessions, the majority of the work can be summarized across three themes. First, a few research teams focused on whole number learning. For example, Samantha Morrison's study[1] focused on "representational flexibility linked to higher attainment in early number learning," and Ola Helenius' group[4] presented a case against coherence in mathematics instruction. Second, Tshesane[3] talked about the South African learner's patterns of performance on additive word problems.

A second theme was multiplicative thinking and reasoning. In particular, Tzur and Ding[7] argued that there was a universal cognitive core in multiplicative reasoning cross-culture (USA and China). Furthermore, they used quantitative data to support that Same-Unit Coordination is the screener in students' multiplicative reasoning and place value concept in base ten. Finally, Corso and her group presented two related papers[8,9], one reported on the quantitative results of 2nd and 4th grade Brazilian students' flexible mental calculation, and the other one described the characteristics of the flexibility in mental calculation of a group of Brazilian elementary students.

Finally, several research teams explored the teaching and learning of fractions. Powell discussed how to improve students' knowledge of fraction magnitude in the early grades. Fernandes and Koudogbo[14] studied the difficulties of learning the decimal positional numeration system and talked about the principle of exchange. They also discussed the decimal number system in the Quebec mathematics program and textbooks.

3. Areas for Future Research

On the final day of the conference, the participants discussed potential future research topics and recommended some papers to publish in related journals.

Topic Study Group 6

Teaching and Learning of Algebra at Primary Level

Jodie Hunter[1], Doris Jeannotte[2], Eric Knuth[3], Ann Gervasoni[4], and Xiaoyan Zhao[5]

1. Aims of the TSG

TSG-6 had a key aim of bringing together a variety of mathematics educators with research interests in early algebra (working with students up to 12 years old). The key overall focus of the group was examining the characteristics and nature of algebraic teaching and learning. This included but was not restricted to the study of numbers, operations, and properties in the context of early algebra, reasoning about functional relationships, the study of structure, and processes related to early algebra such as making conjectures, justifying, generalizing, and developing age-appropriate forms of proof. We called for submissions that offered empirical and/or theoretical contributions and also examined the teaching and learning of early algebra across a wide range of contexts including teacher education, different cultural settings, and with different groups of students.

During the presentations for TSG, we worked collectively to explore themes as well as similarities and differences in relation to the methodologies, theories, and results of both the empirical and theoretical contributions. Overall, we attended to four inter-related areas which included 1) Characteristics and nature of algebraic thinking and reasoning including across different mathematical strands and contexts; 2) Classroom culture and the role of the teacher (including pedagogical practices) in fostering early algebraic thinking for all students; 3) Nature of teacher education and professional development that supports teachers' capacity to foster early algebraic reasoning in classrooms and; 4) analysis of forms of curricular activity that support early algebraic reasoning.

1.1. Submissions

We received 27 submissions from 14 countries (South America: 1; North America: 9; Asia: 6; Middle East: 1; Europe: 6; Australasia: 4) which represented a diverse cultural spread from different international settings. We accepted twenty-three as paper presentations (including both long and short paper presentations) and two as poster presentations, and one submission was rejected. This included three invited paper presentations.

[4] Monash University, Australia. E-mail: Ann.Gervasoni@monash.edu
[5] Utrecht University, Netherlands. E-mail: xiaoyanzhao@njnu.edu.cn

1.2. Sessions

TSG-6 hosted three sessions for presentations which were led and moderated by different members of the TSG organisers given the time difference in the respective locations. Each session followed a similar structure beginning with an introduction from the TSG convening group chair and short oral presentations (10 minutes) with questions, answers, and discussion and then long presentations (15 minutes) or an invited presentation (25 minutes) with questions, answers, and discussion. Over the three sessions, we engaged all participants in a short collective discussion at the end of the session to foster networking opportunities along with identifying themes across the research field and to reflect on potential new ideas or existing gaps in the research field.

1.3. Paper topics

Of the 23 accepted papers, only 15 papers were able to be presented during the online conference. A list of these papers and authors are included in order of presentation and are organized in Tab. 1.

Tab. 1. List of papers presented

Papers and author(s)
[1] Mathematical learning disabilities in algebra. ***Francesca Gregorio*** (Switzerland).
[2] The pedagogical journey from arithmetic to algebraic reasoning in a professional development project through the theme of fractions. ***Yuriko Yamamoto Baldin*** *and Aparecida Francisco de Silva* (Brazil).
[3] Generalizing about odd and even numbers. ***Susanne Strachota***, ***Karisma Morton***, *Ranza Veltri Torres, Ana Stephens, Yewon Sung, Angela Murphy Gardiner, Maria Blanton, Rena Stroud, and Eric Knuth* (USA).
[4] Toward a common view of algebraic thinking through design of resources by primary and secondary teachers. ***Jana Trgalová***, *Mohammad Dames Alturkmani, and Sophie Roubin* (France).
[5] Cognitive routes of algebraic thinking in pre-school and elementary school: Literature review. ***Passaro Valeriane***, ***Elena Polotskaia***, *and Azadeh Javaherpour* (Canada).
[6] Highlighting the potential for developing early algebraic thinking: A praxeological framework of reference. ***Doris Jeannotte***, *Hassane Squalli and Virginie Robert* (Canada).
[7] Development and implementation of the unit of pattern and correspondence to foster functional thinking. ***Jeongsuk Pang*** (invited speaker) *and Sunwoo Jin* (South Korea).
[8] The relation between the evolution of generalization and the development of relational thinking and functional thinking: a study with grade 4 students. ***Celia Maria Mestre*** (Portugal).
[9] Enhancing elementary teachers' functional thinking. ***Ahmad Reza Haghighi*** *and Nasim Asghary* (Iran).
[10] Arithmetic problems with natural numbers in a multi-grade primary school. ***Lorena Trejo Guerrero*** (Mexico).
[11] Investigating early algebraic thinking in primary school: An empirical study from China. ***Siyu Sun*** (China).
[12] Multiplication and division problems as a context for developing young children's algebraic thinking. ***Ann Gervasoni*** *and* ***Anne Roche*** (Australia).
[13] Young students noticing and generalising growing pattern tasks. ***Jodie Louise Miller*** *and Jodie Hunter* (Australia).
[14] Designing an evidence-based learning progression for algebraic reasoning. ***Lorraine Day***, *Max Stephens, Marj Horne, and Derek Hurrell* (Canada).
[15] Fraction tasks which identify algebraic reasoning. ***Catherine Anne Pearn***, *Max Stephens, and Robyn Pierce* (Australia).

In addition, we had two posters presented during the online conference. A list of the posters and authors are included in Tab. 2.

Tab. 2. List of posters presented

Poster and author
[16] Reasoning with patterning tasks. ***Adam Ross Scharfenberger*** (USA).
[17] Research to improve education guidelines for promoting children's understanding of mathematical functions. ***Yoshiki Nisawa*** (Japan).

2. Conference Themes

A review of the conference papers and presentations highlights a range of key themes which were evidence. The first theme is encompassed by the characteristics and nature of algebraic thinking and reasoning including across different mathematical strands and contexts. Passaro and colleagues[5] reported on an analytical literature review to distinguish the approaches identified in research studies to facilitate algebraic reasoning in elementary classrooms. They identified three key approaches across the literature. First, an emphasis on grounding the teaching of algebra in the arithmetic knowledge that students develop. Second, developing tasks to introduce algebraic topics not covered by arithmetic. Third, developing student understanding of quantitative relationships and general laws.

A growing area of interest is the opportunities for early algebraic reasoning across different strands of mathematics. This was represented by a paper which focused on the teaching and learning of algebra through fractions. Pearn and colleagues[15] investigated students' responses to three reverse fraction tasks and from this developed a classification scheme for students' written responses. They argue that students' generalizations related to the strategies that students used to solve the task. Similarly, Guerrero[10] examined how arithmetic problems support students to engage in argumentation and develop understandings of natural numbers. Another paper by Sun[11] highlighted the capability of students from different grade levels in China in solving algebraic tasks. All students demonstrated strengths in in generalized arithmetic tasks, however, older students were more likely to use symbolic representation.

The second key theme identified across the conference papers was the relationship between task design and differing types of algebraic reasoning. Within this theme, there continues to be ongoing interest in the types of reasoning and generalization that students use when asked to solve patterning tasks. Two different presentations, one a poster by Scharfenberger[16] and the second a paper by Mestre[8] illustrate the importance of considering task design and characteristics when supporting students to engage in early algebraic reasoning. Scharfenberger developed a clinical interview using TIMMS items to analyse student responses to patterning tasks. He highlighted that dependent on the context or representation of the pattern, students were provided with differing opportunities to engage in_recursive, covariation, and correspondence thinking. Mestre also focused on generalization and used data from a teaching experiment to analyze the relation between the development of generalization and the development of relational thinking and functional thinking. This study found that task characteristics had the potential for both acting as an enabling factor or barrier to the development of algebraic reasoning. Specifically, pattern exploration tasks and those that focused on relational thinking contributed to functional thinking development.

Also drawing on the theme of task design, a number of papers focused on both the task characteristics and the use of materials to develop algebraic reasoning. Baldin and de Silva[2] focused on using fractions and concrete material to develop algebraic reasoning. These researchers highlight the value of manipulatives in supporting student understanding of operations (multiplication and division) with fractions. This has some overlap, with the work by Gervasoni and Roche[12] who examined multiplication and division problems as a context for developing young students' early algebra understandings. They highlight the important role of models to support students to shift to seeing structure when solving problems. Additionally, Strachota and colleagues[3] examine both task design and identify the affordances of specific tools (concrete material) to support students to make generalizations about odd and even numbers.

Building further on the theme of task design was the facilitation of professional development to support teachers to design tasks and resources. Two papers focused on different aspects of professional development. Firstly, Haghighi and Asghary[9] reported on an intervention that supported teacher capacity to develop and implement resources to support functional thinking in the classroom. Secondly, Trgalová and colleagues[4] worked collaboratively with primary and secondary teachers to design, implement and re-design tasks. Both studies highlight how professional development can support teachers to develop a shared view of algebraic reasoning and the types of classroom activity that support this.

Another key theme was focused on frameworks of learning progressions and the associated teaching approaches to develop algebraic reasoning. Jeannotte et al.[6] highlights the approach of some countries which do not explicitly introduce the development of algebraic thinking in primary school. Their research instead introduces a framework to be used to analyse the potential for developing algebraic thinking in curricula such as textbooks. In contrast, Day and her colleagues[14] report on the explicit development of an evidence-based learning progression across different aspects of early algebra. This included teaching advice designed to support teachers to use a targeted teaching approach to move students along the progression. Three of the papers focused on functional thinking as a route to foster early algebraic thinking. For example, Pang and Jin[7] highlighted the development of a pattern and correspondence unit in a Korean elementary mathematics textbook and the resulting student thinking. Miller and Hunter[13] examined how young students notice structure in growing patterns and the teaching actions that supported this and Nisawa[17] developed a learning framework to support students' understanding of mathematical functions both with the use of numerical values and in other activities without numerical values.

Finally, a key aspect of curricular activity that supports early algebraic reasoning is providing access to all students to engage in early algebra. Gregorio[1] highlights the lack of equity for specific groups of students including those with mathematical learning difficulties. This research focused on classification of different types of algebra tasks and the development of an assessment tool to identify students with difficulties in accessing algebraic concepts.

3. Areas for Future Research

Across the conference paper and presentations, there continues to be potential for further research to address existing gaps in the field. Firstly, future research could include a focus on diverse and marginalized learners including students from different cultural backgrounds or students with specific learning needs including learning difficulties. Also of interest is a focus on specific teacher actions beyond those related to task design and enactment. This could include questioning and prompts, specific classroom practice, and formative assessment methods that facilitate or support student development of early algebra.

We note that at the conference, there were a number of areas that were under-represented. This includes the use of digital tools such as virtual manipulatives in developing early algebraic thinking. Additionally, while a number of papers focused on task design, learning trajectories or curriculum development, there is a lack of work that focuses on cross-national comparative analyses. Finally, an important addition to the research field would be longitudinal studies which analyse the impact of early algebraic thinking on students' later study of algebra or mathematics in general.

https://doi.org/10.1142/9789811287152_0031

Topic Study Group 7

Teaching and Learning of Algebra at Secondary Level

Boon Liang Chua[1]

1. Scope and Focus of TSG-7

The teaching and learning of algebra at the secondary level is a well-researched field. TSG-7 aims to bring together international researchers, teacher educators and teachers who investigate students' ways of doing, thinking and talking about algebra, and investigate teachers' ways of designing and implementing the teaching of algebra at the secondary level and the knowledge needed to support effective algebra student learning. The group envisages integrating young researchers and established scholars in the field with the intention of sharing new findings and current research trends in the teaching and learning of algebra at the secondary level. In addition, we aim to foster discussion of theoretical and methodological issues challenging the field. The topic study group will engage a group of interested participants in rigorous discussions emphasising the following themes:

- Algebraic thinking: defining and characterising algebraic thinking in students; issues of representation, symbolisation, and manipulation, and how algebraic thinking is identified and assessed; relationships between conceptual and procedural knowledge of algebra; and, how students progress from arithmetical to algebraic thinking
- Proving and justifying: Their role in the learning of algebra; ways of characterising and understanding their features and processes (e.g., in expressing generality); and, socio-mathematical norms and didactical contracts associated with generalising, proving and justifying
- Mathematical tasks: Principles of task design aiming at developing algebraic thinking, and analysis of algebraic tasks used as instruments in classroom research
- Relationships between teacher knowledge, teaching practice, and student learning: Mathematical knowledge for teaching algebra; classroom practices that support algebra learning and their connection to teacher knowledge; links between teacher practice and changes in student learning of algebra

[1] National Institute of Education, Nanyang Technological University, Singapore. E-mail: boonliang.chua@nie.edu.sg

- Teaching experiments and design research studies: Conditions that enable or hinder the teaching and learning of algebraic thinking; how new teaching and learning opportunities (e.g., the role of technology, the design principles used) are created and studied in terms of their impact on teachers, students and other actors; the classroom discourse during the teaching experiment; and, how the transition of research into practice is studied

2. Submission to TSG-7

Tab. 1 below shows the number of papers submitted and accepted for presentation.

Tab. 1. Number of papers submitted and accepted for presentation

Number of papers	Received	Accepted
Total	30	17
Long oral		5
Short oral		10
Poster		2

The 30 papers came from 17 countries. Tab. 2 shows the breakdown of papers by countries.

Tab. 2. Breakdown of papers by countries

Country	Number of papers	Country	Number of papers
Australia	1	Luxembourg	1
Belgium	1	Malaysia	1
China	4	Nepal	2
Indonesia	1	Norway	1
Iran	2	Panama	1
Israel	2	Russia	1
Japan	1	Rwanda	1
South Korea	1	South Africa	2
		USA	7

3. Program Overview

During the congress in July 2021, three sessions were organised for TSG-7. Of the 17 accepted papers, there were eventually 4 long oral presentations, 8 short oral presentations and 1 invited talk (Tab. 3 on the next page).

4. Future Directions and Suggestions

Many studies in the literature on teaching and learning of algebra at the secondary level had investigated students' learning difficulties and misconceptions. There is already much for researchers in different countries to learn from these existing studies. Instead

Tab. 3. The list of papers presented

Paper and author(s)
Session 1
[1] Knowledge for teaching algebra: variation in the use of knowledge in the light of classroom constraints. ***Demonty Isabelle*** (Belgium) *and Vlassis Joëlle* (Luxembourg).
[2] Constructing the link between graphical visualization and algebraic computation by means of analogy: the case of a system of equations. ***Klila Copperman*** *and natoli Kouropatov* (Israel).
[3] Using an online card game-based activity to build algebra foundation. ***Jiqing Sun*** (Australia).
[4] Investigating students' algebraic proficiency from a symbol sense perspective. ***Al Jupri*** (Indonesia).
[5] Diagnosis and treatment of students' algebraic misconceptions and errors. ***Mukunda Prakash Kshetree*** (Nepal).
[6] Examining the quality of classroom interactions in the teaching of algebra for upper secondary schools. ***Aline Dorimana****, Alphonse Uworwabayeho, and Gabriel Nizeyimana* (Rwanda).
Session 2
[7] Generalization as a marker for robust mathematical meanings among in-service algebra teachers. ***Lori Burch*** *and Erik Tillema* (USA).
[8] Student knowledge of exponential functions. ***Robert Powers****, Alees Lee, Melissa Troudt, and Jodie Novakl* (USA).
[9] The importance of teacher–student interactions in mathematical learning: the example of generalization. ***Vlassis Joëlle*** (Luxembourg) *and Demonty Isabelle* (Belgium).
[10] Learners' number patterns generalizations in a south African evaluative assessment. ***Zwelithini Dhlamini*** (South Africa).
Session 3
[11] Thinking about algebra from the anthropological theory of the didactic: reference models for the analysis and the design. ***Noemí Ruiz-Munzón****, Marianna Bosch, and Josep Gascón* (Spain).
[12] Students' unconventional graphical representations of covariational reasoning. ***Laurie Cavey****, Tatia Totorica, and Patrick Lowenthal* (USA).
[13] The impact of an online learning platform in algebra. ***Zachary Stepp*** (USA).

of duplicating some of these studies on students in different countries, perhaps, in order to add new knowledge to this field, future studies could examine students' learning (a) using different theoretical lenses, for example, through a constructivist lens, (b) using different concrete manipulatives or technological tools or approaches that might improve and deepen students' understanding of algebraic concepts and procedures, and (c) in a different learning environment, for example, a virtual setting which becomes vital during the COVID-19 pandemic. For the teaching of algebra, future studies could consider examining the "invisible" professional thinking of teachers behind their teaching practices. One such potential aspect for research is to capture teachers' pedagogical reasoning and actions.

https://doi.org/10.1142/9789811287152_0032

Topic Study Group 8

Teaching and Learning of Geometry at Primary Level

Nathalie Sinclair[1], Michael Battista[2], Eszter Herendiné-Kónya[3], Haiyue Jin[4], and Jesús Victoria Flores Salazar[5]

1. Aims of the TSG

This group provided a forum for discussion of the learning and teaching of geometry, with a focus on the elementary grades, K-6 (or preK-8). We had short presentations on, and discussions of, important new trends and developments in research or practice, in geometry teaching and learning, and expositions of outstanding recent contributions to it.

The focus of the group was on theoretical, empirical or developmental issues related to the themes below. The issues raised were considered from the historical, epistemological and ontological, cognitive and semiotic, and educational points of view. The following subthemes are proposed:

- Studies of the use of new/alternate geometry curricula or curriculum components (including topological ideas, ethnomathematical approaches, etc.);
- The use of tools/resources such as physical manipulatives (e.g., pattern blocks, cubes, paper folding, mirrors) and digital technologies;
- Problem solving in geometric contexts;
- Task design for the teaching and learning of elementary geometry;
- Explanation, argumentation, and proof in elementary geometry education;
- Spatial and geometric reasoning about two- and three-dimensional shapes;
- Psychological roots of spatial, visual and geometrical thinking;
- The role of geometrical transformations in learning and teaching geometry;
- Teacher knowledge and preparation in geometry education.

1.1. Submissions

We received 16 submissions from 12 countries (Canada 1, China 2, Japan 2, Great Britain 1, France 1, Austria 1, Denmark 1, Switzerland 1, Hungary 1, Turkey 2, Australia 1, New Zealand 2), thus reaching our goal of diverse cultural representation. Of those 16 submissions, 8 were accepted as long orals and 8 as short orals.

1.2. Sessions

In our first 90-minute session, the TSG co-Chair, Michael Battista, introduced the rest of the Team and described the format of the sessions. The second 90-minute session was introduced by co-Chair Nathalie Sinclair. The third 120-minute session was introduced by TSG-8 members Eszter Kónya and Haiyue Jin. Generally, all three sessions led with two or three long oral presentation and discussion and two short oral presentations with a short collective discussion. Throughout the three days, we encouraged participants to engage in discussion around each presentation, as well as across the presented papers.

1.3. Paper Topics

Of the 16 accepted papers, only 13 papers were able to be presented during the online conference. There were seven long oral presentations and six short oral presentations. A list of these papers and authors are included in order of presentation and are organized in Tab. 1.

Tab. 1. List of papers presented

Paper and author(s)	
[1]	Mathematical knots as a teaching material to improve pupils spatial abilities in elementary school. ***Tomoko Yanagimoto****, Akiyo Higasio, Madoka Koyama, Hisashi KinoShita, and Moe Miyazaki* (Japan).
[2]	The transition from informal to formal area measurement. ***Eszter Herendiné-Kónya*** (Hungary).
[3]	Tilings and symmetry using the labosaique. *Paolo Bellingeri,* ***Emmanuelle Feaux De Lacroix****, Eric Reyssat, and Andre Sesboue* (France).
[4]	The knowledge to be taught: a novice mathematics teacher plans to teach quadrilaterals in 5th grade. ***Nazlı Akar*** *and Mine Işıksal Bostan* (Turkey).
[5]	Supporting the development of young children's spatial reasoning: insights from the math for young children (m4yc) project. ***Catherine Diane Bruce,*** *Zachary Hawes, and Tara C Flynn* (Canada).
[6]	The basic routines of spatial thinking and acting. ***Marion Zoggeler*** (Austria).
[7]	Developing spatial abilities and geometrical knowledge with use of a virtual city. *Jean-Luc Dorier and* ***Sylvia Coutat*** (Switzerland).
[8]	Understanding path descriptions in a Manhattan-like map — a comparison of German 2nd and 3rd graders. ***Elisabeth Mantel*** (Germany).
[9]	Impact of teacher professional learning on students geometric reasoning relating to prisms. ***Ann Patricia Downton*** (Australia).
[10]	Unpacking language in geometry lesson on shapes in a New Zealand multilingual primary class. ***Shweta Sharma*** (New Zealand).
[11]	Spatial visualisation reasoning about 2d representations of 3d geometrical shapes: the case of G4–6. ***Taro Fujita****, Yutaka Kondo, Hiroyuki Kumakura, Susumu Kunimune, and Keith Jones* (UK).
[12]	Exploring second graders performances on reading comprehension of mathematics picture book with words and no-word. ***Yan-Hong Chen*** (China).
[13]	Implementing the project-based approach in teaching the area of circle: An explorative study. ***Jinyu Yu*** (China).

2. Conference Themes

The highest proportion of papers focused on the subtheme of spatial reasoning, with two long orals and two short orals presented on the second day. While two of these papers related specifically to geometry, two others were broader in terms of their mathematics curriculum connection. It seems clear that spatial reasoning has become a significant area of attention, and that it can offer an interesting opportunity for connecting the arithmetic/algebra and geometry components of curriculum. The researchers all emphasized the strong correlations between spatial reasoning and success in school mathematics, while also pointing to the relative paucity of focus on spatial reasoning activities in most primary school mathematics classroom. The tasks studied across the four research presentations covered a variety of contexts (using physical materials as well as digital technology; occurring in both indoor and outdoor situations). The third day's presentations also included presentations on spatial reasoning skills. In addition, the role of everyday language in concept formation was discussed, with a special focus on multilingual classrooms. 2D-3D visualization, interpreting representations, and switching between representations were also discussed. The presentations also touched on related areas of teacher training beyond the teaching of geometry in primary schools.

We list below the main TSG-8 Meeting Themes/Research Questions

- How can instruction support the learning of geometric measurement and formulas relationally (conceptually) in a way that is integrated with procedural fluency?
- What ways of visualizing and representing (including verbally describing) enable students to understand the structure of 3D shapes?
- How is spatial structuring — in say, tiling and using isometries — related to knowledge of geometric properties?
- How does the depth of teacher knowledge of geometric content affect how they teach that content?
- How can mathematics education researchers productively investigate ideas in cognitive science spatial ability research in ways that reveal students' actual sense making in mathematics contexts? That is, how can mathematics education researchers (perhaps in collaboration with cognitive scientists) use qualitative research to elaborate and deepen the knowledge produced in spatial reasoning quantitative research?

3. Areas for Future Research

With respect to spatial reasoning, there has emerged a variety of ways of describing, characterizing and identifying instances of it. The conference offered an excellent opportunity for researchers to find some convergence and overlaps, and continued work in this direction would facilitate future research collaboration. While spatial reasoning is recognized as an important aspect of mathematical thinking, more research on how the spatial reasoning activities are used by teachers in ways that support specific conceptual development is warranted. Finally, greater attention to the theoretical framing of spatial reasoning would help researchers better understand how engaging visual and kinaesthetic ways of thinking can support learning — in particular, theories of embodied cognition could offer much to future research in this area.

As preschool and primary school children are already part of the alpha generation, it would be important to extend research on how digital manipulations can contribute to a better understanding of geometric concepts. What differences in cognitive development are caused when physical manipulative activities are replaced by digital applications in early childhood?

4. TSG-8 Future Research Ideas

Research investigating interrelationships between spatial and geometric reasoning is essential — unfortunately, it has been neglected in recent mathematics education research. Future research should include:

- detailed research that investigates, from a cognitive perspective, exactly how spatial reasoning supports geometric reasoning, and vice versa.
- an understanding of how visualization and geometric property knowledge become integrated to form abstract geometric reasoning that is grounded in students' real-world experiences, and how instruction can support this integration.
- investigating the role that mental models play in mathematical reasoning, with spatial reasoning playing a critical role in constructing and operating on mental models.
- going beyond general theories of relationships between spatial and geometric reasoning to detailed elaborations of spatial-geometric interrelationships for specific topics in geometry (which may lead back to general theories).
- investigating, with student interviews and teaching experiments, the nature of, and causes for, the correlation between spatial and mathematical reasoning found by cognitive psychologists, moving towards understanding underlying reasons for how spatial reasoning is related to, and supports, mathematics reasoning for various topics.
- investigating area measurement through decomposition and composition, that is, to consider the possibility of finding the measure of the area of a polygon from its reconfigurations. Also, the existence of other variables that favor the decomposition and composition operation, such as the use of the grid mesh, can be incorporated in other studies.
- carrying out more research about the learning of 3D geometry, because spatial geometry, deserves a different reflection and analysis, since drawing representations of three-dimensional figures, on the board or in paper, does not allow the student to fully observe the characteristics and properties.

Topic Study Group 9

Teaching and Learning of Geometry at Secondary Level

Keith Jones[1], Matthias Ludwig[2], Liping Ding[3], Joris Mithalal[4], and Yiling Yao[5]

ABSTRACT At ICME-14, the Topic Study Group (TSG) on the teaching and learning of geometry at the secondary school level, TSG-9, enabled participants from around the world to share research results, research projects, new developments, and updates on ongoing projects concerning geometry education at the secondary school level. The TSG embraced the four themes of connections between geometry education and mathematical practices and processes, teacher preparation and teacher knowledge for geometry, developments in geometry teaching, and curricular issues in school geometry. The discussion during the TSG sessions at the congress benefitted from the good range of quality presentations on each of the themes.

Keywords: Teaching; Learning; Geometry; Secondary school.

1. TSG-9 Themes and Description

Geometry holds a major place within the secondary school mathematics curriculum. In preparing for the Topic Study Group (TSG) on the teaching and learning of geometry at the secondary school level, TSG-9, at ICME-14, the TSG-9 Team built on existing research and development on geometry education, including the equivalent TSG at ICME-13 (Herbst, Cheah, Richard and Jones, 2018) and reviews such as Jones and Tzekaki (2016), to identify a set of themes to guide and encourage contributions and discussions. The themes were as follows:

- Connections between secondary school geometry education and mathematical practices and processes such as argumentation and proof, visualization, figuration, and instrumentation;
- Teacher preparation and teacher knowledge for geometry at the secondary school level;

[1] University of Southampton, UK. E-mails: dkjones1121@gmail.com; d.k.jones@soton.ac.uk

[2] Goethe University Frankfurt, Germany. E-mail: ludwig@math.uni-frankfurt.de

[3] Norwegian University of Science and Technology, Norway. E-mail: liping.ding@ntnu.no

[4] University of Lyon, France. E-mails: joris.mithalal@univ-lyon1.fr; joris.mithalal@espe-paris.fr"

[5] Hangzhou Normal University, China. E-mail: yaoyiling.m@163.com

- Developments in secondary school geometry teaching, including geometrical modeling and out-of-school problem solving;
- Curricular issues in secondary school geometry, including reform initiatives in school geometry, and new forms and applications of geometry.

In advance of ICME-14, TSG-9 received 43 submissions from all around the world, thereby providing diverse cultural representation that addressed the full range of the identified themes. Of the submitting participants, a number were impacted by the COVID-19 pandemic prevalent at the time and could not take part in the TSG at ICME-14. During the congress, 23 papers and 4 posters were presented in the final programme for TSG-9.

2. TSG-9 Programme

During the TSG-9 sessions, one part of the programme of presentations and discussion was devoted to each of the themes. Within three of the four themes, the TSG-9 Team identified one paper for extended presentation to enable deeper discussion. Each themed session was chaired by a member of the TSG-9 Team.

2.1. Geometry education and mathematical practices and processes

The theme of connections between secondary school geometry education and mathematical practices and processes (such as argumentation and proof, visualization, figuration, and instrumentation) comprised the four papers set out in Tab. 1.

Tab. 1. Geometry education and mathematical practices and processes

Paper and author(s)	
[1]	A teacher's use of dynamic digital technology to address students' misconceptions concerning the use of additive strategies within geometric similarity. ***Ali Simsek***, *Celia Hoyles, and Alison Clark-Wilson* (UK).
[2]	Students spatial ability and solving-strategies for spatial geometrical, mathematical, and physical task. ***Marion Zoeggeler*** *and Guenter J. Maresch* (Austria).
[3]	Introduction of an auxiliary element as a shift of attention. ***Alik Palatnik*** *and Avi Sigler* (Israel).
[4]	Construction program as a link between drawing and language to prepare proof process. ***Joris Mithalal*** (France).

Within this theme chaired by Joris Mithalal, the paper for extended presentation was by Alik Palatnik.

2.2. Teacher preparation and teacher knowledge for geometry

The theme of teacher preparation and teacher knowledge for geometry at the secondary school level comprised the four papers set out in Tab. 2.

Tab. 2. Teacher preparation and teacher knowledge for geometry

	Paper and author(s)
[5]	Understanding student teachers' mathematical knowledge for teaching geometry in a history of mathematics course. ***Svein Arne Sikko***, *Iveta Kohanová, Magdalini Lada, and Liping Ding* (Norway).
[6]	Teacher knowledge related to secondary school level geometry: Evidence from teacher development in South Africa. ***Jogymol Alex*** (South Africa).
[7]	A pre-service teacher mental structure development for understanding the geometric reflection in terms of motion and mapping view: Alexis case. ***Murat Akarsu*** (Turkey)
[8]	Distinguishing content knowledge and pedagogical content knowledge for geometry teaching. ***Liping Ding*** (Norway) *and Keith Jones* (UK).

Within this theme chaired by Liping Ding, each presentation was allotted the same time.

2.3. Developments in geometry teaching

The theme of developments in secondary school geometry teaching (including geometrical modeling and out-of-school problem solving) comprised the eight papers set out in Tab. 3.

Tab. 3. Developments in geometry teaching

	Paper and author(s)
[9]	Possibility of the pirates' treasure problem for teaching elementary geometry. Satoshi Takahashi, ***Ryoto Hakamata*** *and Koji Otaki* (Japan).
[10]	Inquiry-based learning using the centroids of the circumscribed equilateral triangles. ***Yuki Osawa*** (Japan)
[11]	Study of angles and trigonometric ratio for 7th grade. ***Tsuyoshi Sonoda*** (Japan).
[12]	Decomposing proof in secondary classrooms: A promising intervention for school geometry. ***Michelle Cirillo*** (USA).
[13]	Distance under the magnifying glass: Developing series of problems around fundamental concepts in geometry. ***Eszter Varga*** (Hungary).
[14]	The grasp of the Pythagorean Theorem and its proof by Chinese pre-service mathematics teachers. ***Hai Li*** (China).
[15]	Implicative relationships among spatial perception, mental rotation and spatial visualisation: Implications for teaching geometry. ***Melih Turgut*** *and Iveta Kohanová* (Norway).
[16]	Geometry modelling outdoors with MATHCITYMAP. ***Matthias Ludwig***, *Iwan Gurjanow, Simone Jablonski, and Moritz Baumann-Wehner* (Germany).

Within this theme chaired by Matthias Ludwig, the paper for extended presentation was by Michelle Cirillo.

2.4. Curricular issues in secondary school geometry

The theme of curricular issues in secondary school geometry (including reform initiatives in school geometry, and new forms and applications of geometry) comprised the seven papers set out in Tab. 4.

Tab. 4. Curricular issues in secondary school geometry

Paper and author(s)	
[17]	Online formative assessment in geometry proving. ***Yael Luz*** *and Michal Yerushalmy* (Israel).
[18]	Geometric reasoning and mechanics experiment: A case study of interdisciplinary integration teaching with graphic center of gravity as an example. ***Feishi Gu****, Zhenzhen He, and Liya Ban* (China).
[19]	A study on the performance of seventh-grade students in mathematical spatial reasoning. ***Zhikun Zhang*** *and Jian Liu* (China).
[20]	Didactic suitability characterization of three levels of achievement on geometric drawing of secondary school students. ***Javier Díez-Palomar*** *and Elvira García-Mora* (Spain).
[21]	Let's make a circle by three persons. ***Ken-ichi Iwase*** (Japan).
[22]	Reconfiguration of polygons to determine the measurement of their area. ***Melissa Denisse Castillo Medrano*** *and Jesus Victoria Flores Salazar* (Peru).
[23]	High school learners' preconceptions on the classification of quadrilaterals. ***Judah Paul Makonye*** (South Africa).

Within this theme chaired by Keith Jones, the paper for extended presentation was by Yael Luz.

3. Summary Discussion and Future Directions

Topic Study Group 9 (TSG-9) at ICME-14 brought together participants from around the world to share research results, research projects, new developments, and updates on ongoing projects concerning geometry education at the secondary school level. The discussion at TSG-9 benefitted from the good range of quality presentations on each of the themes.

The discussion during the theme of connections between secondary school geometry education and mathematical practices and processes ranged from considering the role of digital technologies in supporting this connection to the place of spatial reasoning and geometrical construction. Future directions are likely to continue to be on argumentation and proof in school geometry, and on visualization, figuration, and instrumentation processes.

During the theme of teacher preparation and teacher knowledge for geometry at the secondary school level, discussions focused primarily on teacher knowledge for secondary school geometry teaching. Future directions are likely to continue to be on such teacher knowledge and on the design of geometry education teacher development both pre-service and in-service.

The theme of developments in secondary school geometry teaching was wide ranging and addressed geometry teaching concerns from spatial perception and visualisation to geometric proof. The presentation of teaching ideas was a strong and beneficial element. Future directions are likely to continue to be on the teaching of spatial and geometrical reasoning, along with geometrical modeling and out-of-school problem solving.

The theme of curricular issues in secondary school geometry was equally wide-ranging, with discussions enriched with ideas being used in schools alongside research into the secondary school geometry curriculum and its assessment. Future directions are likely to continue to be on the scope of the secondary school geometry curriculum, including reform initiatives and possible ways of incorporating new forms and applications of geometry that occur in mathematics.

Acknowledgments

The TSG-9 Team began as Keith Jones (Chair), Matthias Ludwig (Co-chair), together with Liping Ding, Flordeliza Francisco, and Joris Mithalal. During the preparation work for the TSG that took place at the time of the COVID-19 pandemic, Flordeliza Francisco had to withdraw. The TSG-9 Team thanks her for her efforts and thanks Yiling Yao for stepping in to join the Team and for playing such a helpful role during the presentations at the congress. The TSG-9 Team is especially grateful for all the submissions to the TSG, and most particularly to participants who presented so well and contributed so much to the success of the TSG. The TSG-9 Team thanks the ICME-14 International Programme Committee liaison person, Maria Alessandra Mariotti, and all the members of the ICME-14 organising committees for all their help in ensuring that TSG-9, and the entire congress, was such a success.

Topic Study Group 10

Teaching and Learning of Measurement

Christine Chambris[1], Richard Lehrer[2], Florent Gbaguidi[3], and Yuquan Wang[4]

ABSTRACT This chapter presents the aims, the work done during the online conference, and perspectives of TSG-10 — teaching and learning of measurement.

Keywords: Teaching and learning of measurement; Variability of phenomena; School arithmetic; Multiplicative reasoning; Interplay between space and measure; Interdisciplinary practices.

1. Aims of the TSG

Measurement topics in TSG-10 include typical domains such as length, area, angle, volume, and mass but also those less studied, such as time, and those commonly visited in science and engineering education. Overall, internationally, there seems to be a lack of attention to measurement instruction in mathematics education, especially at the primary levels. This is in spite of measure's links to everyday contexts and to STEM disciplines. Although the historic role of measurement has declined in some areas of mathematics, substantive mathematical ideas, such as number and quantity, originated in practices of measure, and these origins continue to be important for student learning about these ideas.

The main objective of the TSG is to better understand the conditions and constraints on teaching and learning measurement in international contexts (from primary to university levels) and to consider new approaches to learning both of measurement and of related forms of mathematics. A diversity of perspectives was expected, e.g., theoretical, methodological, historical, epistemological or empirical, and from various points of view, including teachers' practices, students' learning, as a mathematical subject, teacher education, curriculum, and so on.

1.1. Submissions

There were 18 submissions in the TSG. These submissions were from a diversity of locales (North America: 3; Asia: 5; Europe: 4; Africa: 3; Australia: 2; Eurasia: 1). Thirteen oral presentations and one poster were planned to be presented in Shanghai during the online conference (but eventually only twelve orals presented).

1.2. Sessions

The TSG work was organized in three sessions: 90 minutes, 90 minutes, and 120 minutes. A brief presentation by the chair (Christine Chambris) introduced the work of the three sessions. She presented the different themes. Then, each presentation was followed by time for discussion. Last, Rich Lehrer drew perspectives for the TSG, at the end.

1.3. Paper list

Tab. 1. List of papers presented

	Paper and author(s)
[1]	Rethinking measure. *Petronilla Bonissoni, Marina Cazzola, Gianstefano Riva,* ***Ernesto Rottoli****, and Sonia Sorgato* (Italy).
[2]	Can length measurement estimation activities contribute to learners' improvement on number line estimation tasks? ***Pamela Vale*** (South Africa).
[3]	Measurement units and numeration units: What reveals the introduction of a "mixed" table in decimals teaching. *Christine Chambris,* ***Lalina Coulange****, and Grégory Train* (France).
[4]	Role of "error" in teaching-learning measurement. ***Ishan Santra*** *and Jeenath Rahaman* (India).
[5]	An investigation of teachers' explanatory talk when introducing standard units of measuring length to standard 4 learners in Malawi. *Liveness Mwale* (Malawi). (Due to connection issues this paper was unfortunately not presented)
[6]	Insight into pupils' errors in solving problems involving calendar dates through analysis of knowledge states. ***Phei Ling Tan*** *and Liew Kee Kor* (Malaysia).
[7]	Measuring the teacher's arm span: Interpreting a data modeling sequence through an aesthetic lens. ***Russell Tytler****, Peta White, and Joseph Ferguson* (Australia).
[8]	The use of geometric construction problems to solve measurement problems at middle school. ***Gbaguidi Ahonankpon Florent*** (Benin).
[9]	Conceiving volume as a multiplication of three quantities: the cases of Stan and Sloane. ***Samet Okumus*** (Turkey).
[10]	Articulations between mathematics and physics education: the concept(s) of unit of measurement, from geometry to formulas. ***Charlotte de Varent*** (France).
[11]	Dynamic measurement for area and volume. ***Nicole Panorkou*** (USA).

[13]	Young students learning the mathematics of measurement through an interdisciplinary approach. ***Peta White****, Russell Tytler, Joanne Mulligan, and Melinda Kirk* (Australia).
[14]	An explorative study of using Picture books to support students' learning of measurement in primary education. *Lanjie Sun* (China). (Poster. Not presented during TSG sessions)

2. Conference Themes

Among the diversity of the topics in the papers to be presented, four main themes emerged that structured the sessions: relationships between numbers and units, negotiating measure and its meanings, interplay between conceptions of space and measure, and fostering development of measure through interdisciplinary practice.

In the first session, papers focused on relationships between numbers and units. For decades now, it is acknowledged in mathematics education that contrary to academic number sets constructions, teaching fractions and decimals should be based on measurement. That said, the specific roles that measurement units might play in teaching and learning mathematical concepts such as these were considered.

Rottoli and colleagues[1] discussed a perspective that views natural number as generated by counting and fraction as generated by comparison. In this perspective, the unit is a common unit between the two compared quantities obtained through subtractions. Vale[2] suggested that through preparing sticks of relative sizes to a referent (i.e., subunits), students develop knowledge in estimation on the number line. Chambris et al.[3] highlighted that poor understanding of units of measurement and of numeration impedes students' abilities to relate place value to metric units. They suggested that a multiplicative understanding of units is required for making this bridge.

The second session consisted of empirical studies of students and teachers that were negotiating measure and its meanings. Observing students and teacher's prompts, Santra and Rahaman[4] demonstrated missed and successful opportunities for "errors" to be a resource in teaching and learning of measurement, and specifically in stressing the variability of phenomena. Tytler and colleagues[7] collected a series of data involving grade-4 students measuring their teacher's arm-span and then constructing representations of the collection of measures. Analyses indicated how students' aesthetics of data display guided how they constructed their representations, and also how their teacher elicited these aesthetic judgments to help students understand some of the common conventions employed to visualize data. Tan and Kor[6] focused on students' errors in calendar learning, and this led to a discussion of relevant tasks to assess student knowledge about the measurement of time, including students' understandings of the meaning of time.

The third session focused on interplay between conceptions of space and measure. Florent[8] presented three geometrical problems that aimed to involve students in the construction of a measured quantity. Such problems seem to be promising for fostering reasoning in geometry to expand the meaning of a geometrical quantity. Okumus[9] investigated the students' understandings of the meaning of multiplication in the volume formula of a rectangular prism. Despite forming stacks of triangles, students were not able to relate the area of a triangle and the height of the stack to the measure of the volume of the prism. Panorkou[11] studied students' development in measurement reasoning mediated with dynamic geometry. She captured instances of meaning students generated by manipulating the software. Students seemed to perceive how dragging a surface area through a length generates volume. They also were able to identify units of area formed through dragging a certain distance a line of a given length, similarly for units of volume formed through dragging a surface of a given area through a particular distance. Students linked the latter to a volume formula (base × height) for a prism. Last, students seemed to reason in terms of continuous change: to make the volume n times bigger, they need to make the area of the base n times bigger. This also demonstrates co-variational reasoning in students. Opportunities for students to reason dynamically about area and volume could be very productive but are not yet incorporated into school curriculum. For instance, in a study of textbooks commonly used in France to teach concepts of measure, de Varent[10] found that length units and area units were related in only one of 13 textbooks in France, in the setting of the formula of the area rectangle. This questions not only coherence between geometry and arithmetic, but also how co-variation between the different quantities is taught. Regarding relationships between time and space, Han and Kwon[12] demonstrated how specific use of two kinds of educative devices — clocks with linked and independent hands — depending on teachers' competences in Korea, engaged students in co-variational reasoning or not.

Finally, the last theme of the TSG was about fostering development of measure through interdisciplinary practice. White and colleagues[13] gave an inspiring example of how interdisciplinary practice supported grade-1-and-2 students to learn robust mathematics of measurement. Based on ecological inquiry of their surroundings, students developed means of measuring, recording, and constructing a display of a class collection of measures within a pedagogical context that notably encouraged exploration of ideas and constructing consensus.

3. Summary, Future Directions and Suggestions

The fundamental problematic of measurement can be seen as inventing symbolic means for describing and quantifying attributes of objects and of quantitative relations among them. The relationship between measure of an attribute and understandings of the nature of the attribute are co-constituted. Thus, communities render measures and phenomena reproducible, so that individual acts of measure are guided and enlarged by a community that values reproduction and clarity about acts of measure. Expressions of and work with measures require development of means, notably more elaborate systems of units and of numbers.

Beyond these epistemological considerations, major teaching and learning issues in measurement appear. Reproducibility of phenomena raises questions about variability: Why are our measures varying? Variability expands the reach of measure, notably in terms of characterizing its sources, of reasoning about co-variation, and of important ideas like distribution. Numbers emerge from the need to record relations through comparison processes that involve units (i.e., a given attribute that can at time be chosen arbitrarily) that enable records of phenomena. Grounding measure in space both via construction, and symbolic means reflect interaction between structures of phenomena and measures. Yet, though promising experiences, analyses of actual learning or teaching process and resources reveal the need of continuing efforts in the domain.

This leads to future directions for research. Interdisciplinary practices appear to be a powerful means to develop meaningful practice of measure, both for students and teachers. Further research is needed that clarifies conditions of teaching and learning of practices and concepts of measure that foster deeper understanding of arithmetic, including multiplicative reasoning, and co-variational reasoning. There is also a critical need to develop longitudinal studies in order to better understand changes in students, and teachers. An emphasis on students' changing conceptions of measure suggests the need to develop means and tools for broader assessment, both for concepts to be learnt and teaching practices.

Generally speaking, TSG-10 had regular attendants who were ready to engage in rich discussion throughout the three sessions in a receptive atmosphere. The relatively small number of papers confirms that there is a lack of attention to this domain. Despite this, new issues in teaching and learning were raised, and the necessity for further international studies in the domain of measurement was reaffirmed. We hope that the topic study group dealing with measurement continues as a well-recognized group of the congress.

Topic Study Group 11

Teaching and Learning of Probability

Emesta Sánchez[1], Sibel Kazak[2], and Egan J. Chernoff[3]

ABSTRACT An overview of the papers that were submitted and accepted to TSG-11 is presented. First, we present the document "Purposes and subthemes" with which we call for papers. Second, we make a very brief description of some features of the papers, organized by school level (primary, secondary and tertiary) and each of these divided according to whether they refer to students or teachers. Next, some relationships between the subthemes of the initial document and the topics that are actually present in the papers are pointed out. Finally, some recommendations are formulated.

Keywords: Probability; Probability education; Probabilistic thinking.

1. Purpose and Subthemes

The general aim of the Topic Study Group on Teaching and Learning of Probability (TSG-11) was to continue the relatively recent, albeit ever-growing trend of providing a dedicated venue to promote the discussion of a variety of perspectives related to probabilistic thinking and the learning and teaching of probability. TSG-11 at the 14th International Congress on Mathematical Education (ICME-14) attempted to provide an overview of the international discussion on probability education, as broadly as possible, by building upon the more recent literature from the field. Further, TSG-11 made every effort to display the progress of the discussion in the intervening years since ICME-13 and ICME-12. Lastly, we would be remiss not to mention that we, to the best of our ability, allowed for insight into less well-known strands of the discussion from researchers around the world, especially those from underrepresented countries. To meet these general and specific objectives, we identified five subthemes for TSG-11.

- *Conceptual frameworks to develop probabilistic thinking.* To continue the emerging creation of frameworks to describe or model the development and growth of probabilistic thinking of students especially at intermediate and tertiary levels. We recognized the importance of discussing models of students' process of integrating the different philosophical interpretations (e.g., classical, frequentist, subjective, and others) of probability.

[2] Department of Mathematics and Science Education, Pamukkale University, Denizli, Turkey. E-mail: skazak@pau.edu.tr

[3] College of Education, University of Saskatchewan, Saskatoon, Saskatchewan, Canada. E-mail: egan.chernoff@usask.ca

- *Connecting probability with statistics.* The development of probabilistic notions through experiments, data explorations and simulations can help students to build basic connections between statistics and probability, but it is required to understand how the process of concept formation emerges in students under such conditions.
- *The role of technology in teaching and learning probability.* The availability of increasingly powerful technology and software for statistical and probabilistic education requires, in addition to the inherent innovation, a parallel development of the theoretical reflection and conceptualization of empirical experiences.
- *Task design and learning trajectories.* One way to ensure that the knowledge accumulated by research in education in probability develops into educational practices is through the design of tasks and learning trajectories to promote the thinking and reasoning of integrated probabilistic concepts, including modeling processes.
- *Probabilistic knowledge for teaching.* Understanding and deepening the knowledge that teachers need to teach probability can help solve potential problems with their learning so that they provide a comprehensive education that includes probability. The availability of models that describe and conceptualize the probabilistic knowledge of teachers and their relationship with their teaching practice is important.

We, of course, welcomed submissions that fell outside the presented topics but within the teaching and learning of probability.

2. General Organization of Papers Presented

TSG-11 at ICME-14 had 21 presentations: three invited lectures of 20 minutes each, seven "long" presentations of 15 minutes and eleven "short presentations" of 10 minutes (Tab. 1 on the next page). Invited lecturers were: Amy Renelle, Stephanie Budgett and Rhys Jones who presented "A consideration of alternative sample spaces used in coin-toss problems"[10]; Vincent Martin, Mathieu Thibault and Marianne Homier presented "Self-reported practices of probability teaching: the use of the frequentist approach, manipulatives and technological tools"[21]; and, Gale Russell who presented "From towers of linking cubes to the binomial expansion theorem: what can be learned about combinatorics?"[18]. In what follows, we summarize the distribution of all 21 papers across three variables: Students/Teacher, School level (Primary, Secondary, Tertiary), and the use (or not) of Digital technology.

In addition to the first fifteen papers[1–15] on studies with students across different ages, the other six papers[16–21] involved pre- or in-service teachers. Parsing a bit further, that is, considering the school level at which the study is focused, the first 15 are distributed as follows: Two papers[1,2] refer to primary school students, nine[3–9; 13,14] to secondary school (middle and high school) and four[10–12;15] at the tertiary level. Of the remaining six, two papers[16,20] do refer to primary school teachers, three[17–19] to secondary school teachers, and one[21] to both primary and secondary school teachers. Five papers included technological resources in their research, two[13,14] were with high school students, one[15] with university students. Of the remaining two, one paper[20] involved pre-service teachers and the other[21] with primary and secondary in-service teachers. We hope that this context, presented in this manner, will help all interested readers better navigate our list of conference papers.

Tab. 1 Papers presented in TSG-11

Paper and author(s)	
[1]	The emerging interplay between subjective and objective notions of probability in young children. ***Sibel Kazak*** (Turkey) *and Aisling Leavy* (Ireland)
[2]	Children's apatial cognitive strategies and their development from the perspective of microgenesis. *Zikun Gong and* ***Du Zhang*** (China).
[3]	Developing a learning progression for probability based on the GDINA model in China. ***Shengnan Bai****, Jiwei Han, Kaijun Zhang, and Xueming Gao* (China).
[4]	How can probability reasoning protect adolescents from problem gambling? ***Catterine Primi*** *and Maria Anna Donati* (Italy).
[5]	Confidence and competence of Indonesian secondary school students in completing probability tasks: findings from a pilot study. ***Bustang Bustang*** (UK).
[6]	Problem sequences for developing two basic notions: probability and expected value in Hungarian secondary schools. ***Öedoen Vancsó*** *and Eszter Varga* (Hungary).
[7]	The frequentist approach of probability, from random experiment to sampling fluctuation. ***Jannick Trunkenwald*** (France)*, Fernand Malonga-Moungabio* (Congo)*, and Dominique Laval* (France).
[8]	Secondary school students' strategies in solving permutation problems. ***Luca Lamanna*** (Italy)*, Magdalena M. Gea-Serrano* (Spain)*, and Carmen Batanero* (Spain).
[9]	Establishing connections between language and probabilistic notions through a wodb task. ***Maria Ricart****, Pablo Beltrán-Pellicer, and Assumpta Estrada* (Spain).
[10]	A consideration of alternative sample spaces used in coin-toss problems. ***Amy Renelle****, Stephanie Budgett, and Rhys Jones* (New Zealand).
[11]	Is it in the cards? Revealing consequential probability. ***Egan J. Chernoff****, Nat Banting, and Ryan Banow* (Canada).
[12]	Use of the empirical rule in the course of probability: an application proposed by students. ***Beatriz A. Rodríguez González****, Omar Alejandro Guirette Barbosa, Gabriela Noemi Figueroa Ibarra, Hector Antonio Durán Muñoz* (Mexico)*, and Difariney González Gómez* (Colombia).
[13]	High-school students' probabilistic reasoning when working with random intervals. *Sandra A. Martínez Pérez and* ***Ernesto Sánchez*** (Mexico).
[14]	The computer simulation as a resource to teach normal distribution. ***Jesús Salinas*** *and Julio César Valdez* (Mexico).
[15]	Modeling eliciting activities for the teaching of the probability in a computational environment. ***Sandiago Inzunza*** (Mexico).
[16]	Alice in randomland: differences in attitudes of future primary school teachers towards probability and its teaching. *Claudia Vásquez,* ***Flavio Guiñez****, Camila Brito, and Salomé Martínez* (Chile).
[17]	Teachers' epistemological assumptions that tend to govern their pedagogy while teaching probability. ***Haneet Gandhi*** (India).
[18]	Concretely developing the binomial expansion theorem: where did the permutations go? ***Gale Russell*** (Canada).
[19]	The mathematical work of secondary teachers in the domain of probability in Chile. ***Katherine Machuca Pérez*** (Chile).
[20]	Understanding elements of a randomization test. ***Susanne Podworny*** (Germany).
[21]	Self-reported practices of probability teaching: the use of manipulatives and technological tools. ***Vincent Martin****,* ***Mathieu Thibault****, and* ***Marianne Homier*** (Canada)

3. Brief Indications on the Topics of the Papers

Regarding the research with primary students, Kazak and Leavy[1] focused on the children's estimations of the likelihood of outcomes from chance experiments observing the interplay between subjective and objective notions of probability, and Gong and Zhang[2] addressed emerging cognitive strategies when children face sample space tasks, as well as how and how quickly they develop. The studies with pre- or in-service primary teachers focused on different topics: Vásquez et al.[16] on attitudes towards probability and its teaching; Martin et al.[21] on the self-reported practices of how teachers use the frequentist approach to probability, manipulatives, and technology in their teaching of probability; and Podworny[20] on the understanding and difficulties about the elements of randomization test. We would also note that these last two do include technology, one asking teachers how they use it and the other using computer simulations.

Considering the secondary level, Bai et al.[3] focused on developing a learning progression of probability for 7–11th grade students by using a diagnosis test of 26 items administered to 1490 Chinese students. Primi and Donati[4] reported on developing and evaluation of a school-based preventive intervention aimed to modify gambling-related distortions on at-risk adolescents, focusing the training activity on the concept of probability. Bustang[5] investigated the confidence and competence of Indonesian high school students and wonders if the biases and misconceptions that affect Western students are also present in other cultures or if the culture of the students affects their probabilistic reasoning. Vancsó and Varga[6] proposed a sequence of problems in the context of betting to develop the secondary students' notions of probability and expected value. Trunkenwald[7] pondered on students' understanding of the frequentist approach to probability, particularly, the relationship of the empirical observation of frequencies fluctuation with the idea of measuring a probability. Lamanna et al.[8] explored the effect of instruction in combinatorial reasoning of secondary school students in Italy by analyzing the students' strategies in solving two permutation problems with and without instruction. Ricart et al.[9] used the technique "Which One Doesn't Belong? (WODB)" to explore, through the mathematical vocabulary used, the ideas that students at different educational levels have about probabilistic notions. Martínez and Sanchez[13] reported on a design experiment to introduce the concept of random intervals from a frequentist approach with the aid of a technology tool and observe, in this context, the students' reasoning for making sense to frequentist approach of probability. Their paper concerned the potential of the use of technology to explore the high school students' reasoning when using the software to understand the normal distribution.

Considering teachers at high school, Gandhi[17] raised questions about the epistemological assumptions with which high school teachers approach the curricular material in their probability classes and the way in which epistemological approaches to probability become part of their pedagogy. The paper explains the evolution of an activity, carried out with pre-service teachers, consisting of starting from towers of linked cubes to arrive at the binomial expansion theorem and what can be learned with it about combinatorics. Machuca[19] presented the design of research project for secondary teachers in which mathematic activity in front of probability modelling tasks will be developed and she wonders about the features of teachers' work when they solve the tasks.

Regarding tertiary level students, Renelle et al.[10] told us about alternative sample spaces used by participants in coin-toss problems and the paper is a reflection on whether one sequence could be more likely depending on the interpretation of the question. Chernoff at al.[11] recounted how different ways of analyzing a problem by students, leads to explore and quarrel the probabilities stemming from a simple standard deck of cards sitting on a table. Rodríguez et al.[12] proposed a perspective on problem posing in probability and statistics that involves the topics of experimental probability, the empirical rule and hypothesis testing with the aim of developing creativity and learning skills of students. And Salinas and Valdez[14] developed modelling eliciting activities with their students and asks: What challenges university students face with a model and computer simulation approach? How is their reasoning when they interact and build statistical models?

Having presented brief indications on the topics of the papers, we now switch our focus. Relationships that emerged with initial subthemes are now presented.

4. Some Relationships with Initial Subthemes

Conceptual frameworks to develop probabilistic thinking. All the papers are based on some theoretical considerations, but only a few[13–15,19] include a section of theoretical or conceptual framework. Gong and Zhang[2] built a four-level hierarchy of children's cognitive strategies, whereas others mention some conceptual framework in the introduction section or in the method. Two papers[19,14] stand out, in that the former mentions the Mathematical Working Space (MWS), and the latter addresses a documentational approach to didactics.

Connecting probability with statistics. Four papers address topics related to statistics: Podworny[20] carried out activities to understand the randomization test technique; Rodríguez et al.[12] reported on the use of the empirical rule in a probability course; in the presentation of Martínez and Sanchez[13] the students solved a problem of random intervals that later can be related to confidence intervals; and Salinas and Valdez[14] showed how to approximate the normal distribution with the help of technology.

The role of technology in teaching and learning probability. Six papers included, in the investigations they report, some use of technology, but only in the case of paper[14] a question is asked about the role it plays in learning; in the other cases it has an ancillary function. Three papers[1,15,20] utilize *TinkerPlots* and two papers[13,14] use *Fathom*. Of note, a paper[21] is included, albeit indirectly because the paper asks teachers about how they use technology in teaching.

Task design and learning trajectories. Vancsó and E. Varga[6] proposed a series of betting problems to promote the understanding of probability and expected value. Podworny[20] mentioned a learning trajectory for inferential reasoning with randomization tests. Others use problems in their investigations. For example, Kazak and Leavy[1] proposed a task to subjectively evaluate the probabilities, Ricart et al.[9] explored students' probabilistic language using the WODB technique, and Chernoff et al.[11] promoted a quarrel about the probabilities stemming from a deck of cards problem.

Probabilistic knowledge for teaching. In six papers the object of study was the probabilistic knowledge of teachers. Martin et al.[21] studied the self-reported practices of teaching by primary and secondary teachers. Gandhi[17] explored the assumptions that teachers adopt in their classes on the curricular material and the role of the three epistemological approaches of probability in their pedagogy. Vásquez et al.[16] examined the attitudes of primary teachers towards probability and its teaching. The other three focus more on teachers' probabilistic content knowledge: combinatorics and binomial expansion[18], randomization test[20], and modelling[19].

Other related notions. Several topics other than those stated in the purposes and subthemes were addressed in the papers, of which we can highlight attitudes and values[2,4,16], problem solving[6,10,11] and combinatorics[8,18].

5. Looking Ahead

Recognizing the dissonance associated with the leaders of a Topic Study Group entitled Teaching and Learning of "Probability" (which is colloquially, albeit widely known as how likely something is to happen) attempting to peer into the future, we nevertheless wish to end this proceedings report with what, we see, comment on a few possible research directions stemming from the papers presented in TSG-11 at ICME-14.

First, we contend that the use of technology in supporting learning and teaching of probability appears to shift the attention for advanced probabilistic concepts, relationships, and procedures. More research on this aspect of technology is needed to develop effective ways of promoting students' conceptual understanding. Second, while most papers addressed student learning at different educational levels, studies involving pre-service and in-service teachers were limited. With the availability of educational technology tools to support student learning, we note that there is need for further research on teacher knowledge and practices on the use of technology in their teaching and learning of probability. Third, a modeling approach to probability, especially with the use of computer simulations, is an emerging area of research. More interest in researching the modeling approach in teaching and learning of probability with teachers and students are welcome. Lastly, we wish to underscore the continual untethering of probability education from that of statistics education. Perhaps particularly present at ICME-14 due to dedicated working groups for Teaching and Learning of Statistics (TSG-12) *and* Teaching and Learning of Probability (TSG-11), we hope to see, again, a Topic Study Group dedicated specifically to probability education at the 15th International Congress on Mathematics Education in 2024 in Sydney, Australia.

Topic Study Group 12

Teaching and Learning of Statistics

TSG-12 Working Team[1]

1. Theme and Description

In today's world rapid technological advances have facilitated the production and management of large data sets in diverse forms. Being able to create value with data by converting them to meaningful information, to critically evaluate and effectively utilize the information for decision-making, and to understand social and natural phenomena are important 21st century skills for all citizens. Thus, the importance of teaching and learning statistics as the "science of data" is increasingly gaining recognition at all educational levels. The study of statistics provides students with tools, skills, ideas and dispositions to use in order to react intelligently to information in the world around them. Reflecting this need to improve students' ability to think statistically, statistical literacy and reasoning are becoming part of the mainstream school and university curriculum in many countries. Emerging issues in statistics education relate to dealing with "big data" and dealing as a "data scientist" and to the use of statistics in thinking about social changes and policy decisions and the impact of these on both the school and university curricula. In light of these trends, statistics education is a growing and exciting field of research and development that will enable us to build from the knowledge we have accumulated in the past about teaching and learning statistics to move forward in productive ways.

At TSG-12, academic work on major issues in statistics education research were presented and discussed along any one of the four themes:

1. Recent research on teaching and learning statistics in school and at the tertiary level including global trends;
2. Development and assessment of statistical literacy, including the connection of statistics education to social and political issues;

[1] TSG-12 Working Team:
Chair: Enriqueta Reston, University of San Carlos, Philippines
Co-chair: Andreas Eichler, University of Kassel, Germany
Members: Leandro de Oliveira Souza, Universidade Federal de Uberlandia, Brazil
Gail Burrill, Michigan State University, USA
Qian Chen, Sichuan Normal University, China

3. Preparation and professional development of statistics teachers and of statistics teacher educators; and
4. The impact of “big data” and technology-rich learning environments in statistics education, and the connection between learning statistics and learning data science.

2. Program Overview

At ICME-14, TSG-12 provided the venue for statistics educators, teachers and researchers for presentation of research and discussion of issues on these themes. The discussion included time to reflect on the status of research in statistics education related to the various themes and highlighted areas of high priority for the statistics education research community. There were four group sessions at TSG-12 which included invited and contributed papers, as well as posters, primarily delivered through online conference platforms.

2.1. Online Paper Presentations

These online presentations in four sessions start with invited papers and move to contributed papers. Except for one on-site presentation by a Chinese national, all these papers were presented virtually using Zoom conference platform with around 20–30 participants per session. The papers presented in these four sessions are outlined in Tab. 1 on the next page.

2.2. Poster Presentations

The posters presented in these four sessions are outlined in Tab. 2 following Tab.1.

3. Future Directions and Suggestions

After TSG-12 at ICME-14, the post-conference discussion focused on submission of selected papers form TSG-12 into a monograph to be published by Springer. The Call for Papers among the TSG-12 presenters was initiated by Gail Burril, one of the TSG-12 team members. This volume of papers from TSG-12 of ICME-14 will not be proceedings but rather collections of papers, each of which shares some common ground with the original paper presented during TSG-12. With the exception of the opening chapter with short country reviews, this volume consists of 14 chapters each representing a paper presented at ICME-14 for TSG-12 and the discussion that ensued. These papers will constitute a book publication entitled Reasoning with Data and Statistical Thinking: An International Perspective to be published by Springer with five sections, namely: Statistics Education Across the World, Data and Young Learners, Data and Simulation to Support Understanding, Data and Society, Statistical Learning, Reasoning and Attitudes. The editors Gail Burrill, Enriqueta Reston and Leandro Souza are members of TSG-12 technical working group.

Tab. 1. List of papers presented

Paper and author(s)
Session 1
[1] Designing embodied tasks in statistics education for grade 10–12. ***Lonneke Boels*** (The Netherlands).
[2] Teaching statistics and sustainable learning. ***Hanan Innabi*** (Sweden).
[3] Reading and interpreting distributions of numerical data in primary school. ***Daniel Frischemeier*** (Germany).
[4] Statistical literacy as central competence to critically understand big data. ***Karen François*** and *Carlos Monteiro* (Brazil).
[5] Students beliefs about statistics and their influence on students´ attitudes toward statistics in introductory courses. ***Florian Berens*** (Germany).
Session 2
[6] Interdisciplinary data workshops. ***Danny Parsons,*** *David Stern, Balázs Szendröl, and Elizabeth Dávid-Barrett* (UK).
[7] Distinctive aspects of reasoning in statistics and mathematics: implications for classroom arguments. ***Anna Marie Conner*** *and Susan A. Peters* (USA).
[8] A school experiment for introductory inferential statistics in Hungarian secondary schools. ***Péter Fejes Tóth*** *and Ödön Vancsó* (Hungary).
[9] An informal statistical inferential reasoning experience with seventh graders: a lesson study. ***Soledad Estrella,*** *Maritza Méndez-Reina, Tamara Rojas, and Rodrigo Salinas* (Chile).
[10] Research on teaching strategies of the mean from the perspective of statistical literacy. ***Jiaqi Wu*** (China).
Session 3
[11] Margin of error: connecting chance to plausible. ***Gail Burrill*** (USA).
[12] Critical citizenship in statistics teacher education. ***Lucía Zapata-Cardona,*** *Cindy Alejandra Martínez-Castro, Lucía Zapata-Cardona, and Gloria Lynn Jones* (Colombia).
[13] Mathematics ability and other factors associated with success in introductory statistics. ***Adam Molnar*** *and Shiteng Yang* (USA).
[14] Elementary students' responses to quantitative data. ***Karoline Smucker*** *and Azita Manouchehri* (USA).
Session 4
[15] Implementation of a course on Tidyverse in Pakistan under the ASA Educational Ambassador Program. ***Saleha Naghmi Habibullah*** (Pakistan).
[16] Young learners' reasoning with informal statistical models and modeling. ***Michal Dvir*** *and Dani Ben-Zvi* (Israel).
[17] The binomial model: coin tosses or clay pots? ***Von Bing Yap*** (Singapore).
[18] Variability modeling and data-driven decision-making using socially open-ended problems: a comparative study of high school students in Thailand, Brunei and Zambia. ***Orlando González*** (Thailand).
[19] Algebraization levels of statistical tables in secondary textbooks. ***Mara Magdalena Gea*** *and Jocelyn D. Pallauta, Pedro Arteaga, and Carmen Batanero* (Spain).
[20] Data modelling with young learners as experiences of allgemeingbildung. ***Stine Gerster Johansen*** (Denmark).
[21] Investigating mathematics teacher educators' conceptions for informal line of best fit. ***Jale Gunbak Hatil*** *and Gulseren Karagoz Akar* (Turkey).

Tab. 2. List of posters presented

Poster and author(s)	
[22]	Does climate change really exist? high school students discover statistical methods by solving a modeling problem. ***Maren Hattebuhr*** *and Martin Frank* (Germany).
[23]	Do students in grade 10 generate ideas of statistical hypothesis testing spontaneously? ***Hiroto Fukuda****, Naoya Miwa, and Yoshiki Hashimoto* (Japan).
[24]	Model proposal to promote the construction of the strong meaning of volatility. ***Miguel Andres Diaz Osorio*** (Columbia).
[25]	Improving statistical pedagogy among K to 12 mathematics teachers in the Philippines. ***Enriqueta Deguit Reston*** (Philippines).
[26]	Developing mathematical knowledge for teaching mean and median of prospective mathematics teachers through the lesson study. ***Thi Ha Phuong Nguyen*** (Vietnam).
[27]	Analysis of the most frequent errors in practical works on tables and graphs in biostatistics. ***Teresita Evelina Teran*** (Argentina).
[28]	Comparing the statistical content of elementary school mathematics textbooks from Japan, India and China. ***Yuqi Li****, Xue Li, and Zhemin Zhu* (China).
[29]	Comparing the statistical content of elementary school mathematics textbooks from Japan, India, the United States, Singapore and China. ***Zhemin Zhu****, Yuqi Li, Yilin Li, Lulu Li, and Xue Li.* (China).
[30]	Aspects of critical thinking in statistical education-research survey on sixth-grade elementary school. ***Naoki Ohta*** *and Ken Teraguchi* (Japan).

Topic Study Group 13

Teaching and Learning of Calculus

David Bressoud[1], Kristina Juter[2], Elizabeth Montoya[3], Armando Cuevas[4], and Xuefen Gao[5]

1. Aims of the TSG

This Topic Study Group sought contributions on research and development in the teaching and learning of Calculus, both at the upper secondary and tertiary levels. Contributions accounted for advances, new trends, and important work done in recent years on the teaching and learning processes of Calculus. These included:

- Introducing and building basic concepts of Calculus in upper secondary education,
- Meeting the challenges of teaching and learning Calculus and Analysis at universities and through online courses,
- Teaching and learning of Calculus for special audiences (*e.g.* professional training, engineering, life sciences),
- Use of technology in the teaching and learning of Calculus, including online courses
- The role of visualisation in the teaching and learning of Calculus,
- Analysis of textbooks concerning the presentation of the concepts of Calculus and Analysis,
- Easing the transition between secondary and tertiary education in the teaching and learning of Calculus, and between Calculus and Analysis at the tertiary level,
- Theoretical approaches to study the phenomena related to the teaching and learning of Calculus.

Contributions also described theoretical or pragmatic research into effective practices for the teaching and learning of key concepts of Calculus such as co-variation

of functions, limits, continuity, differentiation, integration, or the Fundamental Theorem of Calculus, among others.

1.1. Submissions

We received 36 submissions from 19 countries (South America: 6; North America: 10; East Asia: 7; Southeast Asia: 1; South Asia: 2, Europe: 5; Middle East and North Africa: 5), thus reaching our goal of diverse cultural representation. Of those 36 submissions, eleven were accepted for long paper presentations, nineteen for short paper presentations, and eight as posters. None were rejected. One presenter selected for a long paper and one presenter selected for a short paper withdrew after the congress was rescheduled for 2021.

1.2. Sessions

Because almost all presenters were joining remotely and representing many different time zones, the presentations were grouped geographically, first those from East and South Asia, then those from Europe, the Middle East, and North Africa, and finally those from the Americas. Each session began with three or four 15-minute presentations, followed by five or six 5-minute presentations. There was little time for discussion.

1.3. Paper Topics

A list of the papers and authors are included in order of presentation and are organized in Tab. 1 (on the next page).

2. Conference Themes

There were three main themes for the papers presented in this topic study group. The first dealt with student understandings and misunderstandings of basic concepts of calculus. These included rate of change, limits, continuity, derivatives, differentials, and definite integrals. At a more basic level, there was also discussion of how to improve the covariational reasoning of students and general student difficulties with the language of mathematics and how mathematics uses language.

A second theme turned to the use of technological tools to help students build understanding of certain fundamental ideas.

Quite a few of the presentations focused on the third theme, presenting a variety of techniques for improving instruction in the calculus classroom. Several described the use of inquiry-based learning. There was discussion of other approaches to creating an active learning environment as well as the use of flipped instruction, an emphasis on modeling, and the use of writing assignments.

Other topics included a comparison of textbooks, a comparison of how physics and mathematics differ in their approach to ordinary differential equations, the introduction of tangents and asymptotes without reference to limits, and a discussion of how to deal with student overgeneralization of the concept of linearity.

Tab. 1. List of papers presented

Paper and author(s)	
[1]	Mathematical knowledge for teaching of calculus: an exploratory study of secondary school teachers mathematical thinking related to concepts in calculus. ***Jonaki B Ghosh*** (India).
[2]	Modeling concepts of derivative and differential with educational software. ***Vladimir Nodelman*** (Israel).
[3]	Constructing knowledge using digital tools: the case of the inflection point. ***Regina Ovoenko*** *and Anatoli Kouropatov* (Israel).
[4]	Students' interpretations of the definite integral. ***Inen Akrouti*** (Tunisia).
[5]	Comparison of mathematics textbooks in IB school and Chinese public high school: take core concept — calculus as an example. ***Yun Lu*** (China).
[6]	Research in calculating areas between curves. ***Gordana Stankov*** *and Djurdjica Takaci* (Serbia).
[7]	The concept of continuity through different types of representations of the function. ***Matthias Antonopoulos*** *and Leonora Antonopoulou* (Greece).
[8]	Actions in the learning environment: analyzing physics and mathematics lessons in the case of ODE. ***Kristina Elisabeth Juter****, Örjan Hansson, and Andreas Redfors* (Sweden).
[9]	From upper secondary school to university calculus: language difficulties versus conceptual difficulties. ***Arne Hole****,* ***Inger Christin Borge****, and* ***Liv Sissel Grønmo*** (Norway).
[10]	The discrete-dense-continuous phenomenon and its implication in continuous. ***Elizabeth Montoya Delgadillo*** (Chile).
[11]	A limit free calculus for introducing the concepts of tangent and asymptote. an educational proposal inspired by the past. ***Maria Astrid Cuida Gomez*** (Spain).
[12]	An approach to reduce the number of failure students in a large calculus class. ***Jianhui Pan*** (China).
[13]	The exponential function from the viewpoint of mathematical modelling: a Chilean lesson study. ***Carlos Andres Ledezma Araya*** *and Elizabeth Montoya Delgadillo* (Chile).
[14]	Using open education resources to promote the active learning of calculus in urban districts. ***Kenneth Horwitz*** (USA).
[15]	Mathematics anxiety levels among students in an inquiry-based calculus class. ***Harman Prasad Aryal*** *and Otto Joshua Shaw* (Nepal).
[16]	Learning difficulties in calculus: an investigation through students' written solutions. ***Raquel Carneiro Dorr*** (Brazil).
[17]	The design and use of low instructional overhead tasks in undergraduate calculus: making student reasoning more accessible to calculus instructors. ***David C. Webb*** (USA).
[18]	The observed impact implementing inquiry-based learning at a calculus classroom. ***Su Liang*** (China).
[19]	Teaching calculus based on complexity theory of teaching and learning. ***Mehmet Turegun*** (USA).
[20]	Notions of continuity of the pre-service teachers: reflections for a problematization. ***Antonio Bonilla*** *and Ricardo Cantoral* (Mexico).
[21]	Resignification of the derivative in a school situation with a perspective of an exclusion-inclusion dialectic: from emulation of the concept to autonomy of uses. ***Jose Luis Morales Reyes*** *and Francisco Cordero Osorio* (Mexico).
[22]	Covariational reasoning: an axis in the construction process of the definite integral concept. ***Mihaly Andre Martinez Miraval*** *and Martha Leticia Garcia Rodríguez* (Peru).
[23]	The "overgeneralization of linearity": difficulty, conflict or obstacle? ***Nicolas Lopez*** *and Gloria Ines Neira Sanabria* (Colombia).
[24]	Rate of change: meanings students have in accordance with context. ***Dafna Elias****, Tommy Dreyfus, Anatoli Kouropatov, and Noah Sella* (Israel).

3. Areas for Future Research

None of the presentations specifically addressed the problems of preparation for calculus. This is a huge issue, especially in places such as the United States where student preparation for university is so varied in quality and so highly correlated with socio-economic status. Good work is being done in trying to address these disparities. They require attention from the research community to understand what works in what situations and why.

Student understanding and misunderstanding of the concepts of calculus has been a rich source for research in the teaching and learning of calculus. Thirty years ago, the focus was on how students misconceive so many of these fundamental ideas. Within the past decade, this has shifted to a more productive line of exploring natural student understandings that can be encouraged and developed to improve student grasp of and ability to use fundamental aspects of calculus. Good examples of this are the development of covariational reasoning and the development of an understanding of limits expressed in terms of narrowing bounds on the distance from the target value, placing the emphasis on what happens to the dependent variable rather than the independent variable. There is still work to be done in identifying productive approaches to basic ideas of calculus and understanding how they can be effectively encouraged.

Technology in its many forms is a constant presence. While most of the work has focused on exhibiting the effectiveness of a clever new tool, much more work needs to be done on how to balance the use of what has become basic and ubiquitous technology such as computer algebra systems. How have they changed what students need to learn and be able to carry with them beyond the calculus class? What procedures for differentiation or integration are still essential and why?

Finally, as the emphasis on improved approaches to teaching and learning in this topic study group has revealed, there is a great deal of work being done on the implementation of a variety of active learning approaches. There is no question that when undertaken by a dedicated and enthusiastic instructor, these can greatly improve student outcomes. The questions that require exploration revolve around how these efforts can be scaled up. How does one convince reluctant colleagues to attempt active approaches to their teaching? What kinds of supports are most helpful? How can departments deal with the fact that later adopters are often discouraged by the difficulties they encounter? What are the ingredients of active learning that are easiest to implement on a broad scale and most effective? These are very broad questions with applications to any aspect of the teaching and learning of mathematics, but there is good research into a variety of approaches to active learning that apply specifically to the context of calculus instruction. Narrowing the focus in this way promises to generate good ideas and significantly improve the teaching and learning of calculus.

Topic Study Group 14

Teaching and Learning of Programming and Algorithms

Chantal Buteau[1], Maryna Rafalska[2], Xuemei Chen[3], and Bakhyt Matkarimov[4]

1. Teaching and Learning of Programming and Algorithms: A New TSG at ICME!

We see the introduction of this new TSG-14 as a response to the increased integration of programming and algorithmics in our school curricula around the world, sometimes within or in relation to mathematics. At the onset of this TSG, is undoubtedly the work and vision by pioneer Seymour Papert. We opened our TSG sessions by recalling the following quote from Papert's influential 1980 Mindstorm book, reminding us that although the broader integration of programming and algorithmics in our schools (compulsory programs) is rather recent, the vision had long been laid out:

> In many schools today, the phrase "computer-aided instruction" means making the computer teach the child. One might say the computer is being used to program the child. In my vision, the child programs the computer and, in doing so, both acquires a sense of mastery over a piece of the most modern and powerful technology and establishes an intimate contact with some of the deepest ideas from science, from mathematics, and from the art of intellectual model building. (Papert, 1980, p. 5)

2. Aim of the TSG

The aim of this new ICME Topic Study Group was to explore questions that raise from such a rapid and widespread interest of integrating programming and computational thinking in education and to exchange information about evolving trends and perspectives within various educational contexts from around the world. Questions and themes at centre of our interests were for example:

- What are the current realities of teaching and learning of algorithmics and programming in relation to school and university mathematics classrooms?
- To what extent and how is research informing teacher education and practices to support the development of computational thinking?

[1] Department of Mathematics and Statistics, Brock University, Canada. Email: cbuteau@brocku.ca
[2] Université Côte d'Azur, France. Email: Maryna.RAFALSKA@univ-cotedazur.fr
[3] Hebei Normal University, China. Email: xuemeichen@hebtu.edu.cn
[4] Nazarbayev University, Kazakhstan. Email: bmatkarimov@nu.edu.kz

- What theoretical perspectives and methodologies are relevant for studying the teaching and learning of programming and algorithms in relation specifically to learning mathematics and what theoretical or practical results have emerged? For example, what is the relation between mathematics (teaching and learning) and programming and algorithmics (teaching and learning)?
- What obstacles to integration have occurred and how have they been overcome?
- What affordances have been observed and how were they exploited?

To this end, we received and discussed research- and practice-based contributions concerning different levels of education (from elementary to university) and various topics related to the teaching and learning of programming and algorithmics, either in support of or as supported by the teaching and learning of mathematics. In the next section, we provide more details about the contributions that were presented and discussed.

3. Program Overview

3.1. Submissions

We received 17 submissions from 12 countries (South America: 1; North America: 2; Asia: 3; Europe: 5; Australia: 1), thus reaching our goal of diverse cultural representation. Of those 17 submissions, one was an invited long paper, five were accepted as long paper presentations for 2020 (3 were presented in 2021), seven as short paper presentations for 2020 (6 were presented in 2021), and three as posters for 2020 (1 was presented), and one was rejected.

3.2. Paper and poster presentation sessions

Each of our three sessions had a similar format: first an introduction by one of the TSG co-chairs of the themes and schedule for the session. It was followed by the oral presentations of (40-minute) *invited* talk (IT) or (25-minute) *long* papers (LO), (15 minute) *short* papers (SO), and the (5-minute) *poster* for the last session. We kept a 20 minutes time window at the end of each session for a collective discussion at which some guiding questions were provided as a way to prompt the conversation. We saw this discussion as critical to promote networking and to engage in deepening our understanding of different issues presented. We ended the last session by summarizing some key points that were raised during our three sessions, as well as highlighting some under-represented topics that should be part in future conversation.

Among the 16 accepted submissions, 11 of them were presented at the 2021 hybrid conference. We list these contributions and authors below in Tab. 1 in order of presentation:

Tab. 1. List of Contributions Presented

Paper and author(s)	
[1]	Algorithmic thinking: emerging implications for school mathematics education. ***Max Stephens*** (Australia) *and Djordje M. Kadijevich* (Serbia). (LO)
[2]	Mathematics education and computational thinking. ***Takuma Takayama*** (Japan). (SO)
[3]	Teachers' perceptions of computational thinking as part of the teaching of mathematics: a hermeneutic literature review. ***Camilla Finsterbach Kaup*** (Denmark). (SO)
[4]	Three important aspects of research on computational/algorithmic thinking. ***Djordje M. Kadijevich*** (Serbia) *and Max Stephens* (Australia). (LO)
[5]	On enumeration in mathematics and computer science: some didactical issues. ***Simon Modeste*** (France). (LO)
[6]	A framework for analyzing the integration of algorithms and programming into mathematics textbooks. ***Tran Kiem Minh****, Nguyen Thuy Viet Anh, and Tran Trong Ha* (Vietnam). (SO)
[7]	Working mathematically and thinking computationally: capitalising on commonalities for integrated teaching. ***Elena Prieto*** *and* ***Kathryn Holmes*** (Australia). (IT)
[8]	Modelling and 3D priniting a circular staircase for a doll's house: teaching computational thinking using a range of different tools. ***Gregor Milicic*** *and Matthias Ludwig* (Germany). (SO)
[9]	Researching the teaching and learning of programming for university mathematical investigation projects. ***Chantal Buteau*** (Canada)*, Eric Muller* (Canada)*, Ghislaine Gueudet* (France)*, Joyce Mgombelo* (Canada)*, Ana I. Sacristán* (Mexico). (SO)
[10]	"Math & CS Labs": a bi-disciplinary course for second-year undergraduates in mathematics or computer science. ***Antoine Meyer*** *and David Doyen* (France). (SO)
[11]	Matlab as a tool for experimental mathematics. ***Yevgeny A. Gayev*** (Ukraine). (Poster)

3.3. Conference themes

Each session focused on different themes. In the following, we list the themes of each session, together with selected guiding questions that were proposed in order to facilitate the discussion session. We see those questions pointing to particular interests from scholars and needs from practitioners in the area of teaching and learning of programming and algorithmics in mathematics education.

In the first session, we focused on the joint development in curriculum of mathematics and algorithmic/computational thinking; pedagogical approaches; and, attitudes and knowledge of (prospective) teachers. We noted that there is a historical and epistemological proximity between mathematics and computer sciences and questioned for example: *In what ways do or 'should' school mathematics curricula exploit this proximity? And is an understanding of this proximity necessary for teachers in order for them to meaningfully integrate algorithmic/computational thinking in their teaching of mathematics?* Furthermore, we wondered, due to the emerging integration in many curricula: *To what extent and how should research inform mathematics teacher education and practices to support the integration and assessment of algorithmic/computational thinking? What are the barriers and challenges experienced by teachers who are integrating algorithms and programming as part of their mathematics teaching? And which pedagogical approaches support students' learning of mathematics in a context with algorithms and programming?*

In this second session, we focused on two main themes, namely the conceptualization of algorithmic and computational thinking, and the interactions between computer science and mathematics and their potentialities in the teaching and learning of mathematics. Early on in our discussion, emerged the need to articulate a conceptualization of algorithmic thinking and computational thinking, and we wondered about its link(s) with: *problem solving, different types of mathematical thinking (in particular, algebraic thinking and statistical thinking), mathematical reasoning (logical thinking, argument, justification, generalisation), and design thinking*. We wondered about the *theoretical frameworks that can be relevant to study algorithmic/computational thinking for mathematics teaching and learning.* And we also asked questions, such as: *How does/should the computer science curriculum impact problem solving in mathematics?*

Finally, in this third and last session, we focused on the incorporation of algorithmic/computational thinking into mathematics curriculum at secondary school and university levels, as well as teaching practices and resources at these levels. Different aspects were discussed, such as the *kind of articulations between programing and mathematics activities that support the students' learning of mathematics and computer science concepts in the most efficient way.* We also questioned, for example, *which domains/subject areas that are the most fruitful basis for the integration of algorithmic/computational thinking in mathematics curriculum*; *and whether there are differences between integration of algorithmic/computational thinking in mathematics curriculum at high school and university levels.*

4. Future Directions (Areas for Future Research)

Different approaches that bring together the learning of programming and algorithmics with mathematics learning were discussed during the sessions, including multiple examples of activities, different models of integration in the curriculum, resources for teachers, and the identification of different areas of mathematics that are particularly fruitful. As we ended our TSG, we identified three under-represented topics in our conversation that we deemed as key to incorporate in future conversation, namely:

- Initial and professional teacher education
- Classroom realities of teacher and student practices
- Theoretical and methodological frameworks to analyse the above two

Topic Study Group 15

Teaching and Learning of Discrete Mathematics

Elise Lockwood[1], Cecile Ouvrier-Buffet[2], Ambat Vijayakumar[3], Mariana Durcheva[4], and Han Ren[5]

1. Aims of the TSG

Discrete mathematics is the study of discrete (as opposed to continuous) structures. It has many applications in a variety of fields, and it often exists at the interface of several disciplines, making it increasingly relevant in our digital world. Discrete mathematics offers many accessible points of entry for students to engage in rich mathematical thinking, as students can interact with ideas and reason about problems without requiring considerable prior knowledge of mathematical content. Further, its accessible nature makes it an excellent context in which students can engage in important mathematical practices such as conjecturing, generalizing, justifying, and proving. For these reasons, we view discrete mathematics as an indispensable part of mathematics education that deserves attention at all levels of education.

The main goal of TSG-15 was for researchers and educators to share current developments in the teaching and learning of discrete mathematics at all levels, ranging from elementary through postsecondary school. We sought to extend previous work on the teaching and learning of discrete mathematics by sharing new research and pedagogical innovations about a variety of topics related to discrete mathematics. We were particularly interested in identifying and exploring the variety of ways in which discrete mathematics is studied and taught across the world. We acknowledge that the teaching and learning of discrete mathematics may involve investigations into both mathematical content (particular mathematical topics within discrete mathematics and other disciplines) and mathematical practices (more general mathematical approaches or habits of mind), and that it may be a setting in which to explore other relevant issues in mathematics education. In terms of content, in this TSG we characterized discrete mathematics broadly as consisting of a variety of topics. This includes topics traditionally associated with discrete mathematics (such as algorithms, coding theory, combinatorics, cryptography, graph theory, languages and automata, logic, number theory, recursion, and set theory), as well as topics that might be considered relatively new (such as complexity theory, existence and constructability, and computational

[5] East China Normal University, China. E-mail: hren@math.ecnu.edu.cn

number theory, algebra, and group theory). In addition, there are a number of mathematical practices that could be related to discrete mathematics, including problem solving, conjecturing, justifying, generalizing, proving, and more. We also acknowledge that there may also be additional topics in mathematics education that might particularly be emphasized — these might include, for example, issues of affect and beliefs, equity and inclusion, classroom discourse, pre-service teacher preparation, or in-service teacher training.

We envisioned that this TSG would include presentations of papers on any of the wide range of topics discussed above, focusing on any level of school. We welcomed papers that were related to the teaching and learning of discrete mathematics, which may include, but were not limited to:

- research on student thinking about relevant concepts in discrete mathematics;
- research demonstrating effective instructional strategies in teaching discrete mathematics;
- research-based ideas for innovative activities and pedagogical interventions in classrooms at a variety of age levels;
- research-based ideas of incorporating technology into the discrete mathematics classroom;
- explorations of discrete mathematics as a setting in which to investigate mathematical practices;
- explorations of discrete mathematics as a setting in which to investigate other relevant issues in mathematics education;
- ways of thinking (or habits of mind) that may be productive in discrete mathematics, such as combinatorial reasoning, algorithmic or computational approaches, or recursive thinking;
- curriculum and educational policy issues related to discrete mathematics.

1.1. Submissions

We received 22 submissions from 12 countries (South America: 2; North America: 4; Asia: 3; Europe: 13). Of those 22 submissions, 18 were accepted as paper presentations, 2 as posters, and 2 were rejected. Four accepted paper presenters were not able to present in 2021 in the virtual format, so we had a total of 14 papers presented during the online conference (of these, one did not show up to the presentation, so there were 13 total presentations).

1.2. Sessions

In general, most presenters were given 20 total minutes, which included time for questions and the transition to the next speaker. Two exceptions were one 30-minute invited presentation (by Erik Tillema and Lori Burch[6]), and one shorter 10-minute presentation (who was a last-minute addition that had not indicated they intended to present). Our first session had four 20-minute presentations and one 10-minute presentation; our second session had one 30-minute presentation and three 20-minute presentations; and our third session had four 20-minute presentations. We also had some time at the end of the third session to have some overall discussion, although this did not seem like enough time to be able to have the kinds of in-depth conversations and discussions we would have liked to have. Still, there was a sense of community during the sessions, and even though we did not have much time for additional discussion, it felt like a productive and valuable shared experience.

1.3. Papers presented

Of the 18 accepted papers, four authors had to withdraw from the 2021 virtual participation. Thus, only 13 papers were able to be presented during the online conference. A list of these papers and authors are included in order of presentation and are organized in Tab. 1.

Tab. 1. List of papers presented

	Paper and author(s) in order of presentation
[1]	Suggestions for an integration of cryptology into a math curriculum. ***Tomas Borys*** (Germany)
[2]	Enriching pre-service teachers' conceptions about proof with discrete mathematics. ***Cécile Ouvrier-Buffet*** (France)
[3]	Graph theory in primary school mathematical education — a quantitative study on the impact of graph theory concepts on psychological characteristics of fourth grade students. ***Melissa Windler*** (Germany)
[4]	The role of discrete mathematics in secondary mathematics for non-STEM paths. ***Jaime Carvalho e Silva*** (Portugal)
[5]	Discrete mathematics in the Hungarian mathematics curriculum. ***Katalin Gosztonyi****, Csaba Csapodi, and Eötvös Loránd* (Hungary)
[6]	Leveraging combinatorial and quantitative reasoning to support the generalization of advanced algebraic identities. ***Erik Tillema*** *and Lori Burch* (U.S.A.)
[7]	Combinatorial counting problems in elementary school: a comparative analysis of German textbooks. ***Karina Höveler*** *and Janet Winzen* (Germany)
[8]	Preliminary levels of sophistication for enumerating permutations. ***Joseph Antonides*** *and Michael T. Battista* (U.S.A.)
[9]	Guiding students' reinvention of combinatorial operations. ***Belmiar Mota*** *and Rosa Antónia Tomás Ferreira* (Portugal)
[10]	Preservice teachers' development of mathematical knowledge for teaching via combinatorial tasks in a computational setting. ***Elise Lockwood*** *and Adaline De Chenne* (U.S.A.)
[11]	Relation between algorithmic and combinatorial thinking of undergraduate students of applied informatics. ***Janka Medová*** *and Sona Čeretková* (Slovakia)
[12]	Some approaches for incorporation of CAS in a discrete mathematics course. ***Mariana Durcheva*** (Bulgaria)
[13]	How can poly-universe sets develop creativity during the solution of combinatorial exercises? ***Eleonóra Stettner*** *and Szabina Tóth* (Hungary)

2. Conference Themes

We had presentations on a variety of topics, and we note some big ideas and themes that emerged during the sessions. These themes mostly align with areas of focus of our papers, and we describe categories of papers that highlight overall areas of emphasis that were covered in our topic study group.

One theme is that there are a number of ways in which discrete mathematics is and can be integrated in school mathematics. We saw examples of papers that demonstrated discrete mathematics for non-STEM majors (Carvalho e Silva[4]), for and for K-12 students in general (Gosztonyi et al.[5]). We also saw ideas for innovative ways to incorporate topics into the discrete mathematics curriculum (including Borys' focus on crytology[1]). This suggests that there are a variety of ways around the world in which discrete mathematics is being integrated into curricula, and this demonstrates that we have many opportunities to explore effective ways to teach discrete topics for students at a variety of age and grade levels.

A second theme is that the field is currently conducting (and would benefit from continuing to conduct) research about specific topics within discrete mathematics. The most common topic that is being regularly investigated is combinatorics, and eight of our papers focused on combinatorics (including the invited presentation by Tillema and Burch[6]). In addition, though, we saw promise for focusing on other topics, including graph theory (Windler[3]) and cryptology (Borys[1]). This suggests that there are opportunities for additional topics to be studied in more depth, and perhaps a next direction for the field is to jointly study other topics as thoroughly as combinatorics is being studied.

A third theme is that it may be productive to explore teacher preparation related to discrete mathematics. A couple of studies in our topic study group focused on pre-service teacher preparation (Ouvrier-Buffet[2]; Lockwood and De Chenne[10]), and this may continue to be a fertile area of research, where we may focus on the preparation of teachers who will teach topics in discrete mathematics. Particularly given the role of discrete mathematics in the curriculum in many different countries (as indicated in theme 1), it may be valuable to investigate in more depth how teachers are prepared to teach discrete topics.

Finally, our last theme is that discrete mathematics interfaces meaningfully with computing and technology. Several of our papers (including those by Medová and Čeretková[11]; Durcheva[12]) examined the role of technology and computing in discrete mathematics, suggesting that there may be valuable connections with researchers who study informatics or computer science. We see opportunities for interdisciplinarity in the future, particularly in this context of computing.

3. Areas for Future Research

There are several opportunities that we as a community identify as areas for future research, and our ideas for future research are related to the themes we described above. In particular, the distribution of topics about which we had presentations highlights different opportunities for more research in certain areas. While combinatorics has been increasingly well-researched in the last decades (which is underscored by our eight combinatorics-focused topics), other particular topics are as yet relatively under-researched. These include topics like cryptology and graph theory, as well as other areas of discrete mathematics like relations, sets, logic, and recursion. In terms of particular topics in discrete mathematics, then, there are many opportunities for researchers to investigate multiple aspects of these understudied topics, including students' reasoning about them and effective instructional interventions. We also hope that the field will continue to expand to investigate the teaching and learning of discrete mathematics as related to teacher preparation, exploring effective ways to prepare teachers to teach discrete topics in particular, and studying pre-service and in-service teachers' understandings of and experiences with discrete mathematics. Finally, there is a clear connection between discrete mathematics and computing, and we see valuable opportunities to continue to explore and examine the intersection of these ideas. We hope researchers will investigate effective ways to leverage computing in the teaching and learning of discrete mathematics, as well as ways to teach discrete mathematics to other populations such as informatics and computer science students.

Topic Study Group 16

Reasoning, Argumentation, and Proof in Mathematics Education

Viviane Durand-Guerrier[1], Samuele Antonini[2], Kotaro Komatsu[3], Nadia Azrou[4], and Chao Zhou[5]

1. Aims of the TSG

There is international recognition (see Stylianides and Harel, 2018) of the importance of reasoning and proof in students' learning of mathematics at all levels of education (elementary, secondary, university) and in all tracks (general, vocational). Indeed, reasoning, argumentation, and proof are at the very heart of mathematical activity, playing a crucial role in learning processes. There is also international research-based evidence showing that many students face difficulties with reasoning about mathematical ideas and constructing or understanding mathematical arguments. This is particularly the case when these arguments meet the standard of proof; in addition, teachers often lack adequate resources for helping their students to develop skills in reasoning, argumentation, and proof. Although the existing body of research offers important insights into this area, there are still many open questions for which theoretical and empirically based responses are needed.

We have welcomed submissions of theoretical or empirical research reports on any topic related to reasoning, argumentation, and proof in mathematics education, including interaction between mathematics and other disciplines (e.g., Computer Sciences, Physics, Economy etc.). The reports could cover any level of education: elementary, secondary, and university (including pre-service teacher education, or in-service teacher professional development).

2. Submissions

We received 45 submissions (38 papers and 7 posters) from 17 countries: Algeria: 1; Brazil: 3; Cameroun: 1; Canada: 1; Chile: 1; China: 7; Colombia: 1; Germany: 4; Italy: 2; Japan: 4; Norway: 2; Peru: 1; South Korea: 2; Tunisia: 1; Turkey: 2; United

[4] University Yahia Fares of Medea, Algeria. E-mail: nadiazrou@gmail.com
[5] Soochow University, China. E-mail: zhouchao@suda.edu.cn

Kingdom: 1; United States of America: 11. Among the 38 submitted papers, 12 were accepted as long oral presentations (Algeria: 1; Cameroon: 1; Canada: 1; China: 1; Germany: 1; Italy: 1; Japan: 1; Norway: 1; United Kingdom: 1; United States: 2; Tunisia: 1) and 26 were accepted as short oral presentations, and the seven submitted posters were accepted. During the conference, in July 2021, there were only 10 long oral presentations[1–10], and 18 short oral presentations[11–28]; during the poster sessions, 2 posters[29,30] have been presented (see Tab. 1 on the next page).

3. Sessions

Considering the high number of submissions, the ICMI organizing committee granted our TSG one more time slot for presentations. Each long oral presentation lasted 10 mins and was followed by 5 min discussion; the short oral presentations were 5 minutes each followed by a collective discussion. Due to the pandemic, the sessions were in hybrid form with a small number of participants and presenters in Shanghai, the majority attending online.

In the first session on July 13th, 2021, after the introduction of the team and of the agenda of the TSG, there were two long oral presentations by Azrou[1] and Chellougui[2], and five short oral presentations by Bae[11], Na and Knuth[12], Meyer et al.[13], Solar et al.[14], and Lin[15]. A 20-min discussion on the short oral presentations followed. The session was chaired by Kotaro Komatsu (online).

In the second session on July 14th, 2021, there were 2 long oral presentations by Jablonski and Ludwig[3] and Soldano[4] and 6 short oral presentations by Shibata and Misono[16], Kempen[17], Lee[18], Dallas[19], Damrau[20], and Murata[21], followed by a 20-min discussion on the short oral presentations together with a 10-min discussion on general issues from the two first sessions in order to prepare the final collective discussion. This session was chaired by Nadia Azrou (online).

In the third session on July 16th, 2021, there were three long oral presentations by Yan and Hanna[5], Zhuang and Conner[6], Buchbinder and Crone[7] (US), and four short oral presentations by Hao and Lin[22], Huitzilopochtli er al.[23], Wong[24], and Mazzi[25], followed by a 20-min collective discussion on the short oral presentations. This session was chaired by Samuele Antonini (online).

In the fourth session on July 17th, 2021, there were three long oral presentations by Makino[8], Gustavsen et al.[9], Stylianides and Stylianides[10], and three short oral presentations by Dong and Liu[26], Zheng and Cheng[27], and Zhang and Wu[28], followed by a 20-min collective discussion on the short oral presentations, and a 45-min collective discussion on future research agenda and possible collaborations. This session was chaired by Viviane Durand-Guerrier (online) and Chao Zhou (from Shanghai).

Obayashi[29] and Barut[30] presented their posters during the related session.

Tab. 1. List of papers and posters presented

[27]	Regional and gender differences in Chinese 8th grade students' mathematical reasoning competency. ***Xin Zheng*** *and Jing Cheng* (China).
[28]	A study of the teaching process of mathematical concept argumentation based on tap - taking function concept teaching between expert and novice teacher in China as a case. ***Yi Zhang*** *and Xiaopeng Wu* (China).
[29]	The transient stages of inductive and deductive reasoning. ***Masanori Obayashi*** (Japan).
[30]	The Last Decade of Proportional Reasoning: A Systematic Review. ***Betül Barut*** (Turkey).

4. Collective Discussions and Future Research Agenda

We have tried to keep, as possible as we could, the collective discussion along the sessions despite the tiny time due to the high number of presentations. In the last session, a 45-min slot was dedicated to discussion on future research agenda. The main issues that emerged from the presentation and discussion in perspective of future research agenda were the followings:

- The need for going on exploring epistemological and philosophical references in mathematics education, considering the increasing role of digital technologies in mathematical activity, including the role of computer assisted provers.
- The role of logic in proof and proving has long been a controversial issue in mathematics education; the body of research has been developing during the last decade and need to be still developed, considering both the use of logic in the teaching and learning of proof, and the role of logic for analyzing students' proving activities.
- The value of symbolism and of formalization in proof and proving and their interplay with heuristic aspects.
- The scope and the role of generic proof in mathematics education is still under research: in which respect such generic proofs could be recognized as *genuine mathematical proofs* by teachers is one among the open questions.
- Examining argumentation and proof in textbooks is not an easy task, because the importance of students' activities and exchanges is crucial in argumentation and proving. Nevertheless, such analysis could inform on what is likely to happen or not in classroom.
- Another important issue concerns the teacher's knowledge related to argumentation and proof, this being related with teachers' own practices, and then with their training in proof and proving in their studies; this last point being related to the double Klein transition, from secondary school to university and then back from university to secondary school.

Topic Study Group 17

Problem Posing and Solving in Mathematics Education

Tin-Lam Toh[1], Manuel Santos-Trigo[2], Puay Huat Chua[3], Nor Azura Abdullah[4], and Dan Zhang[5]

ABSTRACT This report presents a summary of the content of the various presentation by the participants in ICME-14 under the Topical Study Group 17: Problem Posing and Solving in Mathematics Education. Some trends in the research on problem solving and problem posing are identified through this study. Other areas which were less explored were also highlighted

Keywords: Problem solving; Problem posing; Processes; Teaching and learning; Teacher education.

1. TSG-17 — A Brief Introduction

1.1. TSG-17 on Problem Solving/Problem Posing

The TSG-17 on Problem Solving (PS) and Problem Posing (PP) attracted large numbers of paper submissions. After the review process and confirmed registration of the participants, there were 35 paper presentations out of which 6 were long paper presentations and 29 were classified as short orals. There were a good mix of presenters from all over the world from the five continents. Hence, the views and trends in this study is a balanced views from researchers from all parts of the globe.

1.2. Questions on PS/PP to be addressed by the TSG

The focus of the TSG-17 is on four aspects of PS/PP: (1) the teaching and learning of mathematics in relation to PS/PP; (2) the enactment of PS/PP in the mathematics classroom; (3) teacher education and (4) the use of digital technologies in PS/PP activities. Mathematical PS has been the focus of a long line of inquiry in mathematics education for more than half a century, which gets back to as far as the publication of the seminal work How to Solve It of George Pólya (1945). With this attention on PS, the mathematics curricula around the world have placed PS as the heart of the national mathematics curriculum in many countries. The four-phase Pólya's problem solving

model became well-known and is an icon for PS. Schoenfeld (1985) introduced his framework to further enhance Pólya's model. Although PS has been in attention for many years, its emphasis has not diminished. For example, in the Singapore context, PS has been the heart of the school mathematics curriculum. Despite the regular curricular revision, the PS framework remains unchanged, with the new initiatives of mathematics education introduced by the Singapore Ministry of Education serving to unpack and elucidate the various aspects of the PS framework. In China, PS and PP are highly emphasized in the national curriculum standard and are the main objectives of the national curriculum. PS/PP are widely used in the mathematics classrooms, although it is recognized that there is still the need to strengthen teachers' ability of encouraging students engage in PS and PP. PS has continued to attract researchers' attention in areas such as the enactment of PS in the mathematics classroom (Toh et al., 2008a, 2008b). For example, in Brunei schools, teachers are studying effective strategies to enact PS in the mathematics classroom. Not only has PS continued to attract attention of researchers even recently, new trends on PS have continued to emerge (Liljedahl and Santos-Trigo, 2019). In particular, in this technological era, studies on how PS can ride on the affordance of technology to enhance students' PS ability emerges (e.g., Santos-Trigo, 2019). Recently in Mexico, curriculum reforms at elementary and high school levels recognize that both PS and PP activities are central for students' development of mathematical thinking. Thus, in the post-pandemic instructional approaches, students are encouraged to always look for different ways to represent, explore, and solve problems and to constantly pose and pursue new questions or problems.

By comparison, PP is a much younger field of inquiry in mathematics education. A quick search of the education literature shows clearly that attention to this topic has grown rapidly in recent decades. Researchers and educators in many countries have incorporated PP as a research and instructional focus respectively. The juxtaposition of these two topics PP and PS in this TSG thus merges a mature field of inquiry with a more nascent one.

2. Content of the Paper Presentation

Although there are 35 paper presentation, we were able to identify three main trends of PS and PP throughout all the paper presentations. In giving a brief description of the papers, the session and the order of the speakers are presented in Tab. 1 (on the next page). There were four sessions: Session 1 (13 July, 14:30 to 16:30 GMT+8), Session 2 (14 July 19:30 to 21:30 GMT+8), Session 3A (17 July, 14:30 to 16:30 GMT+8) and Session 3 (17 July, 21:30 to 23:30 GMT+8). As this is a synchronous online presentation, the presentation slots were arranged mainly based on the time zone of the speakers, instead of the content. In re-classification of the content of the paper, four trends were visible: (1) teaching and learning in relation to PS/PP; (2) processes involved in PS/PPS; (3) teacher education in relation to PS/PP; and (4) textbook analysis and comparative studies on PS/PP. The details are discussed in the following subsections.

Tab. 1. List of papers presented

Paper and author(s)
Session 1
[1] Analysis on creating problem situation in middle school mathematic teaching. ***Peijun Zheng*** (China).
[2] Historical comparison and analysis of problems and problem-sovling in middle school mathmatics textbooks. *Rong Wang and* ***Cuiqiao Wang*** (China).
[3] Problem posing among Pre-service and in-service mathematics teachers. ***Ma Nympha Beltran-Joaquin*** (Philippines).
[4] Regulation of cognition during problem posing — a case study. ***Puay Huat Chua*** (Singapore).
[5] Characterizing the problem-solving processes used by Pupils in classroom: propositioin of a descriptive model. ***Stephane Favier*** (France).
[6] A framework on examining mathematical commuication in problem posing. ***Ling Zhang****, Jinfa Cai, and Naiqing Song* (China).
[7] Using problem posing to disgnose and understand perservice teachers conceptual understanding. ***Yiling Yao*** *and Jinfa Cai* (China).
[8] Elementary mathematics teachers learning to teach through problem posing:initial findiings of a longitudinal study. ***Dan Zhang****, Yiling Yao, and Jinfa Cai* (China).
[9] Primary school teachers' behaviors, beliefs, and their interplayt in teaching for problem solving. ***Benjamin Rott*** (Germany).
Session 2
[10] Teaching students how to pose mathematical questions. ***Peter Juhasz****, Reka Szasz, Lajos Posa, and Ryota Matsuura* (Hungary).
[11] How elementary and middle school teachers formulate multiplication and division word problems. ***Sintria Lautert****, Alina Galvao Spinillo, Rute Elizabete Borba, Juliana Silva, and Ernani Martins dos Santos* (Brazil).
[12] Gifted students strategy felxibility in non-routine problem solving. ***Yeliz Yazgan*** (Turkey).
[13] Types of reasoning promoted in mathematics classes in the context of problem-solving instruction in Geneva. ***Maud Chanudet*** (France).
[14] Investigating elementary school students' STEM problem posing: the walkstem after-school club. ***Min Wang*** *and Candace Ann Walkington* (USA).
[15] Designing professional development programs that support teachers' incorporation of problem solving in their mathematics instruction —the DCP mode. ***Jillian White****, Patrick Johnson, and Merrilyn Enid Goos* (Ireland).
[16] Mathematics problem multicontextual exploration, solving and posing in the classroom and teacher education: a perspective in critical education. ***Silvanio de Andrade*** (Brazil).
Session 3
[17] How do Chinese textbooks incorporate mathematical problem posing in different stages? ***Jiajie Yan****, Yufeng Guo, and Wenjia Zhou* (China).
[18] Appreciation of the aesthetic qualities of mathematical objects: an analysis of students problem sovling. ***Hayato Hanazono*** (Japan).
[19] Towards LITE, a local instructional theory for mathematicall explorations. ***Jayasree Subramanian****, K. Subramaniam, and R. Ramanujam* (India).
[20] Graphic organizers for problem-solving in primary mathematics: teachers' reflections. ***Nor Azura Abdullah*** (Brunei).
[21] The effect of problem-posing strategies on primary Pre-service teachers conceputual knowledge of fractions. ***Eda Vula*** (Albania).
[22] Investigating mathematics teachers' knowledge for teaching problem-solving. ***Brantina Chirinda*** *and Patrick Barmby* (South Africa).
[23] Elements of mathematical activity that emerge when future teachers of secondary school mathematics use digital technologies to solve problems. ***Matias Camacho-Machin****, Alexander Hernandez, and Josefa Perdomo-Diaz* (Spain).
[24] A study on evaluating prospective teachers' problem posing activity. ***Zoltan Kovacs*** (Hungary).
[25] Use of video clips to engagestudents in mathematical problem soling. ***Tin Lam Toh*** *and Eng* Guan *Tay* (Singapore).
[26] Problem solving and generalization with an advanced computing environment. ***Marina Marchisio****, Alice Barana, Alberto Conte, Cecilia Fissore, and Fabio Roman* (Italy).
[27] A study on improving flexibility in problem solving: unit teaching based on big-idea in mathematics. *Hongyun Li, Jian Dun, and* **Qilei Feng** (China).

Session 4

[28] Supporting students to compress mathematical knowledge while problem solving. ***Rogier Bos** and Rona Lemmink* (Netherlands).
[29] A strategy for enhancing mathematical problem solving. ***Miguel Cruz Ramirez*** (Cuba).
[30] A study on primary school mathematical problem-posing abilities in China. ***Na Yan*** (China).
[31] The process of posing problems: development of a descriptive process model for problem posing. ***Lukas Baumanns** and Benjamin Rott* (Germany).
[32] Automation of math discovery support: reinforcement of problems with criteria for evaluating partial solutions. ***Sergei Nickolaevitch Pozdniakov*** (Russia).
[33] Divison problem posing of fifth graders: a cross-national study in China and the United States. ***Fenqjen Luo**, Yali Yu, Monte Meyerink, and Ciara Burgal* (USA).
[34] Students engagment in problem posing while solve a fermi problem. ***Nelia Amado**, Susana Carreira, and Monica Alexandra Robelo Valadao* (Portugal).
[35] Develop your own problem! — problem posing in given real-world situations. ***Luisa-Marie Hartmann**, Stanislaw Schukajlow, and Janina Krawitz* (Germany).

2.1. *Teaching and learning in relation to PS/PP*

This category contains both empirical and theoretical discussion papers that were classified into several categories.

2.1.1. Creating Problems (or PP) in classroom situations

Both Zheng[1] and Harmann et al.[35] discussed the creation of problems by students. Zhang focuses more on the theories and characterization of problems created by middle school students while Harmann et al., to find out the type of problems students can pose and solve, which are problems that are related to the real world. Peter Juhasz et al.[10] propose how best to facilitate problem posing for mainstream students based on a method (which they term Posa method) that was originally developed for gifted students.

2.1.2. Processes involved in PS/PP

Lukas Baumanns and Rott[31] presented a descriptive model of the processes involved in students' problem posing through his empirical studies. Chua[4], through a case study, presented the regulatory cognitive phases during PP of students. Favier[5] characterizes the processes used by students when they solve problems in the mathematics classrooms. Zhang et al.[8] presented a framework for examining mathematical communication in problem posing, which refers to the process of conveying and expressing information during activities of problem posing.

Yazgan[12] examined students' flexibility in solving non-routine problems. Chanudet[13] studied the types of mathematical reasonings that students exhibited in problem solving instruction. Wang[14] presented a paper on investigating students problem posing ability. A study by Yan et al.[17] compared the problem posing ability between Han Chinese student and the students from the minority groups in China. Hanazono[18] discussed how students are able to appreciate the aesthetic qualities of mathematical objects through appropriate teacher intervention discussed in his paper.

Studies on intervention to improve students' processes in PS/PP are presented in this paper. Regarding the flexibility, Li et al.[27] discussed a teaching model that has been shown in their studies to improve students' flexibility in problem solving. Bos and Lemmink[28] presented strategies to compress mathematical objects, procedures and statements, which could play a major role in achieve success in mathematical problem solving. Ramirez[29] presented a strategy, heuristic strategy, for enhancing mathematical problem posing. With the use of a type of modelling problems, the Fermi problems, Amado et al.[34] showed that students' assumptions made of a problem are very closely connected to the types of problems that they pose.

In a study conducted by Luo et al.[33], the similarities and differences of the problems posed on division posed by students from China and the United States were analyzed.

2.1.3. Technology and PS

Three papers on the use of technology to enhance PS/PP were among the paper presentation. Pozdniakov[32] proposed the use of modern computer technologies to support independent PS, based on Polya's model of problem solving as the framework. Marchisio et al.[26] proposed the use of technologies, an ACE (Advanced Computing Environment), to support PS through representing and exploring mathematical tasks. Toh and Tay[25] discussed the creation and adaptation of video clips for the teaching of PS.

2.1.4. Enactment of PS/PP in mathematics classrooms

Subramanian et al.[19] presented a Local Instructional Theory for Exploration for classroom enactment of mathematical exploration. The study was based on the Realistic Mathematics Education framework. Abdullah[20] proposed the use of graphic organizers in developing PS ability amongst students in the Brunei schools.

2.2. Teacher education in relation to PS/PP

Beltran-Joaquin[3] presented a study on pre-service and in-service teachers' PP, she highlighted the need to strengthen PP skills among mathematics teachers. Lautert et al.[11] offered a zoom-in view in studying how elementary and middle school teachers formulate multiplication and division word problems, showing that the teachers could have difficulty posing complex and challenging word problems. Kovacs[24] presented a study on evaluating pre-service teachers' PP activity, by examining how the mathematical background of the original problem changes during PP.

Yao and Cai[7] presented a study and asserted that PP contributes to pre-service teachers' conceptual understanding of division of fractions, but also to diagnose and appreciate their mathematical understanding. Another study by Vula[21] showed that PP resulted in positively impact pre-service teachers' conceptual understanding of fractions. Further, Zhang et al.[8], in their large-scale longitudinal study, claimed PP could be an approach to build teachers' pedagogy in mathematics.

Chirinda and Barmby[22] investigated South African in-service teachers' knowledge for teaching PS using Chapman's MPSKT framework. White et al.[15], through an extensive literature review, summarized into the DCP model into the features of an effective professional development that support infusing of PS into mathematics instruction. The finding of Rott[9] suggests the importance of teachers' beliefs in the success of the teaching of PS. Matias Camacho-Machin et al.[23] discussed the impact on a group of pre-service teachers in using digital technology (GeoGebra) in solving mathematics problems. There was evidence of mathematical creation and reasoning and much activities among the pre-service teachers.

2.3. Textbook analysis in relation to PS/PP

There are two papers on this sub-topic. Wang and Wang[2] presented a historical comparison of the problems and PP tasks of three series of middle school mathematics textbooks in China and found an increasing trend in PP tasks in the textbooks over the years. Yan et al.[17] examines how PP tasks were introduced into the Chinese textbooks in different stages. The nature of the PP tasks was different in the primary and junior high levels.

2.4. Social context in relation to PS/PP

There is one paper on this sub-topic. Andrade[16] in his presentation calls for a PS and PP interconnected approach vis problem exploration in a critical education perspective. PS/PP should be seen, in addition to the pedagogical consideration, from the wider level of socio-political-cultural context, as are the other dimensions of education.

3. What Next?

The TSG-17 had very rich discussion over the four sessions described in the above section. All the papers were compiled into pdf format and made available to all the participants of the TSG. The work of the TSG does not end with the conclusion of the congress. As an afterwork of the congress, selected presenters from the above presentation were invited to contribute their work to (1) a special issue in Hiroshima Journal of Mathematics Education which has been published in October 2022; and (2) a book on PS/PP to be published by Springer which targeted before the next ICME. The authors were invited to refine their papers, which will be peer-reviewed for the publication process.

Acknowledgment

The TSG-17 team would like to thank the organizing committee for this opportunity to helm the TSG on PS/PP. In particular, the chair would like to acknowledge Professor Ed Silver who was the original chair of TSG-17, and started the initial work with the chair in the paper review process prior to the COVID-19 pandemic. Professor Silver

withdrew from this participation due to health reasons. The TSG-17 team wish he could continue to enjoy a good health.

Topic Study Group 18

Students' Identity, Motivation, and Attitudes towards Mathematics and Its Study

Maike Vollstedt[1], Masitah Shahrill[2], Karin Brodie[3], Donglin Chen[4], and Bozena Maj-Tatsis[5]

ABSTRACT This report provides a short summary of the work of TSG-18 on "Students' Identity, Motivation, and Attitudes towards Mathematics and Its Study". We begin with a characterization of the field of students' affect before we provide information on the review process, the participants, sessions, proceedings, and the mode of publication of papers after the conference.

Keywords: Students' affect.

1. TSG Description

In TSG-18, we focused on students' affect with a special focus on students' identity, motivation, and attitudes towards mathematics and its study. There was a parallel Topic Study Group on teachers' affect (TSG-34: Affect, beliefs, and identity of mathematics teachers).

Affective variables can be seen as either hidden or explicit factors that influence learning processes and outcomes. The different research perspectives used in the study of students' affect include psychological, sociological, philosophical, and linguistic, and all these as well as other perspectives were welcome. In addition to the general domain "affect", the title of this Topic Study Group highlighted three concepts that have been popular in the field of mathematics education: identity, motivation, and attitudes. This was not seen as restrictive. On the contrary, we invited discussion on all areas of affect, encompassing anxiety, attitude, beliefs, emotion, flow, goals, identity, interest, meaning, motivation, needs, norms, self-concept, values etc. All of them play a crucial role in students' learning of mathematics and there are also subtle differences among them. In addition, we welcomed the analysis of the mutual relationship between

affective constructs and their connection to cognition and other constructs studied in mathematics education as well as the description of programs for promoting aspects of affect.

According to the call for papers, the activities of the working group were aimed at

- clarification of the dimensions of affective constructs and their relationships;
- development of measurement instruments (questionnaires, rubrics for qualitative analysis etc.) and other methodological tools for research on affect;
- role of the different affective concepts (see the list given above) in learning of mathematics, problem solving, proof, etc.;
- developmental aspects of affect, e. g. development of interest, anxiety etc.;
- intervention or comparative studies aimed at changes in affective variables;
- relationships between students' and teachers' affect, role of affect in communication among students or between students and teachers;
- affect as sociocultural phenomenon and lifelong learning;
- development of learning communities that foster positive affective climate;
- relationships between affect and gender/ethnicity/mathematical activity etc.

2. Participants

The participation in the Topic Study Group highlights the growing interest in research on affective issues. At ICME-13, there was only one affect related TSG in which 86 researchers were involved and 22 papers were presented on both students' and teachers' affect (Hannula et al., 2017). For TSG-18 in 2021, that focused on students' affect only, we had 2.5 times as many papers. In total, 57 contributions were considered in the review process. Based on the reviews as well as gender and regional balance, the TSG organizing committee decided to welcome 38 short oral presentations, and eleven authors were invited to hand in an extended version of their paper. In addition, eight posters were accepted for presentation.

The COVID-19 pandemic caused the shift from an on-site conference in 2020 to an online-conference format in 2021. Therefore, some authors were not able to attend the conference, and we finally had 35 presentations in our topic study group in which 80 researchers from all around the world were involved. Most of the researchers participated online, but in addition there was always a significant number of participants in the room in Shanghai.

3. Sessions

As TSG was the biggest TSG at ICME-14, we were allowed an additional time slot for the organization of our program. Thus, we had two sessions of 120 minutes and two sessions of 90 minutes time for the work in our TSG. Still, we had a very strict time limitation due to the very high number of presentations. There were 20 minutes time for presentation and discussion of a long paper, 10 minutes for a short paper, and five minutes for a poster (Tab. 1).

Presentation times were primarily organized according to the time zones of the presenters to enable every presenter to give their presentation at their daytime. In addition, we also tried to group presentations on similar topics wherever possible.

The first session started with an opening and welcome message by the TSG organization committee. Each session was then chaired by a different member of the committee. They paid special attention to making sure that contributions came both from the online participants and from the room in Shanghai. The discussions prove to be fruitful for the presenters.

Tab. 1. List of papers presented

Paper, poster and author(s) in order of presentation
Session 1
[1] Mathematics-anxiety students reasons and feelings when choosing to solve particular problems. ***Kai Kow Joseph Yeo*** (Singapore).
[2] Mathematical problem-solving beliefs of Filipino seventh graders. ***Katrina Grace Q. Sumagit*** *and Nympha B. Joaquin* (Philippines).
[3] Understanding the intentions of shadow education in Brunei Darussalam. ***Masitah Shahrill*** *and Ai Len Gan* (Brunei).
[4] Developing and validating a scale for measuring students' critical thinking disposition in mathematics educatioin. *Changgen Pei and* ***Jiancheng Fan*** (China).
[5] Exploration of math mindset changes over time in an urban sample of elementray and secondary school students in the United States. ***Beijia Tan****, Jenee Love, Leigh M. Harrell-Williams, and Christian E. Mueller* (USA).
[6] Classroom goal structures, Chinese students' goal orientations and mathematics achievement. ***Meng Guo*** *and Xiang Hu* (Hong Kong SAR, China).
[7] Applying the Theory of Planned Behaviour to 2012 Australian PISA data. ***Mun Yee Lai*** *and* ***Pauline Wong Wing Man Kohlhoff*** (Australia).
[8] The non-intellectual level of efficient mathematics learning of junior high school students and their influence pathways on mathematics learning performance. ***Rui Yang****, Guangming Wang, and Shuang Li* (China).
[9] Different contributions of parental expectations and teacher's behaviors to students' mathematics-related beliefs. ***Sheng Zhang*** *and Guangming Wang* (China).
[10] Does parents' attitude towards math matter to young adolescents' math achievement in China? Meditating effects of math anxiety. ***Mingxuan Pang*** *and Xiaorui Huang* (China).
[11] Mathematical identities of a high school mathematics learner in landscapes of mathematical practice. ***Wellington Munetsi Hokonya*** *and Pamela Vale Mellony Graven* (South Africa).
Session 2
[12] Make a tutorial! The impact of a classroom video project on emotions, motivations and achievement. ***Daniel Barton*** (Germany).
[13] Perceived difficulty in answering mathematical task: reflections on metacognitive factors. ***Marta Saccoletto*** *and* ***Camilla Spagnolo*** (Italy).
[14] Affective issues in the learning of abstract algebra. ***Marios Ioannou*** (Canada).
[15] A framework of learners' mathematical identities. *Aarifah Gardee and* ***Karin Brodie*** (South Africa).
[16] A conceptual framework relating mathematics clubs and mathematical identities. ***Lovejoy Comfort Gweshe*** *and* ***Karin Brodi*** (Zimbabwe).
[17] Influence of collaborative learning on student attitudes toward mathematical problem solving. ***Farzaneh Saadati*** (Chile).

Session 3

[18] A quantitative analysis of six aspects of student identity and creativity-fostering instruction. ***Paul Regier****, Miloš Savić, and Houssein El Turkey* (USA).

[19] Does types of problem influence on interest? A replication of a German study in the Spanish context. ***Clara García-Cerdá*** *and Irene Ferrado* (Spain).

[20] Attitudes, beliefs and emotions towards graph theory. ***Claudia Vargas-Díaz*** *and Victoria Núñez-Henríquez* (Italy).

[21] Predicting college major choice in STEM with students data at grades 9 and 11. ***Jihyun Hwang*** *and Kyong Mi Choi* (USA).

[22] The role of interpersonal discourse in small-group collaboration in developing mathematical arguments and student identity. *Shande King* (USA)*, Lynn Hodge* (USA)*, and Qintong Hu* (China).

[23] Exploring pre-service teachers persistence through multiple strategies tasks. ***Amanda Meiners****, Kyong Mi Choi, and Dae Hong* (USA).

[24] Meaningful reasons for learning mathematics. ***Maike Vollstedt*** (Germany).

[25] Positive emotions in early algebra learning. ***Yewon Sung****, Ana Stephens, Ranza Veltri Torres, Susanne Strachota, Karisma Morton, Maria Blanton, Angela Murphy Gardiner, Eric Knuth, and Rena Stroud* (USA).

Session 4

[26] Stereotype on female's success boosts female's math learning. ***Xiaorui Huang*** *and Bo Dong* (China).

[27] Peer pressure effect on student teachers' affective relationship with problem posing. ***Bozena Maj-Tatis*** (Poland)*,* ***Konstantinos Tatsis*** (Greece)*, and Andreas Moutsios-Rentzos* (Greece).

[28] Questionnaire of attitudes toward statistics for junior high school students in Japan. *Yoshinori Fujii and Koji Watanabe* (Japan).

[29] "Dear Kingos, it's all right to be noisy!" why is it so hard to get them talking? ***Natanael Karjanto*** (South Korea).

[30] The character of students mathematical values in learning mathematics. ***Miho Yamazaki*** *and Wee Tiong Seah* (Japan).

[31] A case study of mathematical research presentation in a public junior high school: focus on the relationship of assumption of others and the quality of learning. ***Tomoaki Shinobu*** (Japan).

[32] Mathematics anxiety: a Portuguese study in higher education. ***Vanda Santos****, Anabela Pereira, Teresa Neto, and Margarida M. Pinheiro* (Portugal).

[33] The transition from school to university mathematics: which roles do students interest and beliefs play? ***Sebastian Geisler*** (Germany).

[34] Exploring 11$^{\text{th}}$ grade students' attitudes towards mathematics. ***Jiraporn Wongkanya****, Naruon Changsri, Kiat Sangaroon, and Maitree Inprasitha* (Thailand).

[35] High school students images, anxieties and attitudes toward mathematics. ***Shashidhar Belbase*** (United Arab Emirates).

The closing at the end of our last session provided some information with respect to the proceedings of our TSG and a very heartful summary of our work: The word cloud in Fig. 1 was created from all papers that were presented in TSG-18.

4. Publication

All papers were collected in the proceedings of the TSG (Vollstedt, 2021), which were also accessible during the conference. In addition, the TSG participants were given the opportunity to publish extended versions of their papers in *Didactica Mathematicae*, an international journal of mathematics education. Four papers were published in volume 43 (2021), while five papers are currently under review for publication in volume 44 (2022).

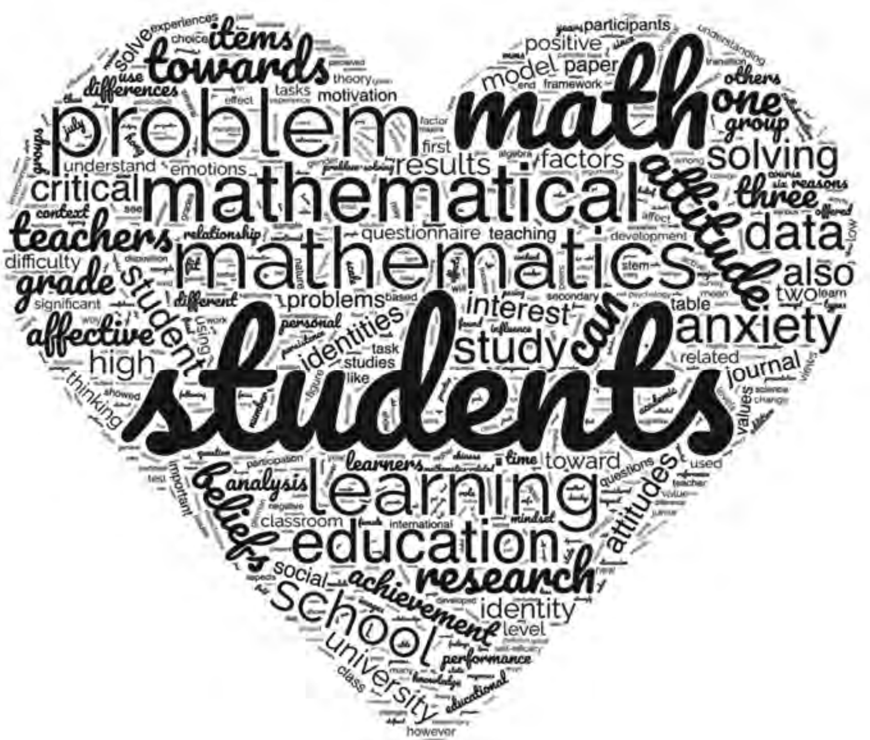

Fig. 1. Heart-shaped word cloud created from all papers of TSG-18

Topic Study Group 19

Mathematical Literacy, Numeracy and Competency in Mathematics Education

Sarah Bansilal[1], Ratu Ilma Indira Putri[2], Vince Geiger[3], Bo Zhang[4], and Kathy O'Sullivan[5]

1. Aims of the TSG

The Mathematical Literacy Topic Study Group 19 at ICME-14 was organized around four key themes that drew from emerging findings in the literature related to discussions about the Mathematical Literacy field:

The "place" of mathematical literacy: What are the specific focuses and topics that can characterize the notion of mathematical literacy? How does the notion of mathematical competency relate to mathematical literacy? How should mathematical literacy be taught directly, as a by product of regular mathematics or integrated across subjects?

Theories of mathematical literacy: What are some theories and methodologies that can help us understand the issues central to the teaching and learning of mathematical literacy?

Research issues: What can research tell us about the teaching and learning of mathematical literacy? What do empirical results from large- and small-scale studies indicate that can inform our thinking about the conceptualization, teaching, learning, or assessment of mathematical literacy? What are some understandings of mathematical literacy, and how do these permeate the curricula, teachers' identities, beliefs, attitudes and practices, teacher education, learning materials, and assessments, etc.?

Views about the future of mathematical literacy: If we are committed to developing mathematical literacy at the school level, what barriers should we overcome? What new types of initiatives, policies, or collaborations (across subject areas, outside schools) are needed? What are potential gains or losses with possible initiatives?

1.1. Submissions

Papers and discussions related to these themes were intended to stimulate discussion about key directions for future research related to mathematical literacy. Overall, at the conference our TSG had a total of 17 oral presentations and one poster presentation.

1.2. Sessions

There were three sessions in total, the first one was 2 hours and the second and third ones were 90 minutes each. There were two invited speakers who presented in the first two sessions.

1.3. Paper topics

The list of papers that were presented in the sessions appears in Tab. 1.

Tab. 1. List of papers and authors

Paper and author(s)	
[1]	Common European numeracy framework — a multifaceted perspective on numeracy. ***Kees Hoogland*** (The Netherlands)*, Javier Diez-Palomar* (Spain).*, and Niamh O'meara* (Ireland).
[2]	Mathematical literacy: what, why and how. ***Ross Turner*** (Australia).
[3]	Elements and definitions of the core literacy of mathematics in primary school from an international perspective: based on NVivo 12.0 coding analysis. ***Xuan He*** *and Yunpeng Ma* (China).
[4]	Top-level design and systematic thinking for the cultivation of math competencies-case study and inspirations. ***Feng Ma*** (China).
[5]	It is time pre-service teachers develop their numerate abilities to support their students numeracy learning. ***Kathy O'Sullivan*** (Ireland).
[6]	Aspects of fair-minded critical thinking in mathematics education: based on the perspective of critical mathematics education. ***Yuichiro Hattori*** *and Hiroto Fakuda* (Japan).
[7]	How teachers generate ideas for classroom numeracy tasks. ***Vince Geiger*** (Australia).
[8]	Pre-service teachers' experiences with the Australian national numeracy test. ***Jennifer Hall*** *and Anna Podorova* (Australia).
[9]	Mathematical Literacy in pre-service teacher-designed mathematics picture books. ***Zetra Hainul Putra****, Gustimal Witri, and Syahrilfuddin Syahrilfuddin* (Indonesia).
[10]	Identifying 9th grade students' errors in solving a mathematical literacy problem. ***Maryam Mohsenpour****, Mahbobeh Rohanipur, and Zahra Gooya* (Iran).
[11]	A new model design to improve mathematical literacy: A dual focus teaching model. ***Cigdem Arslan****, Murat Altum, Tugce Kozakli-Ulger, Isil Bozkurt, Recai Akkaya, Furkan Demir, Zeynep Ozaydin, and Burcu Karaduman* (Turkey).
[12]	Unpacking some challenges of learning mathematical literacy in South Africa. ***Sarah Bansilal*** (South Africa).
[13]	Designing PISA-like mathematics task using Asian games context. ***Ratu Ilma Indra Putri*** *and Zulkardi Zulkardi* (Indonesia).
[14]	Assessing PISA-like tasks considering levels of context use for mathematics problems. ***Ahmad Wachidul Kohar****, Tatag Yuri Eko Siswono, and Dayat Hidayat* (Indonesia).
[15]	Financial numeracy practices in secondary school: A study with mathematics teachers from Quebec. ***Alexandre Cavalcante*** *and Annie Savard* (Canada).

2. Themes

There were a large variety in research topics presented during the sessions, however there seemed to be three overarching themes that emerged across the presentations. The first related to interpretations of mathematical literacy and its broader purposes in different countries. The second theme concerned issues related to developing mathematical literacy skills or practices. The third theme related to issues about task design for mathematical literacy. The discussion around these themes are presented below.

2.1. Understanding mathematical literacy and exploring interpretations of constructs related to mathematical literacy

In his invited talk[2] Ross Turner raised the point that although there is no agreed definition of the term "mathematical literacy", there are components which need to be considered in any definition. These are: practical aspects including number sense, arithmetic and spatial skills; procedural knowledge which includes knowledge about procedures, theorem and definitions; and, a more pervasive way of thinking about mathematics including thinking mathematically, reasoning and communication. Hoogland in his invited talk[1] presented findings raising from the project that aimed to develop a Common European Numeracy Framework (CENF) for adult learning. The framework recognizes numeracy as a social practice and takes into account meta-cognitive aspects, psychological and sociological facets, and power-related factors, which influence the quality of numerate behavior among adults.

Many presentations focused on the curriculum interpretation or on teachers' interpretations of constructs related to mathematical literacy in various countries. He and Ma[3] looked at the elements considered as the core literacies in primary school mathematics curricula in the US, UK, Australia, Japan and Singapore while Ma[4] focused on the competencies covered in the mathematics curriculum of the 2-year IB programme designed for high school learners. Bolstad[17] analysed curriculum documents to identify how mathematical literacy was treated in Norway and suggested that teachers need more advice and support about how to implement the ideas in the classroom. Kim and Kim[16] conducted an analysis of 30 mathematics teacher guidebooks from Korea to better understand how information literacy was interpreted and recommended for use by teachers in their classrooms. Li[18], in a poster session, reported on a survey on primary school mathematics teachers' conceptions of mathematics core literacy from a rural district in the context of Chinese curriculum reform. Arslan and her colleagues[11] outlined a dual focus model that was introduced to middle school mathematics teachers in Turkey which focuses on acquisition of concepts as well as on applications in order to develop the mathematical literacy skills of their students. Cavalcante and Savard[15] conducted a study with Canadian teachers to understand how they incorporated financial numeracy in their classrooms and found that the teachers delved into issues mainly related to personal finances and not those of citizenship or social justice.

2.2. Research about developing skills related to mathematical literacy

Hattori and Fakuda[6] looked at the notion of fairminded critical thinking and how this could be actualised amongst their students. They shared an example of how this was targeted in lesson practices. The lessons focused on developing critical citizenship through the implementation of statistics education in the context of the environment.

O'Sullivan[5] researched the numeracy skills of 204 preservice-teachers in Ireland and found that most were not able to complete all of the numeracy tasks. Hall and Podorova[8] explored the experiences of 458 PST's with the high stakes, mandatory test, Literacy and Numeracy Test for Initial Teacher Education (LANTITE). They found that there were connections between the students' preparation and their perceptions of the test as well as differences by demographic groups.

Mohsenpur and her colleagues[10] conducted interviews with nine Grade 10 students in Iran, to better understand the errors they made when solving a mathematical literacy problem. Bansilal[12] presented a contextual attributes framework for identifying and describing some of the challenges experienced by learners in working with contexts within mathematical literacy tasks.

2.3. Research related to the design of Mathematical literacy tasks

Putra[9] and her colleagues from Indonesia looked at tasks designed by 13 groups of preservice teachers and found that the most popular contexts were those based on personal issues. Kohar[14] and his colleagues from Indonesia analysed 130 mathematical literacy task to identify the levels of context use and found that 29%, 65% and 6% displayed a zero, first and second order use of contexts respectively. Putri and Zurkardi[13] from Indonesia set out to assess how well tasks set within the Asian Games context, could work to support learning. Geiger[7] looked at the different ways in which teachers generate ideas for the design of numeracy tasks, including taking advantage of incidental events; bringing together elements of curriculum from different learning areas; and archiving ideas.

3. Areas for Future Research

The closing discussion touched on a number of areas such as the fact that there is no established definition of mathematical literacy for which there is wide agreement. It is clear that there are varying ideas about the need for, and value of, mathematical literacy and how it fits into the curriculum. One presenter commented that if one thinks about mathematical literacy as the ability to implement mathematics, then it reproduces the view that mathematical literacy is a discipline instead of it being recognised as a practice. This discussion highlights the need for more interrogation of what mathematical literacy is and how mathematical literacy practices could be enhanced. Most participants agreed that we need increased attention to teaching practices, as well as teacher preparation and professional development programmes which can help teachers to improve the numerate behaviour of their students. The presentations also articulated the need for more attention in future research to assessment design as well as curriculum policies.

Topic Study Group 20

Learning and Cognition in Mathematics (Including the Learning Sciences)

Gaye Williams[1], Pablo Dartnell[2], and Wenjuan Li[3]

ABSTRACT This paper includes the themes and descriptions for TSG-20 Learning and Cognition, the session topics developed in response to the themes, a report of the review process and results of this, the TSG-20 program including the research focus for each invited speaker, profiles of the invited researchers, the content of their submitted papers, and the authors and titles of other papers. It also includes participant reflections about sessions that provide indicators of future intended research directions.

Keywords: Learning; Cognition; Teacher practices; Student activity.

1. The Theme, Subthemes, and Descriptions

The scope of research on learning and cognition in mathematics education is extensive and diverse in relation to questions posed, theoretical frameworks selected, and methodologies employed. Theoretical perspectives include (but are not limited to) forms of cognitive constructivism, and social constructivism, and more recently, interconnections between these (including integration, partial integration, and networking of such theories). Affective, and embodied elements, and personal characteristics of learners and teachers are amongst the many other constructs that form part of various theoretical frameworks. Learning and Cognition in Mathematics, TSG-20, 2020 specifically included 'the Learning Sciences' which interrogates interplays between cognitive, social, psychological and cultural elements of learning processes in diverse contexts, for the purpose of 'improving' learning environments. Research into learning mathematics through STEM (Science Technology Engineering and Mathematics) Education although increasing, is not yet reflected in the proportion of STEM related papers submitted to TSG-20 in ICME14. Although this description contains illustrations of research foci within TSG-20, there are opportunities for intending contributors to focus within these, or to justify other foci associated with learning and cognition in mathematics education.

1.1. Subtheme 1: teacher change processes and influences upon them

Processes of teacher learning, that can enhance student learning of mathematics, have been researched with various theoretical frameworks employed (including but not limited to cognitive, social, belief based, and dispositional frameworks, and interconnections between various of these frameworks). Areas of research into influences on teacher change processes include but are not limited to professional learning models employed, types of pedagogical approaches under focus: teacher-controlled or teacher-guided learning, and approaches enabling various degrees of student autonomy in the learning of mathematics. Depending on the personal characteristics of the teacher, some approaches may be easier to employ than others. Such personal characteristics include but are not limited to types of knowledge possessed, prior experiences, and whether resilience and/or self-efficacy are possessed. There are many other factors associated with teaching that could become the focus of a submitted paper, as long as that focus can be justified as belonging to TSG 20 Learning and Cognition.

1.2. Subtheme 2: student learning processes and influences upon these

Theoretical frameworks employed to study processes of student learning of mathematics include, but are not limited to, those associated with cognitive constructivism, social constructivism, and embodied, cultural, and material conceptions of mathematics cognition. Various combinations of these theoretical framings have also been developed. Influences on the nature of mathematical understandings developed include, but are not limited to, the degree of student autonomy in the learning situation, affective elements of the process, the nature of the learning environment, and personal characteristics of the student. Study of processes associated with the construction of mathematical insights are crucial to this theme because they can build deep mathematical understandings and positive student personal characteristics. Study of learning processes in situations in which students have little to no autonomy is also important as many mathematics teachers employ such pedagogical approaches. Studies of how to increase students' feelings of safety in such controlled learning situations or decrease the boredom of other students are important areas of research, as is study of learning in particular mathematical situations.

1.3. Subtheme 3: the learning sciences

The Learning Sciences is dedicated to furthering the scientific understanding of learning processes for the purpose of designing and implementing learning innovations to increase learning opportunities. This research field highlights the social nature of learning and the many different settings in which learning may occur. Studies interrogate various interplays between cognitive, social, psychological and cultural factors in learning processes in diverse contexts. To enable study of learning as it occurs in messy naturalistic settings, creative research designs have been, and continue to be, developed.

Studies in this multidisciplinary field include but are not limited to foci such as: the situated nature of knowledge and ways of knowing and learning; individual, and group learning processes; and mathematics learning in out-of-school settings, such as, museums, and homes; mathematics learning difficulties and disabilities. Student learning and teacher learning are two of the many areas of researcher attention within this field. Further study of mathematics learning in out of school settings has the potential to inform mathematics learning more generally.

2. Organizing TSG-20

2.1. Panel

The Study Topic Group, TSG-20 Learning and Cognition included the following panel members, all of whom contributed in various ways to the development of the TSG:

Chair: Gaye Williams, University of Melbourne;
Co-chair: Pablo Dartnell, University of Chile;
Members:
Wenjuan Li, New York University,
Zain Davis, University of Cape Town, and
Chunli Zhang, Beijing Normal University.

This team was drawn from universities in various countries across the world. All five team members took part in the review process. Gaye Williams, Pablo Dartnell, and Wenjuan Li hosted the three sessions of TSG-20 at ICME14.

2.2. Invited speakers

Selection of invited speakers was guided by the themes of focus. These speakers were Alison Castro Superfine (USA), Keiko Hino (Japan), Lieven Verschaffel (Belgium) and Alejandro Maiche (Uruguay). However, Alejandro was unable to participate due to circumstances at the time.

2.3. Review process

25 submissions were received for TSG-20. The 4 from invited speakers were accepted without review. One was a poster, and one paper was referred to another TSG for which it was more appropriate. The other 19 were research papers. The 5 TSG-20 panel members undertook the reviews. Each paper was reviewed by 2 panel members (one chair/cochair and another panel member). Where there was disparity between these two reviews, the other chair/co-chair also reviewed the paper before it was discussed by the chair and cochair. Where a paper was close to being judged a long paper, authors were provided with advices and invited to resubmit their papers before a final judgement was made. 14 papers had two reviewers, and 5 papers had 3 reviewers. The review process classified the 19 contributions as 5 long papers and 14 short papers, and authors from 12 of these 19 papers accepted and presented in TSG-20. The 12 presentations, together with the invited talks, were set into 3 sessions and listed in Tab.

1, in which IT stands for invited talks, LO for long oral presentations, and the others are short oral presentations.

Tab. 1. List of presentations presented in TSG-20

Paper and author(s)	
Session 1	
[1]	Exploring new models for teacher professional learning: Working *with* teachers rather than on. ***Alison Superfine Castro*** (USA). (IT)
[2]	Introduction of STEM education through collaborative action research practices. ***Fatlume Berisha*** *and Eda Vula* (Kosovo). (LO)
[3]	Theorizing teachers' learning of students' mathematical thinking in the context of student-teacher interaction. ***Biyao Liang*** *and Kevin C. Moore* (USA). (LO)
[4]	Students' ways of thinking in a computer-based mathematics investigation project. ***Joyce Mgombelo****, Wendy Ann Forbes, Chantal Buteau, Eric Muller* (Canada)*, and Ana I. Sacristán* (Mexico).
[5]	Reciprocity between teachers' and students' problem-solving actions enables teacher change. ***Gaye Williams*** (Australia).
Session 2	
[6]	Interactive patterns that lead to children's discursive changes in lessons comparing fractions. ***Keiko Hino*** *and Yuka Funahashi* (Japan). (IT)
[7]	Assessing mental abstraction activities using eye-tracking techniques. ***Eivind Kaspersen*** *and Trygve Solstad* (Norway). (LO)
[8]	Mathematics itself: reflections about an often neglected, but pivotal dimension. ***Michael Neubrand*** *and Carl von Ossietzky* (Germany). (LO)
[9]	On the epistemological significance of contextualizing in mathematical cognition. ***Marcia M. F. Pinto*** *and Thorsten Scheiner* (Australia).
[10]	Learning strategies used by high achieving and low achieving students in mathematics. ***Bishnu Khanal*** (Nepal).
Session 3	
[11]	The amazingly frequent, efficient, and flexible use of the subtraction-by-addition strategy in elementary school children's mental multi-digit arithmetic: A challenge for cognitive psychology and mathematics education. ***Lieven Verschaffel****, Joke Torbeyns, Gwen Verguts, and Bert De Smedt* (Belgium)*,* (IT)
[12]	Numerical processing profiles in children with varying degrees of arithmetical achievement. ***Nancy Estévez*** (Cuba)*, Danilka Castro* (Chile)*, Eduardo Martínez* (Cuba)*, and Vivian Reigosa* (Uruguay). (LO)
[13]	How proper use of mathematics can help students to build quantum physics thinking to learn the subject: simple harmonic oscillator. ***Jose Vieira Do Nascimento Junior*** (Brazil).
[14]	A cognitive model of learning applied to data analysis of mathematics learning. ***Jairo Alfredo Navarrete*** (Chile).
[15]	Exploring basic numerical capacities in children with varying degrees of arithmetical achievement. *Danilka Castro Cañizares,* **Pablo Dartnell** (Chile)*, and Nancy Estévez Pérez* (Cuba).

2.4. TSG-20 Program

Challenges associated with program organization arose from the online nature of the program (caused by a) the global pandemic, and time constraints associated with panel decision that all participants should be involved in all sessions. Safety nets were constructed to cater for technological problems that might arise. They included setting up multiple ways that a presentation could be uploaded, and construction of a TSG-20 Website where presentations could be made available, session information provided, and additional questions and discussions uploaded. Time constraints were reduced through email and website introductions to sessions and to invited researchers. The sessions and researchers are displayed below with capitalization of paper presenters. Discussion times were factored into each presentation and a short discussion time occurred at the end of each session. Twenty to thirty participants attended each of the three sessions.

2.4.1. Session 1, July 13th. Host: Wenjuan Li

Processes of teacher learning, that can enhance student learning of mathematics, have been researched with various theoretical frameworks employed (including but not limited to cognitive, social, belief-based, and dispositional frameworks, and interconnections between various of these frameworks). Areas of research into influences on teacher change processes include but are not limited to professional learning models employed, types of pedagogical approaches under focus: teacher controlled or teacher-guided learning, and approaches enabling various degrees of student autonomy in the learning of mathematics. Presenters shared their recent work on new models or approaches to support teacher learning, and their theory or framework to analyze teacher change.

The invited talk[1] in Session 1 was given by Alison Superfine Castro, who is a Professor of Mathematics Education and Learning Sciences at the University of Illinois at Chicago. Her research interests focus primarily on studying and supporting mathematics teacher learning. Alison has developed different analytic approaches to study mathematics teacher educators and the knowledge needed to teach teachers. She has received various grants to design and study learning environments for mathematics teacher preparation courses and published extensively in the areas of mathematical knowledge for teaching, professional noticing, mathematics teacher's learning trajectory-based formative assessment practices. Alison is an active member of the international mathematics community. She is currently serving as an associate editor for the Journal of Mathematics Teacher Education and the EURASIA Journal of Mathematics, Science & Technology. In this ICME-14 TSG-20 invited talk, she presented new models and the design principles to support teacher professional learning.

The author gave the abstract as follows:

> New models for supporting teacher professional learning generate new conceptualizations of teacher learning, afford new designs for studying teacher learning over time, and situate teacher learning in problems of practice relevant to their own circumstances. In this paper, I describe two examples in which we engaged teachers in new models to support their professional learning, including examples of the various forms of inquiry we developed, as well as ways in which teachers engaged in the activities as part of these efforts. I then discuss a set of design principles underlying both examples. Finally, I discuss tensions that emerged from these efforts.

2.4.2. Session 2. July 16th. Host: Gaye Williams

This session focused around the learner — student learning processes, influences upon these learning processes, learning strategies employed, the degree of student autonomy in the learning process, the nature of the mathematical objects developed, and theoretical frameworks employed.

The invited talk[6] in Session 2 was developed by Keiko Hino with her colleague Yuka Funahashi. Hino is a Professor of Mathematics Education at Utsunomiya University in Japan. Her scholarly interests include the development of students' mathematical thinking through classroom teaching, international comparative study of the teaching and learning of mathematics, and mathematics teachers' professional development. Hino has produced many scholarly publications and undertaken positions to improve mathematics education, including as an editor of Japanese Primary and Lower Secondary School Mathematics Textbooks, as an external expert for Lesson Study in Mathematics, and as a member of the Editorial Board of MTED (Mathematics Teacher Education and Development Journal). Keiko Hino and Yuka Funahashi (Nara University of Education, Japan) have collaborated on research that informs the professional learning of teachers for more than ten years now, undertaking detailed analyses of problem-solving activity during mathematics lessons.

The abstract of the talk is as follows:

> The analysis presented in this paper examined the changes in the way children explained equivalent fractions and explored the teacher's key interactions that enabled such changes. Data from nine consecutive fifth-grade lessons in Japan taught by an experienced teacher were examined using a guided focusing pattern framework, from which it was found that the changes in the explanations were mostly in the focusing phase. The teacher's key interactive actions were classified into three categories: proposing focus, modifying focus, and narrowing focus. In particular, it was found that the teacher consistently attempted to change the children's focus from procedure to quantity and quantitative relationships using intervening language and by evoking discursive rules.

2.4.3. Session 3. July 17th. Host: Pablo Dartnell

This session is built mostly around TSG-20 ICME-14's 3rd subtheme: The Science of Learning, although it necessarily has some components from the other two subthemes. The science of learning is dedicated to furthering the scientific understanding of learning processes for the purpose designing and implementing learning innovations to increase learning opportunities. Among the presentations scheduled for this session, our invited speaker shares findings about surprisingly frequent and efficient use among Belgian elementary students of a mental subtraction strategy. In addition, results are shared about basic cognitive numerical capacities and their relationship with arithmetic difficulties, conducted in two different Latin American countries; relationships between the use of mathematics and the building of knowledge in quantum physics; and a proposed cognitive model of learning with implications for the analysis of data regarding the learning of mathematics.

The invited talk[11] in this session was given by Lieven Verschaffel, who is a full professor in Educational Sciences, and director of the Center for Instructional

Psychology and Technology (CIP & T) at the Katholieke Universiteit Leuven, Belgium. His research work in Mathematics Education covers a wide variety of topics, many of them related to TSG-20, such as problem solving, strategy choice and change, conceptual change, metacognitive and affective aspects of learning, and early and elementary mathematical education. The quality of his research work has led to him. receiving many awards, invitations as plenary lecturer, and member of plenary panels of many international conferences, including some previous versions of ICME. In addition, he. has become a member of many editorial boards. On this occasion he presented the result of two studies (conducted in collaboration with other researchers from KU Leuven) dealing with a mental subtraction strategy used by elementary school students.

The abstract of the talk is as follows:

> In two related studies — a first study with 6th grade elementary school children and a second study with children from 4th until 6th grade of elementary school, we investigated the use of the subtraction-by-addition strategy in children with different levels of mathematics achievement. In doing so, we relied on Siegler's cognitive psychological model of strategy change, which defines strategy competencies in terms of four parameters — strategy repertoire, distribution, efficiency, and selection — and the choice/no-choice method, which is essentially characterized by offering items in two types of conditions — choice and no-choice conditions. In both studies, children of different mathematics achievement levels solved multi-digit subtraction problems in the number domain up to 1,000 in one choice condition (wherein they could choose between direct subtraction or subtraction by addition on each item) and two no-choice conditions (wherein they had to use either direct subtraction or subtraction by addition on all items). Distinction was made between two types of subtraction problems: problems with a small versus large difference between minuend and subtrahend. Although mathematics instruction only focused on applying direct subtraction, most children reported using subtraction-by-addition in the choice condition. Subtraction-by-addition was also applied surprisingly frequently and efficiently, particularly on small-difference problems, and children flexibly fitted their strategy choices to both numerical item characteristics and individual strategy speed characteristics. Interestingly, these results were obtained for children of all grades and all mathematical achievement levels. These remarkable findings — both from a cognitive psychological and a mathematics educational perspective — add to our theoretical understanding of children's strategy acquisition and challenge current mathematics instruction practices that pay exclusive attention to direct subtraction.

3. Reflections and Future Directions

Time for discussion of future directions was limited by participants' interest in continuing discussion of research from the third session. Post-session reflections from participants (see italics below) indicated intended future directions though. Slight changes to quotes were made to increase clarity. Names of invited speakers or presenters are used to refer to studies in this section.

In Session 1, Alison Superfine Castro[1] stimulated new thinking about models to support teacher professional learning: *I enjoyed the presentation of Dr Castro very much, it was an eye-opener for future research paths*. Participants connected other research from this session to her work: *Alison Castro Superfine's contribution was quite informative to me, as was Williams'*[5] *and other presentations (e.g., Berisha's*[2]*). Collaboration seems to be a key point in teacher education.*

In Session 2, Keiko Hino's presentation[6] was appreciated by participants for the detailed way it examined interactions between the teacher and the students, and diagrammatic representations communicating this: *The way the research and the teaching in the classroom were analysed was very good*, and *the diagram helped in seeing the large amount of time the classroom teaching dedicated to interactions between teachers and students*. This research was referred to in subsequent presentations and reflections. Comparisons were made between Pinto's *proposal*[9] *for working with fractions, developed from the perspective of contextualizing* and Keiko Hino's presentation *typical of Japanese teaching undertaken without the usual context (real world etc) but still in the reflection mode.* Pinto's team intend to use Keiko Hino's work to extend their *thinking about other possible approaches to equivalence of fractions.*

The interconnected nature of most presentations in Session 2 was also recognised: *the research presented is interwoven in many senses. Four presentations focused on strategies of learning or modes of learning (or a specific mode of learning), to inform teaching or educational policies. Neubrand*[8] *and Kaspersen*[7] *focused on abstraction but differed in their conceptions of the interpretative model built. Further discussion of these two approaches and methodologies should be productive. Pinto*[9] *and Neubrand*[8] *proposed different categories for organizing understanding of the same phenomena — the leaning of maths*. *Both also attempted to avoid dichotomies*.

In Session 3, Lieven Verschaffel's presentation[11], participants were *surprised by the prevalence of use of the Subtraction-by-Addition method and the accuracy and speed of responses found in Belgium*. This presentation raised questions for future research including a*) could these results be replicated in other places* and b) *might there be alternative strategies that could be employed for other mathematical procedures, that could produce similarly strong results?* Questions for future research were also raised by Dartnell's presentation[15]: *Given that very low achievement in mathematics can have a variety of causes—not always related to a disability—what might be found if students with Mathematics Learning Disabilities were the focus of such research?*

In Summary, sessions for TSG-20 were vibrant and extended the thinking of various participants in different ways. Our thanks to all participants.

Topic Study Group 21

Neuroscience and Mathematics Education/Cognitive Science

Inge Schwank[1] and Marie-Line Gardes[2]

1. State of the Art

Without a doubt, doing mathematics depends on creative, problem-solving thinking. Mathematics didactics provides mathematics with some cloak: What is to be understood is the teaching and learning of mathematics and how the acquired knowledge can be used for teaching processes. In a fundamentally oriented manner, borrowings from cognitive science are taken up and mental processes are examined using neuroscientific methods. Mathematics is a vast field of knowledge full of concepts and tools, mathematical thinking is highly complex. Fig. 1 displays the complex of areas and approaches relevant to TSG-21.

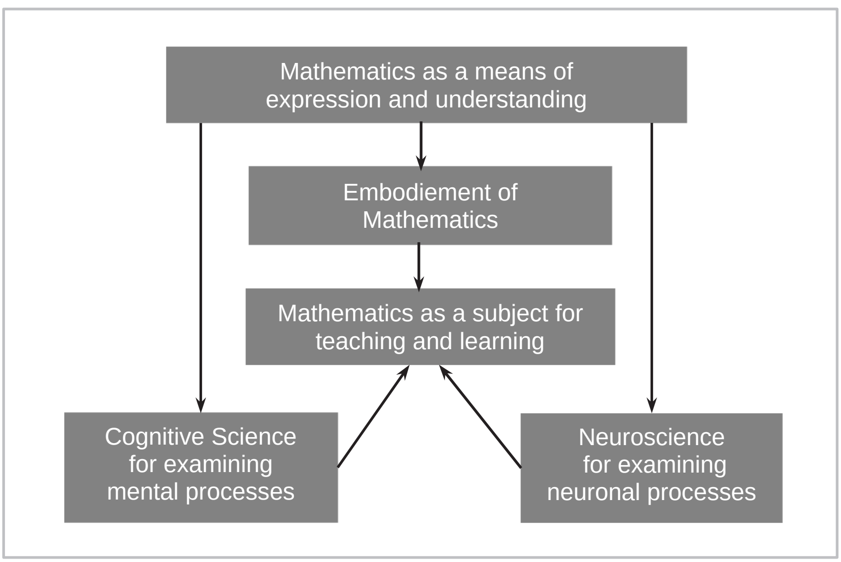

Fig. 1. Relevant complex of areas and approaches

[7]	Even Young Children Are Able to Grasp and Apply Logical Rules in Mathematically Structured Environments — the Puzzle of Cognition. ***Inge Schwank*** *and Elisabeth Schwank* (Germany).

Contribution by Zhou et al. (Cao's presentation)[1] falls into the area of cognition-oriented mathematics didactics. By the use of relevant tests the connections between general cognitive and mathematical abilities were examined. Apparently, general spatial ability has a greater impact on ill-structured problem solving than special mathematical ability.

Contribution by Bhatia et al. (Gardes' presentation)[2] also comes from the field of cognition-oriented mathematics didactics and examines, how fraction knowledge and competencies are processed in adults with mathematical learning difficulties. Results indicate that different pathways are utilized for accessing the magnitude of non-symbolic line ratios and symbolic fractions. Mathematical learning difficulties when dealing with fractions had a greater impact on failures in calculation and estimation and less on representing symbolic fractions in verbal form and vice versa.

Konto et al.[3] used cognitive science methods. Teaching spatial geometry is challenging. This contribution's objective is to better understand the basics of cognitive processes in view of spatial geometry. For this purpose, the present study examines the characteristics of eye movement and brain activity during mental rotation tasks. The result shows: The mental rotation tasks that required lesser time involved a high frequency of looking at the same parts of left and right solids and reached max activation time quickly.

Solstad et al.[4] applied to the mathematical modeling of cognitive processes when doing mathematics. The initial question is: Can our mathematical abilities be explained in neuroscientific or computational terms? Some of the properties of representations generated by idealized neural network models for numbers are examined and described. Furthermore, the question of how computational tools can contribute to a greater understanding of the relation between mathematics education and neuroscience is addressed.

Zhao et al.[5] applied a neuroscientific method and examined the electrophysiological characteristics in the first-grade children at different levels of number sense in a number comparison task. In fact, there are differences in brain activity in children with a high level of number sense compared to children with a middle or low level of number sense. The results suggest that children with different levels of number sense show different electrophysiological characteristics during number sense processing.

A joint contribution[6] by German and Austrian researchers comes from the field of cognition-oriented mathematics didactics with the use of mathematical modeling. Learning processes when dealing with a special arithmetic are examined. A distinction is made between "know-how"; i.e.: learning how to solve arithmetic problems and "know-that"; i.e.: learning arithmetic facts. The power-law function is used for the description with a view to its coefficients and any correlations between these coefficients. This worked satisfactorily only with regard to fact learning. Correlations between the two learning processes turn out to be weak.

Finally, Schwank and Schwank[7] came from the field of cognitive mathematics. Based on the theory of functional-logical thinking versus predictive-logical thinking, different scenarios are examined. Access to (first) arithmetic is easier for children dominantly using the approach of functional-logical thinking, mathematically gifted children show special talents here. The development of mathematical thinking can be promoted through the use of special mathematical play worlds as the results from an early support study with preschoolers indicate. Particularly children with difficulties in the area of early mathematics seem to benefit from the support provided by mathematical play worlds.

3. Outlook onto Future Research Activities

There is still a large discrepancy between the possibilities of gaining knowledge based on theoretical concepts as well as experimental methods offered by Cognitive Science and Neuroscience and the needs for knowledge acquisition, which arise due to the complexity mathematical thinking, mathematical knowledge, mathematical problem solving as well as mathematical creativity. Nevertheless, it can be expected — especially if interdisciplinary research is intensified — that the mental processes when dealing with Mathematics will be increasingly understood more thoroughly and that these findings for mathematical teaching and learning processes can be used specifically and successfully. An important issue will be gaining professional mathematicians' cooperation as well as further people, especially children with so-called special needs. The digital transformation of society will play a big role in this advancement. Accessibility issues have never been easier to adapt to the addressee (e.g. in terms of font size, contrast, images, interactions, problem variations). The variety that is thereby made possible in a considerably easier way, sets a whole new potential for research questions and scientific studies. Cognitive Mathematics will be the state of the art (Fig. 2).

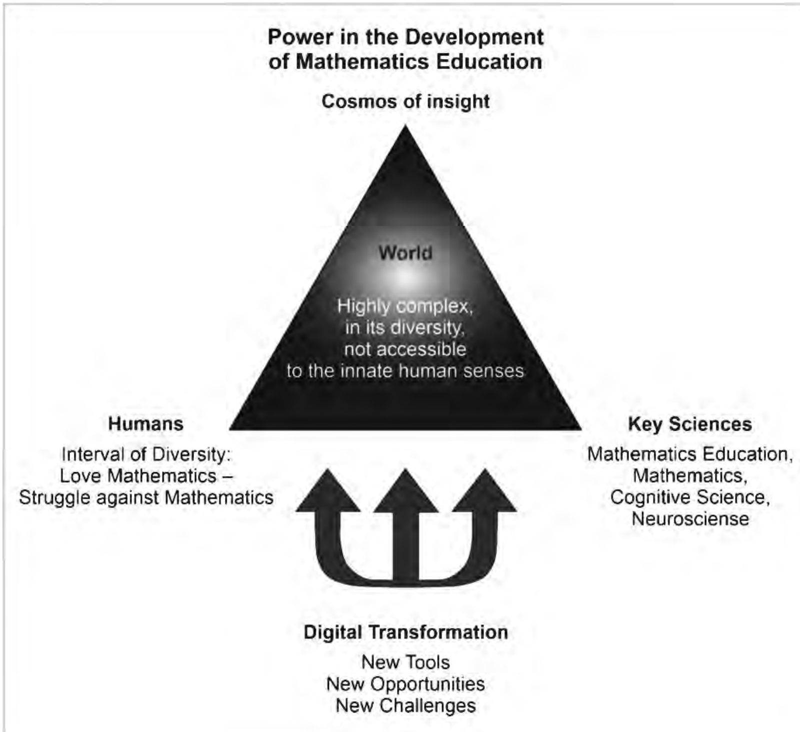

Fig. 2. Cognitive Mathematics as a combination of important approaches to the world of understanding, learning, teaching and strengthen mathematics

Topic Study Group 22

Mathematical Applications and Modelling in Mathematics Education

Gilbert Greefrath[1] and Susana Carreira[2]

ABSTRACT In the field of applications and mathematical modelling there is intensive research. Within the TSG, we have thematically addressed the teaching of mathematical modelling, teacher education, and modelling processes and competencies of school and university students. Future research directions are expected to consider theory building, empirical studies, including developing standardized research instruments, and the use of technology.

Keywords: Mathematical modelling; Teaching modelling; Teacher education; Modelling competencies and processes.

1. Theme and Description

The teaching and learning of mathematical applications and modelling is a world-renowned field of research in mathematics education and it has been an important theme for teachers and researchers especially during the last 50 years; and the importance has been growing worldwide during the last decade. This is evident, for example, in the International Congress on Mathematical Education (ICME) regular topic study groups and lectures on applications and modelling, and the series of conferences of the International Community on the Teaching of Mathematical Modelling and Applications (ICTMA) since 1983. This increasing interest is a consequence of several factors; on the one hand there is the public demand for the relevance of mathematics outside the discipline, and on the other hand there is an increasing number of research projects and empirical studies which focus on specific aspects of applications and modelling in mathematics teaching and learning. Many recent qualitative and quantitative research studies on mathematical modelling in school and higher education have focused on students and their modelling processes; however, teachers clearly play an important role in implementing mathematical modelling into mathematics lessons and in fostering students modelling competencies. Furthermore, classroom settings also play an important role. Enriching the focus on teacher practice in proposing and implementing interventional activities, there has been

[1] University of Muenster, Münster, 48149, Germany. E-mail: greefrath@uni-muenster.de

a research approach to the design of single modelling lessons as well as to the whole modelling learning environments at different school levels.

This topic study group (TSG-22) considers the importance of exploring relations between mathematics and the real world that occur in educational environments. It also recognizes the value of examining the discussions in research and development on the applications and modelling issues at the primary, secondary and tertiary school levels, including the mathematics teacher education. The TSG also recognizes the interplay between research and development of modelling learning environments (Greefrath et al. 2023).

2. Program Overview

2.1. Team and participants

The TSG-22 team was composed of Xiaoli Lu (China), George Ekol (South Africa), Susana Carreira (Portugal, Co-Chair) and Gilbert Greefrath (Germany, Chair). From the large number of submissions, 10 long oral, 26 short oral and 8 posters were presented during the conference. The first authors of these papers and posters came from 20 different countries. The countries most strongly represented in TSG-22 were Chile, China, Germany and Japan.

2.2. Structure of the sessions

For the TSG, four sessions of 90 to 120 minutes each were available. Each session was chaired by one of the team members. The sessions were structured thematically. During the session, long and short oral contributions alternated. For some presentations, a joint discussion took place together, as far as the high number of contributions allowed. In the first session, in addition to the thematic part, there was an introduction for the group and a presentation as a thematic overview of the current state of research.

2.3. Theme 1: introduction and teaching mathematical modelling

Following a welcome and overview of sessions by the chair, Gabriele Kaiser made a long oral presentation on *The Teaching and Learning of Mathematical Modelling. A Description of the Current State-of-the-Art*. In particular, she addressed theoretical perspectives (Kaiser and Sriraman, 2006) and modelling competencies (Niss and Blum, 2020). This was a very relevant starting point for the work of the TSG. Subsequently, the *teaching of mathematical modelling* was examined from different angles. For example, sociocultural and geographical aspects were discussed, but also specifics of statistical modelling were highlighted (see Tab. 1).

Tab. 1. Presentations on the themes "introduction and teaching mathematical modelling"

	Paper and author(s)
[1]	The teaching and learning of mathematical modelling. a description of the current state-of-the-art. ***Gabriele Kaiser*** (Germany).
[2]	Sociocultural influences on mathematical modelling: an ethnomathematical perspective. ***Milton Rosa*** *and Daniel Clark Orey* (Brazil).
[3]	Teaching methods for modelling problems. ***Stanislaw Schukajlow*** *and* ***Werner Blum*** (Germany).
[4]	Examining the geographical features of the nasu area. analysing the origin of the nasu area using mathematics. ***Masahiro Takizawa*** (Japan).
[5]	A mathematical modelling technique as tool for teaching mathematics. ***Eloisa Benitez-Mariño*** (Mexico).
[6]	Theorizing tensions between mathematical modelling processes and conventional mathematics instruction. ***Wenmin Zhao*** *and Samuel Otten* (China).
[7]	The rationales of statistical modelling in education research from a mathematical modelling perspective. ***Takashi Kawakami*** *and Jonas Bergman Arleback* (Japan).
[8]	Modelling in a teacher education programme. ***Dragana Martinovic*** (Canada).

2.4. *Theme 2: teacher education*

The second topic of the TSG was teacher education. On the one hand, there were contributions on specific topics such as global warming or subject areas like STEM. On the other hand, there were contributions to promote certain aspects of professional competencies such as noticing skills or self-efficacy. Different types of school levels were taken into account (see Tab. 2).

Tab. 2. Presentations on the theme "teacher education"

	Paper and author(s)
[9]	Mathematical modelling in STEM contexts. Characterization of STEM skills and gender gaps in initial formation of mathematics teachers. ***María Aravena Diaz****, Marcelo Alejandro Rodriguez, Susan Valeria Sanhueza Henriquez, Maria Jose Seckel, and Angelica Urrutia Seplveda* (Chile).

[17]	Prospective teachers of mathematics suspend common sense in solving word problem. ***Abolfazl Rafiepour*** *and Zohreh Khazaei* (Iran).

2.5. Theme 3: students modelling processes

The topic with the most contributions was on modelling processes and modelling competencies of students. Here the particular situations in different countries were considered and also different age groups were considered. Also, different ways of measuring modelling competencies were discussed. Various models for describing modelling processes were also discussed here, and the use of technology in modelling was explored (see Tab. 3).

Tab. 3. Presentations on the theme "students modelling processes"

Paper and author(s)	
[18]	The mathematical modelling landscape: a literature review on perspectives, methodology, content, unit of analysis, and geography. ***Armando Paulino Preciado Babb****, Fredy Peña Acuña, Andrea Ortiz Rocha, and Armando Solares Rojas* (Canada).
[19]	Distinguishing the distinctions: observing the solving of a mathematical modelling task. ***Paola Andrea Ramirez Gonzalez*** (Chile).

[23]	How do undergraduate students hold the individual assumptions in collaborative modelling? ***Kazuhiko Imai*** *and Akio Matsazaki* (Japan).
[24]	Investigating students data moves in a citizen science based data-rich model-eliciting activity. ***Jeffrey Allen McLean****, Corey Edison Brady, Hyunyi Jung, Aran Glancy* (USA)*, and Angeles Dominguez* (Mexico).
[25]	Differences in students conceptions about mathematics when participating in a mathematical modelling contest. ***Flavio Guiñez*** (Chile).
[26]	Measurement mathematical modelling competency and its relationship to mathematical interests of seventh grade. ***Zhiyong Xie****, Yaling Li, Tian Wang, and Jian Liu* (China).
[27]	Assessment of four-grade students mathematical modelling competency: take one city of china as an example. ***Tian Wang****, Zhiyong Xie, and Jian Liu* (China).
[28]	Study of a problem solving using the extended mathematical working space framework. ***Laurent Moutet*** (France).
[29]	Introducing a composite model for investigation in real world problem. ***Kazem Abdollahpour Chenary*** *and* ***Abolfazl Rafiepour*** (Iran).
[30]	A computer-based learning environment on mathematical modelling: research design and pilot studies. ***Lena Frenken*** (Germany).

2.6. Theme 4: university students modelling processes

The fourth and last topic of the TSG was dealing with modelling processes and modelling competencies of students at the university. Various models for describing modelling processes were discussed and the use of technology in modelling at the university was considered. Also, different instruments for the assessment of modelling competences at the university were presented. It was also described how one can learn certain mathematical contents through mathematical modelling (see Tab. 4).

Tab. 4. Presentations on the theme "university students modelling processes"

Paper and author(s)
[31] Undergraduate students' modelling routes mediated by technology in the learning of linear transformations. ***Susana Carreira***, *Guillermo Enrique Ramirez Montes, and Ana Claudia Henriques* (Portugal).
[32] Is quality teaching favourable for the development of modelling competency? an empirical study with engineering students over two years. ***Rina Durandt***, *Werner Blum, and Alfred Lindl* (South Africa).
[33] Validating a modelling competencies assessment. ***Jennifer A. Czocher***, *Sindura Kandasamy, and Elizabeth Roan* (USA).
[34] Mathematical modelling with biology undergraduates: using activity theory to understand tensions. ***Yuriy Rogovchenko*** (Norway).
[35] Calculus learning competency through mathematical modelling. ***Lorenza Illanes*** *and* ***Roberto Retes*** (Chile).
[36] Research on evaluation of college students' mathematical modelling ability based on AHP and BP neural network. ***Yixin Dong***, *Huanhuan Zhang, Meng Ci, and Ziyi Wang* (China).

3. Future Directions and Suggestions

Even though mathematical modelling in mathematics education is currently being very intensively discussed and researched, there are still some open questions for the future. These relate to both theoretical areas and empirical areas. For example, the further development of central constructs such as modelling competencies or professional competencies for teaching modelling is an interesting field of consistent research development. For further empirical studies, appropriate standardized test instruments are needed, which should be developed and shared in the community. This could also contribute to a better interlinking of studies on the methodological and thematic side. Furthermore, the changes caused by a heterogeneous school population and the use of technology in all school levels up to university should be responded to accordingly.

Topic Study Group 23

Visualization in the Teaching and Learning of Mathematics

Cristina Sabena (chair)[1], Marc Schäfer (co-chair)[2], Marei Fetzer[3], Hui-Yu Hsu[4], and Zhiqiang Yuan[5]

1. Introduction and Aims of the TSG

In mathematics education research, visualization is generally referred to as the product and the process of creating, using, interpreting, and reflecting on visual information. It plays an important role in mathematical thinking and in most branches of mathematics: there is general consensus in the mathematics education community that visualization is a vital component of conceptual understanding, reasoning, problem solving and proving.

The aim of the TSG-23 was to interrogate the significance for research in understanding the role of visualization processes in the teaching and learning of mathematics at all school levels. Specifically, it was the aim of TSG-23 to not only show-case this research in a global context, but also to start thinking about and considering possible visualization research trajectories and frameworks that could support scholars with articulating their own visualization research agendas.

In the call for papers we proposed some subthemes, which highlighted the close connection of visualization with different aspects involved in mathematics learning and teaching, such as:

- *Visualization as a cognitive process*, including visualization and reasoning, justification, argumentation, imagination, and difficulties with visualization.
- *Visualization as a mathematical construct*, including visualization and mathematizing, visualization and generalizing, visualization as a mathematical proof.
- *Visualization and new technologies*, including technologies such as interactive dynamic software, 3-D printing, augmented reality, virtual reality and other digital media.
- *Visualization and neurological functioning*, including research into neurological activities in the brain associated with visualization processes and

[5] Hunan Normal University, China. E-mail: zhqyuan@hunnu.edu.cn

their implications to mathematical thinking and teaching-learning processes

- *Visualization and language*, including interrogating the relationships between visualization, signs and language(s), including embodied aspects such as gestures and bodily actions.
- *Visualization in school practice and in teacher education*, including research into the explicit inclusion of visualization in school curriculum, practice and assessment, and interrogating the development of visualization skills in teacher education programs.
- *Visualization as a social process*, including research about the negotiations on visualization in classrooms as well as diversity aspects across various cultural contexts.
- *Visualization and research methodology*, including asking questions about visualization research design and methodological approaches that foster visualization.
- *Visualization and theory*, including research into possible overarching theoretical frameworks that could frame and orient visualization research such as embodied cognition theories, learning theories, socio-cultural theories.

This list was not meant to be exhaustive, and we encouraged contributions based on empirical research, including ongoing studies, as well as theoretical elaborations and reflections on a theme.

2. Submissions

We received 29 submissions of papers and 13 submissions of posters from 16 countries (South America and North America, Asia, Europe and Africa), which shows a very encouraging cultural diversity. Papers underwent a peer review process that involved two submitting authors and one team member for each paper submission, and two team members for each poster submission. The review process was guided by criteria that included innovation, theory and methodology, coherence, interest for an international audience and clarity. Paper proposals could be accepted as either long or short papers. After the review process was completed, and the conference finally took place, 13 long papers and 9 short papers were presented and discussed during the conference sessions.

3. Sessions

During the conference, we met in a blended modality (in presence and at distance) in four sessions, for a total of six hours. Onsite facilitators in Shanghai helped us to manage a reliable connection between onsite and online participants.

As TSG-23 we wanted to provide sufficient time for scientific exchange and discussion. As we had not enough time to discuss and interact with the presenters during our official sessions, we met in additional interactive sessions during dinner times (Shanghai times) in order to share moments of scientific discussion and exchange pertaining to the specific presentations. These meetings were realized only at distance and made use of the parallel rooms facilities. Throughout the four days we attempted to facilitate dialogue between participants in order to give constructive feedback to the presented studies, identify possible research themes and opportunities that emerged from the presentations. We found that the discussion time proved very fruitful in facilitating networking opportunities and sustaining the interest momentum that was generated during the presentations. At the end of the last session, we hosted a 50-minute whole group reflection session to consider some research implications that arose.

4. Paper Presentation and Emerging Themes

The long papers (LO) were allocated 15 minutes for presentation, and short papers (SO) were allocated 10 minutes. Papers were briefly discussed in the official sessions, and then discussed in more depth in the parallel rooms during the additional sessions.

Our programme was organized around eight themes or clusters which characterized the submissions. Below we present each theme as they appeared in the programme and list the related papers in Tab. 1 (on the next page).

- *Theme 1: Visualization and problem-solving.* This theme related specifically to research that looked at how visualisation process and mathematical problem-solving articulated with each other.
- *Theme 2: Classroom interaction.* This theme interrogated how issues of visualization played out in particular classroom interaction contexts.
- *Theme 3: Visualization and teaching*. The focus of this theme was how selected teachers used visualization tools and media (including dynamic geometry software) to teach mathematics.
- *Theme 4: Different kinds of representations, different technologies.* In this theme the presenters looked at how different representations and diagrams could be meaningfully utilized in the mathematics classroom.
- *Theme 5: Diagrams and mathematics visualization.* Here the specific focus was on how mathematical visualization related to mathematical representations.
- *Theme 6: Math, visualization and other disciplines.* In this theme researchers engaged with mathematical visualization processes using means from other disciplines.
- *Theme 7: Visualization and (latest) technologies.* Here researchers considered how different digital resources were used either as a research tool or means to engage with mathematics.
- *Theme 8: Educational materials.* In this theme the presenters considered how specific educational materials, in the context of visualization processes, could be used in the mathematics classroom.

Tab. 1. List of papers presented

Paper and author(s)
Session 1
Theme 1: Visualization and problem-solving
[1] Imaging and visualizing in geometry: Explorations by mathematics university students. ***Ferdinando Azarello**, Cristina Sabena, and Carlotta Soldano* (Italy). (LO)
[2] Visualization as an embodied problem-solving process. ***Beata Dongwi** and Marc Schäfer* (South Africa). (LO)
[3] Characterizing visualization and spatial analytic reasoning for solving isometry problems. ***Leah Michelle Frazee** and Michael Battista* (USA). (LO)
[4] The role of visualization towards student's mathematical abstraction and representation: The case of probability. ***Dennis Lee Jarvis Baring Ybanez** and Catherine Vistro-Yu* (Philippines). (LO)
Theme 2: Classroom interaction
[5] The use of gestures and language as co-existing visualization teaching tools in multilingual classes. ***Clemence Chikiwa** and Marc Schäfer* (South Africa). (LO)
[6] On objects and visualizations — An interactionistic perspective. ***Marei Fetzer*** (Germany). (LO)
Session 2
Theme 3: Visualization and teaching
[7] How teachers scaffold students in visualizing diagram for understanding geometric problem solving. ***Hui-Yu Hsu*** (Chinese Taiwan). (LO)
[8] Preservice and Inservice teachers' mathematics visualization skills. ***Vimolan Mudaly*** (South Africa). (LO)
[9] Dynamic visual instructions by GeoGebra for introducing Takada's theorem on pentagons. ***Hirotshi Furutsu**, Yukiko Ishii, Hisashi Kato, Yusuke Washio, and Noriko Hirata-Kohno* (Japan). (SO)
[10] High school mathematics inquiry teaching based on GeoGebra visualization environment. ***Wei Wang** and Xue Huang* (China). (SO)
Theme 4: Different kinds of representations, different technologies
[11] The development of 3D representations using physical manipulatives, technology-aided design and 2D drawings. ***Jill A. Cochran*** (USA). (LO)
[12] The social construction of knowledge in a new pedagogical setting: The same activity presented as three different interactive diagrams. ***Elena Navtaliev*** (Israel). (LO)
Session 3
Theme 5: Diagrams and mathematics visualization
[13] Visualization as vision, imagination and intuition: reflections on graduate students struggling with a visual conjecturing problem. ***Francesco Beccuti*** (Italy). (LO)
[14] Mapping diagrams: Function visualization of real and complex analysis and matrix algebra. ***Martin Flashman*** (USA). (SO)
[15] Interactive visualizations of topics in engineering mathematics. ***Antti Rasila*** (China). (SO)
Theme 6: Math, visualization and other disciplines
[16] Drawing (on) diagrams: Typicality of geometric shapes in concept image elicitation for secondary students. ***Santanu Dutta**, Charudatta Sharad Navare, and Harita Raval* (India). (SO)
[17] Research on visualization in mathematics learning based on mathematical drama performance or by video. ***Yan Li**, Pan Liu, and Xinyu Liu* (China). (SO)
Session 4
Theme 7: Visualization and (latest) technologie
[18] Some like it social: Looking into the interplay between math and internet memes. ***Giulia Bini** and Ornella Robutti* (Italy). (LO)
[19] Children's ambiguous interpretation of visualizations — eye tracking as a diagnostic tool for division concepts. ***Daniela Götze*** (Germany). (LO)
[20] A review of the application cases of augmented reality (ar) in mathematics education. ***Luona Wang*** (China). (SO)
Theme 8: Educational materials
[21] Using geometric intuition in the domain of number and algebra: From textbook designers' perspective. ***Jiling Gu** and Fei Zhang* (China). (SO)
[22] Methodology visual experience based mathematics education 2019. ***Janos Szasz Saxon** and Zsuzsa Dardai* (Hungary). (SO)

5. Areas for Future Research

In our last session we consolidated our deliberations by identifying possible visualisation avenues for further research that emerged. These were:

- Visualisation as a cognitive process. This includes visualisation and reasoning, visualisation and imagination, difficulties with visualisation.
- Visualisation and mathematising.
- Visualisation and new technologies, such as interactive dynamic software, augmented reality and other digital media.
- Visualisation and language, specifically the relationship between visualisation, signs, language(s), including embodied aspects such as gestures and bodily actions.
- Visualisation as a social process, including negotiations on visualisation in classrooms as well as diversity aspects across various cultural contexts.
- Visualisation and theory, which includes researching possible overarching theoretical frameworks that could frame and orient visualisation research such as embodied cognition theories, learning theories and socio-cultural theories. Do we have a visualisation theory?

https://doi.org/10.1142/9789811287152_0048

Topic Study Group 24

The Role and the Use of Technology in the Teaching and Learning of Mathematics at Primary Level

Sitti Maesuri Patahuddin[1] and George Gadanidis[2]

1. Aims and Themes

The aim of TSG-24 at ICME-14 was to share, discuss and advance knowledge and understanding of key aspects of research and practices related to the role and use of technology in the teaching and learning of mathematics at the primary school level.

For these aims, we invited contributions within four sub-themes.

1.1. Sub-theme 1: student interaction

In the ICME-13 Monograph Uses of Technology in Primary and Secondary Mathematics Education, several contributions concern students' learning. Some research suggests that digital technologies have the potential to support the learning of mathematics, giving a unique experience. At the same time, contributions highlight that few works focus on student interaction with digital media, and why and how these technologies have an impact on learning. Therefore, in this TSG, we are interested in continuing to deal with this theme:

- How does the use of apps enhance students' learning?
- What kinds of activities/tasks are proposed for students?
- What are the differences, if any, in the use of touchscreen apps (mobile or not) from the perspective of learning processes of specific mathematical content?
- What is the potentiality of coding activities for exploring mathematical concepts?

1.2. Sub-theme 2: digital and analog tools

Digital technologies are not considered alone. In many primary schools, depending on the culture of each country, there are physical manipulatives also in use. This is taken into account in some projects, focusing on digital and analog tools, from different perspectives (e.g., artefacts, coding to model mathematical relations, DGS simulations). We solicited contributions on this aspect:

- How do analog and digital technologies support students'learning?

[1] STEM Education Research Centre (SERC), Faculty of Education, University of Canberra, Australia. E-mail: Sitti.Patahuddin@canberra.edu.au

[2] Western University, Whitby, Canada. E-mail: ggadanid@uwo.ca

- In which specific situations do digital and physical tools display advantages for overcoming students' difficulties?

1.3. Subtheme 3: new technologies

From the discussion on technology, it emerges that many kinds of technology (e.g., tablets, IWB, and personal computers) are available for primary education. Nevertheless, their diffusion and how they are used at school are different from one country to another one (one-to-one tablet, BYOD, IWB). At the same time, new technologies are available and experimented in the classroom (e.g. VR, AR). In this sense, we would discuss:

- Which types of technology use are emerging to enrich and foster mathematics learning in kindergarten and primary school?
- Which digital technology for education do enable primary children to inquire, problem solve and think mathematically and share their learning?
- Which are the most spread technologies at kindergarten and primary school? Which mathematical contents do they concern about?

1.4. Subtheme 1: teacher's role

We were also interested in questions about teacher evaluation of apps. We aim to investigate the different aspects of this question. In particular, which criteria could be suggested to teachers for choosing apps in their teaching.

The spread of digital technologies at school depends on teachers' engagement (training and practice). A pedagogical approach taken by the teacher is complementary to the potential of the affordance of the apps to influence students' learning. The tasks given to students and the classroom culture the teacher develops are key elements of the learning. So, we aim to deepen the discussion about the teacher's role:

- How do schools and teachers use technology to enrich mathematics learning at the primary level?
- How do teachers choose the technology they use in their classrooms?
- A specific question is addressed to each participant, in order to know the state of the art: What are the typical digital technologies in used in kindergarten and primary school classrooms in your country?

2. The Sessions

Due to the global pandemic caused by coronavirus disease (COVID-19 pandemic), only 9 out of 21 contributors participated in this conference. Therefore, the work of TSG-24 was organized into three main TSG Sessions, and these were supplemented by oral communication and poster presentation (Tab. 1). The three sessions were chaired by Sitti Patahuddin and supported by George Gadanidis.

The contributors of this TSG were from seven countries: China, Malaysia, Japan, Australia, USA, India, and Canada. The nine contributions are as follow:

Tab. 1. List of papers presented

Paper and author(s)
Session 1
[1] Impact of computer-mediated sharing on classroom activities. ***Shaikh Sashid Rafikh****, Harita Raval, Harshit Agrawal, and Nagarjuna Gadiraju* (India).
[2] ELPSA framework uses in designing lessons with web-based resources: A case of equivalent fractions. ***Sitti Patahuddin*** *and Jonathan Adam* (Australia).
Session 2
[3] Using mathematically-focused text messages to connect families with their childs learning. ***Mollie Helen Appelgate****, Christa DeAnn Jackson, and Kari Nicole Jurgenson* (USA).
[4] Exploring the use of digital platforms in supporting dialogue in primary mathematics classrooms. ***Qian Liu*** (China). (Poster)
[5] Computational modelling in Grades 1-3 mathematics. ***George Gadanidis****, Janette Hughes, Immaculate Namukasa, and Ricardo Scucuglia* (Canada).
[6] Building computational thinking (CT) readiness: a self-assessment framework and tools for integrating CT in primary math classrooms. ***Heater Sherwood*** (USA). (Poster)
Session 3
[7] Proposal on how to use digital textbooks at primary level and research directions. ***Manabu Goto*** (Japan).
[8] Coding in elementary mathematics lessons. ***K. M. Leung*** *and P. Y. Tang* (Hong Kong SAR, China).
[9] Effectiveness of digital game-based learning (DGBL) in enhancing fraction skills among primary four pupils. ***Jia Yi Boo*** *and Kwan Eu Leong* (Malasya).

The TSG-24 started with a short introduction from each participant followed up by an overview of the TSG-24 programs by Sitti and George. The TSG sessions progressed well and we did not face any technological issues. All contributors did a live presentation and followed up by discussions. They shared their screen without a need to send their pre-recorded video or slide presentation.

TSG-24 also had an additional discussion forum led by George Gadanidis. George shared practices related to “Coding in the Ontario Mathematics Curriculum for Grade 1-8”. This session stimulated great discussion among the participants. George invited the participants to share in what ways coding was a part of the school curriculum in their countries. George emphasised that despite the fact that coding is not a new thing, being an explicit part of the curriculum offered opportunities to show the relevance and the value of mathematical thinking in this digital world.

In conclusion, TSG-24 was a learning space where various topics were shared and discussed, including digital game-based learning, theoretical frameworks in designing mathematics lessons with technology, digital textbooks, computational thinking and coding. The challenge of this TSG was mainly a lack of connections among the participants due to the online setting and the time zones as some participants had to join the session in the middle of the night and very early in the morning.

Topic Study Group 25

The Role and the Use of Technology in the Teaching and Learning of Mathematics at Lower Secondary Level

Morten Misfeldt[1], Hans-Stefan Siller[2], Mariam Haspekian[3], Arthur Lee[4], and Mailizar Mailizar[5]

ABSTRACT Topic Study Group 25 (TSG-25) on the role and the use of technology in the teaching and learning of mathematics at lower secondary level discussed this topic over four sessions. These sessions focused on diverse topics such as immersive learning environments in the second session topics as self-efficacy, use of digital technologies outside the classroom and pedagogical aspects of using digital technologies were discussed. In the third session we discussed cultural aspects of technologies in the classroom, and in the last session we discussed communication and the mediating role of digital technologies. The group had contributions from all continents (apart from Antarctica), with a slight overweight of the contributions from European countries. The contributions consisted of five long papers, 21 short papers and eight posters

Keywords: Digital tools; Technology; Immersive learning; Computational thinking.

1. Themes and Description

Topic Study Group 25 (TSG-25) on the role and the use of technology in the teaching and learning of mathematics at lower secondary level was focused on three interrelated themes: (1) Technology in lower secondary education as a scientific endeavor. (2) The role of technologies in the teaching and learning of mathematics, and (3) Teacher in- and pre-service training with technologies or as a reply to new demands of technologies.

The work departed in an acknowledgement that technology and mathematics has a huge and increasing influence on many aspects of society, and hence that the educational attendance to the combination of mathematics and technology is of paramount importance.

[4] Faculty of Education, University of Hong Kong, Hong Kong SAR, China.
E-mail: amslee@hku.hk

[5] Department of Mathematics Education, Syiah Kuala University, Indonesia
E-mail: mailizar@unsyiah.ac.id

We had contributions from all continents (apart from Antarctica), with a slight overweight of the contributions from European countries. The contributions consisted of 5 long papers, 21 short papers and 8 posters.

1.1. Technology in lower secondary education as a scientific endeavor

The focus on technology in lower secondary teaching as a scientific endeavor was initiated in order to frame a theoretical and methodological discussion. The concern being that several theoretical constructs and methodological approaches have been applied and developed in order to investigate the role of technology in mathematics learning, as well as in teachers' difficulty to integrate them. But these are somehow compartmentalized in local theoretical traditions. Networking of theories and the development of shared knowledge and methodologies are important, and in the group, we were trying to cross internal barriers and build a paradigmatic organization.

1.2. The role of technologies in the teaching and learning of mathematics

The range of technologies that suggest themselves to the mathematical classroom is wide and expanding. Some technologies come in relatively stable form (such as calculators spreadsheets and physical manipulatives), while others are in rapid flux (intelligent CAS tools as Wolfram Alpha, Applications within Virtual Reality and programming languages are examples of this). Some are specifically designed for school mathematics teaching (such as GeoGebra), some have been imported from business area (such as spreadsheets). These technologies influence the teaching and learning process in mathematics, in ways that have been studied by research for the last three decades, and continue to generate results.

1.3. Teacher in- and pre-service training

The discussion of what mathematical knowledge, skills and competence that technological development requires, or favors reaches decades back to the introduction of handheld calculators in schools, but more recently the rapid digitalization of the social and economic spheres is increasing the demand for students to develop algorithmic and computational competences. Technologies and digital tools are of growing importance to all educational systems and call for teacher training. For this reason, there is an ongoing research interest in the field of professional development of teachers using technology. Even if evidence-based methodologies can tell us whether these tools are succeeding and should be introduced in pre-service teacher education, it remains still the question of the transferability of successful experiments and, more generally, that of how to train teachers to integrate these technologies in their practices. In the Topic Study Group we had the possibility of taking a genuine international audience and perspective on this important issue.

2. Overview of the Program and the Sessions

The four sessions where thematically organized and ran in sprints with 2–5 presentations followed by a shared discussion.

2.1. First session

In the first session we discussed technologies that somehow changed the learning environment through immersive artifacts such as augmented and virtual reality, game-based learning and simulations, but also by a combination of historical sources and digital tools as well as other ways of bringing CAS and DGS into students mathematical reasoning.

Session one contained the opening, followed by two long oral presentations (LO, each 10 minutes) and a shared discussion of the two papers (also over 10 minutes). After a break the session continued with three short oral presentations (SO, each of eight minutes), and a shared discussion of these papers. Following one more break five posters where presented and discussed (Tab. 1).

Session one had many and rather diverse contributions. In the discussions it became clear that even though trends as game-based learning, virtual reality are both new and important to the teaching of mathematics it also makes sense to consider the pedagogical situations that these tools can lead to in continuity with other aspects of mathematics education, such as organization and implementation, and the use of history and cultural artifacts. In this session we also aimed at establishing a collaborative atmosphere.

Tab. 1. List of papers presented in Session 1

Paper/Poster and author(s)	
[1]	An immersive learning experience for teaching equations equation lab. ***Morten Elkjaer*** *and Lui Albaek Thomsen* (Denmark). (LO)
[2]	Student's autonomy and digital technologies: collective documentation work in preservice teacher education. ***Ghislaine Gueudet*** *and Sophie Joffredo-Le Brun* (France). (LO)
[3]	Using augmented reality technology for instructional media in mathematics education. ***Shiwei Tan*** (China). (SO)
[4]	Mediations and rules when working with the interplay between original sources and GeoGebra. ***Marianne Thomsen*** (Denmark) *and Uffe Thomas Jankvist* (Afghanistan). (SO)
[5]	Developing spatial skills in a virtual reality environment for carpentry apprentices. ***Sylvia Van Borkulo*** *and Paul Drijvers* (The Netherlands). (SO)
[6]	Application of GeoGebra in the function study: the use of ICT in teaching mathematics. ***Wesley Matheus Moura Balbino****, Medeiros de Oliveira, and Francismar Holanda* (Brazil). (Poster)
[7]	EVA: an educational tool to simulate evacuations of buildings. ***André Greubel*** *and Hans-Stefan Siller* (Germany). (Poster)
[8]	Perspectives on the use of ICT in the high school mathematics classrooms. ***Erin Herz and George Ekol*** (South Africa). (Poster)
[9]	Role of ICT to enhance mathematics teaching. ***Santosh Paudel and Binaya Bhandari*** (Nepal). (Poster)
[10]	The mathema kids research seed: a GeoGebra youth club that tells stories. ***Carlos Eduardo Leon and Jefer Camilo Sachica-Castillo*** (Colombia). (Poster)

2.2. Second session

Session 2 addressed key elements relevant to the use of digital technologies from a scientific perspective — subject knowledge, self-efficacy, use of digital technologies outside the classroom and pedagogical aspects of using digital technologies.

All these issues are highly relevant and can have a lasting positive or negative impact on the use of digital technologies. Therefore, effectiveness research, subject knowledge testing and pedagogical measures to understand the content are enormously important. In this session we discussed these topics through two long oral presentations (LO, 10 minutes each) and 4 short oral presentations (SO, 8 minutes each) and discussed in detail future research possibilities (Tab. 2).

Tab. 2. List of papers presented in Session 2

Paper and author(s)	
[11]	Instrumental orchestration with dynamic geometry: A Chinese case study. ***Fangchun Zhu*** (China). (LO)
[12]	Gray-boxing as a means for mathematical communication. ***Cecilie Carlsen Bach*** (Denmark). (LO)
[13]	Desmos App in the mathematics classroom: limitations and potentialities. ***Jair Dias de Abreu*** *and Silviano de Andrade* (Denmark). (SO)
[14]	Augmented reality for outdoor modeling tasks: bridging real problems with mathematical concepts. ***Adi Nur Cahyono**, Yulius Leonardus Sukestiyarno, Mohammad Asikin and Matthias Dieter Ludwig* (Indonesia). (SO)
[15]	Micro-teaching of landmark jobs fostering self-efficacy for teaching mathematics with technology. *Daniel Thurm and* **Baerbel Maria Barzel** (Germany). (SO)
[16]	Digital competency found by prospective secondary teachers according ontosemiotic approach. ***Joaquin Gimmenez**, Silvia Carvajal, and Vicenç Fon* (Spain). (SO)

2.3. Third session

Session 3 had focus on different cultural influences on different cultures and countries approaches to teaching mathematics with technologies. Case studies from China, France, India, Mexico and Denmark, and the ways that different school cultures and local policies was in interplay with the pedagogical possibilities and difficulties of various tools and technologies. We also discussed the way that cultural artifacts such as historical sources, buildings and museums can be used to enhance teaching and learning of mathematics and how digital tools can be instrumental in that respect. The session included presentation and discussion of two long papers (LO, 10 minutes for each presentation and 10 minutes for a shared discussion), three short papers (SO, presented for eight minutes) and a short presentation of a poster. These four contributions were discussed jointly (Tab. 3).

Tab. 3. List of papers and poster presented in Session 3

Paper and author(s)	
[17]	The development of technological craft knowledge within a community of inquiry. ***Ahlam Anabousy*** *and Michal Tabach* (Israel). (LO)
[18]	Mobile learning of mathematics with apps for math trails. ***Ana Donevska-Todorova*** (Germany). (LO)
[19]	Media, cognition and assemblage perspectives on ict in education: a three-part study in an indian school. ***Prateek Shah****, Harshit Agrawal and Sanjay Chandrasekharan* (India). (SO)
[20]	Evolution of teaching practices with ICT: a case study with scratch in the French new mathematics curricula. ***Mariam Haspekian*** (France). (SO)
[21]	Connecting conjectures and proof using dynamic geometry environments and a toolbox puzzle approach. ***Ingi Heinesen Hojsted*** (Denmark). (SO)
[22]	Technology in classroom: a report of 3 researches. ***Alejandro Miguel Rosas Mendoza*** (Mexico). (Poster)

2.4. Fourth session

In session 4 we departed in the fact that effective use of digital technology inevitably leads to the mediating role of it. This is not only about how digital technologies are used in the classroom, but also about how digital tools enable or change interaction between teacher and learner. This consideration is not new in the discussion of digital technologies, but it is precisely through the use of new technologies and through the linkage with other process-related activities that this perspective continues to gain attention and contains sufficient research potential.

In the fourth session, which just put the scientific perspective on the mediating role of technology, 7 short-papers (SO) for 8 minutes each and 1 poster in the duration of 3 minutes were presented. An extensive discussion in the group rounded off this session, which then also closed TSG-25 (Tab. 4).

Tab. 4. List of papers and poster presented in Session 4

Paper and author(s)	
[23]	Impact of online automated learning path on student learning: the mindmath project in elementary algebra. ***Brigitte Grugeon-Allys****, Elann Lesnes-Cuisiniez and Fabrice Vandebrouck* (France). (SO)
[24]	Engagement and moderation of mathematical modelling tasks in virtual environments. ***Joseph Simon Madrinan*** *and Catherine Vistro-Yu* (Philippines). (SO)
[25]	Computer-dependent mathematics teaching in schools. *Rabindra Kumar Bhattacharyya* (India). (SO)
[26]	Type of mathematics tasks with dynamic geometry software. ***Liping Yao*** (China). (SO)
[27]	Strategic use of content-specific and content-neutral technologies to cater learning diversity in mathematics. ***Thomas K. F. Chiu*** (Hong Kong SAR, China). (SO)
[28]	Digital tools and mediation in informal justification. ***Rikke Maagaard Gregersen*** (Denmark). (SO)
[29]	Digital technology in relation to the mathematical thinking competency. ***Mathilde Kjaer Pedersen*** (Denmark)*, Uffe Thomas Jankvist* (Afghanistan)*, and Morten Misfeldt* (Denmark). (SO)
[30]	Students mathematics experience of the technology self-directed learning (TSDL) pedagogy. ***Hoi Kei Melody Wong*** *and I. A. C. Mok* (Hong Kong SAR, China). (Poster)

3. Future Directions and Suggestions

The work in the TSG gives a good outset for continuation. Firstly, it became clear that we have a solid base of research on how technology is used in lower secondary mathematics. The work is most elaborated in relation to tools such as CAS and DGS where a shared language and some sort of paradigmatic organization. The language coming from the theory instrumental genesis has facilitated this positive development.

Apart from consolidating the concerns about CAS and DGS the TSG also showed the development of two new areas for mathematics education and technology in lower secondary teaching. The first of these areas can be described as embodiment, immersion and virtual/augmented reality. This area stood out as a promising future direction for mathematics education in the sense that augmented and virtual reality tools provide platforms for new mathematical experiences, and for the development of teaching materials. Lastly it was clear that computational thinking and programming is becoming very prominent in the curriculum and educational practices of mathematics teaching in various countries but is still under researched in mathematics education.

After the conference we had a survey-based evaluation of the work in TSG-25. Rather few participants answered the survey, but there was agreement that TSG was a good academic experience despite the online and hybrid format. There was also an interest in continuing collaboration and discussion on the topic. One participant asked for better possibilities for post conference publishing of the conference papers.

Topic Study Group 26

The Role and the Use of Technology in the Teaching and Learning of Mathematics at Upper Secondary Level

TSG-26 Working Team[1]

1. Introduction

The TSG-26 counts 17 papers presented, in a double modality: as a long paper (three in the 1st Session), and as a short paper, (fourteen, in the 2nd and 3rd Sessions). The participants to the Sessions have been 24, divided in these countries: Australia, Botswana, Brazil, Canada, Chile, China, Colombia, France, Italy, Mexico, the Netherlands, Philippines, South Africa, United Kingdom, and USA.

The call for papers of TSG-26 has been divided into 5 themes:

- Theoretical and methodological aspects: current/new frameworks for developing and analyzing new technology's integration in mathematics teaching and learning from didactical, cognitive and epistemological perspectives.
- Role of emerging devices and technologies, such as tablets, smartphones, virtual learning environments, augmented reality environments, and haptic technologies.
- Interrelations between technology and the mathematics taught at this age level.
- Students' education and the relationships between teaching and learning.
- Teachers' professional development.

Each theme has been articulated in different questions, ideas, suggestions for discussions, research results, and methodologies that guided the authors to the submission of papers and posters.

2. Sessions

The works of TSG-26 took place in three sessions, two of 90 minutes and one of 120 minutes. In the first session, a panel of three long papers was organized with the three presentations followed by a discussion. The other two sessions have been divided into two sub-sessions each, around common topics, with presentations of short papers and

[1] Working team:
Chair: Ornella Robutti, Italy, Università di Torino, Dipartimento di Matematica
Co-Chair: Gilles Aldon, France, ENS Lyon
Members:
Mario Sánchez Aguilar, Mexico, Instituto Politécnico Nacional
Verônica Gitirana, Brazil, Universidade Federal de Pernambuco
Jinyu Zhang, China, East China Normal University

discussions in the end. Each communication was videotaped and made available for all participants before the sessions. During sessions, presentations were limited to 10 minutes (long papers) and 5 minutes (short papers) in order to allow the maximum time for the discussion within the TSG.

This report is structured according to the sessions and sub-sessions of the TSG.

2.1. Session 1

The first session of the TSG was dedicated to three long papers on the role of the students in a "digital class" at different levels (Tab. 1). The presentations of the long papers have been organized as a panel, followed by a discussion. The panel dealt with the different roles that students may have in educational processes: as protagonists of learning processes, as active designers of resources for education purposes, and as subjects evaluated by a system of formative assessment.

Tab. 1. Papers presented in Session 1

Paper and author(s)	
[1]	Students as designers of digital curriculum resources. ***Annalisa Cusi*** *and Agnese Ilaria Telloni* (Italy).
[2]	Formative assessment and technology: an attempt of framework. ***Gilles Aldon*** (France)*and Monica Panero* (Switzerland).
[3]	Straightening the bend: sequencing embodied experiences with high and low-tech designs for the notion of Radian. ***Rosa Annalucia Alberto***, *Anna Shvarts, Arthur Bakker, and Paul Srijvers* (The Netherlands).

The first paper[1] presented by Cusi shows an educational programme aimed at involving upper secondary students in the design of digital curriculum resources (DCR) using the GeoGebra software. The study characterizes the praxeologies (made of practices and theoretical reflections on them — Chevallard, 1991), developed by the students in relation to the task of DCR-design, through the analysis of the reflections they proposed during semi-structured interviews at the end of the educational programme. This characterization of students' praxeologies highlighted their awareness both on the characteristics of the DCR that supports students' learning and on the role of the design process in fostering the designers' learning itself.

The second paper[2], by Aldon and Panero, presents a research study on the place and the role of technology in the assessment process, specifically on formative assessment (FA) processes. It addresses the professional development of teachers integrating technology into their practices in order to enhance formative assessment and to give students the awareness and the ownership of their learning. The main claim of this paper is that technology does modify classroom assessment processes, but at the cost of a reorganization of the act of teaching by promoting student ownership of their learning. Technology is not only a facilitator in the implementation of FA-strategies, but more profoundly a modifier of the didactic contract, making teacher and students together responsible for teaching and learning.

Alberto, Shvarts et al.[3] aimed to investigate how to support students in moving from calculation to reasoning strategies in trigonometry by the design of technology-enhanced learning activities inspired by embodied mathematical cognition and embodied design. They conjectured that novel mathematical relations need to be enacted physically to provide opportunities to actively conceptualize these relations. They followed up on this by exploring embodied interactions that foster students' understanding of the input of trigonometric functions in the unit circle and the sine graph. Students appeared to lack physical experience with measuring circular arc lengths and using the radius as a unit of measurement. Low-tech paper materials and practices — like folding and bending — seem to afford sensible enactments better than would digital materials. Embodied approaches and interactions are essential for the emergence of mathematical conceptualization.

In the three presentations, students learn through an awareness of a reversal of responsibilities: this awareness is provoked by the teacher and the situations he/she sets up in the classroom. Technologies and actors' relationships with artifacts are responsible for the awareness of an evolving role for students in their learning processes. The use of digital technologies seems to favor a change of roles in students and teachers and also a change in the dynamics of the classroom: co-responsibility and cross-responsibility foster an active participation, modifying students' praxeologies used in learning processes (design, assessment, conceptualization). Technologies, in these cases, are no longer studied for themselves but rather for the role they play in the new organization of learning.

2.2. Session 2

Session 2 was split into 2 parts, totally 7 papers were presented (Tab. 2).

Tab. 2. Papers presented in Session 2

Paper and author(s)
Part 1
[4] Questions of design research: a technology mathematics lesson framed by the didactical triangle. ***Marie Joubert****, Geoff Wake, and Marc North* (UK).
[5] Merlo item as boundary object in teachers professional development. *Ornella Robutti* (Italy)*,* ***Theodosia Prodromou*** (Australia)*, and Gilles Aldon* (France).
[6] Acceptability of the proposed multimedia instructional module in selected pre-calculus topics among STEM students of Muntinlupa National High School. ***Maxima Joyosa Acelajado*** *and Arlene B. Miyas* (Philippines).
[7] Twitter, emotion and mathematics. ***Mario Sanchez Aguilar*** (Mexico).
Part 2
[8] Integrating GeoGebra in classroom teaching of 3D geometry: contrasting a French and a Chinese case. ***Mingyu Shao*** (China/France).
[9] Mathematics prospective teacher display of technological content knowledge in a GeoGebra-based environment. ***Kim Agatha Ramatlapana*** (Botswana).
[10] An implementation of technological pedagogical content knowledge framework for analysing the design of tasks in a digital environment. ***Carolina Guerrero-Ortiz*** (Chile).

2.2.1. Session 2 part 1

This sub-session was devoted to the role technology can play in the interactions between teachers and students, but also between teachers and researchers or teacher trainers.

Joubert et al.[4] analyzed these interactions by means of knowledge, technology playing a role of support of interactions between students and knowledge. Joubert's communication concerns the process of design research, within the context of teaching a 'technology' mathematics lesson in Further Education colleges in England. It explains the context, then uses the "didactic triangle" to frame an analysis of the design requirements for a lesson on factors and multiples. Having determined the design requirements, an example of a lesson was given, with an explanation of how it meets the requirements. It concluded that, although the design requirements had been met, the end product perhaps lacked a sufficiently coherent narrative. It ended by speculating on whether a fourth vertex, to represent technology, should have been added to the didactic triangle or whether there was a way of capturing a coherent narrative within the design requirements.

Prodromou et al.[5] considered the technology as a component of a boundary object providing a place to interact between teachers and researchers. The presentation was focused on the possibility to consider Meaning Equivalence Reusable Learning Objects (MERLO) itemed as a boundary object in crossing the boundary between two communities: researchers and teachers. The boundary crossing was seen as a process of transformation that can influence a modification (more or less stable) in the meta-didactical praxeologies (namely practices and theoretical reflections on them — Arzarello et al., 2014) of the teachers. Primary pre-service teachers were engaged in this experiment, during their professional development. Results were on the possible existing intertwining of their praxeologies and the MERLO items they produce, seen as boundary objects in their evolution over time.

Acelajado et al.[6] presented a tool, the Multimedia Instructional Module, aiming at helping learners to overcome difficulties in understanding mathematics. The authors developed and analyzed a new technological tool, the Multimedia Instructional Module, whose goal was to help students with mathematics learning difficulties, specifically on basic concepts of calculus. Statistically significant differences in the post-test meant scores between the two groups reveal that the experimental group performed better and that the participants of this group perceived the MIM to be "Highly Acceptable".

Aguilar[7] started by the use of a communication tool considered as a medium that provides us with an insight into students' emotional experiences related to the teaching and learning of mathematics. Aguilar took advantage of the familiarity of Twitter in students' everyday life to engage mathematics students in and out of the classroom. In his article, he argued that this social network could serve as a medium that provides us with an insight into students' emotional experiences related to the teaching and learning of mathematics. To illustrate this, a selection and categorization of tweets about mathematics was presented.

The discussion following the paper presentation focused on the theoretical background that supports the study of these interactions. More precisely, what can be the role of digital technologies in the development of educational actors' interactions? Examples given in all the presentations show that digital technology provides a powerful media helping for communication between actors, but also with knowledge at stake. It could also be the place of interactions encouraging actors to look at knowledge from a different perspective. The discussion that followed the presentations returned on the concept of boundary object (Prodromou et al.[5]), showing at a micro level how two communities (researchers and teachers) can approach each other by crossing the boundary. In this case of crossing, technology played the role of a shared place where different points of view from two communities could crystallize on a common one then adopted by both communities. At a meso level, interactions between two communities (teachers and students) could profit from social media (Aguilar[7]) and emotional experiences that students face during their mathematics studies were revealed. More investigation should be done for recognising and studying in different educational contexts objects at the boundary between communities, and their evolution over time, along with the causes of this evolution process, including not only cognitive reasons, but also meta-cognitive aspects that may have propulsor roles in these processes.

2.2.2. Session 2 part 2

The second part of the session was dedicated to different uses of Digital Geometry Software in the teaching of Geometry.

Shao[8] reported on orchestration of lessons using 3D geometry software in contrasted cases in France and China. Drawing on the instrumental orchestration (Trouche, 2004) and the instrumental genesis frameworks, Shao's paper contrasted the case of a Chinese mathematics teacher with a French one, investigating how they have managed to integrate GeoGebra in their class on 3D geometry. The results opened some perspectives for further investigation, including the teacher's documentation work before the class, and the factors that could influence their choices of instrumental orchestration.

Ramatlapana[9] explored geometry technological content knowledge of mathematics prospective teachers within a GeoGebra environment. The presenter explored geometry technological content knowledge displayed by mathematics prospective teachers when working on a high school circle geometry task within a GeoGebra-based environment. The investigation analyses six prospective mathematics teachers' thinking as displayed in their solutions to the technological content knowledge-based task, particularly on what the GeoGebra constructions revealed about teachers' competence with geometry diagrams within a GeoGebra environment. The narratives and constructions were expected to reflect the teachers' ability to transform the statements from a static environment to a dynamic construction, employing GeoGebra as a construction tool. The affordances and constraints of GeoGebra when making connections between the construction and geometric principles emerged.

Guerrero-Ortiz[10] dealt with task design, highlighting the possibilities offered by a technological environment, according to the TPACK (Koehler and Mishra, 2009) framework and following a qualitative perspective. The paper presents different tasks designed by pre-service mathematics teachers, analyzing their peculiar elements related to the domains of TPACK. In the study aspects related to modeling, simulation, visualization and the use of the tools of a Dynamic Geometrical System (DGS) are highlighted. This work allows us to know how in the tasks design the pre-service teachers' knowledge can be evidenced, the results also show how they conceptualize modeling in a technological environment.

The discussion started with the three following questions:

- How is it possible to go beyond the identification of teachers' knowledge in the use of DGS?
- Is it possible to think through a networking of theories both the use of DGS and the design of resources?
- How can we contrast and compare different contributions of these theories?

The first question refers to works such as the one by Guerrero-Ortiz[10] and Ramatlapana[9], who paid attention to the specialized knowledge manifested by prospective teachers when facing the resolution or design of mathematical tasks based on the use of dynamic geometry systems. These studies confirmed how the analysis of the use of digital tools by mathematics teachers could serve as a window to teachers' specialized knowledge. However, we ask ourselves how we can use this identified specialized knowledge to promote an adequate and rational implementation of technological tools in the teaching of mathematics.

The second and third questions are theory-oriented investigations whose purpose was to promote the discussion of the potential that theory networking could offer for the study of situations involving the use of DGS as a teaching tool, but also as a means to design and implement mathematical tasks. Likewise, the particular affordances that different theories could offer for the study of the role and the use of technology in the teaching and learning of mathematics at upper secondary level were put at the center of the discussion. These presentations, as well as the plenary discussion, lead us to consider DGS through different theoretical filters which each of them brings a particular highlighting on the relationships between the artefact and its use.

2.3. Session 3

Session 3 was also split into 2 parts with 7 papers presented (Tab. 3).

Tab. 3. Papers presented in Session 3

Paper and author(s)
Part 1
[11] Mathematics VR teaching design mode and its practice at upper secondary level: based on VR All-in-one Computer. ***Jijian Lu****, Xiaoyuan Shen, and Yi Lv* (China).
[12] Mobilizing mathematics: how technology enhances embodied learning. ***Stefan Rothschuh*** (Canada).
[13] The reading and the comprehension of mathematics text: an eye-tracking study with primary pre-service teachers. *Roberto Capone, Federica Ferretti, Alessandro Gambini, and* ***Camilla Spagnolo*** (Italy).
[14] Computational thinking for mathematical learning. ***Yahya Tabesh*** (USA).
Part 2
[15] Students' understanding of the notion of collinear vectors in dynamic geometry environment. ***Jose Orozco-Santiago*** (Mexico).
[16] Enhancing metacognition by using flipping classroom with GeoGebra. ***Chak-Him Fung****, Kin-Keung Poon, and Michael Besser* (Hong Kong SAR, China).
[17] Students coping with a post-16 mathematics course: flipped learning, self-regulation and technology. ***Sofya Lyakhova****, Marie Joubert, and Dominic Richard Oakes* (UK).

2.3.1. Session 3 part 1

The first part of the third session was dedicated to discuss the research on interactive technologies, particularly Augmented and Virtual Reality, embodiment and reasoning.

Lu et al.[11] addressed the creation and use of VR all-in-one virtual simulation software and hardware platform as an alternative to overcome the limitations of traditional online technologies. They used VR head display and VR glasses in students' collaborative interaction and integration in mathematics teaching at upper secondary level, building a mathematics VR teaching design mode, including: resource selection, interaction design, development and innovation.

Their team constructed the high school mathematics teaching design mode assisted by VR all-in-one computer, and would address more studies towards the extended practice of mathematical maker education, teachers and students could carry out interdisciplinary inquiry learning practice.

Rothschuh[12] discussed the theoretical considerations and the practical implementation of a research on technologically enhanced embodied mathematics learning. It sought to study and improve the practice of learning and teaching mathematical functions at the secondary level by incorporating embodied learning designs. It drew on established theories of how individuals learn mathematics, recent developments that aimed to incorporate embodiment and technology in mathematics learning processes, and the desire to study learning where it naturally occurs, as the long paper by Alberto et al.[3]. Using a design-based research approach, the researcher and partnering teachers developed and implemented a set of technologically enhanced embodied lesson designs. Over the course of three iterations, the lesson designs were continuously revised and improved, to promote embodied learning of the function concept, and harmonize technology-integration in these learning environments. It showed how calculus became meaningful for modeling everyday experiences in technologically augmented classroom inquiry, rather than being a domain that is merely focused on number and calculation.

Capone et al.[13] dealt with the type of text — by using eye track tools — to investigate students' attention during reading tasks. It pointed out that, being recognized in literature, the central role of argumentation in the teaching-learning process and the type of text affecting students' reading, the use of eye-tracking might render it possible to understand students' reading of a mathematical text. In particular, we may understand if selective readings with a focus on some textual elements considered essential may lead students to a lack of understanding of the problematic situation. The research, carried out with the innovative tool of eye track, shows a first exploratory study conducted with primary pre-service teachers while dealing with mathematics texts.

Tabesh[14] presented an intuitive digital learning model, focused on problem-solving through computational thinking and is targeted to empower teenagers. The proposed model is a hands-on interactive web platform for mathematical problem-solving that enables creative engagement, develops mathematical skills, and supports a growth mathematical mindset. It illustrated the benefits arising from engaging youth with progressively more complex tasks and giving them increased ownership of their learning. As a theoretical foundation, the development teams consider the use-modify-create framework to offer a helpful progression for developing mathematical thinking. It presented a computational thinking playground and a functional programming paradigm in a platform for creative problem-solving. In the platform one can use models and simulations to represent phenomena which, by playing with a mathematical framework, will be learned through creative and innovative thinking. The gained knowledge and skills of this cognitive learning both empower learners and enhance creativity.

After all the presentations, the discussion started by the following three questions:

- What advances can the use of interactive technologies provide to research in Mathematics Education?
- How can interactive technology be used in mathematics education? How to use or combine embodiment, virtual reality, augmented reality, particularly when solving mathematical problems?
- What is the role of these environments in the development of computational thinking itself?

Motivated by the third presentation — that highlighted innovative tools for research methodology advances — the first discussion question supported reflections on different lines of innovation in the studies. It used eye-tracking contact with the text as a tool to collect data for the study about argumentation. It led us to question the processes shown by tracks. The first presentation focused on the advances regarding cognitive development by using VR devices. The second and fourth presentations focused on developing tools. The second regarded a model of lesson design with embodiment technology. The fourth was a playing platform to support students' problem-solving. The second discussion question was motivated by the different uses and the variety of interactive technologies such as Virtual Reality all in one computer and computing thinking, creativity on embodied cognition with the integration of technology and graphs generation through movements linked to the classification of gestures. However, the uses are more isolated for a while. The fourth presentation led to our third discussion question. The TSG-26 discussion to reach the importance of computational thinking incentive through a platform to solve problems; using interactive games. Nonetheless, we need more research on tasks and students' work associated with these innovative tools to improve mathematical learning.

2.3.2. Session 3 part 2

The second part of the session was focused on the ways (i.e. flipped classroom) of using dynamic geometry software to promote students' understanding and teaching effect. Orozco-Santiago[15] proposed a contribution to the current/new frameworks for developing and analyzing new technologies integration in mathematics teaching and learning from didactical, cognitive and epistemological perspectives. They designed the tasks considering the potential of the dragging tool in a dynamic geometry environment. The tasks were assigned in a linear algebra course in engineering, and the work of one student in France was analyzed, as a case study, to examine the actions instrumented under the framework of instrumental genesis. They showed that the suggested design supported the student to explore what remains invariant under dragging, and to conjecture about the meaning of collinearity.

Fung et al.[16] followed a quasi-experiment design to study the Flipping Classroom (FC) assisted by GeoGebra to increase Chinese college students' mathematical metacognition in comparison to FC assisted by video and/ or direct instruction. The result revealed that the main effect of the metacognition was significant, while the interaction between the metacognition and the teaching methods was not significant. It suggested that significant improvement could be observed among students but no significant difference could be observed among the teaching methods in terms of the metacognition. In other words, the FC supported by GeoGebra is an effective teaching method in terms of students' metacognition development.

Lyakhova et al.[17] interviewed sixteen students from two research projects in the UK which employed technology to compensate for the lack of in-school resources (advanced post-16 mathematics course). The study showed the evidence that technology could create new learning situations as well as new learning materials that students perceive as beneficial, although perhaps an effort is required from students (i.e., self-regulation skill) to successfully adapt to these.

Inspired by the three reports mentioned above, our panel discussion focused on the following two areas:

- What is the theory behind dynamic geometry software to promote students' understanding of geometric concepts?
- How to effectively improve the effectiveness of flipped classroom teaching?

The discussion of the first question revealed the challenges that iterative updates in technology pose on how to study the effectiveness of classroom instruction that incorporates information technology, and that research on this issue needs to be supported by further theoretical exploration. The discussion of this problem focused on how to develop theoretically relevant assessment frameworks to track students' development in mathematical thinking at a higher level. The second discussion topic focused on the popular flipped classroom model, in which participants were very concerned about how to improve students' self-discipline and initiative in the flipped classroom? The effective use of flipped classrooms requires a change in students' attitudes toward learning. On the one hand, the content of the flipped classroom needs to be carefully designed, and on the other hand, the improvement of students' self-learning ability, an issue that involves further exploration of meta-cognition such as self-monitoring and self-evaluation.

3. Poster Presentations

In a special session, ten posters also composed TSG-26 studies with researchers from Belgium, Cambodia, China, Morocco, Nepal, and Peru (Tab. 4).

Tab. 4. Posters with TSG-26

Poster and author(s)
[18] The study of mathematic classroom teaching integrated information technology and mathematic multirepresentations. ***Hua Wu*** (China).
[19] A blended approach to support aspiring engineering students. ***Paul Georges Igodt*** (The Netherlands).
[20] The study of mathematical multi-representations and teaching scaffolding in the smart-classroom environment. ***Na Han*** (China).
[21] Integration of ICT in modeling and experimentation of interdisciplinary problems. ***My-Lhassan Riouch*** (Morocco).
[22] Instrumentation of the symbolic artifact quadratic function. *Daysi Julissa Garcia Cuellar*.
[23] Application of GeoGebra based on AR/VR technology in high school solid geometry teaching. ***Xue Huang*** (China).
[24] Students self-regulated learning strategies, perceptions and mathematics performance in a mobile technology-integrated mathematics classroom. ***Gerald Cristobal Apostol*** (Nepal).
[25] The effective strategies of teaching trigonometry function using ICT applications: GeoGebra and Wolfram. ***Leangsim Im*** (Cambodia).
[26] Practical research on the application of information technology in function review lectures. ***Xiayan Shao*** (China).
[27] A case study on TPACK performance of Chinese middle school mathematics teachers. ***Huishui Ye*** (China).

These posters also discussed Interactive technologies with a study applying GeoGebra based on AR/VR technology in high school solid geometry teaching by Huang[23]. Multirepresentation was the focus of two posters. Wu[18] discussed IT and its integration into the classroom. Han's study[20] focused on approaching it in a smart-classroom environment with the lens of teaching scaffolding. As for different teaching methodologies, Igodt[19] presented a blended approach specially built to support students aspiring to study engineering, and Riouch[21] discussed interdisciplinarity as modelling and experimentation of interdisciplinary problems. Regarding the instrumental approach, Cuellar[22] presented an analysis of the instrumentation of the symbolic artifact quadratic function. Mathematics functions were also highlighted by Im[25], while discussing the effectiveness of a teaching trigonometry function approach using GeoGebra and Wolfram. As for the literature on ICT integration, Shao[26] showed a review of practical research on the application of IT in Function. Apostol's paper[24] about self-regulated learning strategies, perceptions, and mathematics performance in a mobile technology-integrated mathematics classroom represented students' learning study. Finally, on the side of teachers' knowledge, Ye[27] presented a case study on the TPACK performance of Chinese middle school mathematics teachers.

4. From the Past to the Future: Challenging Themes of Discussion

The TSG-26 has been the occasion for contrasting, discussing, and comparing different themes with arguments in relation to theories, to teachers' education and engagement, and to students, in relation to the use of technologies in educational settings.

What emerged in relation to theories is the use of TPACK to investigate teachers' knowledge, when they are engaged in design cycles, or the new emerging approach of boundary crossing between communities, when speaking of a methodological tool to favor deep understanding: MERLO item. Commognition theory seems to have a fundamental role in analyzing the learning present in virtual reality context. Likewise, the notion of praxeology — including the particular case of meta-didactical praxeologies — was the key element to analyse the involvement of students in designing digital curriculum resources, and to outline the evolution of teachers' interactions when designing learning objects. More than in the past studies, recently the importance of explicitly defining the role of the teacher in multiple didactical tasks, and their engagement in design/use/orchestrate mathematical activity emerges in the papers and posters presented. And, moreover, the students' role has been addressed with a higher level of engagement and sharing of responsibility: not only in solving tasks, but also both in co-designing tasks and in being engaged in the assessment process with more awareness. Here the notion of instrumental orchestration (Trouche, 2004) becomes relevant to establish and organize the conditions that favor the involvement of students and the sharing of responsibility for their learning. This gaining in responsibility of teachers and students is possible also thanks to the technology used, which mediates the participation in common activities, and gives immediate feedback of the actions done. Technologies such as dynamic software, or Web 2.0 environments give the educational support to learning and teaching mathematics in many different kinds of activities: inquiry tasks from simple variation to co-variation situations. Also technologies for embodied approaches that detouch motions/eye movements/virtual exploration are providing us with empirical data that support new ways of looking at the construction of knowledge.

These tools and the data that they produce have the potential to offer a fresh look at the study of the complexities of mathematics teaching and learning. Future research in this area could address how these technologies can be integrated into the rapidly changing instructional landscape.

Topic Study Group 27

The Role of History of Mathematics in Education

Ysette Weiss[1] and Desiree Agterberg[2]

1. Rationale and Aim of the TSG

Mathematics is a human intellectual enterprise with a long history and a vivid present. Thus, mathematical knowledge is determined not only by the circumstances in which it becomes a deductively structured theory, but also by the procedure that originally led or may lead to it, and which is indispensable for understanding processes of change in mathematics. Therefore, learning mathematics includes not only the "polished products" of mathematical activity but also the understanding of (implicit) motivations, the sense-making actions, and the reflective processes of mathematicians, which aim to the construction of meaning. Hence, teaching mathematics should include giving the opportunity to students to "experience mathematics in the making." That is, although the "polished products" of mathematics form that part of mathematical knowledge that is communicated, criticized (in order to be accepted or rejected), and serving as the basis for new work, the process of producing mathematical knowledge is equally important, especially from a didactical point of view. This perception of mathematics should be central in the teaching of mathematics, and the image of mathematics communicated to the outside world. In this perspective, putting emphasis on integrating historical and epistemological issues in mathematics teaching and learning constitutes a possible natural way for exposing mathematics in the making that may lead to a better understanding of specific parts of mathematics and to a deeper awareness of what mathematics as a discipline is.

TSG-27 aims to provide a forum for participants to share their research interests and results, as well as their teaching ideas and classroom experience in connection with the integration of the history of mathematics in mathematics education. Special care is taken to present and promote ideas and research results of an as broad as possible international interest, while still focusing due attention to the national aspects of research and teaching experience in this area. Every effort will be made to allow researchers to present their work, get fruitful feedback from the discussion, and stimulate the interest of newcomers by giving them the opportunity to get a broad overview on the state-of-the-art in this area. This TSG refers to all levels of education

— from primary school to tertiary education, including in-service teachers' training — preferably on work and conclusions based on actual classroom experiments and/or produced teaching and learning materials.

1.1 Submissions

We received 41 submissions from 16 countries (South America: 2; North America: 5; Asia: 23; Europe: 10; Africa: 1). Of those 41 submissions, 6 were rejected, 2 were redirected to another TSG, 6 were accepted as poster and 27 were accepted as paper presentations (long or short). The main part of the review process was organized and carried out by former TSG Chair Kathleen M. Clark, former Co-Chair Constantinos Tzanakis and former team member Uffe T. Jankvist.

Three papers were withdrawn by the authors after the postponement of the conference.

Of the remaining 24 accepted papers and 6 posters, only 13 papers and 2 posters were able to be presented during the conference. A list of the papers and authors are included in order of presentation and are organized in Tab. 1:

Tab. 1. List of papers presented

Paper and author(s)	
[1]	Methodological proposal for the analysis of historical sources of mathematics. ***Erika Zubillaga-Guerrero****, Flor Monserrat Rodríguez-Vásquez* (Mexico)*, and María Teresa González-Astudillo* (Spain).
[2]	Towards qualitative and participative research on history of mathematics in mathematics education: some arguments and possible paths. ***David Guillemette*** (Canada).
[3]	The application of HPM micro-video in the teaching of the binomial theorem. ***Jiaye Han*** (China).
[4]	The design and cases of primary school HPM micro-video. ***Zhuochen Li*** *and Jiaye Han* (China).
[5]	Combining cognitive demand with history of mathematics in mathematics (teacher) education. ***Desiree Agterberg*** (The Netherlands).
[6]	The Gradual Linearization of German Geometry Teaching. ***Ysette Weiss*** (Germany).

1.2 Sessions

A new team was formed to organize the hybrid sessions in which the papers were presented. The TSG Chair Ysette Weiss, Co-Chair Desiree Agterberg and team member Silvia Schöneburg-Lennert led the sessions. The sessions were attended by at least 21 participants. This number does not account for some of the live audience in the Shanghai conference room that were not on the list of authors nor paid participants for TSG-27.

The ICMI organizing committee granted our TSG four timeslots for presentations. Generally, all four sessions started with one or two 15 minutes *long* oral presentations and a discussion afterwards and one or two 10 minutes *short* oral presentations with collective discussion afterwards. At the end of our last session, we did a short group reflection.

2. Conference Themes

The thematic call for proposals for TSG-27 was broad and reflected main research areas in the history of mathematics in mathematics education:

- Theoretical and/or conceptual frameworks — in particular from general mathematics education research — for integrating history in mathematics education;
- History and epistemology implemented in mathematics education: Classroom experiments and teaching materials, considered from various perspectives; e.g., cognitive, didactical, pedagogical, affective, etc.;
- Surveys on the history of mathematics as it appears in curriculum and/or textbooks;
- Original sources in the classroom, and their educational effects;
- The role of history of mathematics in relation to the use of digital technologies in the teaching and learning of mathematics;
- History and epistemology as a tool for an interdisciplinary approach in the teaching and learning of mathematics and the sciences by unfolding their productive interrelations;
- Cultures and mathematics fruitfully interwoven.

Almost all presentations contributed not only to one of these subject areas, but affected several topics. The introduction to a conceptual frame for the inclusion of the history of mathematics and mathematics teaching in the teaching of mathematics was often accompanied by the discussion of its implementation, the display of empirical results and the consideration of possible educational effects of the use of historical sources as a tool.

Guillemette[2] reflected in his contribution on existing theoretical frameworks and their potentials and limits. Conceptual frameworks were also in the focus of the contribution by Zubillaga-Guerrero et al.[1]. They presented a methodology for the qualitative analysis of historical sources and demonstrated their tool in the analysis of the concept of isomorphic groups in Arthur Cayley's work. Agterberg[5] introduced a cognitive demand framework that she developed for the analysis of tasks and classroom activities involving historical facts and sources and illustrated it with various examples. As the discussion showed, in several European and Asian countries there is an increasing involvement of history of mathematics in mathematics lessons and school curricula. Associated with this, one can find a growing number of contributions in mathematics textbooks that take the history of mathematics into account in varying ways.

Three contributions were directly devoted to curricular developments in textbooks, but in very different ways: in Weiss' study[6] of representations of conic sections in mathematics textbooks and curricula during the last 150 years, the focus was on the connections between institutional and curricular reforms. Lei's comparative textbook analysis[13] of high school mathematics textbooks in Chinese mainland and Chinese Taiwan concentrated on the integration of mathematics history. It was shown that the differences in the two editions were mostly related to applications. Yu[10] analysed 20 lessons from 2012–2018, regarding the implementation of the intention of mathematical culture in the reformed senior high school mathematics curriculum. All three contributions also examined the development of conceptual frameworks for the selection of curricular content.

Three papers with different emphases addressed the use of the history of mathematics to promote the understanding of mathematical concepts. Liu and Shen[7] studied the development of students' conceptual understanding of the concept of a function, using milestones of the historical development of this concept. Shen and Zou[11] presented a study on the development of teachers' mathematical knowledge over a semester at the HPM Studio in Shanghai.

The contributions by Li and Han[3,4] on the use of history-based micro videos (HPM micro-videos) in the teaching and learning of mathematics dealt with history of mathematics in relation to the use of digital technologies. The study focused on strengthening the motivation to learn mathematics and the selection of suitable topics for the promotion of general educational aspects. Jiang[12] presented a study, which also aimed on strengthening motivation, improvement of self-efficacy and changing beliefs, but this time in the context of an HPM teacher professional development program. The empirical study, he carried out, served him as a starting point for further conceptual development of this program.

In the contribution by Schöneburg-Lennert and Krohn[8], as well as in the contribution by Soto-Andrade et al.[9], the use of historical sources in mathematics lessons was foregrounded. The first contribution on the Organum Mathematicum presented teaching material from the 17th century and its educational potential. The second presentation of intercultural history of the concept development of the binary tree, beginning in ancient China in the 11th century up to the present, showed a variety of inspiring, enlightening and educational possibilities to approach mathematics and related subjects.

The great diversity of the presented historical sources made for an interesting and inspiring discussion. The wide range of implementations, which included primary and secondary education as well as university education and in-service teachers' training, also enabled a holistic view of mathematical-historical education.

3. Areas for Future Research

The topics discussed in the TSG-27 "The Role of the History of Mathematics in Mathematics Education" reflect actual research areas and significant recent scientific development in mathematics education.

The great importance of action and developmental research in our group raised the question of new formats with an international reach.

Another new accent was set by the question of possible cooperation between historians of mathematics, mathematicians, mathematics educators and mathematics teachers.

Since many topics that are relevant in other TSGs are also relevant to our TSG, the question of cooperation with other TSGs arose. A lot of TSGs come to mind, such as the teaching and learning of algebra/geometry/calculus, teacher education, mathematics and interdisciplinary education, the use of technology and so on. For example, digital media offer new opportunities to have historical sources more easily accessible in the classroom. This opens up new possibilities for accessing historical materials, for instance virtual museum tours or film material. Tools such as GeoGeobra can be used to rediscover Greek geometry or transcendental curves.

Topic Study Group 28

Preservice Mathematical Teacher Education at Primary Level

Salvador Llinares[1], Craig Willey[2], Hui Jiang[3], Rukiye Didem Taylan[4], and Ban Heng Choy[5]

ABSTRACT The rationale of TSG-28 was to engage participants in reflection on, and discussion of, the theoretical, empirical and practical issues. Twenty-five papers were reported, from twelve countries showing a great diverse cultural. The papers were grouped in four themes: Noticing, Preservice Teachers' Learning, Preservice Teachers' Knowledge, and finally one group with various issues (Other: University-school partnership, beliefs, and textbooks).

Keywords: Preservice primary teachers; Noticing; Knowledge; Learning; Beliefs; University-school partnership.

1. Background and Rationale of TSG-28

It is a multi-faceted task to prepare preservice teachers of mathematics (PSTs) to conduct high-quality teaching. Many agree that teaching competence is not based merely on PSTs' academic qualifications, and consequently the concern for problems of practice has grown in programmes for teacher education. This is evidenced, for instance, in attempts to reconsider the knowledge needed in instruction; to work with representations of practice in college-based parts of programmes; to have prospective teachers rehearse and plan for instructional activity while at college; and to capitalize on prospective teachers' field experiences. This links research and development in mathematics teacher education (MTE) to scholarship on teaching and raises issues of (1) what high-quality instruction entails in different contexts and (2) how prospective teachers may develop their capacity to conduct teaching accordingly under different circumstances. In spite of the common interest in preparing PSTs for practice, it is still contentious how best to do so, and the answer to this question may vary across contexts. The rationale of TSG-28 was to engage participants in reflection on, and discussion of, the theoretical, empirical and practical issues.

Twenty-five papers were reported in this TSG (add two posters), from twelve countries showing a great diverse cultural. The papers were grouped in four themes: Noticing, Preservice Teachers' Learning, Preservice Teachers' Knowledge, and finally one group with various issues (University-school partnership, beliefs, and textbooks). TSG-28 had assigned two time slots of 120' and two time slots of 90'. Authors of papers presented key points from their work and for each theme one member of the team synthesized the relevant aspects and underlined differences and similarities (Tab. 1), and all the contributions to TSG-28 are listed in Tab. 2 (on the next page).

Tab. 1. Themes and countries

TOTAL	**7**	**5**	**8**	**5**	**25**

2. Noticing

Mathematics teacher noticing is a set of core practices through which teachers interact with the different aspects of a teaching situation. Conceptualizing it and understanding how it develops are the focus of some papers discussed. The studies about noticing focused on three aspects: factors influencing the preservice teachers' reasoning process involved in noticing; on the relationships between different skills such as attending to, interpreting and decision making; and on the design principles of tasks to enhance noticing.

Firstly, the papers discussed how PSTs attend to the students' answers to mathematics problems and which factor might or might not influence their interpretations. This set of papers makes explicit the relationship between the PSTs' reasoning process and their decision making. So, Laschke et al.[4] examines the explicit criteria that PSTs refer to when confronted with an unexpected student solution of a probability problem and to which extent these criteria are influenced by students' social status background. The findings showed that although PSTs mostly used content-specific criteria, also implicit criteria were relevant as evaluations of student work were biased by students' social background.

Tab. 2. List of papers presented

Paper and author(s)	
Noticing	
[1]	A study on written feedback on preservice teachers' teaching practices and its impact on noticing. *Müjgan Baki and Zeynep Medine Özmen.*
[2]	Designing tasks for support preservice primary teachers' noticing of geometrical thinking. ***Melania Bernabeu***, *Mar Moreno, and Salvador Llinares* (Spain).
[3]	Relationships between preservice teachers' knowledge and their responses to students errors: Making word problems for the concept of division. ***Qintong Hu*** (China), *Lynn Hodge, and Shande King* (USA).
[4]	How preservice teacher judge and unexpected student solution — explicit and implicit criteria. ***Christin Laschke***, *Bettina Rösken-Winter, and Sven Schüler* (Germany).
[5]	An analysis of preservice teachers' noticing of student pattern generalization strategies. ***Ji-Eun Lee*** *and Mi Yeon Lee* (USA).
[6]	Prospective teachers' noticing of student's algebraic thinking: Pattern generalization. ***Zeynep Özel***, *Mine Işiksal-Bostan, and Reyhan Tekin-Sitrava* (Turkey).
[7]	Developing preservice teachers' noticing of productive struggle with video analysis. *Hiroko Warshaue*, **Christina Starkey**, *Christine Herrera, and Shawnda Smith* (USA).
Preservice teachers' learning	
[8]	Preservice Mathematics Teacher Education for the Montessori Teachers. ***Kinful Lartebea Aryee***, *Immaculate Kizito Namukasa, and Marja Bertrand* (USA).
[9]	Tracing threads of awareness in initial teacher education: peer-collaboration. ***Gwen Ineson, Julie Alderton***, *Chronoula Voutsina, Kirsty Wilson, Gina Donaldson, and Tim Rowland* (UK).
[10]	Preservice teachers designing meaningful digital learning environments using makerspaces for math. ***Anjali Khirwadkar*** *and Candace Figg* (Canada).
[11]	Exploring pre-service teachers' mathematics learning experiences and self-efficacy in teaching primary level mathematics. ***Sangyeon Park*** (USA).
[12]	Where the journey to reflective practice begins: A case of preservice teachers. ***Chikiwa Samukeliso*** *and Graven Mellony* (South Africa).
Preservice teachers' knowledge	
[13]	Exploring how prospective teachers pose problems: The case of $\mathbf{8 \times (-2)}$. ***Miguel Angel Montes***, *Juan Pedro Martin, Maria Isabel Pascual, Nuria Climent, and Jose Carrillo* (Spain)
[14]	Integrating EDTPA Preparation in a methods of teaching elementary mathematics course. ***Norma J. Boakes*** (USA).
[15]	Contribution of a didactic course on the development of primary preservice teachers' knowledge of Measurement and Geometry. ***Israel García-Alonso***, *Josefa Perdomo-Díaz*, ***Diana de las Nieves Sosa-Martín*** (Spain).
[16]	Using Technology for virtual representations of Teaching for developing math talk during problem solving. ***Melva R. Grant*** *and Signe Kastburg* (USA).
[17]	Torpedo: A Digital learning environment for developing mathematical problem-solving ability in primary teacher education. ***Marjolein Kool*** *and Ronald Keijzer* (The Netherlands).
[18]	Design of a learning unit for preservice elementary school teachers: definition of the boundary of a 2D Shape. ***Alejandro López***, *Salomé Martínez, Aldo Ramírez, and Ricardo Salinas* (Chile).
[19]	Explanatory talk in the teaching of number concepts and operations to preservice teachers: A case of one mathematics teacher educator. ***Justina Longwe-Mandala*** (Malawi).
[20]	Preservice teachers' conceptual understanding of fraction: Implications for improving curriculum Standards and classroom practices. ***Suhaidah Tahir***, *Masami Isoda, Munirah Ghazali, and Dominador Dizon Mangao* (Malaysia).
University-school partnership, reliefs, and textbooks	
[21]	In what ways does a mathematics curriculum based on the theory of multiple intelligences affect the attitudes and beliefs of preservice elementary school teaches toward mathematics? ***Mark Arvidson*** (USA).
[22]	Mathematics workshops: Changing the perceptions of both inservice and prospective teachers with regard to mathematics. V*alentina Celi* (France), *José Ignacio Cogolludo, Raquel García Catalán, Elena Gil Clemente,* ***Inmaculada Lizasoain*** (Spain), *Ana María Millán Gasca, and Luigi Regoliosi* (Italy).
[23]	School University Partnership in Mathematics Teacher education: How Prospective Mathematics Teachers view their experiences. ***Rukiye Didem Taylan***, *Zelha Tunç-Pekkan, and Mustafa Özcan* (Turkey).
[24]	Building a university-school partnership: from early missteps to emerging success. ***Ryan G. Zonnefeld*** *and Valorie L. Zonnefeld* (USA).
[25]	Features of exemplary lessons over different decades: A comparative analysis of eleven elementary mathematics lessons in China. ***Dongchen Zhao*** *and Yunpeng Ma* (China).

Other three papers focused on how PSTs decide what to do next in teaching based on their interpretations of students' mathematical thinking. Lee and Lee[5] examine the characteristics of elementary PSTs' attention to students' work in order to suggest how to follow up in supporting the students' progress. They conclude the lack of sophistication in the analysis of student thinking influence how PSTs decide about the teaching. Hu et al.[3] revealed the difficulties of PSTs to pose word problems for the measurement model of the concept of division and respond to students' errors. Also, Özel et al.[6] indicated that PSTs had difficulties in interpreting students' algebraic thinking, but they could support the student's algebraic thinking when the solution was incorrect by asking follow-up questions. These studies underline two aspects. First, the complex relationships between the skills of attending to students' mathematical thinking and how to support the student's progress. Secondly, the relationship between PSTs' knowledge and their reasoning processes

The findings of these studies suggest the important role of professional tasks in PST noticing skills in mathematics education. A third set of papers focused on aspects to enhanced noticing. Bernabeu et al.[2] provide designing principles for the tasks in primary teacher education that are designed to enhance the core practices which constitute professional noticing. The authors consider three dimensions: a sociocultural perspective of PSTs' learning, the necessary introduction of information about the development of students' mathematical thinking (e.g. learning trajectories of mathematical topics), and practical registers from mathematics teaching (e.g., a set of students' answers indicating different features of students' development). Baki and Özmen's paper[1] underlines the impact on noticing of the written feedback that preservice teachers received. Finally, Starkey et al.[7] underlined the role of providing PSTs with a framework about noticing. Their findings suggest that the use of a productive struggle framework helped PSTs develop a language for discussing.

3. Primary Level Preservice Teachers' Learning

Five papers focused on PSTs' learning using different theoretical frameworks and with specific foci. One common aspect of these papers is to identify specific intervention (or contexts) that influence PSTs' learning.

Inesson and colleagues' study[9] draws on aspects of enactivism and the notion of reflective spection to trace threads between PSTs' retrospection of their own learning and pro-spection of their approach to teaching. The findings suggest the importance of collaboration in 'seeing' what others 'see' and its influence on PSTs' own teaching. Aryee and colleagues' study[8] underlines the role played by the Montessori mathematics-for-teaching training on how teachers organize and prepare classroom learning environments. Samukeliso and Mellony[12] focused on the PSTs' reflective practice to identify its influence on learning. Park's study[11] underlines the role played by the mathematics content courses in reforming the PSTs' self-perceived competence in the mathematical concepts and in teaching mathematics to students. Finally, Khirwadkar and Figg's study[10] focuses on how to prepare PSTs for teaching in digital classrooms to create meaningful digital learning experiences. This study introduces makerspaces to PSTs and analyses how PSTs connect mathematics teaching and makerspaces experiences.

Globally these studies underline different types of activities influencing the PSTs' learning and their approaches to teaching. Some of these activities are the collaboration in seeing what others see when analyzing mathematical tasks as tools for teaching; the nature of their own experience as mathematics learners influencing on their self-perceived competence; participating in a training with a specific approach (e.g. Montessori teacher education system); and participating in a reflective practice in the context of video-based lesson analysis.

4. Primary Level Preservice Teachers' Knowledge

PSTs' knowledge and features of learning environments aimed to improve the PSTs' knowledge was the focus of eight papers. What PSTs should learn and in which environments are presented from different perspectives and relationships. For example, PSTs' knowledge about posing problems or about the knowledge necessary to teach mathematics (and how we can measure them). Other papers focus on the features of learning environments for enhancing the reflective activities and its relation with problem solving ability, or to learn to facilitate productive math talk during problem solving.

Montes et al.'s study[13] focuses on how prospective teachers pose problems involving a specific operation with negative numbers. The findings showed inconsistencies in the problems posed by the prospective teachers (regarding the relationship between negative numbers and the contexts). Also, Tahir et al.[20] analyzed PSTs' conceptual understanding and pedagogical content knowledge in teaching fractions. Boakes' study[14] presents how to prepare the PSTs for the mathematical aspects of the performance-based assessments that measure PSTs' pedagogical competencies. Garcia-Alonso et al.[15] reported the results of a study aimed to measure the primary PSTs' geometric and measurement knowledge. Globally, these studies support the hypothetical relationship between teacher's knowledge and the development of teaching skills (such as planning the mathematical lessons).

Features of different approaches to improve PSTs' knowledge are the foci of other group of papers. Kool and Keijzer[17] presented a digital learning environment (TORPEDO) for developing PSTs' mathematical problem-solving abilities. The environment enhanced the PSTs' reflections after solving non-routine mathematics problems. The relationship between how PSTs perceived that the reflection contributed to their problem-solving ability was analyzed. Also, Grant and Kastburg[16] analyzed how the participation in a virtual teaching (classroom simulation environment) help PSTs to facilitate productive math talk during problem-solving. The teach-reteach approach to microteaching within a simulated representation of practice using avatars as students seem to support the PSTs' knowledge of how facilitate productive math talk during problem-solving. Lopez et al.[18] presented the features of a learning environment (learning unit) aimed at developing the specific mathematical knowledge involved in the construction and use of a definition of the boundary of 2-D shapes.

Finally, Logwe-Mandala[19] studied the talk of a mathematics teacher educator teaching number concepts and operations to PSTs as a key feature of the learning environments in teacher education programs. Globally, these studies present features of learning environments and the activities generated in them to improve the different dimensions of PST knowledge.

5. Others: University-School Partnership, PST Beliefs, and Textbooks

The foci of five contributions were on contextual and institutional factors such as partnership between university and school; cognitive factors such as beliefs and attitudes, and finally characteristics of the lessons from a textbook. The issue of how to change the PSTs' beliefs and attitudes toward mathematics and its teaching reflects the recognition that PSTs sometimes do not hold productive beliefs or do not have attitudes compatible to support students in primary education. So, some studies have the goal to change PSTs' beliefs and attitudes. Lizasoain and colleagues[22] presented a mathematical workshop to bring the PST mathematical training closer to the school classroom reality. The workshop has as a goal to influence the PSTs' confidence and beliefs about the nature of mathematics and their attitudes towards the mathematics teaching. Arvidson[21] reported a course based on Multiple Intelligences aimed to change the attitudes toward mathematics showing the difficulties of this change.

The school-university partnership in Primary Mathematics Teacher Education is a key issue to the success of the primary teacher training. School-University partnership is the focus of two papers. Taylan and colleagues[23] reported a model of university-school partnership addressed to integrate theoretical knowledge of teaching with school–based practical knowledge. Different forms of school and university partnership experiences and PSTs' views of these experiences are described together. Zonnefeld and Zonnefeld[24] reported the trajectory of how to build the university-school partnership (from early missteps to emerging success).

Finally, Zhao and Ma[25] reported a comparative study on exemplary lessons of primary mathematics over different decades in Chinese mainland using five dimensions in order to identify the influence of the mathematics education reforms. This study reported how mathematics teaching can be reflected in mathematics lessons and how this can influence the practices of primary level teachers.

6. Final Remarks and Future Implications

In TSG-28, we discuss research and development work on MTE, including the underlying assumptions about classroom practice and PSTs' and school students' learning. We also discuss the potentials of, and challenges for, the research endeavour itself, that is, questions concerned with the use of different theoretical frameworks and methodologies.

Topic Study Group 29

Preservice Mathematical Teacher Education at Secondary Level

Olive Chapman[1], Jing Cheng[2], Tracy Helliwell[3], Benita Nel[4], and Immaculate Kizito Namukasa[5]

ABSTRACT Topic Study Group 29 (TSG-29) addressed preservice secondary mathematics teacher education. Its aim was to engage participants in sharing and discussing significant new trends and development in research, theory, and practice related to the various aspects of the initial education of secondary mathematics teachers. This report includes the themes of the TSG, overview of the TSG program, themes of the presentations, and future directions for research.

Keywords: Secondary preservice teachers; Mathematics teacher education; Topic Study Group.

1. TSG-29 Aims and Themes

1.1. Aims

The aim of Topic Study Group 29 (TSG-29) was to engage participants in sharing and discussing of significant new trends and development in research, theory, and practice related to the various aspects of the initial education of secondary mathematics teacher. The intent was to offer a program consisting of an overview of the current state-of-the-art, invited contributions from experts in the field, presentations of high-quality research reports from an international perspective, and discussion of directions for future research. Through this program, participants were expected to learn about and discuss research studies from different countries as well as have opportunity to learn about practices used around the world in relation to the education of preservice secondary mathematics teachers such as similarities and differences in the formal mathematics education of teachers, types and routes of teacher education and pathways

to certification, curricula of mathematics teacher education, and factors that can influence similarities or differences.

1.2. Themes

Five themes were selected to frame the program on Preservice Secondary Mathematics Teacher (PSMT) education and satisfy the aim of the TSG. The call for proposals invited submissions of papers on research that addressed the suggested topics or other related topics for each theme. Tab. 1 consists of the themes and related topics.

Tab. 1. TSG-29 themes and topics

PSMT knowledge

- Nature of PSMTs' content and pedagogical content knowledge
- Theoretical and methodological frameworks for studying PSMTs' knowledge
- Development of PSMTs' knowledge during teacher education
- Relationship between PSMTs' knowledge and their practices

PSMT professional beliefs and identities

- Theoretical and methodological frameworks for studying PSMTs' professional identities
- Experiences contributing to the development of PSMTs' identities
- Experiences contributing to changes in PSMTs' professional beliefs during preservice education
- Relationship between PSMTs' practicum teaching and professional identity
- Nature of PSMTs' productive disposition

PSMT field experience

- Effective teaching practices
- PSMTs' experiences in mathematics classrooms and issues related to their school placements
- Mechanisms that foster bidirectional relationships between partner schools and higher education institutions to support PSMTs in their field experiences
- Experiences that PSMTs should have prior to student teaching
- Activities to help PSMTs to become reflective practitioners during student teaching
- Different types of field experiences required for PSMTs' certification
- Best practices for preparing mentor teachers to work with PSMTs

Technologies tools, and resources

- Characteristics of technology, pedagogy and content knowledge (TPACK), development and assessment of PSMTs' TPACK
- Video cases and online interactive environments that support PSMTs' learning
- Mathematics tasks, textbooks, and other curriculum materials to support PSMTs' learning
- Assessment tools used in PSMTs' mathematics education programs
- Tasks to assess PSMTs' mathematics knowledge for teaching

Teacher educator knowledge

- The nature of mathematics teacher educators' knowledge for teaching PSMTs

2. TSG Program Overview

The TSG-29 program was based on the proposals submitted and the presenters who were able to participate in the online sessions. The following overview of the program outlines the TSG's submissions, format, presentations, and presentation themes.

2.1. Submissions

The call for submissions to the TSG resulted in 51 proposals: four from invited presenters, 40 for oral presentations, and seven for poster presentations. The paper and poster proposals were reviewed by two reviewers — one from the organizing team and one from the list of authors. Based on the reviews, 17 papers were accepted as long oral presentations, 18 as short oral presentations, and 12 as posters. The invited paper proposals were reviewed by the organizing team to provide feedback to the authors. The final breakdown of the 51 proposals accepted consisted of: 4 invited presentations; 17 long oral presentations; 18 short oral presentations; and 12 poster presentations.

2.2. Format

The initial plan was to structure the TSG program based on the TSG themes (Tab. 1). However, this plan was revised when several participants indicated that they were not able to attend the online conference. The remaining papers were not well distributed among the TSG themes, which made organizing them into meaningful discussion groups across the three sessions impractical. The final format of the program consisted of individual presentations ranging from eight to 20 minutes depending on whether long or short oral or invited. There was limited interaction and discussion of questions due to the tight timeframes for the presentations and the online setting. Each session was opened by the chair of the organizing team, Olive Chapman, and chaired by one of the team members. For the first session (120 minutes), Tracy Helliwell chaired the first hour with five presentations and Jing Cheng chaired the second hour with five presentations. Benita Nel chaired the second session (90 minutes) with six presentations and Immaculate Namukasa chaired the third session (90 minutes) with six presentations.

2.3. Oral presentations

Of the 39 accepted oral presentation submissions to the TSG, only 22 were presented during the online conference because some authors were unable to attend. Tab. 2 consists of the oral presentations given at the conference. In the table, IT stands for Invited Talk, LO for Long Oral presentations, and SO for Short Oral presentations. It is organized alphabetically within the different categories of presentations. Each session consisted of at least one invited presentation, one long oral presentation, and two short oral presentations.

Tab. 2. TSG-29 Oral presentations

Paper and author(s)	
[1]	Using multiple scripting tasks to probe preservice secondary mathematics teachers' understanding of visual representations of function transformations. ***James Mendoza Álvarez***, *Theresa Jorgensen, and Janessa Beach* (USA). (IT)
[2]	Measuring prospective secondary mathematics teachers' knowledge. ***Kim Beswick*** (Australia). (IT)
[3]	A case study on the development of pedagogical design capacity of mathematics prospective. ***Meiyue Jin*** (China). (IT)
[4]	Mentor teachers as inductors of preservice mathematics teachers at secondary schools. ***Kakoma Luneta*** (South Africa). (IT)
[5]	Developing an identity as a mathematics teacher: connecting with the community of teacher graduates. ***Judy Anderson*** *and Debbie Tully* (Australia). (LO)
[6]	Teacher educators' use of technology to represent instruction. ***Daniel Chazan*** *and Patricio Herbst* (USA). (LO)
[7]	Tertiary and secondary mathematical knowledge for prospective teachers: a comparison of teacher employ-ment tests for secondary math in Korea and China. ***Xiaoying Chen*** *and Bomi Shin* (South Korea). (LO)
[8]	Developing preservice teachers' ability to enact formative assessment for mathematical practices. ***Jacqueline Coomes*** (USA). (LO)
[9]	A situated approach to assess prospective mathematics teachers' professional competencies. ***Le Thi Bach Lien*** *and Tran Kiem Minh* (Vietnam). (LO)
[10]	Transforming secondary mathematics teacher preparation: a multi-dimensional problem. ***Gary Martin*** *and Marilyn E. Strutchens* (USA). (LO)
[11]	Instrumental genesis and the growth of preservice secondary mathematics teachers' technological content knowledge. ***Xiangquan Yao*** (USA). (LO)
[12]	Prospective secondary mathematics teachers' learning of problem solving and modelling for teaching. ***Olive Chapman*** (Canada). (SO)
[13]	Direct and indirect effect sizes on secondary mathematics teacher candidates' content knowledge & pedagogical content knowledge as measured by national examinations. ***Jeremy Zelkowski*** *and Tye Campbell* (USA). (SO)
[14]	Emotional awareness and support for preservice teachers during micro-teaching. ***Réka Szász*** (Hungary). (SO)
[15]	Teacher candidates' and mentor teachers' perspectives of using co-planning and co-teaching during clinical experiences in secondary mathematics. *Ruthmae Sears,* **Cynthia Castro-Minnehan**, *Laurie Riggs, Pier Junor Clarke, Jamalee Stone, Charity Cayton, Maureen Grady, Jennifer Oloff-Lewis, Patricia Brosnan, and Marilyn Strutchens* (USA). (SO)
[16]	Should school and university mentors agree in their feedback to pre-service mathematics teachers? ***Viren Ramdhany*** (South Africa). (SO)
[17]	Physical representations and understanding of multivariate functions. ***M. Kathleen Heid*** *and Matthew Black* (USA). (SO)
[18]	Developing prospective teachers' knowledge to promote students' mathematical reasoning: design of a teacher education experiment. ***Ana Claudia Henriques***, *Hélia Oliveira, Leonor Santos, and Henrique Guimarães* (Portugal). (SO)
[19]	A case study on applied lesson study for Korean secondary pre-service teachers. ***Na Young Kwon*** (South Korea). (SO)
[20]	Investigating the professional learning of pre-service mathematics education students using reflection and collective feedback to enhance teaching. ***Benita Portia Nel*** (South Africa). (SO)
[21]	Concept cartoon design in preservice teacher training: an opportunity to learn from the practice. ***Cristina Ochoviet*** (Uruguay). (SO)
[22]	Integrating computational making tools in mathematics thinking activities. ***Immaculate Namukasa***, *George Gadanidis, and Derek Tangredi* (Canada). (SO)

2.4. Poster presentations

Of the 12 posters accepted, only six were presented at the conference. The other authors were unable to attend the online conference. The poster presentations occurred during a separate poster session and not as part of the program of this TSG. Tab. 3 consists of the posters that were presented.

Tab. 3. TSG-29 Poster presentations

Paper and author(s)	
[23]	Online live teaching of mathematics methodology course with tencent classroom. ***Peijie Jiang*** *and Bin Xiong* (China).
[24]	Common construction of pre-service mathematics teachers practical capacity. ***Xiaofeng Lan****, Ying Zhou* (China)*, and Tommy Tanu Wijaya* (Indonesia).
[25]	Pre-service teachers problem solving in trigonometry. ***Kristi Renea Martin*** (USA).
[26]	Encouraging student success: exploring the use of technology based pedagogic strategies within mathematics higher education milieus. ***Jayaluxmi Naidoo*** (South Africa).
[27]	Development of TPACK of preservice secondary mathematics teachers. ***Mária Slavíčková*** (Slovakia).
[28]	A didactic model to favor the positive use of error in the initial teacher training. ***Osvaldo Jesus Rojas Velazquez*** *and Carlos Berrío Pérez* (Colombia).

2.5. Themes of oral presentations

The areas of research covered in the TSG oral presentations addressed seven themes regarding PSMT education. Each theme was addressed in different ways by the studies.

Theme 1 studies focused on the development of the knowledge and ability of PSMTs, which received the most attention by the presentations. The studies included investigations of the following topics: (i) Development of the PSMTs' ability to understand and enact formative assessment as a way to leverage mathematical practices for student learning. (ii) Development of the PSMTs' mathematical and didactical knowledge to promote students' mathematical reasoning. (iii) Use of applied lesson study to help PSMTs to learn about teaching. (iv) A technique involving emotion cards used to give emotional support to PSMTs during micro-teaching. (v) Multi-dimensional issues faced by PSMT preparation programs. (vi) PSMTs' learning through designing and using open-ended concept cartoons. (vii) Supporting PSMTs' learning of problem solving and modelling for teaching.

Theme 2 studies addressed measuring PSMT knowledge. They investigated ways of measuring/assessing the PSMTs' knowledge for teaching mathematics; professional competencies for teaching mathematics from a situated perspective; content and pedagogical content knowledge based on national examinations; and mathematical knowledge based on teacher employment tests for secondary mathematics.

Theme 3 studies focused on PSMT field experience. They investigated: (i) PSMTs' learning using reflection and collective feedback of practice teaching to enhance teaching; (ii) practicum experiences of PSMTs supervised by school and university mentors; and (iii) PSMTs' and mentor teachers' perspectives of using co-planning and co-teaching during practicum.

Theme 4 studies focused on PSMT content knowledge. They explored: (i) the PSMTs' understanding of visual representations of function transformations and capacity to connect multiple representations of functions and (ii) the PSMTs' physical representations and understanding of multivariate functions. One study used a method involving multiple scripting tasks to conduct the exploration.

Theme 5 studies focused on PSMT teacher educators. They investigated: (i) a training program around mathematics teacher induction and mentorship of PSMTs and (ii) PSMT teacher educators' use of technology to represent instruction and facilitate collaboration on both teaching and research.

Theme 6 studies focused on PSMTs' use of technology. They explored: (i) PSMTs' integration of "computational making tools" in mathematics thinking activities in teaching mathematics and (ii) types of technological content knowledge emerging in the process of instrumental genesis when PSMTs engaged in problem-solving with the Geometer's Sketchpad.

Theme 7 focused on identity. It consisted of only one study that investigated a strategy to build community of practice to support PSMTs' development of identity as a mathematics teacher.

3. Future Directions for Research

Research on mathematics teacher education continues to be of importance to support international efforts to reform mathematics education for a digital and changing world. As reflected in the number of submissions to this TSG, there is high level of interest in engaging in research on PSMT. The presentations and the themes of the TSG suggest future directions for ongoing research on PSMT. Tab. 4 presents summaries of the TSG themes and the themes emerging from the oral presentations to highlight how they are related. While all of the topics for the TSG themes (Tab. 1) are important to guide future research of PSMT education, the following discussion focuses on aspects of them that overlap with the presentation themes as outcomes of the TSG program with implications for future directions of research.

Tab. 4. Summary of themes of TSG-29 and oral presentations

TSG-29 themes	Themes of oral presentations
PSMT knowledge	Exploring PSMT content knowledge Development of PSMT pedagogical knowledge
PSMT professional beliefs and identities	Development of PSMT identity
PSMT field experience	Field experience
Technologies, tools, and resources	Measuring PSMT knowledge Technology
Teacher educators' knowledge	Teacher educators

PSMTs' knowledge for teaching mathematics (the first TSG theme) is central to teacher education programs. Thus, ongoing research is necessary to offer further insights of the nature of this knowledge and instructional approaches to effectively support the PSMTs' development of it. The TSG presentations included studies that explored PSMTs' knowledge of functions and the use of unique ways of conducting the exploration. The presentations also included studies that investigated PSMTs' development of different aspects of their pedagogical ability (e.g., use of formative assessment; promoting mathematical reasoning) and instructional approaches to support PSMTs' learning of pedagogical knowledge for mathematics (e.g., use of lesson study; emotion cards; concept cartoons). Based on these studies, one implication for future research is consideration of different mathematics content topics associated with secondary school curricula and of innovative approaches to explore these topics to offer alternative ways of understanding PSMT content knowledge for teaching. Another implication is the need for further research to deepen our understanding of: (i) the development of different aspects of PSMTs' pedagogical ability and (ii) innovative, effective approaches to support PSMTs' development of both pedagogical ability and pedagogical content knowledge for mathematical practices.

The TSG theme of PSMT professional beliefs and identities was the least represented by the TSG presentations. One study addressed the development of PSMTs' identity through community of practice. However, while math-related beliefs have received lots of attention in research, the same has not been the case for identity, which is also an important component in defining the mathematics teacher. Thus, identity remains an area that should receive more attention in future research on PSMT.

The TSG theme of technologies, tools, and resources highlights specific ways (e.g., use of digital tools, mathematical tasks, textbooks) of engaging PSMTs in their learning and ways of measuring the level of what they learned or know. The TSG presentations included studies that addressed technology in the context of exploring PSMTs' use of "computational making tools", PSMTs' technological content knowledge, and teacher educators' use of technology in instruction. The presentations also included studies that addressed ways/tools of measuring or assessing content and pedagogical knowledge (e.g., performance measures; a situated perspective framework; national examinations; teacher employment tests). The implications from this group of studies is that more attention is needed on this TSG theme in future research to explore it with more breadth and depth. For example, future research could further investigate innovative and effective ways for integrating technology in teacher education and tools for determining the quality of PSMT mathematics knowledge for teaching to inform teacher education. The current pandemic also opens up the importance of considering and researching its impact on PSMTs' education regarding what technological knowledge they should hold (e.g., regarding remote learning) and how to support their learning of it.

The TSG theme of PSMT field experience highlights another central area of PSMTs' education that requires ongoing attention in research. The TSG presentations included studies that investigated PSMTs' learning using reflection and collective feedback of practicum teaching to enhance it, PSMTs and mentor teachers working together, and joint supervision of PSMTs by school and university mentors. Thus, implications for future research include the need to further investigate innovative, effective ways for PSMTs to learn from their field experiences and the types of practices under university and school advisors that are best for practicum experience.

The final TSG theme is teacher educator knowledge, which recently has been receiving growing attention in research. The TSG presentations included studies that investigated an education program for PSMTs' mentor teachers and how teacher educators represented classroom interaction through use of digital tools. Based on this theme, implications for future research on teacher educators at school or postsecondary levels include exploration of innovative, effective approaches or programs to support their development of knowledge for teaching PSMT; the nature of the content and pedagogical content knowledge needed to prepare PSMT in the context of a digital age and changing world; and alternative approaches to researching this knowledge. For example, self-based methodologies (Chapman et al., 2020) such as narrative inquiry and self-studies need more attention as promising ways of exploring and understanding mathematics teacher educators.

Other important areas of PSMT education that should be addressed in future research but not explicitly addressed in the TSG themes include the following: (1) The cooperation between mathematicians and educational researchers is of value in the field of mathematics education, in general, and PSMT education, in particular. Thus, research needs to explore how mathematicians could play a more important role in PSMT education in addition to teaching advanced mathematics courses. (2) Different countries and regions have rich theories and practices in PSMT education. Research should explore new paths of international cooperation in addressing these theories and practices for the benefit of the international field of PSMT education. (3) Preservice teacher education is closely related to previous primary/elementary and secondary school education and subsequent in-service teacher professional development. Thus, research should attend to the correlations and connections among the three in the context of PSMT education. (4) The development of artificial intelligence is constantly changing people's way of life and even the way students learn inside and outside schools. Research should attend to what should or would happen to the content and methods of PSMT education in this changing context.

To conclude, TSG-29 was successful in achieving the goal of sharing meaningful, insightful research on PSMTs from around the world. Through the themes of the TSG and the themes of the paper presentations, the outcomes of the TSG offer implications for future research to advance the field of PSMT education. In general, research needs to address PSMT education in the context of a digital age and rapidly changing world.

Topic Study Group 30

In-Service Mathematical Teacher Education and Mathematical Teacher Professional Development at Primary Level

TSG-30 Working Team[1]

1. Introduction

The entire organizing team worked together before the congress in planning and organizing TSG-30 since 2018. There are 36 proposals submitted, and finally 4 accepted and presented as long-oral reports and 15 accepted and presented as short-oral reports. The TSG-30 was well attended in two 90-minute sessions and one 120-minute session in July 2021, which indicates strong interest in this topic by congress delegates. This report provides an overview of the aim and focus of TSG-30 and a summary of the presentations and discussions that occurred throughout the sessions.

2. Aims, Focus, and Themes

As set by the organization team, the general aim of TSG-30 was, in the international mathematics education community, to provide a venue for congress participants to share research, policy, design or practice that focuses on in-service mathematical teacher education and mathematical teacher professional development at primary school level.

The focus of TSG-30 was a discussion of research related to in-service mathematical teacher education and mathematical teacher professional development. In-service mathematics teacher education and professional development are integral parts of teachers' life-long learning process, and take many different formal or informal formats with various focuses and requirements within and across education systems. The situation becomes especially complex at primary school level, where teachers can be generalists in many education systems but content specialists in some other systems. Understanding and researching in-service mathematical teacher education and

Xingfeng Huang (China), Shanghai Normal University
Mazakazu Okazaki (Japan), Okayama University

mathematical teacher professional development at primary level, therefore, call for special attention to policy, design, and practice situated in special system and sociocultural contexts. For example, it is not difficult to notice contrasting practices in which mathematics teachers work and learn in different ways through various forms of collaborations in the East versus in the West. Efforts to understand what in-service mathematics teachers may do in and for improving their teaching and expertise have led to ever-increased interest in exploring and examining different programs, activities, and the nature of various collaborations and processes through which primary school teachers are engaged to learn. Consistently, new theoretical perspectives have also been developed and proposed about in-service teachers' professional development (e.g., practice-based professional education of teachers, locating teacher learning in communities, lesson study in Japan and China, communities of teachers working in contact with communities of researchers and evolving in their professional practices). It is important to understand through research the nature of different programs and activities, the focus and process of various teachers' knowledge learning and professional development, the extent of teachers' learning effects, the roles of policy and administrative support, and specific system and sociocultural factors associated with different teacher education programs and activities.

With this focus, TSG-30 was intended to provide an international gathering place for all interested parties (e.g., mathematics educators, teacher educators, school teachers, educational researchers, etc.) to share and disseminate findings from their research on in-service mathematical teacher education and mathematical teacher professional development at primary level, with the use of various theoretical perspectives and methodologies, and to exchange ideas in research, development, and evaluation of in-service mathematical teacher education and mathematical teacher professional development at primary level.

In TSG's call for contributions, the following five themes were outlined:

1. Theoretical perspectives and methodological advances in research on in-service mathematical teacher education and mathematical teacher professional development at primary level;
2. Research on the design and/or implementation process of specific programs, approaches, and practices, such as the use of video clips and IT, for in-service mathematical teacher education and mathematical teacher professional development at primary level;
3. Research on documenting the effectiveness of specific programs, approaches, and practices for in-service mathematical teacher education and mathematical teacher professional development at primary level;
4. Research on comparing and documenting system and sociocultural factors contributing to in-service mathematical teacher education and mathematical teacher professional development at primary level;

5. Issues concerning possible (dis)connections between research and practice in in-service mathematical teacher education and mathematical teacher professional development at primary level.

The original plan was then to organize accepted proposals for presentations in theme-based sessions. Unfortunately, due to the unexpected pandemic that started in early 2020, the organizers had to not only postpone the Congress from July 2020 to July 2021, but also to offer all the sessions in a hybrid format due to the international travel restrictions. At the same time, however, the hybrid format itself won't be able to solve the issue of time zone differences for international contributors as they may not be able to join a specific session. In fact, many international contributors decided not to join the Congress to present, even though their proposals were accepted. At the end, there were 19 accepted proposals remaining with the contributors agreed to participate and present during the Congress. Thus, the session organization was no longer to follow specific themes, but mainly to accommodate presenters' availability and preference to present at certain times.

Given the three sessions (two 90-minute sessions and one 120-minute session) that were allocated for TSG30, the first 90-minute session on July 13th was devoted to four long-oral presentations (LO), and the other 90-minute session on July 16th and the 120-minute session on July 17th were organized for the 15 short-oral presentations (SO) (see Tab. 1 on the next page). In the following sections, we briefly summarize the paper presentations and discussions during these sessions.

2.1. Session 1

The first long oral presentation (Huang and Zhang)[1] shared the scope of a program that involved mathematics teachers from Shanghai and Britain that, in a collaborative environment, taught two weeks in the other country. Taking the Anthropological Theory of the Didactic as a theoretical framework, this strategy provided the professional development of the teachers participating in the project. The study focused on two primary teachers from Shanghai that had their teaching experience in Britain. The results revealed that they encountered difficulties in the implementation of the lesson (the approach they used in their country was not suitable in this new context of practice), which led them to reflect on their practice and to adjust their didactic tasks and techniques in time for teaching improvement.

The long presentation by Livy et al.[2] was to understand how the lesson structure of teaching a challenging task might impact on a Year 2 teacher's pedagogical approaches for teaching mathematics. An inquire-based approach of teaching students with a challenging task was explored in three phases: Launch the task (without telling); Explore the task (students' attempt on the task by themselves); and Summarise (the teacher's selection of particular students to share their work during the lesson to support student learning). The results revealed that the work sample chosen by the teacher in the summarise phase helped students to learn from each other, and permitted

[17]	Contingencies as moments of collaboration: a report on investigating and supporting mathematics teachers' knowledge. ***Shikha Takker*** *and K. Subramaniam* (India). (SO)
[18]	Re-conceptualizing primary mathematics in-service teacher professional development in nigerian context. ***Lawan Abdulhamid*** (South Africa) *and Balarabe Yushau* (Nigeria). (SO)
[19]	Development of critical lenses among teachers in lesson study. ***Tan Saw Fen*** (Malaysia). (SO)

the teacher to experience success with her own teaching by building knowledge of pedagogy from practice.

The long presentation by Choi et al.[3] shared a programme with its main objective to develop teachers' mathematical knowledge for teaching (MKT) and beliefs (B) on instructional practices. Using the Reasoning and Modelling approach, the study aimed to understand if this programme has the effects as expected and in which way the 22 participating teachers grew in these two domains. The results suggested that there were significant changes in mathematical knowledge for teaching and beliefs on instructional practices.

The last long presentation, by Li et al.[4], focused on both in-service Chinese teachers' (ITs) confidence about their knowledge and the extent of their conceptual knowledge for teaching (MCKT) on the topic of fraction division. The results revealed how these ITs' confidence may or may not be supported by their knowledge for teaching fraction division, an important topic they need to teach as part of the curriculum standards in China. The results also illustrated the importance of specifying knowledge components in mathematics instruction in order to help build and support ITs' confidence for classroom instruction.

2.2. Session 2

Santos et al.[5] shared the project REASON (Mathematical Reasoning and Teacher Education) that investigated ways to support primary and secondary prospective and practicing teachers' development of mathematical and didactical knowledge to promote students' mathematical reasoning. The presentation highlighted that, when systematic intervention was carried out with prospective and in-service mathematics teachers, their capacity to engage students in mathematical reasoning was evident. The initial result showed that the tasks developed were helping teachers to build their knowledge, skills and capacity to teach students to promote their reasoning skills.

Serrazina and Brocardo[6] reported part of the research developed by the project REASON (Mathematical Reasoning and Teacher Education). They highlighted the key findings of the project with primary school teachers (grades 1–6) following a Design-Based Research approach. The presentation included examples from the training material used in developing teachers' understanding of the nature of tasks that promote mathematical reasoning among students. Also, the students' work indicated that teachers were able to implement their learning acquired in the project to promote mathematical reasoning in their class.

Sturgill[7] presented the research findings from working with three Grades 4–6 teachers of mathematics who taught in the Midwestern United States in the classroom inquiry projects. The study highlighted that classroom inquiry, a structured form of teacher research, is a powerful tool for improving teachers' knowledge for teaching and their practice. The study findings included improvement in teachers' knowledge of teaching and student learning, knowledge of classroom inquiry and action research, and students' engagement with the support and time to enact their respective inquiry projects.

France et al.[8] presented a study that aimed to examine 25 mathematics teachers' competencies in the context of Latvia's curriculum reform in general education, with a particular focus on teachers' preparedness to develop student cognitive skills and ways to stimulate more appropriate and individualized teacher professional development. Based on the study findings, four groups of teachers were identified, each requiring individualized professional development to ensure implementation of reform-relevant ideas into the school practice.

Moeller et al.[9] shared Math for All (MFA), an intensive professional development (PD) program for in-service teachers. They reported on a randomized controlled trial (RCT) of MFA involving 32 schools, 98 4th and 5th-grade general and special education teachers, and approximately 1,500 4th and 5th-grade students. The findings indicated that MFA had statistically significant, positive effects on teachers' self-reports of their preparedness and comfort with teaching. A school-level analysis found a moderate MFA effect on student achievement. Quasi-experimental analyses of a subgroup of teachers being observed showed initial evidence of MFA impacts on their classroom practices.

Hummes et al.[10] discussed the combination of two major instruments for professional mathematics teachers' development: the lesson study (LS) and the didactical suitability criteria (DSC). Drawing on a literature review, presenters argued that combining LS and DSC offers teachers the opportunity to draw on a consensual structured approach covering the main educational dimensions embedded within their classroom practice.

Yuan[11] focused on one of the job-embedded and expert-assisted professional development programs. The study examined Shanghai in-service primary mathematics teachers' acquisition of pedagogical content knowledge (PCK) through participating in Teaching Research Group (TRG) activities. The study findings showed that teachers developed their PCK by creating supplementary teaching materials, studying students' thinking, and teaching mathematical thinking by working closely with teaching research coordinators during TRG activities; and writing reflection reports afterwards. The study has implications for teachers' community of practice which, in turn, improves students' learning of mathematics.

2.3. Session 3

Okazaki et al.[12] shared how teachers' in-depth study of instructional material can be examined in the context of lesson study. In particular, the four levels of teachers' instructional material study were reported, which were identified as a result of the studies that compared three types of teachers who were different in their experiences.

Choy and Dindyal[13] discussed teachers' professional development in the in-service training program in Singapore. They conceived the aspects of the professional development in terms of Desimone's framework, and focused on the first phase of needs analysis. As a result of analysis, they clarified the teachers' insufficient understanding of the connections among mathematics, students' learning difficulties, and teaching approach. Thus, they suggested the importance of positioning every teaching action as opportunities for professional development and of exploring teaching approach in terms of mathematics and students' learning.

Nakawa and Matsuo[14] reported a pre-school teacher in Japan who improved her mathematical abilities in teaching through experiencing PD program based on the ALACT model under the guidance of the researchers. The results showed that the teacher could develop knowledge of content and teaching and knowledge of content and curriculum in the framework of mathematical knowledge for teaching through the program.

Cheeseman[15] reported the change in the teachers' views through participating in the professional development project FliM that focused on problem solving and inquiry. The results showed that the teachers believed they had improved professional skills, knowledge, pedagogies, enthusiasm, and confidence in their teaching of mathematics with young children through the FliM project.

Amirali[16] shared the urgent situation in Pakistan, where primary school teachers are struggling to teach basic mathematical concepts as they have been recruited as the "primary school teachers" rather than "subject specialist teachers" ... Teachers lose the opportunities of choosing grades they want to teach as the administrators would assign mathematics teaching to those whom they think are able to teach mathematics, especially in grades IV and V or even higher grades. Moreover, the researcher also pointed out the basic situation in Pakistan that after the schooling, teachers who teach mathematics received very limited training in mathematics by themselves.

Takker and Subramaniam[17] pointed out that contingencies arising in the context of teaching practice are important moments in the teacher-teacher educator collaboration. These moments would require teacher educators to revisit their goals and use these moments as learning opportunities for all participants. Researchers discussed two episodes (connection between a method and the algorithm & teaching the missing ideas in the textbooks) and found out when teachers sought supports, that dynamic contingent situations emerged. If researchers wanted to respond well to those situations, that would mean they needed more flexibility in their roles and had the knowledge and awareness to deal with. Moreover, these contingent situations created possibility for teachers to try alternative practices and for the researchers to take a more active role in the practice of teaching, and also challenge teachers' existing knowledge of the content, students and specific topics.

Abdulhamid and Yushau[18] presented a re-conceptualization of mathematics teacher professional development that highlights the policy implications for addressing the gaps among Nigerian primary mathematics teachers in their fundamental understandings of basic mathematics. Despite the fact that huge rollout of PDs in Nigeria that focused on teachers' content knowledge and content-specific pedagogy, the researchers found that PDs typically were not based on the research and teachers' specific needs. They called for the need to disaggregate the levels at which in-service mathematics teacher professional development interventions could usefully start across lower (grade 1–3), middle (grade 4–6) and upper (grade 7–9) basic teachers, and the need for a longer period of PD, with interim assessments.

Fen[19] presented a study that explored the development of teachers' critical lenses when they were conducting lesson study within two lesson study groups. The two lesson study groups, comprised of 6 teachers and 3 teachers respectively, conducted five lesson study cycles. Teachers from both lesson study groups developed student and curriculum developer lenses. But those teachers only developed curriculum developer and student lenses within this study, rather than the researcher lens as the development of their critical lenses might be affected by the knowledgeable others, anticipation of students' responses and difference in experience and seniority among the participating teachers. Researchers pointed out that when planning to set up lesson study group in a specific school, administrators might want to focus on the experience and seniority of teachers which showed great importance to teachers' professional development.

3. Closing Remarks

Among the main points discussed and summarized across these three sessions we highlight the following ones:

- Efforts to explore and document effective programs and approaches to improve mathematical teachers' knowledge for teaching and related beliefs in diverse system and cultural contexts;
- The search for possible approaches and solutions to address the weak mathematical training that many primary school teachers often have in diverse system and cultural contexts, and possible policy implications;
- The changes in teacher professional development needs in the context of educational reforms, including curriculum and in-service learning, and efforts to address such changes;
- The development of new conceptions (or re-conceptions) of what teachers need to know and be able to do in teaching, and teacher professional development;
- The development and use of various assessment and analytical tools to document possible changes in teachers' knowledge, beliefs, and/or practices through participating in professional development programs.

Naturally, in such a broad topic as mathematical teacher education and mathematical teacher professional development at primary level in diverse system and cultural contexts, many questions remain to be addressed. The diversity of approaches and foci presented suggests many different perspectives that contributors took to develop, search, and document effective programs or approaches, which aspects of professional development were to be focused, what may need to be developed and implemented to address the critical needs in teacher professional development in various contexts, and how professional development may be positioned to facilitate educational reforms. The participants shared a strong interest in various topics covered in the TSG's presentations through online discussions across these sessions.

Topic Study Group 31

In-Service Mathematical Teacher Education and Mathematical Teacher Professional Development at Secondary Level

Konrad Krainer[1], Betina Duarte[2], Talli Nachlieli[3], Craig Pournara[4] and Youchu Huang[5]

ABSTRACT The focus of TSG-31 for ICME14 was the study of in-service and/or professional development initiatives aimed at improving secondary mathematics teaching on a *large scale*. We adopted the definition of *scaling up* as reaching many classrooms, and potentially whole schools, districts, cities, or even a whole state or nation. We also encouraged submissions dealing with the adaptation and implementation of an initiative from another country. TSG-31 covered a wide range of secondary in-service courses and professional development programs, as well as school development projects, and collaborative networks of practitioners and researchers.

Keywords: Scaling up; Professional development; Large scale programs.

1. Topic under Study: General Description

At ICME-14, the Topic Study Group "In-Service Mathematical Teacher Education and Mathematical Teacher Professional Development at Secondary Level" (TSG-31) focused on the study of in-service and/or professional development initiatives aimed at improving secondary mathematics teaching on a large scale. *Scaling up* means to reach many classrooms ($n \geq 10$), and potentially whole schools, districts, cities, or even a whole state or nation. The TSG team expressed openeness for a broad range of initiatives, including in-service courses, professional development programs, school development projects, and collaborative networks of practitioners and researchers. Each initiative was asked to be research-based and to provide new insights into the challenge of improving mathematics teaching on a large scale. Some of the research questions considered were: What does it take to up-scale a professional-development

program? What are the factors that need to be considered when adapting a certain program to new cultural settings? Which aspects of the intervention could be scaled up and which couldn't? How could the impact of large-scale approaches be evaluated? What types of diagnostics about students' mathematics learning can be applied and why? To what extent can a steady collaboration between research and practice be achieved on a systemic level? What are the key factors in sustaining such collaboration? What challenges arise during such collaborations?

In order to facilitate the organization of activities, the TSG-31 team carried out a voluntary online-meeting one day before the first session. Among others, we explained our chat & notes system which helped us to record questions, answers and comments by onsite and online participants as well as by us during the week.

2. Contributions

Overall, 40 papers and posters had been submitted to TSG-31. Due to several reasons (review process, pandemic etc.), we finally had 20 paper presentations and one invited talk (IT) (18 online and 3 onsite), representing countries on six continents (Tab. 1 on the next page). In addition, five posters were presented in an extra session outside the topic study groups.

2.1. Core ideas about scaling up

Paul Cobb[1], the invited speaker, pointed out the significant progress reached by research on the teaching and learning of mathematics in recent years. However, these findings have limited impact on classroom instruction in many countries, including the USA.

On a recent investigation, Cobb collaborated with mathematics teachers, school leaders, and the leaders in several large urban school systems for eight years to investigate what it takes to support improvements in the quality of instruction and thus students' learning on a large scale. Their findings from this work take the form of an empirically-grounded theory of action (ToA) for instructional improvement at scale that spans from the classroom to system instructional leadership and encompasses: curriculum materials and assessments; pull-out teacher professional development; school-based teacher collaborative meetings; coaches' practices in providing job-embedded support for teachers' learning; school leaders' practices as instructional leaders in mathematics; and system leaders' practices in supporting the development of school-level capacity for instructional improvement.

Scaling up is a special case of implementation which can be understood as "a change-oriented process of endorsing an action plan" (Koichu et al. 2021). Implementation, that aims at scaling up (e.g., to thousands of mathematics classes or schools) has much more complex issues to deal with than a smaller project (e.g., working with some mathematics classes or schools). When reaching a larger regional or national level, a sound interaction between research, practice and policy is needed. Regarding the balance between research, practice and policy, two contrasting approaches — Technical rationality and Reflective rationality (Schön, 1983; Altrichter et al. 2008) — have been described so far. In order to combine the strengths of both approaches and to avoid weaknesses, a third approach — Societal rationality — is introduced (Krainer, 2021) and discussed.

2.2. Professional development issues at large scale

China has a level-by-level teaching competition system. Every selected contestant teacher from a lower-level competition, together with their community, prepares for a higher-level competition through iterative and incremental preparing sessions. These preparing sessions all start with a mock-teaching lesson with randomly selected students and are followed by discussions within the community. As a part of an ongoing research, Zhu and Wang[2] reported findings from these preparing sessions through an analysis of 28 interviews. These sessions share similar features in objectives, procedures, participants, resources, and effects; as they mature, there are changes and trends; all participants improve their knowledge, abilities and beliefs related to mathematics teaching. The process of the preparing sessions is constructive, resourceful, inspirational, and problem-solving-like. Moreover, the influence of this type of work is progressive, productive, transferrable and pointed to all participants' long-term professional development.

Chinese lesson study is powerful in linking theories and practices in the reform context. However, the mechanism behind such effectiveness is still under-researched. Zhao et al.[3] contributed to this issue exploring how teachers learn to use theories to guide their teaching in a Chinese lesson study. Taking activity theory as the theoretical lens, their research identified contradictions between activity systems of research and teaching, and how they were dealt with through the lesson study activities. This can shed light on how teachers learn in lesson study and necessary conditions that support their learning.

Nachlieli and Heyd-Metzuyanim[4] provided another contribution to the understanding of the processes of teachers change through professional development programme. The study explored processes of change in teachers' practice as a result of participating in a professional development (PD) for cognitively demanding, discourse-rich, instruction, titled TEAMS (Teaching Exploratively for All Mathematics Students). The TEAMS PD was "imported" from the USA to Israel, relying on two programmes: "The 5 Practices for Orchestrating Productive Discussions" and "Accountable Talk". Participants included 50 middle- and elementary-school teachers who participated in PD meetings during one school year and videotaped themselves teaching cognitively demanding tasks. Lessons were coded using a lesson-observation protocol. Individual Growth-Curve Model analysis indicated statistically significant growth in several parameters. Their findings contributed to shed light to the challenges of transferring a PD programme between two cultural contexts. As an example, it is pointed out that the "travel" of observational measures for studying the cognitively demanding instruction across cultures, is limited.

Schallertn and Schallert[16] agreed in her presentation with Cobb on the difficulty of getting educational innovations beyond the pilot phases. To scale up educational innovations, they combined professional mathematics teacher development and online learning environments (OLE). By applying a grounded theory approach and design-based research, they have investigated how OLE should be designed to support scaling-up. Analyzing written and oral research data indicated that (a) teachers make their own decisions concerning online learning, (b) OLE highlights benefits and practical relevance of an approach/technologies, (c) OLE does not lead to additional work, and (d) security and privacy of OLE could be crucial for teachers.

Related to online environments, Hollebrands and Lee[11] investigated the use of MOOCs for professional development. The design of three MOOCs for mathematics and statistics teachers based on principles of effective online professional development were guided by design principles and describe characteristics and engagement of 5,767 registrants with these designed features. Through this experience, the researchers claim that design principles provided opportunities for educators to develop their pedagogical skills.

Coming back to sustainability issues, the paper [10] of Koh and colleagues discussed the factors that influence the sustainability and scale-up of a school-based professional development programme for mathematics teachers in the Singapore context. In particular, this study considered factors such as shared vision and mutual accountability, influencing the scale-up and sustainability of a school-based professional development programme's impact on mathematics teachers' knowledge or practice.

Special characteristics of professional development are to be considered in the case of novice teacher as it was pointed out by Çelik et al.[14]. Although many studies have determined the professional needs of novice teachers, there are limited articles that have introduced interventions to address these needs. As part of a large-scale project, this paper presented two cycles of a design-based study aimed to develop the pedagogical content knowledge (PCK) of novice mathematics teachers. The study was conducted with the participation of twelve novice mathematics teachers in total and the change between two cycles is described. The analyses of the data show that teachers in the cycle which was enriched with additional video content presenting student thinking made better progress in knowledge of students, particularly related to misconceptions and learning difficulties compared to other teachers. Overall, both cycles appeared to support novice teachers' PCK. Finally, some suggestions are made for further research and practices for teacher learning.

The challenge of improving students' mathematical reasoning is addressed by a study aimed at improving the professional development of secondary teachers in charge. Mata-Pereira and Ponte [15] identified the main characteristics of a professional development experiment (PDE) centered on developing secondary teachers' mathematical and didactical knowledge to enhance students' mathematical reasoning. This design-based research is one of the strands of project REASON and concerns a PDE with secondary teachers that begins in October 2019. One of the main features of this PDE is the close link between research-based knowledge about enhancing students' mathematical reasoning and participant teachers' practice, thus providing innovative PD strategies and materials to enact such link.

Linked to the intention to consider the PD's specific characteristics are needed to improve school performance of students from lower secondary schools in the South African context, Pournara[5] showed some evidence to promote mathematics teachers' interventions. The Transition Maths 1 course was designed for teachers many of whom were under-prepared for this task. Following the initial pilots, a quasi-experimental study revealed conditions to impact student attainment. The intervention was scaled up and has now been completed by more than 150 teachers from approximately 80 schools. A recent quasi-experimental study provides further evidence of impact at student-level although this impact is not necessarily evident in the year immediately following course completion, suggesting a delayed impact of PD on students.

In a different context, the shortage of mathematics teachers in secondary schools of many German Federal States have promoted professional development courses in mathematics for teachers who already teach or want to teach mathematics out-of-field, which means teaching mathematics without official qualification. Since 2014 the German Centre for Mathematics Teacher Education and the regional government in Detmold (North Rhine-Westphalia) have conducted three of these professional development courses for out-of-field teachers in mathematics (secondary schools). Lünne and Biehler[18] presented an experience with the research aim to improve the knowledge about the group of the participating teachers and about aspects of success in the design of the courses as well as with the goal to develop curriculum material for such courses, which can be put to broader use all over Germany. During the second and the third course they investigated participants' development of school-level content knowledge in elementary algebra. The results show that participants with little prior knowledge can build up content knowledge in the PDC, while participants with a high level of prior knowledge are probably under-challenged by the test.

2.3. Collaborations between researchers and teachers

Some presentations showed the complexity of working with in-service teachers and their great potential. Terry[6] explored how action learning processes contribute to teachers' understanding and practice of self-regulation (SR) in secondary mathematics classrooms. Three constructs of SR, cognitive, metacognitive and motivational informed this study. Ten secondary teachers who participated in this study during 2019 reported that action learning was key in building teacher understanding of SR and improved pedagogical approaches that enhance student SR. Observations of their classroom behavior confirmed the targeted impact on the classes.

Peña et al.[7] presented preliminary results of a qualitative study with the purpose to analyze the collaboration processes between teachers' dyads of special education and mathematics that favor the development of argumentation in the mathematics classroom. Using case studies methodology, they conducted interviews and classroom video recordings. From a sample including 24 pairs of 7th-grade math and special education teachers, three pairs of cases were selected because they showed high levels of argumentation and had worked collaboratively. Through analyses of interviews, they identified facilitators and obstacles of collaboration to promote argumentation. They supported that, in order to promote argumentation, teacher dyads need to have common goals and shared workspaces for planning and decision making, but time devoted to shared work is still insufficient.

Albert et al.[8] addressed the collaboration with educators in high need schools. As students in high need school districts of United States generally do not do as well in mathematics as students in other districts, they are ultimately less likely to become part of the STEM workforce. Addressing this gap requires both the development and the retention of high-quality math teachers in high need districts. They reported on a project, now in its seventh year, to do so. The project features university level math educators and mathematicians working together, allowing for foci on content knowledge, pedagogical content knowledge and expertise in pedagogy as well as the development of a professional community concerned with supporting secondary math teachers. The project has been broadly successful, and the experience provides lessons that may be taken for other programmes with similar concerns.

In a similar way, students showing low language proficiency struggle with learning mathematics, especially in comprehending conceptually. Thus, teachers challenged with the language-responsive mathematics teaching needed, engage in Professional Development (PD). Look et al.[12] presented a design research approach to prepare PD facilitators who provide support teachers' learning. To prepare facilitators for their challenging role, and to foster their noticing of teacher learning they opted for using videos, taken from PD. Their approach was twofold: by an expert rating, involving five experienced facilitators, they confirmed that the videos address PD-PCK aspects, and yielded noticing prompts to be added to the videos. In the implementing study they showed that 60% of the discussion was related to PD-PCK, the remaining 40% on general PK. When facilitators reflected on content-specific aspects, 31% of the time was dedicated to describing, 44% on interpreting the situation, and 25% on making suggestions for alternative actions. On a re-design they will concentrate to further push discussions towards PD-PCK.

The need of qualified facilitators is found in different scenarios and Nieszporek et al.[17] presented the case of professional development for the teaching of probability and statistics. Although facilitators and their competencies play an important role for the success of PD courses, there is only little research on their orientation towards central learning goals. The need of providing facilitators a strong development including material for their work justifies this study as a scaling-up context. This case study casts a light on facilitators' decision-making, using an expertise model for the PD level. Preliminary results on the choice of learning goals by facilitator Mike (the study case) and his justifications enable a better understanding of his practices and thinking.

2.4. Constructing professional development maps

Chen et al.[9] presented a research base on a questionnaire administered to 61 rural middle school mathematics teachers from China to investigate their professional development and their views of its influencing factors on their professional development. The questionnaire was designed in four dimensions: teachers' personal information; teachers' professional development (i.e., identity as rural teachers, self-development consciousness); impact of other influencing factors (i.e., rural students and their parents, school atmosphere); and their training requirements. Firstly, results revealed that rural teachers held slightly positive beliefs in their professional development, as well as the impact of influencing factors on their professional development. Secondly, results revealed a significant positive relationship between teachers' points of view in their identities, self-development consciousness, the impact of rural students and parents, and the impact of school atmosphere.

Ma[13] presented a qualitative survey designed to document on 110 primary and secondary mathematics teachers' independent development, teaching and research activities, routine training practices, induction culture and exceptional professional development approaches. The study seeks to determine the basis for the selection of the methods of mathematics teacher education.

2.5. The challenge of a new curriculum and education general reforms

The development of a new curriculum is a starting point for a professional development process insofar this kind of changes arouses confusion among teachers. Yan and Wang[20] used an open questionnaire and statistical methods to investigate the confusion for high school mathematics teachers in Henan Province. The researchers found that the core literacy of high school mathematics is the most conspicuous, the new curriculum structure and content related issues need to be solved, teaching quality evaluation needs to be operated, and in consequence new curriculum training needs to be expanded and upgraded. Based on these findings, suggestions from four aspects are established: strengthening the implementation of new mathematics curriculum standards of high school mathematics, giving play to the leading and radiating role of the experimental area, giving full play to the leading role of the college entrance examination, and training the new high school mathematics curriculum well.

Several reports reveal that the Moroccan Educational System, despite some registered progress, is still facing some dysfunctions, in particular the In-service Mathematical Teacher Education and Mathematical Teacher Professional Development has not yet been placed in a strategic position to respond to teachers' real needs. El Yacoubi[21] presented the priorities of the system reform, one of them aiming to enable teachers to complete and perfect their training.

3. Summary

In the following, we sketch some important assumptions and questions that emerged from our discussions in TSG-31:

- The starting point for many scaling up initiatives is the wish to take an instructional innovation that has proved effective in supporting students' learning in a small number of classrooms and reproducing that success in a large number of classrooms (Cobb and Smith, 2008). Clearly we could replace classrooms with schools, districts or regions etc.
- Scaling up initiatives must take into consideration a wide range of contextual constraints. This is particularly important when importing from or exporting

to vastly different cultural settings. For example, different countries have different general conditions for their education systems (centralized versus decentralized, public or private sector, relatively well resourced versus relatively poorly resourced, urban areas versus rural areas, top-down versus bottom-up steering, voluntary versus compulsory professional development etc.).

- Also, it makes a difference whether an initiative focuses on a specific mathematical content or theme (e.g., algebra or proving), on a reform that aims at improving mathematics teaching, or a larger reform focusing on STEM teaching (where mathematics is only one subject).
- Scaling up an initative might change the character of the initiative: For example, will it lose its focus on the micro-level (e.g., students' learning, student-teacher interaction etc.)? Does it get more policy-driven? What does this mean for research and teaching practice?
- Scaling up of initiatives poses new challenges for researching the initiative. For example, what kind of data become more important? What kind of knowledge is aimed at: for the scientific community (publications, presentations etc.), for practice (suggestions, materials etc.), and for policy (steering information, policy advice etc.)? Which knowledge regarding teachers gets specific focus (content knowledge, pedagogical content knowledge, pedagogical knowledge etc.)? Are larger projects more under pressure than the initial interventions to produce "success stories"?
- Studies of scaling up do not necessarily involve only quantitative methods. A good mixture of quantitative and qualitative methods helps to generate "numbers and stories".
- Scaling up involves working with stakeholders who may be less relevant in smaller initiatives (e.g., from mathematics teachers to district lead teachers, from single mathematics education researchers to research institutions, from superintendents to a country's policy makers).
- What can we expect from school-based interventions on a large scale? How can we respect/consider the particularities of a school in a large-scale education intervention project? (e.g., the existence of teachers with specific qualifications in mathematics education)? Which financial implications need to be taken into consideration?
- Collaboration among mathematics teachers and collaboration between teachers and researchers in mathematics education are both important means to make initiatives successful (Borko and Potari, 2020). How can the benefits of such collaborations be drawn into the scaling up of initiatives where such collaborations may not easily occur?
- What can we learn from lesson and learning studies as collaborative approaches in mathematics education? And how might these learnings inform the scaling up of lesson and learning studies?

Topic Study Group 32

Knowledge in/for Teaching Mathematics at Primary Level

Stéphane Clivaz[1], Kam Ling Lao[2], Janne Fauskanger[3], and Verónica Martín-Molina[4]

1. Themes and Description

Following Shulman's (1986) suggestion that teaching requires knowledge that is distinctive of the teaching profession, teachers' knowledge in/for teaching mathematics has attracted researchers worldwide. Different approaches have emerged on how this knowledge can be studied, developed, and strengthened and Topic Study Group 32 (TSG-32) has extended this conversation, with a focus on several emerging issues. TSG-32 at ICME 14 invited paper submissions on significant (new) trends and developments in research, theory, and practice about all different aspects that relate to the knowledge in/for teaching mathematics at primary level (learners' ages 5–13).

The following (often partly overlapping) themes have been considered.

(1) Focus on children's mathematics
- How attending to children's mathematical thinking can influence teachers' knowledge
- How elementary teachers use the leverage of core mathematical knowledge to nurture children's mathematical minds

(2) Focus on teacher learning
- Learning in collaborative communities (e.g., professional learning communities, lesson study, etc.)
- Acquisition of mathematical knowledge in teacher training
- Learning through teaching

(3) Focus on various aspects and uses of knowledge in/for teaching mathematics
- Cultural aspects such as cultural responsiveness, equitable teaching, teaching of mathematics in social and political contexts, etc.
- Aspects of teaching practice, such as high-levering/ambitious practices, attention to diverse learners, etc.

[4]Departamento de Didáctica de las Matemáticas, Universidad de Sevilla, Sevilla 41013, Spain. E-mail: veronicamartin@us.es

- Use of mathematical knowledge in the different phases of teaching (lesson planning, observation of students, task design, situations of contingency, etc.)

(4) Focus on methods for studying mathematical knowledge in/for teaching

2. Program Overview

TSG-32 had 3 sessions with presentations of papers and discussions of them. 26 papers and posters were submitted to TSG-32 and 3 papers were invited, resulting in the acceptance of 2 invited talks (IT), 8 long oral presentations (LO), and 8 short oral presentations (SO). However, several authors did not attend the TSG-32 sessions, probably due to the COVID-19 pandemic and postponement of ICME 14 and/or because of the online mode of the conference. There was also a joint poster session, and 4 posters were accepted. Tab. 1 includes the 10 papers and 2 posters that were actually presented during the conference.

Tab. 1. Papers and posters presented at TSG-32

Paper and author(s)

[11]	Unpacking performance indicators in the TPACK (Technological Pedagogical Content Knowledge) levels rubric to examine differences in the TPACK levels for teaching mathematics in primary schools. ***Aleksandra Kaplon-Schilis*** *and Irina Lyublinskaya* (USA). (Poster)
[12]	Developing analytical models of pedagogical content knowledge: a case study of mathematics teachers in Macao. ***Huey Lei*** (Macao SAR, China). (Poster)

Despite the difficulty of attending some sessions for many participants, probably due to the time difference, the discussions were of high quality.

3. Future Directions and Suggestions

Some of the papers presented in TSG-32 offered suggestions for future directions. Firstly, more studies are needed to determine how teachers develop knowledge in/for teaching mathematics in collaborative settings, which is very complex. Secondly, it would be interesting to study teachers' beliefs about the importance of their students' conceptual understanding of the mathematics that they should learn in school, or how that conceptual understanding could be promoted. While there is a need to investigate the diverse mathematical knowledge base among in-service teachers, there is also much to be discovered concerning how to help pre-service primary teachers to acquire an appropriate level of mathematical content knowledge. Focusing on mathematics through the lens of mathematical thinking could be used to help teachers (since their view of their students would become "richer and more nuanced"), but how to implement this in teacher training programs remains to be seen.

In their review of studies of mathematical knowledge for teaching, Hoover et al. (2016) identified 190 studies published between 2006 and 2013. Based on this review, they suggested that "a central problem for progress in the field is a lack of clearly understood and practicable methodology for the study and development of mathematical knowledge for teaching" (Hoover et al., 2016, p. 20). They further argue that the use of measures and interviews might draw attention away from the actual work of teaching (Ball, 2017). In the presentations in TSG-32, different methods for studying knowledge in and for teaching mathematics — more or less close to the work of teaching — were explored. Based on this exploration, a suggestion for future research might be similar to what Hoover et al. (2016) conclude based on their review, namely to "use sites where professional deliberation about teaching are taking place as sites where we might productively research the work of teaching and its mathematical demands" (p. 23). A lot of work remains to develop methodologies for studying mathematical knowledge in/for teaching through the work of teaching mathematics. Future papers, posters and discussions in TWG-32 at future ICME conferences will be an important site for discussing and developing such methodologies.

Topic Study Group 33

Knowledge in/for Teaching Mathematics at Secondary Level

Nils Buchholtz[1], Miguel Ribeiro[2], Miroslawa Sajka[3], Qiaoping Zhang[4], and Thorsten Scheiner[5]

ABSTRACT The chapter summarizes the results of TSG-33: "Knowledge in/for teaching mathematics at secondary level". We provide all titles of all the scientific contributions in the program overview and address suggestions for future directions of research in this field in the report about the discussions.

Keywords: Mathematics teacher knowledge; Knowledge for teaching mathematics; Secondary education.

1. Themes and Description

The TSG-33 assembled international mathematics educational researchers on the topic of "Knowledge in/for teaching mathematics at secondary level". Since ICME-13 in Hamburg 2016 (Even et al., 2017), research, theory, and practice in this research topic have evolved and, in particular, questions about the relationship between teachers' knowledge and the practice of mathematics teaching at secondary level have been taken up by many researchers around the world. The goal of TSG-33 was to focus on a number of critical issues in research on knowledge in/for teaching mathematics at secondary level and to foster international discussion about the findings and challenges researchers, mathematicians, teacher educators, teachers, and policy makers face in addressing issues in this area of research. In particular, the role of teachers' knowledge in practice and practical implications for teacher training and professional development also played a stronger role. The discussions in TSG-33 focused on the following issues and respective key questions driving current research in this research field:

(1) Conceptualization of knowledge in/for teaching mathematics at secondary level

[1] Faculty of Education, Mathematics Education, University of Hamburg, Hamburg, Germany. E-mail: Nils.Buchholtz@uni-hamburg.de

- What kind of knowledge in/for teaching mathematics should be considered to become a proficient/effective mathematics teacher at secondary level?
- What core characteristics, basic abilities, attitudes, and beliefs are in play? (Are there some normative orientations?)
- What aspects are considered in the various existing theoretical frameworks?

(2) Measurement of knowledge in/for teaching mathematics at secondary level
- What aspects are measured in the study of knowledge in/for teaching mathematics at secondary level?
- How is knowledge in/for teaching mathematics at secondary level measured?
- Are these measurements/instruments appropriate for different contexts?

(3) Relationships between knowledge in/for teaching mathematics at secondary level and teaching practice in mathematics, including instructional quality in mathematics teaching, and student achievement
- What distinguishes (theoretical) knowledge in/for teaching mathematics at the secondary level from teaching practice (enacted knowledge)?
- What are the relationships between teachers' affect and their knowledge in/for teaching mathematics at the secondary level?
- What kind of situational knowledge and skills are needed or observable in practice and how does teachers' knowledge influence the quality of mathematical instruction and relate to students' mathematical achievement?

(4) Practical implications for teacher education and professional development and validation of research findings on knowledge in/for teaching mathematics at secondary level
- What are appropriate measures in teacher education and professional development to develop knowledge in/for teaching mathematics at secondary level?
- What kind of knowledge is relevant for teaching practice and where and how do teachers learn this knowledge?
- How can studies on teachers' knowledge be used to improve the quality of teacher education and professional development?

2. Program Overview

As one of the larger Topic Study Groups at ICME-14, TSG-33 was able to benefit from the possibility of a fourth program session. Due to the ongoing COVID-19 pandemic, the program was offered in a hybrid format (i.e., presentations were given both remotely and on-site). The program provided an opportunity for participants to discuss the questions stated in Section 1 in depth. However, as many researchers participated remotely, the time difference presented challenges for the scientific discussion with researchers working in different parts of the world. The names of the presenters in TSG-33 are listed in Tab. 1, along with the country of their affiliated institution and the title of their presentation.

Tab. 1. List of papers presented

[21]	Mathematics teachers' perceptions of teaching competencies: a study of grades 5 through 8. ***Heather Bleecker*** *and Polly Dupuis* (USA)
[22]	Identifying mathematical learning opportunities in a task as a missing, essential skill of teaching. ***Michelle King****, Jodie D. Novak, Robert A. Powers, Alees T. Lee, Adam Ruff, and Shweta Naik* (USA).
[23]	The validation of an assessment instrument for measuring mathematical knowledge for teaching (MKT). ***Mihyun Jeon*** (USA). (Poster)
[24]	The specialized knowledge of a new generation of mathematics teachers under STEM training. ***Jenny Patricia Acevedo-Rincon*** (Colombia). (Poster)
[25]	A case study on MPCK of junior middle school mathematics teachers with different characteristics. ***Ruifang Zhao*** (China). (Poster)

[6]Achmad Nizar unfortunately passed away a few days before the conference, but we would like to highlight his contribution to TSG-33 nevertheless.

The presentations were accompanied by introductory remarks and discussion prompts from the team members.

3. Results of the Discussion, Future Directions and Suggestions

The discussions of the presentations led to various observations that will be documented here as a result of the conference. Of course, such summaries can only reflect a subjective impression of the organizing team. Compared to the presentations of the corresponding Topic Study Groups at ICME-12 in Seoul and ICME-13 in Hamburg, an increase of studies on the differences between mathematical knowledge at the university level and secondary school level could be observed. Considerations of the nature and kind of subject matter knowledge for teaching have evolved in various directions, including directions that diverge from Shulman's original notion of pedagogical content knowledge. Moreover, with the increasing recognition of the situated nature of teacher knowledge (Even et al., 2017), it is not surprising that the role of teachers' school mathematics knowledge is again becoming the focus of several research contributions.

The greater importance of professional practice for the development of teacher knowledge in teacher education and professional development is also accompanied by a stronger focus in research. The need to conduct studies of the development of teachers' knowledge over the course of a teacher's career (especially the need for longitudinal studies of high scientific standard) was again evident.

There have also been developments in research at the level of conceptualizing theoretical frameworks for teacher knowledge, partly due to the influence of the significance of the unfolding of teacher knowledge in situated (and culturally shaped) teaching practice[7]. On the basis of the still prevalent work of Shulman, various dimensions of teacher knowledge were distinguished and delineated, depending on certain content-related aspects or aspects of teaching practice. New conceptualizations are partly more fine-grained or take into account specific cultural conditions, such as the teaching knowledge of indigenous populations or national traditions. Overall, a more critical use and enrichment of common conceptual frameworks was observed. The frameworks discussed were not mainly analytical, but reflected both normative and descriptive approaches. However, for research on situated teacher knowledge, the more context-oriented knowledge is analyzed in teacher practice, the more difficult it becomes to empirically distinguish the knowledge from other factors like teachers' personality or affect. As the field seeks to better account for the ways in which teacher knowledge and its frameworks are culturally constituted, the question of how findings of studying teacher knowledge can be generalized to other cultural contexts becomes even more significant. In this context, there is a great need for further development of research methods (both quantitative and qualitative) to study situated and contextual teacher knowledge that meet high scientific quality criteria.

---

[7] For further research in this field, it is worth looking at the developments in research on teacher knowledge in other disciplines (i.e., Science education), where consensual models of practice-relevant teacher knowledge have emerged in recent years (Hume et al., 2020).

Topic Study Group 34

Affect, Beliefs, and Identity of Mathematics Teachers

Francesca Morselli[1], Einat Heyd-Metzuyanim[2], Narumon Changsri[3], Forster Ntow[4], and Shengying Xie[5]

ABSTRACT We present the organization of Topic Study Group 34 and summarize the main themes that were discussed during the session. Finally, we outline direction for further research on the topic, as emerged during the TSG work and discussions.

Keywords: Affect; Beliefs; Identity; Teachers.

1. Aims of the TSG

In TSG-34 we addressed the themes of affect, beliefs and identity in mathematics education, with a special focus on mathematics pre-service and in-service teachers.

Following Hannula (2012), we conceptualize theories related to affect into three dimensions. The first dimension describes three different types of affect: cognitive (e.g. beliefs), motivational (e.g. value, motivation), and emotional (e.g., emotion, engagement). The second dimension concerns stable aspects of affect (i.e. traits) versus dynamically changing aspects of affect (i.e. states). The third dimension concerns the different research traditions for theorizing affect: physiological theories, psychological theories, and socio-cultural theories.

Research on affect-related theme is indeed traditionally rich and diverse and such a diversity and richness was evident in the contributions to the TSG-34.

The starting point for the work of the Topic Study Group was the previous work in ICME-13 (Hannula et al., 2019) that led us to outline a list of relevant themes:

- Theoretical and methodological issues concerning research on teacher's affect and identity.
- The analysis of the mutual relationship between affective constructs.

E-mail: fntow@ucc.edu.gh
[5]Department. of Mathematics, Hunan Normal University, Changsha, China.
E-mail: syxie@ hunnu.edu.cn

- The connection of affective constructs to cognition and other constructs studied in mathematics education.
- The design and implementation of teacher education programs for promoting aspects of affect and identity.
- The domain (mathematics) specific research on affect and identity (i.e. in which ways research and results take into account the specificity of mathematics teaching and learning?).

1.1. Submission

We initially received 32 submissions, that underwent a first round of review and were accepted as papers (13), short papers (16), and posters (3).

Because of the pandemic there were some withdrawals and some new submissions, so that finally we had 24 submissions, from 16 countries. Of those 24 submissions, 8 were long oral presentations (LO), 15 short oral presentations (SO), and 1 poster.

1.2. TSG sessions

The accepted papers were presented during the three TSG online sessions. In order to improve the quality of communication during the online sessions, presenters were asked to prepare a video presentation in advance (5 minutes presentation for short papers, 8 minutes communication for long papers). Such presentations were shown during the session. There were discussions after each long paper presentation and after the presentation of a group of short papers.

Forty minutes of the last session were devoted to a general discussion on the emerging themes and directions for further research.

Moreover, participants could write their comments and questions to the presenters in a shared virtual board (Padlet), so that the discussion could be carried out also in an asynchronous way.

1.3. Presented papers

A list of the accepted papers (in order of appearance) and authors is presented in Tab. 1 (on the next page).

2. TSG Themes

As evidenced by the titles in Tab. 1, the presentations during the sessions addressed a wide range of themes and issues, with a variety of research methods, including surveys, interviews, observations and focus groups**.** Analytical methods varied from statistical inferences, to thematic analysis, narrative inquiry and more. The focus varied from studies on teachers' affect and identity to studies on professional development interventions to make teachers reflect on their affect and identity and possibly promote

[19]	Touching the untouchables: promoting non/linear mathematics pedagogy. ***Indra Mani Shrestha****, Bal Chandra Luitel, and Binod Prasad Pant* (Nepal). (SO)

through that professional development. Both pre-service and in-service teachers were taken into account.

Besides the main theoretical constructs, such as emotions, beliefs, attitudes, identity, the authors often introduced other affect-related constructs such as curiosity, failure, shame, challenge. The issue of teacher change was often referred to.

We may note that for the first time in ICME, Topic study Group on affect and identity was divided into two strands: student dimension and teacher dimension. This was due to the growing amount of research on the field. Such an organization was efficient in order to address more in detail teachers' affect and identity, even if all the participants recognized that teachers' affect and identity are strictly linked to students' ones.

Participants also noted that, even if there is mutual relationship, focusing on teachers entails focusing on their professional learning and not (only) on their mathematical learning. However, the division between the two TSGs (one on students' the other on teachers') may have left those researchers whose research focuses on relationships between students and teachers without a "home".

3. Directions for Further Research

During the last session the participants were engaged in a discussion on directions for further research in the field.

A general reflection concerns the emerging role of the context (cultural, institutional), that should be considered in an even more explicit way in studies on affect and identity.

The contributions showed a transition in research from focusing on "describing" affect to "intervening" with affect. Further research is needed in the design of "interventions", and it is important to reflect on a reliable methodology to study such interventions.

The issue of teacher change was deeply addressed in the contributions. It would be interesting to go on in this direction, carrying out long-term studies on affect and identity development as part of professional development.

From a methodological point of view, it was noted that small-scale studies are prevailing. Further research should take the challenge of large-scale studies.

Despite the organization of the TSGs in two separate strands, there is the need for studies that take into account both students and teachers' dimensions, and the relations between them. For instance, it is important to realize classroom experiments in order to study how teachers' teaching practice may impact on students' affect.

Topic Study Group 35

Knowledge and Practice of Mathematics Teacher Educators

TSG-35 Working Team[1]

1. Introduction of the Background

The last decades of research in mathematics education are best summarized by Anna Sfard's survey team at ICME-10 (2004) as "the era of the teacher" due to researchers' uncontested focus on teachers. Such attention is also represented in the launching in 1998 of an international journal dedicated to mathematics teachers' education, the Journal of Mathematics Teacher Education. Questions about what teachers need to know and be able to do, as well as how they develop their knowledge, skills, and beliefs have become central to the mathematics education research literature.

More recently, there is also growing attention on mathematics teacher educators (MTEs), that is, those who educate mathematics teachers, who design and implement opportunities for mathematics teacher education and development (MaTED). The goal of the TSG-35 at ICME-14 is two-fold: to collect information about mathematics teacher educators working in a variety of MaTED programs around the world and understand their contexts and cultures; and to discuss growing research about mathematics teacher educators, their knowledge, practice and beliefs.

The wording "mathematics teacher educator" (MTE) in some sense suggests a focus on academics only. This may be true for those countries/regions where MaTED is mainly at universities. But there are countries/regions where MaTED takes place within the instruction system or in teacher education institutes that are independent of universities. The recently launched ICMI Study 25 (co-chaired by Potari and Borko) focuses on the idea of mathematics teachers learning through collaboration in schools or larger communities, drawing on an ICME-13 survey team by Robutti et al. Collaborative groups may be teams, communities, schools and other educational institutions, professional development courses, local or national networks. This means that mathematics teacher educators can be working in formal or informal groupings, in

[1]Working team:
Chair: Maria Giuseppina Bartolini Bussi, Università di Modena e Reggio Emilia, Italy
Co-chair: Paola Sztajn, North Carolina State University, USA
Members:
Nada Vondrová, Charles University, Czech Republic
Ruchi Kumar, Tata Institute for Fundamental Research, India
Chi-Tai Chu, Taiwan Normal University, Chinese Taiwan

either face-to-face or distance settings. They can be facilitators such as trainers, coaches, or mentors.

2. Paper Invitation and Submission for TSG-35

Given the variety of ways in which mathematics teacher educators can work, and the different settings in which they can operate, we invite papers that address the growing need to further understand these professionals.

Some questions to be answered might be:

1. Who are mathematics teacher educators?
2. What do we know about their knowledge, practice, and beliefs?
3. What is their work and under what conditions do they operate?
4. What framework should we adopt to illustrate different aspects of their knowledge?
5. What and how do the different avenues/contexts contribute to the growth in their practice?
6. What counts as experience and what difference does it make in their practice?
7. In what ways do mathematics teacher educator and teacher's knowledge and beliefs come into play in teacher education contexts?

To answer similar questions several teacher educators from different parts of the world met virtually on the occasion of the ICME-14 in shanghai. The list of papers presented can be found in Tab. 1 (on the next page).

3. A Brief Description of the Contributions

To address the first question, Goos and Marshman[1] took a sociocultural perspective on MTEs learning as identity formation. Brief case studies of MTEs who participated in two Australian research studies were illustrated.

MTEs' competence including knowledge is concerned in many ways under different contexts. Alacaci et al.[20] compared two frameworks of competencies for MTEs in mathematics and in technology, aiming to contribute to the discourse on the nature of teacher educator competency frameworks, identify areas of variances, and suggest possible reasons as well as inherent tensions. Huang[21] examined pedagogical practices of MTEs who provide online professional education programs for prospective and practicing mathematics teachers to unpack MTEs' knowledge. Three MTEs' knowledge structure was analyzed using teacher educator knowledge tetrahedron. Cross-case analysis revealed knowledge that was specific for MTEs' decisions about online mathematics teacher educating.

Focused on the practice, Kumar[2] made an analysis of math teacher educator's practice using vignettes illustrate the way different knowledge needs to be integrated in practice of teacher educator in designing and facilitating the tasks and discussion using them. The analysis revealed that though the dialogic approach in workshops

Tab. 1. The list of papers presented

Paper and author(s):
Session 1
[1] Boundary crossing and mathematics teacher educators' hybrid identities. ***Merrilyn Goos*** (Ireland) *and Margaret Marshman* (Australia).
[2] Analyzing challenges in the practice of a math teacher educator for developing community of math educators. ***Ruchi S. Kumar*** (India).
[3] Mathematics and science teacher educators learning induced by common research on professional vision. ***Nada Vondrova*** (Czech).
Session 2
[4] Teacher educators' preparation model: example from a successful professional development. ***Paola Sztajn,*** *Kristen Malzahn, and Reema Alnizami* (USA).
[5] Using a community of practice perspective to analyze mathematics teacher educator learning during lesson study. ***Melissa Soto***, *Lara Dick, Mollie Appelgate, and Dittika Guptal* (USA).
[6] Characterizing mathematics teaching research specialists' mentoring in the context of Chinese lesson study. ***Zhenzhen He***, *Feishi Gu, and Lingyuan Gu* (China).
[7] Didactical suitability criteria used by Italian teachers in lesson studies. ***Carola Manolino*** (Italy), *Viviane Hummes, Adriana Breda, Alicia Sánchez, and Vicenç Font* (Spain).
[8] The lesson study cultural transposition: from Chinese lesson study to Italian lesson study. ***Alessandro Ramploud***, *Maria Mellone, Silvia Funghi, and Simone Esposito* (Italy).
[9] Using a nested structure of lesson study approach: a self-study as a mathematics teacher educator. ***Yinkang Wu*** (China).
[10] A collaborative work of four mathematics teacher educators. a study in Uruguay. ***Daniela Pages*** (Uruguay).
Session 3
[11] A collaborative self-study of two mathematics teacher educators learning and growing as culturally responsive pedagogues. ***Lindsay Keazer*** *and Kathleen Nolan* (Canada).
[12] Exploring power and oppression: a study of mathematics teacher educators' professional growth. ***Craig Joseph Willey***, *Michael Richard Lolkus, Jill Newton, and Troy Bell* (USA).
[13] Differing contexts and tensions mathematics teacher educators experience in content courses for elementary preservice teachers. ***Hwa Young Lee***, *Emily Miller, Travis Weilan, Tuyin An. And Daniel Clark* (USA).
[14] Developing mathematics education leaders in schools in Guatemala and implications for work in other countries. ***Chadd McGlone*** (USA).
[15] Transitioning between different identities: how the different positions assumed by the mathematics teacher educator impact their practice. ***Natalia Ruiz***, *Nicole Fuenzalida, and Luz Valoyes-Chávez* (Chile).
[16] Mathematics teacher educators as role model: intentions and strategies. ***Helena Montenegro***, *Salomé Martínez, and Francisco Rojas* (Chile).
[17] Experience of learning to teach mathematics: what do prospective teachers learn from their mathematics teacher educators? ***Francisco Rojas***, *Helena Montenegro, and Flavio Guiñez* (Chile).
[18] Narratives of maths teachers: students & teacher ratio in mathematics classes in private schools. ***Sagar Dahal*** (Nepal).
Session 4
[19] Integrated mathematics teacher educators' professional development program. ***Haw-Yaw Shy***, *Ting-Ying Wang, Yen-Ting Chen, Chi-Tai Chu, Chen-Ju Pai, and Mei-Hsien Chen* (Chinese Taiwan).
[20] Talking across professional communities: teacher educator competencies in mathematics and in technology. ***Cengiz Alacaci*** (Norway)., *Bulent Cetinkaya, and Ayhan Kursat Erbas* (Norway).
[21] Mathematics teacher educators' knowledge for designing online professional development. ***Dinglei Huang*** (USA).
[22] Mathematics teachers' professional noticing in teaching of inverse functions and graphs in grade 12? ***Annie Mamoretsi Kgosi*** (South Africa).
[23] Examining teacher educator noticing during rehearsals of teaching: a focus on attending. ***Marta Kobiele*** (Canada).
[24] Mathematics teacher educator care and questioning in mathematics methods early field debriefing discussions. *Signe Kastberg, Lizhen Chen,* ***Sue Ellen Richardson***, *and Mahtob Aqazade* (USA).
[25] Un/intelligent way to professional development of mathematics teachers: a case from Nepal. ***Amrit Bahadur Thapa*** (USA).

allows teachers to articulate their thoughts and ideas, further research is needed to identify the knowledge and practice of math teacher educators for developing the sense of the community. According to Ruiz et al.[15], the processes through which a novice facilitator navigates between teachers' and facilitators' identities (triggered by contextual aspects) is explored. The results indicate that to faithfully and flexibly replicate professional development programs in new and unfamiliar school contexts, it is critical to understand the processes of identification experienced by novice facilitators as part of their process of learning.

There are also several researches regarding collaborative work. Vondrova[3] reported the experience of a biology teacher educator and a mathematics teacher educator which started as collaborative research on professional vision but gradually became a learning experience for them. Pages' talk[10] was about a collaborative work of four MTEs in Uruguay. The researchers proposed them to plan a lesson in the first Calculus course of the mathematics teacher education program, to implement that lesson, and analyze it in a collective way. A theoretical model was found by using Classic Grounded Theory. The process called looking for agreements is resolved by the activation and eventual mobilization of the personal theories built in practice of each MTE, which constitutes the core category that emerged during the study. Keazer and Nolan[11] presented a collaborative self-study of two MTEs developing their own culturally responsive pedagogies (CRP) when teaching mathematics education courses. To answer the question "What do MTEs learn from attempts to grow and reflect on their own CRP?", they developed an MTE framework for growing CRP, which applied to their practice for data collection and for further iterations of examining their CRP.

MTEs play an important role in working with teachers. Paper by Sztajn et al.[4] described a model used to prepare MTEs to facilitate a professional development program that has demonstrated it can be implemented with integrity and has also shown positive impact on elementary teachers' knowledge and practice. In paper by Lee et al.[13], five MTEs who teach mathematics content courses for elementary preservice teachers (ePTs) at institutions across the USA present the differing contexts in which they teach such courses. The sequencing and integration of content and pedagogy, content coverage and mathematical rigor, and interactions with ePTs views and prior experiences in learning mathematics were explored from the perspective of MTEs. Montenegro et al.[16] reported a phenomenographic research which aimed to explore the approaches to modeling held by MTEs. Data were collected through semi-structured interviews conducted face-to-face with fifteen MTEs working in three Chilean primary initial teacher education programs. The analysis identified four approaches to modeling, ranging from performing pedagogical activities and interactions to developing teaching practices linked to the school classroom. Rojas et al.[17] reported on part a Self-Study aimed to investigate the challenges of two Chilean MTEs when teaching how to teach mathematics. The prospective teachers' perceptions of the teaching practices enacted by their MTEs was explored. Data were collected through focus groups and analyzed using thematic analysis. Conclusion showed prospective teachers look at the mathematics teacher educators as a role model and would replicate some of their teaching practices when they become schoolteachers. The teacher educator facilitating the rehearsal plays a key role in supporting pre-service teachers' learning opportunities. Kobiele[23] presented an analysis of four teacher educators' noticing when facilitating rehearsals of one instructional activity — quick images. Using video-based interviews with each of the teacher educators, eight aspects within rehearsals that they attended to were identified. Kastberg et al.[24] examined how caring-relations influenced MTE questioning practice in the context of debriefing discussions with prospective teachers (PTs) during early-field experience linked to a mathematics methods course. Findings revealed that the MTE's ability to maintain focus on the PTs' objects of interest was informed by the MTE's feelings of reciprocal care.

Some contributions concerned the LESSON STUDY, a model of teacher education spread all over the world after the origin in the far east. Soto et al.[5] shared research on the use of lesson study for MTEs' professional development. Using Wenger's (1998) Social Theory of Learning framework based on communities of practice, they demonstrated how MTEs' learning changed across the process of the lesson study. He et al.[6] examined how mathematics teaching research specialists mentor practicing teachers during post-lesson debriefs of a lesson study in China. On the basis of the data analysis, a framework for analyzing mentoring activities emerged. The strengths and weaknesses of the teaching research specialists' mentoring strategies are identified through the framework, and suggestions to improve the teaching research specialists' mentoring strategies are discussed. Manolino et al.[7] aimed to identify the Didactical Suitability Criteria used by a group of Italian teachers participating in Lesson Studies. The written reflections and report documents — such as the Lesson Plans — are qualitatively analysed. The results suggest that all the Didactical Suitability Criteria are considered: the Epistemic, Cognitive, Interactional and Ecological criteria are particularly prominent; the Emotional and Mediational criteria sporadically appear. Ramploud et al.[8] aimed to show the process of deconstruction, functional to start a Cultural Transposition. Starting from the awareness of the "disorientation" generated by different cultural approaches to mathematics teaching, this process aims to produce versions of a didactic practice that are compatible with other cultural context and are suitable to support changes in teacher' beliefs. Wu[9] reported a nested structure of lesson study approach adopted in teaching pre-service mathematics teachers the course entitled Design of Mathematics Teaching. The underlying consideration and activities of each phase of lesson study at levels of MTE and preservice secondary teachers are both presented. Some preliminary findings regarding the effect of this approach on both the enrolled preservice secondary teachers and the MTE herself were provided.

Part of the researches concern the professional development of MTEs. Paper by Willey et al.[12] showcased the process and findings from an examination of MTEs professional growth as a result of engaging in a collaborative interrogation of critical texts outside of mathematics education. Findings suggest that this series of structured reading and dialogue led MTEs to develop a deeper understanding of the historical movements and events that created todays local and global status quos. Shy et al.[19]

reported a four-year (two stages) professional development program called "New Horizon of Mathematics (NHM)" in Chinese Taiwan. The findings indicate that all MTEs and in-service teachers participating in the study have a great transformation on the understanding of CK and PCK and some satisfactory results on mathematics teacher education are obtained.

Other interesting research such as McGlone[14], reported that a program "Teachers2Teachers Global", starting in Guatemala, has developed and implemented teacher training strategies that are rooted in the best practices in mathematics education. The research problem of Dahal[18] was to know the practices of class size with student teacher ratio in private school in the context of Kathmandu district with academic performances in mathematics. Two maths teachers' stories were collected for knowing the gain and pain of the classroom with larger number of student and smaller number of student. Kgosi[22] discussed Mathematics Teachers' professional noticing in the teaching of inverse functions and graphs in Grade 12 in South Africa. As a result, the paper looks deeper in how professional noticing can be used to provide assistance for teachers to notice learner(s) mathematical thinking and how to interpret their mathematical understanding while learning inverse functions and graphs. Under the attention to the strong beliefs teachers possess of mathematical intelligence, Thapa's Paper[25] showed a case in Nepal using multi-paradigmatic research space to inquire about the dis/empowering environment teachers create in math class. The researcher discussed and shared the exploration and practices towards 'un/intelligent educational approach' for a reform in content, pedagogy and assessment of mathematics teaching through teacher development.

Topic Study Group 36

Research on Classroom Practice at Primary Level

Shuhua An[1], Birgit Brandt[2], Benedetto Di Paola[3], and Jiushi Zhou[4]

ABSTRACT The aim of TSG-36 was to share the experiences of research on classroom practice at the primary level, address its research methods and theories, describe innovative classroom practice, and discuss the impact of research on classroom teaching and learning mathematics in different countries. A total of 32 submissions of research articles, project reports, and posters addressed related topics.

Keywords: Classroom practice; Primary level; Integrating technology; Action research; Teacher education.

1. Themes and Description of TSG-36

1.1. The aim of TSG-36

The aim of TSG-36 at ICME-14 was to share the experiences of research on classroom practice at the primary level, discuss its methods developed, and address its impact on classroom teaching and learning mathematics in different countries. The experiences of research on classroom practice can come from various levels of practitioners, educators, and researchers. The complexity of teaching practices in the current rapidly-developing technology era raises a variety of questions for research on classroom practice, such as teacher as researcher, how to use research-based teaching strategies and evidence-based teaching strategies to support effective classroom teaching, appropriate methods for classroom teaching research that informs teaching practice, development of multidisciplinary integration (STEM) projects in mathematics classrooms, effective methods for different teaching approaches, using new technologies in classroom teaching research, effective collaboration on classroom teaching research between classroom teachers and researchers, and effective training

programs for research expertise in higher education and professional development. The principles of teaching have been addressed in many national standards, but there is no clear answer on the principles of effective instruction in elementary mathematics classrooms. These challenges call for action to reflect and discuss important needs in research on elementary classroom practice. The TSG-36 explored state of the art strategies and approaches to address the concerns and problems, and advance the research on classroom practice at the primary level from international perspectives with an ultimate goal of supporting elementary mathematics classroom teaching and learning.

1.2. Themes and description of TSG 36

TSG-36 included the following four themes from:

- **Theme 1.** Empirical studies that investigate using effective classroom practices to support teaching and learning elementary mathematics, integrating technology and/or STEAM education into elementary classrooms, assessing student mathematics learning outcome, and using adaptions to support diverse student mathematics learning.
- **Theme 2.** Effective programs and projects related to teachers as researchers who conduct action research in practices which support effective classroom teaching and learning.
- **Theme 3.** The challenges, diverse and emerging research methods, and tools of effective research on classroom practice at the primary level.
- **Theme 4.** Effective approaches in training and developing expertise in research on elementary classroom practice in teacher education programs and in professional development for classroom teachers.

2. Program Overview

2.1. Format of TSG-36

The format of TSG-36 was a hybrid format — onsite and online meetings synchronously.

2.2. Submissions of TSG-36

A total of 32 submissions were received from 16 countries (Canada: 1; China: 9; Denmark: 1; France: 1; Germany: 1; India: 1; Italy: 1; Japan: 3; Malaysia: 1; Mexcio:1; Sweden: 1; Switzerland: 1; The Philippines: 1; UK: 1; USA; 7; Uzbekistan: 1). These submissions cover a variety of important topics in four TSG-36 subthemes by authors from different cultural backgrounds and countries. Of the 32 submissions, 15 were accepted as paper presentations (seven long presentations and eight short presentations), seven as posters, and 10 could not be presented.

2.3. Sessions and presentations

TSG-36 had three Class B sessions: sessions 1 and 2 had 90 minutes and session3 had 120 minutes. Each session started with a brief introduction, followed by an invited talk, then long oral presentations, and short oral presentations, see Tab. 1. Each session also included at least 20 minutes' open discussion for participants to ask questions and reflect on their learning. In addition, each session included not only diverse topics on classroom practice at the primary level, but also included presenters from different countries and regions to provide an opportunity for participants to interact and exchange their research expertise among various scholars. Furthermore, session 3 provided a 35 minutes next step for the whole group discussion and reflection. The following tables show the papers presented in the three sessions:

Tab. 1. List of papers presented in session 1

Paper and author(s)
Session 1
[1] The benefits of using videos from research studies for teacher education: attending to students reasoning and argumentation. ***Carolyn A. Maher*** (USA).
[2] Examining U.S. elementary teachers' perceptions of and comfort with students' mathematical mistakes. ***Jinqing Liu*** (USA), *Dionne Cross Francis* (USA), *and Ayfer Eker* (Turkey).
[3] Problems with variation: an educational experience of cultural transposition with prospective Primary teachers. ***Benedetto Di Paola*** (Italy).
[4] Shanghai practice of primary mathematics classroom activities. ***Min Zhang*** (China).
Session 2
[5] Conjecturing teaching as competency-based instruction. ***Pi-Jen Lin*** (Chinese Taiwan).
[6] How does a Japanese primary school teacher manage the whole-class discussion named Neriage? ***Valérie Batteau*** (Switzerland).
[7] Teaching mathematics at Mexican elementary schools. ***Edith Arévalo Vázquez***, *Hilda Alicia Guzmán Elizondo, and Elvira Alicia Sánchez Díaz* (Mexico).
[8] Action-research group on Go game as classroom practice to learn mathematics at primary level. ***Antoine Fenech*** *and Richard Cabassut* (France).
[9] A grade 2 teacher's shift in the use of mediational means within and across two addition lessons. ***Fraser Gobede*** (Malawi).
Session 3
[10] Using math clinic to support classroom teaching practice and sharpen teachers' pedagogical content knowledge. ***Shuhua An*** (USA).
[11] Data use to inform mathematics instruction: an exploratory study. ***Jong Cherng Meei*** (Malaysia).
[12] Concept of collective milieu to understand the Japanese mathematics lesson. ***Takeshi Miyakawa*** (Japan), *Valérie Batteau* (Switzerland), *and Minbom Ryu* (Japan).
[13] Exploring the differences between expert and pre-service teachers noticing. ***Yiru Pei***, *Min Chen, and Qiaoping Zhang* (Hong Kong SAR, China).
[14] From loser to user, from special to general education, learning Inside mathematics through outside actions. ***Allan Tarp*** (Denmark).
[15] Storytelling as a resource for fostering 'love of challenge' for mathematics in primary grade students. ***Pooja Keshavan Singh*** *and Haneet Gandhi* (India).

2.4. Main outputs

The three TSG-36 sessions resulted many important outcomes. The main findings included the following:

2.4.1. *Effective approaches in elementary classroom practice*

A number of studies addressed effective classroom practices in elementary classrooms. For example, Lin[5] introduced a conjecturing teaching model with five stages as a competence-based instructional approach. The development of the model was characterized into six periods of investigation. Each period had a focus for eliciting the model. Some studies used a lesson study or classroom teaching as a focus on data collection and analysis. For example, Batteau[6] analyzed teacher practices in a Japanese context with a focus on a specific phase of structured problem solving lessons, a whole-class discussion named Neriage. The study by Gobede[9] also observed teaching practice on mediational moves made by a grade 2 teacher while teaching the addition of whole numbers for the first time at this level and suggested the need to move further to more efficient calculation strategies.

Other presentations introduced interdisciplinary in mathematics classroom. For example, Fenech and Cabassut[8] demonstrated a game activity — Go game — as classroom practice to learn mathematics at the primary level by an action-research group. Singh and Gandhi[15] examined the cognitive engagement of primary grade students with a mathematical content that was embedded in the story situation. It was observed that the attachment of the students with the story characters motivated them to go beyond the basic requirements of the task, seek challenges and expand their vistas for more complex tasks. The study recommends storytelling as a resource for fostering a ‘love of challenge’ for doing mathematics with primary grade students. Zhang[4] introduced using three types of classroom activities — perceived experience, exploration and discovery, and understanding and application to stimulate students’ desire for inquiry, enhance students’ participation, improve students’ learning styles, and realize Mathematics Subject’s multiple-quality function and advantages in fostering qualified personals.

2.4.2. *Teacher education programs for effective classroom practice*

Various presentations related to this theme. Maher[1] addressed the benefits of using videos on attending to students’ reasoning and argumentation from research studies for teacher education programs. Di Paola[3] studies effective approaches in training and developing expertise research on elementary classroom practice in teacher education programs and in professional development for classroom teachers. An’s study[10] examined the impact of Math Clinic on classroom teachers’ questioning strategies, understanding students’ thinking and misconceptions and their intervention strategies of correcting errors in a mathematics graduate program. Using pre-recorded exemplary lessons, Pei et al.[13] examined the noticing ability among expert teachers and explores the difference and similarities between expert teachers and pre-service teacher's noticing on exemplary lessons via a multiple case study. The findings showed that the pre-service teacher has a relatively low noticing ability and tend to focus on the pedagogy and classroom environment.

2.4.3. Important issues and challenges in elementary classroom practice

The presentations in TSG-36 investigated important issues and also address various challenges in classroom practice at the elementary level. For example, a study by Liu et al.[2] examined seven U.S. elementary teachers' perceptions of and comfort with students' mathematical mistakes via interviews. The results showed that teachers believed mistakes are important for proactively teaching, essential for supporting student learning as well as for lesson planning. However, the challenge was that teachers did not feel very comfortable in addressing student mistakes. A study by Vázquez et al.[7] examined teaching mathematics in the categories of teaching strategies, forms of class organization, classroom organization, use of teaching materials, assessment tools and textbook at Mexican elementary school in public elementary schools in Mexico by assessing the practices of 70 elementary school teachers. The results show that despite the implementation of the current curriculum, most educators continue to use teaching strategies that are far from the suggested didactic recommendations. Meei[11] shared an exploratory study on data use to inform mathematics instruction by investigating the state of data use to inform instruction among primary school mathematics teachers in Malaysia.

Results of the questionnaire and interviews indicate that the data which was most frequently used was classroom-based assessment data. Although teachers indicated that training needs and support for data use were adequate and they were confident in using data to inform mathematics instruction, they also like to have more professional development courses so that they can use data effectively and systematically to inform their practice. Miyakawa et al.[12] addressed the concept of collective milieu to understand the Japanese mathematics lesson by highlighting a collective construction of the inquiry or the problem solving process step by step, in terms of the collective milieu due to a lack of theoretical tools to analyze the Japanese mathematics lessons with their specificities: the approach by problem solving, the collective dimension of the teaching, and the focus on the development of mathematical thinking. Based on the observation of how children communicate about Many before school, Tarp[14] indicated that accepting numbers with units means that counting, recounting and solving equations come before adding on-top or next-to introduce integral and differential calculus as well as proportionality in early childhood education.

3. Future Directions and Suggestions Themes

3.1. Future directions

Throughout the presentations and discussions at three TSG-36 sessions, the participants explored and identified current and future trends, merging research themes, and areas of research interest for classroom practice at the primary level, as follows:

(1) Training and developing expertise in teaching and research on elementary classroom practice for classroom teachers;
(2) Training and developing expertise in teaching and research on elementary classroom practice in teacher education programs Role of expert teachers in teacher education programs;
(3) Using videos in teacher education programs;
(4) STEM Education in pre-service elementary teacher training program;
(5) Using interdisciplinary approaches into mathematics instruction;
(6) Data science in mathematics education;
(7) Theoretical tools for analyzing mathematics lessons;
(8) Innovative approach in early children education.

3.2. Suggestions

The participants enjoyed their learning from all presentations on diverse topics at TSG-36 sessions. Despite the promising results from the presentations, some questions remain unanswered at present. Future studies on the classroom practice at the primary level are therefore recommended:

(1) Future work is suggested to design the effective training and profession development on the 21st century teaching and research expertise for elementary classroom teachers and pre-service teachers in teacher education programs;
(2) Future work is suggested to establish the sound theoretical framework for research on using videos, classroom observations, and lesson studies;
(3) Further research should be undertaken to explore topics related to current trends, such as: STEM, data science, and other innovative approaches.

Topic Study Group 37

Research on Classroom Practice at Secondary Level

Yoshinori Shimizu[1], Carmel Mesiti[2], Jarmila Robova[3], and Li Tong[4]

1. Aims of the TSG

The aim of this Topic Study Group was to improve understanding of the research practices, methodologies, results, and supporting theories related to classroom teaching and learning at the secondary level. We intended to promote exchanges and collaboration around the identification and examination of issues of interest to classroom researchers across different education systems with the goal to enhance the quality of research on teaching and learning in secondary mathematics classrooms.

The TSG focused on research related to mathematics teaching and classroom practice at the secondary level. Research on the activities that teachers and students do within the mathematics classroom can involve a variety of methodologies including videography, ethnography, self-reports by participants, scenario-based assessments, first-person research, stimulated commentary by practitioners, simulations, and others. Research on the classroom practice recorded with those approaches involve examination of the interactions among the mathematical content to be taught and learned, the instructional practices of the teacher, or the work and experiences of the students within educational settings. As the report below shows papers presented in the TSG relied on a variety of theories and contributed to the growth of knowledge of a variety of research foci: the mathematics transacted in classroom practice, the complexity of the work of teaching, the roles of teacher and students vis-à-vis the mathematical content at stake, the knowledge used in practice, and more.

This TSG served as an international forum for mathematics education researchers who wanted to disseminate findings and practices from their research on teaching and classroom practice and for practitioners who were interested in learning about how this research was done and on its possible implications for practice. The organizers made a balanced use of the time allocated, with presentations by two invited speakers and

devoting the majority of the time to the discussion of contributed papers, with the goal to maximize exchanges among participants.

1.1. Submissions

We had 47 submissions from 17 countries (South America: 1; North America: 5; Asia: 23; Europe: 12; Africa: 4; Australia/New Zealand: 2) including two invited talks. Each proposal was reviewed by two members of organizing team. Of those 45 submissions, 30 proposals were accepted as paper presentations, 12 as posters, and 3 proposals were rejected. For paper presentations, 16 papers were assigned for a long oral presentation while 14 papers were for a short oral presentation.

1.2. Sessions

TSG-37 had sessions in four time-slots as follows.

- Session I: 14:30-16:30 on 13th of July
- Session II: 19:30-21:00 on 14th of July
- Session III: 14:30-16:30 on 17th of July
- Session IV: 21:30-23:00 on 17th of July

After a short overview of the aim and topics of the TSG, session I started with three *long* oral presentations (10 minutes) of paper followed by a 10 minutes collective discussion for two rounds. Then, three short oral presentations (8 minutes) were made with a short question and answer time. Generally, paper presentations were grouped based on the similarity of topics presented. Session II was exclusively allocated for two invited lectures. Sessions III and IV also included both long and short oral presentations. In each session, the organizers attempted to facilitate participants' discussion and dialogue in order to identify emerging research questions and themes, alternative approaches, and future research opportunities. A whole group reflection time was taken at the end of Session IV, for discussing some issues and suggestions for the next step of research on teaching and learning in secondary mathematics classrooms.

1.3. Invited talks

We were privileged to invite two prominent researchers in the area of research on teaching and learning in secondary mathematics classrooms. Tab. 1 shows two speakers with the title of the papers. These two invited talks provided TSG participants perspectives on the complexity of teaching and learning in secondary mathematics classrooms and pointed out the need of theoretical frameworks to explore the complexity with describing the quality of instruction in the classrooms embedded in sociocultural contexts for students' learning.

Tab. 1. Invited talks

	Paper and author
[1]	Studying instructional quality in mathematics: the need for content-specificity and other open challenges. ***Charalambos Charalambous*** (Cyprus).
[2]	An Approach of mathematics teaching and learning based on activity theory: principles and examples of results. ***Aurelie Chesnais*** (France).

Charalambous[1] discussed the issues related to capturing instructional quality of teaching and learning in mathematics classroom. He first underlined the importance of studying instructional quality through content-specific lenses, in addition to generic lenses, in order to avoid obtaining partial delineations of the quality. After substantiating the thesis with reference to four arguments, he raised three challenges related to studying instructional quality through classroom observations that need to be addressed to move the field forward.

Chesnais[2] presented a theoretical framework based on an activity theory designed to investigate the mathematics learning and teaching process in classrooms with a focus on the questions related to the logics of teachers' practices and the way they impact students' learning. After sharing the theoretical principles of the framework and its methodological consequences, she exemplified the use of the framework in her specific study. The study aimed at investigating how the relationships between the sociocultural background of students and their mathematics achievement were constructed within the mathematics classroom.

1.4. Paper topics

Of the 30 accepted papers, only 22 papers were able to be presented during the online conference. A list of these papers and authors are included in order of presentation and are organized in Tab. 2 (on the next page).

2. Themes to Topics

A variety of research related to mathematics teaching and classroom practice at the secondary level was presented in the TSG as shown in Tab. 2. The presented papers relied on a variety of theories and contributed to the growth of knowledge of a variety of research foci: the mathematics transacted in classroom practice, the complexity of the work of teaching, the roles of teacher and students vis-à-vis the mathematical content at stake, the knowledge used in practice. Given the variety of the presentations, the classical didactic triangle in which student, teacher, and content form the vertices of a triangle may be useful to conceptualize research topics and themes arose across the sessions, although such conceptualization needs to be extended (Goodchild and Sriraman, 2012).

Tab. 2. List of papers presented

Paper and author(s)	
[3]	A large-scale study of teachers' practices in algebra. ***Julie Horoks**, Julia Pilet, Brigitte Grugeon-Allys, Sylvie Coppé, and Marina De Simone* (France).
[4]	Teaching functions using RME approach to improve students' perceptions of mathematics learning and learning functions. *Ayse Kaya and F**atma Aslan-Tutak*** (Turkey).
[5]	Teachers promoting student interaction: what happens when teachers enter a mathematical discussion? ***Marie Aasa Viktoria Sjöblom**, Paola Valero, and Clas Olander* (Sweden).
[6]	The lexicon project: seeking a structure for the australian mathematics teachers' professional lexicon. ***Carmel Mesiti**, David Clarke, and Jan van Driel* (Australia).
[7]	The lexicon project: understanding the universality and applicability of the czech teachers professional lexicon. ***Jarmila Novotná**, Alena Hošpesová, Hana Moraová, and Iva Žlábková* (Czech).
[8]	Technical vocabulary of Japanese mathematics teachers: the Japanese lexicon in the tradition of lesson study. ***Yoshinori Shimizu**, Yuka Funahashi, and Hayato Hanazono* (Japan).
[9]	Inquiry-based learning in the mathematics classroom: insights from a case of two lessons. *Cheng Lu Pien, **Cynthia Seto**, Lee Ngan Hoe, Wong Zi Yang, and June Lee* (Singapore).
[10]	The practice of project-based mathematics extended curriculum at secondary level. ***Dan Shen*** (China).
[11]	The implementation of project-based learning (PBL) in middle school mathematics classroom in Malaysia and South Korea. ***Abdul Halim Abdullah*** (Malaysia) *and Bomi Shin* (South Korea).
[12]	A multi-stage attempt at narrowing the gap between contemporary mathematics and high school mathematics. ***Nitsa Movshovitz-Hadar**, Ruti Segal, Karni Shir, Atara Shriki, Boaz Silverman, and Varda Zigerson* (Israel).
[13]	Puzzle-based class format to foster students' mathematical oral production and exchange. ***Luca Agostino**, Bruno Durand, Laetitia Sonia-Doucet, Dimitri Zvonkine, and Varda Zigerson* (France).
[14]	Developing students' metacognitive practice: a systematic approach. *Low Leng, **Ang Yue Hua**, and Lee Ngan Hoe* (Singapore).
[15]	Learning situation analysis: problem, focus and method. ***Yu Hongyu*** (China).
[16]	A lesson design model to enhance students' activities with examples. ***Mayumi Kawamura**, Kazuya Kageyama, and Masataka Koyama* (Japan).
[17]	Re-visiting instructional explanations: how might the organisation of a lesson contribute to an explanation. ***Vasantha Moodley*** (South Africa).
[18]	Anthropological perspective on japanese mathematics teachers' professional knowledge of board writing. ***Yukiko Asami-Johansson*** (Sweden).
[19]	The implementation of a set of tasks for the development of spatial ability in secondary schools. ***Jarmila Robová** and Vlasta Moravcová*(Czech).
[20]	Productive struggle: a focus on sense making and connecting. ***Azita Manouchehri** and Reyhan Safak* (USA).
[21]	Promoting student questions in mathematics classrooms. ***Melissa Kemmerle*** (USA).
[22]	English language learners learning statistics in multilingual classrooms. ***Sashi Sharma*** (New Zealand).
[23]	A class for conceptualizing lagrange's four-square theorem. ***Tomohiko Shima** and Minoru Ito* (Japan).
[24]	Different Learning opportunities for students provided by teachers in high school mathematics classrooms: a classroom video analysis. ***Changjie Li** and Yun Lu* (China).

First theme that arose across the sessions related to teaching a particular content and topics of secondary school mathematics (Robová and Moravcová[19]; Shima and Ito[20], Sharma[22]). Kaya and Aslan-Tutak[4] for example, proposed the use of RME approach to improve students' perceptions of mathematics learning and learning functions. Movshovitz-Hadar et al.[12] presented their research on the instructional materials developed for narrowing the gap between contemporary mathematics and high school mathematics. These studies challenged the long-standing issue of teaching mathematics at secondary school so as to be meaningful and useful to the students. Also, there were reports of the analysis of classroom activities related to the new trends in teaching and learning in secondary mathematics classrooms, such as project-based mathematics extended curriculum (Shen[10]) and Project-based learning (PBL) (Abdullah and Shin[11]), inquiry-based learning (Pien et al.[9]) emerged a new area of exploratory studies.

A second theme that arose across the sessions was related classroom interaction between the teacher and students as well as communication among students (Manouchehri and Safak[20], Asami-Johansson[18], Sjöblom et al.[5]). Also, there were presentations of particular focus on teacher or students. Further, a particular method of developing students' metacognitive practice (Leng et al.[14]) and "puzzle-based class format" was proposed for fostering students' mathematical oral communications (Agostino et al.[13]). In this context, the role of example (Kawamura et al.[16]) and the importance of explanations (Moodley[17]), and promotion of student's questions (Kemmerle[21]) in mathematics was emphasized through the empirical studies.

A third theme that arose across the sessions involved the analysis of lexicon, a focus on teachers' use of technical vocabulary that describe activities in mathematics classrooms. Three papers from the same project provided the analysis of lexicon in the different cultural traditions (Mesiti et al.[6], Novotná et al.[7], Shimizu[8]).

Research on the classroom practice recorded with those approaches involve examination of the interactions among the mathematical content to be taught and learned, the instructional practices of the teacher, or the work and experiences of the students within educational settings. Research on the activities that teachers and students do within the mathematics classroom involved a variety of methodologies including both a large scaled study of teachers' practices (e.g. Horoks et al.[3]) and case studies of lessons and video analysis (e.g. Pien et al.[9], Li and Lu[24], Sharma[22]). Also, for the empirical studies, various methods were used in the study presented in this TSG. videography, ethnography, self-reports by participants, and so forth.

3. Areas for Future Research

At the end of Session IV, the participants had an opportunity of reflecting on the trends and issues in research on teaching and learning in secondary mathematics classrooms based on the presentations and discussion in this TSG. A few potential future research topics were discussed. First, given the complexities of teaching and learning in secondary mathematics classrooms, empirical studies need to capture the quality of instruction with a focus on content and educational values of mathematics taught in secondary mathematics classrooms. Second, classroom interaction between the teacher and students as well as communication among students need to be examined further in relation to the development of students' mathematical thinking and learning. Third, research on teaching and learning in secondary mathematics classrooms needs to be scrutinized from a "meta-level". That is, an overarching theoretical framework is needed to discuss and integrate findings of empirical studies.

Acknowledgement

The original Chair (Professor Patricio Herbst) and Co-chair (Professor Fabrice Vandebrouck) were unfortunately unable to participate in the TSG due the postponement of ICME-14 caused by the COVID-19 pandemic. They had a major contribution in planning and preparing for the TSG, including reviews of the submitted papers and inviting speakers. We greatly appreciate their initial organization and contributions.

Topic Study Group 38

Task Design and Analysis

Minoru Ohtani[1], Michiel Doorman[2], Berta Barquero[3], Heather Johnson[4], and Xuhua Sun

1. Themes and Descriptions the TSG

1.1. Themes of the TSG

In TSG-38, we focused on a variety of theoretical and practical topics related to task design and its analysis. Since there exists a complex, layered relationship between task designers, teachers, and students, which is well-illustrated by successful, theoretically-based long term design research projects, which have resulted in novel materials and approaches impacting teachers and students. Throughout the presentations we actively searched for connections both in regards to methodology, theory and the possible impact of the presented research. We aimed to explore seven related themes: ① frameworks and principles for task design; ② methodological advances for studying task design in mathematics education; ③ relationships between task design, anticipated pedagogies, and student learning; ④ the role of tools in task design; ⑤ task sequences for promoting conceptual understanding and/or higher order thinking skills; ⑥ task design in innovative learning environments; and ⑦ textbook task analysis. We encouraged submissions that offered theoretical and/or empirical contributions and sought to include research from a variety of cultural contexts to enhance our discussions.

1.2. Submissions

We invited two presentations and received a total of 38 submissions from 17 countries (South America 1, North America 2, Asia 7, and Europe: 7), with diverse cultural representation. Of those 38 submissions, thirty-one papers were accepted as paper presentations (fourteen as long oral and seventeen as short oral), five as posters, and two were rejected.

1.3. Paper topics

Of the 31 accepted papers, only 24 papers were able to be presented during the online conference.

A list of these papers and authors are included in order of presentation and are organized with related themes in Tab. 1.

[19]	Task for introducing the vector concept using technology. ***Sofia Paz Rodriguez****, Carlos Armando Cuevas Vallejo and Hosé Orozco-Santiago Cinvestav* (Mexico). ①④⑤
[20]	Design tasks in MLR environment: Constructing examples for proving logical statements. ***Galit Nagari-Haddif*** (Israel). ①⑤⑥
[21]	Didactic sequence planning for the study of the teaching and learning of isometries in future primary school teachers. ***Marta Martin Nieto*** *and Natalia Ruiz-Lopez* (Spain). ①③⑤
[22]	Analyzing primary two pupils' errors answering fractions' task using the Newman procedure. ***Rosmawati Mohamed*** *and Munirah Ghazali* (Malaysia). ①⑤
[23]	Effects of low floor high ceiling mathematical tasks on students' mathematical proficiency in seventh-grade geometry. ***Franklin Falculan*** *and Maria Alva Aberin* (Philippine). ①⑤
[24]	Collaborative design of unit that fosters reification of a mathematical object. ***Minoru Ohtani*** (Japan). ①⑤

2. Program Overview

2.1. Sessions

There were so many high-quality submissions, the ICMI organizing committee granted our TSG one more time slot for presentations. In our first 90-minute session, the TSG Chair, Minoru Ohtani, introduced the rest of the Team and described the format of the sessions. Generally, all four-time sessions led with 20 minutes *invited long* oral and presentation and discussion and *long* and *short* oral presentations with a 30- and 10-minutes collective discussion respectively. Throughout the four days, we attempted to facilitate participant dialogue to collectively identify emerging research themes, potential interdisciplinary approaches and future research opportunities. We used an online discussion platform, "Padlet," to facilitate communication among participants. We shared roles of online chair, note taker, and onsite organizer, to foster participant networking as well as to counter "virtual conference" fatigue. At the end of our last session, we built in 20 minutes for whole group reflection, discussion, and suggestions for needed research trajectories.

2.2. Session 1

In the session 1, we had one invited and three long oral presentations. The invited presentation by Trigueros[1] discussed an example of a task designed from the viewpoint of APOS theory to examine students' understanding of linear transformations. The analysis of students' responses from the lens of APOS theory, coupled with observations made by using the Anthropological Theory of Didactics (ATD) offer important elements that can be used in the redesign of the task. The design of task with APOS theory made it possible for students with different conceptions to start working on the task and obtain an answer that they considered satisfactory. At the same time APOS theory enables researchers to look closely into details involved in students' responses and discern different conceptions. The design of task with ATD evokes the issue of students' interpretation and performance of the task in reference to the social and institutional situations. Viviani and White[2] proposed task design for automatic formative assessment of student responses in a calculus class which provides students with opportunities to engage in exploration to change and develop their mathematical perspectives. Johnson et al.[3] elaborated a joint embodied and simulation design methods which are rooted in different theoretical traditions. The empirical evidence and implications of two phases of joint design method were discussed. Joining genres brings in a correspondent theory and highlights aspects of learning, together providing the rich affordances for covering a variety of possible gaps in mathematics understanding. This approach is particularly relevant for task sequences involving socially shared, and yet spatially articulated, mathematical notations, such as Cartesian graphs. Barquero and Esteve[4] reflected on the work of transposing research and methodological tools to teacher education for primary school teachers' practice of designing and analysing tasks. The case of the study and research paths had theoretical underpinning of the anthropological theory of the didactic and the research methodology proposed by didactic engineering.

2.3. Session 2

In the session 2, we had seven short oral presentations. Mittal and Ahuja[5] investigated the exploration of mathematical task design by pre-service teachers from three aspects: their source, type, and appropriateness, all of which can give holistic understanding to the researchers. Sun[6] delineated the fundamental idea of task design for algebra knowledge development with specific emphasis on Chinese cultural context. Muñoz[7] presented research results on the relationship between the schooling experience by prospective teachers, their instructional beliefs and practices, and the way they design mathematical tasks. The analysis showed a predominant pattern oriented towards constructivist teaching practices, which was influenced by the schooling of the prospective teacher. García et al.[8] presented results of a teacher's task design in combinatorics based on the "mode 5e". Transformation of task sequences with the 5e mode broadened teacher's vision and promoted high school students' perception. Kristinsdottir et al.[9] presented results of design research project on developing silent video tasks in collaboration with researcher, upper secondary teachers, and students. The research showed that the silent video tasks could be used as formative assessment and in classroom discussion. Otaki et al.[10] analyzed an authentic inquiry in didactic situations within the framework of the anthropological theory of the didactic (ATD), especially by the Herbartian schema. Inquiry process by prospective mathematics teachers who engaged with a task about calculation cubic root by pocket calculators was deliberately analyzed by the schema. Li and Zhou[11] reported on SOLO taxonomy-based action research on the design of multiple task examples for high school students. The examples had holistic, hierarchical, and self-explanatory nature and benefit most students at different levels.

2.4. Session 3

In the session 3, we had one invited and seven long oral presentations. The invited talk[12] by Ärlebäck discussed research on so called "Fermi problems" and the fundamental principles underlying this type of tasks and their use. Based on the model and modeling perspective on teaching and learning, the research developed the "FPAT-framework" for supporting the design and use of Fermi problems to facilitate not only students' learning mathematics concepts and higher order thinking skills but also interdisciplinary collaborations with other subjects, especially STEM subjects. Luhuan Huang et al.[13] presented a comparative textbook task analysis of lower-secondary schools in Beijing and the Netherlands, using an inquiry-based learning (IBL) framework. The analysis showed that tasks in both textbooks provide some opportunities for IBL in phases related to solution procedures and representations.

Meryansumayeka et al.[14] illustrated design research on digital task design which aims at developing higher order thinking skills (HOTS) for junior high school students. The digital tasks were developed based on the PISA problems and were validated and evaluated for the field test. Zhang et al.[15] posited that the variation in task design has a profound theoretical foundation and developed an analytic model of "teaching mathematics through variation" which distinguishes potential variation and practical variation. The model illustrated a teacher's documentation work from potential to practical variation in in China and France. Jäder[16] addressed how students' opportunities to engage in mathematical problem solving is limited by the prevalence of routine tasks in textbooks. An analytic framework was developed to better understand some of the important components of mathematical problem solving and possibly also be of support in the design of mathematical problems. Doorman et al.[17] discussed task design with scenarios in promoting inquiry-based mathematics teaching. The combination of the RME and the TDS afforded the development of open and context-rich tasks and to support teachers in balancing phases of student-led inquiry with phases for creating a whole class shared understanding of mathematical structures. Dawn et al.[18] proposed four interacting elements for consideration when developing a mathematical activity to support the construction of mathematical concepts. Analysis of students' work from the activity revealed different trajectories of how teachers can plan for differentiated instruction to promote students' robust construction of concepts.

2.5. Session 4

In the session 4, we had seven short oral presentations. Rodriguez et al.[19] prezented a sequence of tasks to help university students to go from an elementary conception of vector in physics to an element of a vector space. The task sequence involved a contextual problem in a digital environment with increasing abstraction. It began with movement of a robotic arm then as an arrow with magnitude and direction, and finally as an ordered pair of real numbers in a geometric environment. Nagari-Haddif[20] demonstrated design pattern of tasks using the Seeing the Entire Picture (STEP) online assessment platform in which students were to construct and submit examples for refuting or supporting a statement in an MLR environment with the activity "asymptotes and parametric functions". Nieto and Ruiz-Lopez[21] reported design reserch on the creation of a didactic sequence of problems and a technological tool to guide the resolution for teaching and learning isometries for prospective primary teachers. Mohamed and Ghazali[22] devised fraction tasks and test items which were validated by experts. Through these instruments and the Newman procedure types of errors concerning fractions were identified. Falculan and Aberin[23] investigated the effects of using Low Floor High Ceiling (LFHC) mathematical tasks on students' mathematical proficiency in seventh-grade geometry by closely examining their conceptual understanding and procedural fluency. Ohtani[24] presented an activity-theoretical approach to collaborative design of task and learning environment in which researchers of different expertise, and secondary teacher play different roles.

3. Recent Trends and Future Directions

We laid out seven themes in section 1.1. In view of the seven related themes, we point out recent trends and pose future directions for further research that arose from the TSG.

1) frameworks and principles for task design

We had many presentations that evidenced productive coordination and/or joint of different frameworks and principles. Among others, emergence of the embodiment perspective demonstrates promise for furthering task design. Chinese variation theory also drew much attention in the TSG. We need to investigate further how different design principles reflect or generate different perceptions of mathematical concepts.

2) methodological advances for studying task design in mathematics education

Many presentations adopted Design Research methodology, including the iterative processes of thought experiments and teaching experiments. The model and modelling perspective were also prevalent in the TSG presentations. In view of the wide interest in STEM movement, it is crucial to incorporate methodological advancements from other disciplines.

3) relationships between task design, anticipated pedagogies, and student learning

In this theme, recent research emphasizes inquiry-based learning, study and research pass, and cooperative learning. In this regard, it is necessary to reflect how different combinations of tasks and pedagogy influence learners' perceptions and mathematical activity.

4) the role of tools in task design

Some research developed digital tasks and video tasks. It is also relevant topic in task design and analysis to investigate how visual features of task presentation affect mathematical activity.

5) task sequences for promoting conceptual understanding and/or higher order thinking skills

In our knowledge-based society students need so called 21st century skills. A way to create opportunities for addressing these skills in classroom is through inquiry-based learning (IBL). In the TSG, we had promising presentations that suggested the design of appropriate tasks could be an important prerequisite for successful implementation of IBL.

6) task design in innovative learning environments

The development of technologically rich environment and assessment system enables us to understand the complex relationship between task design and individual learner differences.

7) textbook task analysis

This theme was not listed in the discussion document of the TSG. However, we had several presentations that compare textbook task in different countries, specifically comparison of Chinese and European countries.

In addition to the aforementioned seven themes, the following themes were prevalent in the TSG.

8) teachers' professional learning on task design and analysis

The professional learning of prospective and practicing teachers about task design, sequencing, and adaptation. This emerging theme, which goes beyond superficial aspects, would require socio-cultural perspectives in task design.

9) notworking among stakeholders

The communities involved in task design are naturally overlapping and diverse and they may act in several of these roles. Stakeholders can include designers, professional mathematicians, teacher educators, teachers, researchers, learners, and policymakers and so on. The effectiveness of forms of collaboration and communication between task designers, classroom teachers, educators, and policymakers.

10) political and ethical dimension of task design

This theme was less obvious in the TSG. The role of task design in promoting equity and other values are less attentive but relevant theme which should be considered in future research.

Looking to the future, TSG participants who are examining interdisciplinary efforts, instructional tools, online resources, and research methodologies could expand their vision by sharing empirically grounded contributions that underlie design principles, theoretical approaches, and carefully analyzed cases and examples of tasks designed for promoting mathematical development. Another area to explore are the multi-dimensional aspects of task design: tasks and sequences of tasks can shape possibilities for interactions between teachers and students. Teachers' pedagogies can include the selection, modification, design, sequencing, installation, observation and evaluation of tasks, through which they may learn more about their students' thinking and experiences. In turn, students' interactions with tasks can afford opportunities to learn mathematical concepts, ideas, strategies, and also to use and develop higher order thinking skills and critical literacy.

Topic Study Group 39

Language and Communication in Mathematics Classroom

Marcus Schütte[1], Jenni Ingram[2], Tran Vui[3], Maíre Ní Riordáin[4], and Fengjuan Hu[5]

1. Core Topics and Research Interests for TSG-39

To begin with, we give a brief overview of the thematic foundations and challenges of TSG-39.

The variety of research shared by the presenters at the ICME conference makes the wide range of individual approaches to theory and methodology visible that research in language and communication in mathematics education is based on. Morgan (2006) refers to this focus to the role and nature of language and communication in relation to the learning of mathematics as a ‘turn to language’, although Pimm (2018) describes a long history of research connecting language within mathematics education. But a recognizable shift in the recognition of the complexity of the relationship between language and the learning of mathematics is taking place.

The research results presented in TSG-39 are based on an understanding of language and communication in a broad sense. The authors presented work focusing on the following fields of research: classroom interactions; interactions between children at play; multimodal analysis; as well as research that focuses on the multi-semiotic nature of mathematical activities, or even the role of silences (e.g., Boistrup and Samuelsson, 2018; Elliott and Ingram, 2016; O’Connor, Michaels, Chapin, and Harbaugh, 2017). Judith Moschkovich (2018) formulated four recommendations concerning the research of language and communication in mathematics education at ICME-13:

(1) using interdisciplinary approaches;
(2) building on existing methodologies;
(3) defining central constructs;
(4) recognizing central distinctions while avoiding dichotomies.

With respect to points (1) and (2) of Moschkovich, it can be stated that research in our field is influenced from a variety of theoretical and methodological ideas from

mathematics education as well as from other fields such as sociology, psychology, anthropology, linguistics, semiotics and many more. Working at the intersection of theories of learning and teaching mathematics and theories of language, interaction and communication is fundamental to doing research in mathematics education with a focus on language, interaction and communication. The connection of existing theories and methodologies is equally important as the development from new theories to drive innovation. A particular challenge when combining theories from different disciplines is on (3) defining terms and central constructs such as language, register and discourse and also to use them in a way that is consistent with the approach to research being taken. Finally, we turn to the recommendation of (4) recognising central distinctions while avoiding dichotomies. Moschkovich emphasises the often-made dichotomy between quantitative and qualitative approaches in contrast to the many examples of work that combines both. Another aspect of the dichotomy that should be considered in more detail is the type of attention given to language in research. However, language and mathematical activities are often intertwined, making it difficult to distinguish whether language is the focus of research or the medium through which researchers can access mathematical thinking or learning (Andersson and Wagner, 2019). The recommendations of Moschkovich (2018) shed light on the topic of mathematics and language from very different perspectives and were addressed in the various papers and posters as well as invited lectures.

2. Presentations in TSG-39

ICME-14 brought together researchers from around the world and TSG-39 included a range of researchers from 13 different countries, drawing on a range of different theoretical perspectives, different methodological approaches and with different focuses. Due to the COVID-19 pandemic, the meeting was held in a hybrid format. Part of the presentations were given online via Zoom, and another part at the location of ICME-14, East China Normal University, Shanghai, China in a lecture hall. A total of 21 papers and 7 posters were accepted for presentation in TSG-39. The papers were presented in 3 sessions over 3 days. In addition, two sessions were dedicated for one invited talk each (Tab. 1).

2.1. Invited talks

The first invited talk[1] is given by Krummheuer from Kassel, Germany and Schütte from Leibniz University Hannover, Germany, and the second invited talk[2] is given by Herbal-Eisenmann from Michigan State University, USA and Ingram from Oxford University, UK. These invited talks enabled TSG participants to reflect on new broader perspectives regarding mathematics and language and to discuss the insights gained on this topic.

Tab. 1. The list of papers presented

Paper and author(s)
Invited talks
[1] Cooperation, argumentation and learning — Three basic concepts referring to everyday procedures in teaching-learning situations in mathematics classes. ***Götz Krummheuer*** *and* ***Marcus Schütte*** (Germany).
[2] A political look at math communication. ***Beth Herbal-Eisenmann*** (USA) *and* ***Jenni Ingram*** (UK).
Session 1
[3] Meeting the challenges of research language and communication in mathematics education. ***Jenni Ingram*** (UK), *Marcus Schütte* (Germany), *Fengjuan Hu* (China), *Máire Ni Riodáin* (Ireland), *and Tran Vui* (Vietnam).
[4] Lifeworld connections in mathematics education — unquestioned, indispensable, and undefined? ***Elisa Bitterlich*** (Germany).
[5] The threshold of multiple representations for students to discover possible solutions for communicating their new ideas in integrated closed-open approach. ***Tran Vui*** (Vietnam).
[6] The practice and examination of opportunities to translate representation through problem-solving. ***Kunihiko Shimizu*** (Japan).
[7] Tau Ke: a software solution for capturing multiple representations of pangarau (mathematics) language. ***Piata Allen*** (Australia).
[8] The effects of using a modified Frayer Model to teach mathematics vocabulary to junior-form English learners in a Chinese medium-of-instruction secondary school. ***Wing-kwan Li*** *and Simon S. Y. Cha* (Hong Kong SAR, China).
[9] It always equalled an odd number: observing mathematical fluency through students' oral responses. ***Katherin Cartwright*** (Australia).
[10] Achieving meaningful statistics classroom learning through bilingualism and multilingualism: a case of selected grade 10 students in Marikina city. ***Mary Jane A. Castilla*** *and Catherine P. Vistro-Yu* (Philippine).
Session 2
[11] Discourse as the place for the development of mathematical thinking through an interactionist perspective. ***Judith Jung***, *Marcus Schütte, and Götz Krummheuer* (Germany).
[12] Language-responsive support of meaning-making processes for understanding multiplicative decomposition strategies. ***Annica Baiker*** *and Daniela Götze* (Germany).
[13] A study on the evaluating of learning opportunities in mathematics classes of secondary schools based on discourse analysis techniques. ***Zhihui Chen*** *and Yuting Tong* (China).
[14] Mathematical expression in different languages: The need for systematic description. ***Cris Edmonds-Wathen*** (Australia).
[15] A comparative study on teaching language of algebra classroom between novice teachers and expert teachers taking linear equation in one unknown as an example. ***Si-kai Wang*** *and Li-jun Ye* (China).
[16] Interactional obligations for collective argumentation in pair and group work. ***Rachel-Ann Böckmann*** *and Marcus Schütte* (Germany).
[17] How pre-service primary teachers engage in language responsive mathematics teaching while working on a scriptwriting task. ***Victoria Shure*** *and Bettina Rösken-Winter* (Germany).
[18] Support Systems as intersubjective processes between Teachers and Students. ***Ann-Kristin Tewes*** (Germany).
Session 3
[19] Epistemic (In)justice in mathematical communication between teachers and students. ***Lauren Hickman McMahon*** (USA).
[20] Identifying language demands for understanding the meaning of similarity. ***Kirstin Erath*** (Germany).
[21] Exploring a teacher's enactment of explanatory communication in a mathematics lesson. ***Fatou Sey*** (South Africa).
[22] Dissent and consensus situation structures in mathematics and computer science learning environments. ***Peter Ludes-Adamy*** *and Marcus Schütte* (Germany).
[23] Quadrilateral woop-de-doos: Language use and geometric property development of two fifth graders in a dynamic geomtetry learning environment. ***Candace Joswick*** *and Michael T. Battista* (USA).

2.2. Session 1

In Session 1 Bitterlich[4] focusses on situations with a lifeworld connection within mathematics lessons. Via interactional analyses and the analysis of linguistical markers her study aims at reconstructing the consequences of lifeworld connections on language use and the negotiation of (mathematical) meaning. Bitterlich underlines that lifeworld connections are frequently posed by the teacher, but seemingly seldom reflected concerning the underlying mathematical content. Shimizu[6] reports research that children will be proactive in their use of diverse mathematical representations when they have questions and explorative tasks in learning problem-solving. Based on this classroom practice, the process of representation was translated by exploring student questions, while students' feelings concerning their approach to mathematics were also important. Further, as students' inquiries deepened, their representation gradually became more sophisticated, and in the process, along with trial and error, a process of returning to representing thought was seen. Allen'***s*** study[7] focused on the use of digital technology in Māori-medium schools as a way of supporting Māori language, Māori knowledge and the acquisition of school mathematics. Following a period of Indigenous language and culture loss, in Aotearoa New Zealand, there has been rapid development of a corpus of mathematics terms and language to enable the teaching of mathematics in the Indigenous language, Māori. Allen's paper highlights the questions and concerns that continue to be raised, about the role of Indigenous mathematical practices in modern schooling. Li and Cha[8] conducted a study about learning Mathematics vocabulary using a Modified Frayer Model in a local secondary school. The model, also a graphic organiser, included four components which were specific to Mathematics: Mathematics symbols, diagrams or pictures, related vocabulary and sample sentences. The results showed that the model not only expanded the participants' Mathematics vocabulary, but also helped them remember it.

Cartwright[9] reports from a deductive analysis of student narrative data (transcripts) and student group work samples (artefacts) aiming to discover what characteristics students displayed both orally and written as evidence of mathematical fluency. She presents the oral and written language features students employed to explain their method and justify their strategies when solving mathematical tasks. Regarding mathematical fluency, Cartwright discusses that students' oral explanations were either procedurally-driven or findings driven. Students that were findings-driven could be identified at a higher level of fluency based on their ability to shift from low to high modality language. Cartwright proposes the need to analyze the language features (as a representation mode) of students' responses–particularly oral responses–as they provide data that might usually be missed or not present within written numerical work samples. Finally, Castilla and Vistro-Yu[10] examined the linguistic interactions that took place in a Statistics classroom using the framework of the second generation Cultural Historical Activity Theory (CHAT) with bilingualism and multilingualism as a potential primary CHAT construct. They looked into how the varying roles of students' alternating use of the Filipino and English languages combined with their mathematical language contributed to the students' participation in the activity.

2.3. Session 2

In Session 2 Jung et al.[11] focus on early childhood mathematics learning. Based on interactionist perceptions of mathematical learning, the development of mathematical thinking is described as increasing participation in mathematical discourses. For a more detailed description of these discourses, the so far common focus of interactionist approaches to mathematics learning on the analysis of mathematical negotiation of meaning is expanded to include a description of emerging argumentative structuring of the mathematical negotiation processes. Baiker and Götze[12] present a study investigating the impact of a language-responsive intervention on students´ understanding of decomposition strategies. Three second grade primary school teachers introduced multiplication ($n = 66$) by using meaning-related phrases of unitizing (e.g., '6 times 4 means 6 fours'), whereas three other classes taught without this focus served as control group ($n = 58$). The analyses of a multiplication post-test and a follow-up test showed a deeper understanding of decomposition strategies of the intervention group children.

Chen and Tong[13] addresses the question of the development of literacy skills of senior high school students in China and how to promote students' skills based on the model of mathematical core competencies in the classroom. Discourse analysis techniques are used to analyze two video-based lessons with different teaching methods. The results show that the evaluation model based on the idea of learning opportunity is reliable in terms of how students can benefit from the mathematical tasks and interaction (initiated questioning and feedback) provided by the teacher in the teaching process. Edmonds-Wathen[14] described a need for more systematic description of the variation in mathematical expression in different languages and the observed or speculated effects of this variation on mathematics education in those different languages, proposing a functional typology approach where languages are classified according to structural similarities and differences. Wang and Ye[15] reported a comparative study about the teaching language of a novice teacher and an expert teacher in algebra instruction. They classified the teacher's teaching language from the perspective of pragmatics, on the basis of which they specifically discussed the similarities and differences between the two teachers' use of teaching language.

Böckmann and Shütte[16] describes interactional obligations for bringing forth warrants or backings within collective argumentations which occur in social interactions of students working collaboratively in multi-age groups. She presents three interactional obligations — contradictions, mistakes and certain types of questions — as well as discusses how students' interpretation of interactional obligations can change within an interaction. Shure and Rösken-Winter[17] report on the results of a scriptwriting task study aimed at examining how pre-service primary mathematics teachers enrolled in a Master's program address language difficulties to support students in gaining mathematical reasoning competencies. They present differences in practices between higher and lower performing pre-service teachers and discuss the study's relevance for teacher education. At the end Tewes[18] focusses on different support systems between students, primary school teachers and special needs education teachers. She therefore located support systems between the participants of the interaction and describes them as intersubjective processes which are designed together. The aim of the study is to reconstruct the potential effects of these support systems for the participation in inclusive mathematic lessons.

2.4. Session 3

The Session 3 begins with McMahon[19] who describes in her paper, two forms of epistemic injustice offered by Fricker (2007) — testimonial and hermeneutic. Using a real-world example, she considers how such injustice can manifest itself in teacher-student communication about mathematics and discusses features of mathematical knowledge and skill that are necessary for children to experience epistemic justice in their interactions with teachers. Erath[20] reports from a Design Research study aiming at developing a language-responsive teaching-learning arrangement for the geometrical topic of similarity with a particular focus on supporting students' interaction in phases of unmoderated group work. She presents and discusses identified discourse practices and language means alongside a intended sequence of larger steps in the process of knowledge construction. Ludes-Adamy and Schütte[22] report on their research on learning environments with core topics of mathematics and computer science are examined. In the focus of digitalization, this topic and its connection to mathematics will play an important role in future curricula, making it an interesting object of investigation. Ludes-Adamy and Schütte present an ongoing study that examines, how the topic of computer science connected to mathematics learning can be approached in primary schools and what and how meanings are negotiated. They focus on the question what roles consensus and dissent play in interactional processes of negotiation and how the learning of the fundamentally new occurs in collective argumentation between pupils. Joswick and Battista[23] use a longitudinal analysis to track the language and geometry concept development of two 5th grade students regarding dynamic geometry for the study of quadrilaterals. In their paper, the authors describe the students' initial use of the term "whoop-de-doo" in their reasoning about quadrilateral shapes and point to the importance of our findings for productive classroom discourse.

3. Summary and Prospect

The papers that have been presented during our TSG present a wide range of research perspectives. They are published in the HAL open archive and can be freely accessed. The challenges that researchers in language, interaction and communication in mathematics education encounter, can also be seen as opportunities to foster innovation and influence teaching and learning of mathematics in a variety of contexts. Working together as a Topic Study Group at ICME, discussing and connecting the differences and similarities in the research, enabled us all to take advantage of these opportunities and develop the field further. This collaboration will continue due to an ever-growing core of collaborating scientists in the field of mathematics, language and communication at the upcoming international meetings, such as those of CERME-2022, ETC-2022 and the following ICME meetings.

Topic Study Group 40

Research and Development on Mathematics Curriculum

Masataka Koyama[1] and Jeremy Hodgen[2]

ABSTRACT The theme of Topic Study Group 40 (TSG-40) at the 14th International Congress on Mathematical Education (ICME-14) (Shanghai, China) is Research and Development on Mathematics Curriculum. TSG-40 was held worldwide on-line style in three sessions of July 13, July 16, and July 17, 2021. This article reports a concise summary of TSG-40 including its organization, theme and description, the list of presentations and program overview, the summary of presentations in the theme of four topics at TSG-40, and future directions and suggestions in the area of research and development on mathematics curriculum.

Keywords: Mathematics Curriculum; Policy; Research; Development.

1. Organization, Theme, and Description of TSG-40

1.1. Organization and theme of TSG-40 for ICME-14

TSG-40 was organized by the organizing team[3].

The theme of TSG-40 at ICME-14 is Research and Development on Mathematics Curriculum. Its aim is to share and discuss the recent results of research and development on mathematics curriculum at all levels, and to identify perspectives for future research and development. Recent mathematics curriculum study has expanded to explore a range of important topics, including policy issues, curriculum development and analysis, and curricular impact on teachers' teaching and students' learning (Li and Lappan 2014, Vistro-Yu and Toh 2019).

Shelly Dole, University of the Sunshine Coast, Australia
Ruilin Wang, Capital Normal University, China

1.2. Description of TSG-40

We called for papers for TSG-40 as follows.

TSG-40 welcomes researchers, teacher educators, teachers, curriculum developers, test developers, and policy makers with research interests in research and development on mathematics curriculum. We invite both theoretical and empirical research contributions that address one or more of the following topics in the research and development on mathematics curriculum.

Topic 1: Mathematics Curriculum Policy

This topic includes policy issues related to mathematics curriculum in different education systems, and the process of curriculum decision-making, curriculum changes, curriculum policy, and education changes viewed from a historical perspective.

Topic 2: Mathematics Curriculum Development and Analysis

This topic includes curriculum design and development in different education systems, explicating and comparison of diverse ideas and practices in curriculum development, textbook design, and changes in curriculum development in different system contexts.

Topic 3: Mathematics Curriculum, Teacher, and Teaching

This topic includes perspectives on the process of improving mathematics education by reform of curriculum and teaching, and the challenges of developing, implementing, and evaluating change in the content objectives and teaching of mathematics.

Topic 4: Mathematics Curriculum and Student Learning

This topic includes curricular impact on students' learning and the challenges of reforming the curriculum to improve students' learning.

2. List of Presentations at TSG-40 and Program Overview of TSG-40

2.1. List of presentations at TSG-40

As a result of both peer-reviews and the payment of registration fee for participating in ICME-14, TSG-40 contributions included 1 long paper (LO), 10 short papers (SO) and 3 posters. Tab. 1 (on the next page) lists the title and author(s) of the papers and posters presented at TSG-40.

2.2. Program overview of TSG-40

TSG-40 had three sessions with 90-90-120 minutes' timeslots for papers. We gave a careful consideration to the worldwide on-line style of TSG-40 especially the time difference and made the program of presentations at TSG-40 including an opening session in Session 1 and a closing session in Session 3 as follows.

Tab. 1. List of papers and posters presented at TSG-40

Title and *author(s)*	
[1]	Identifying the quality of teacher created curriculum shared via the teachers' pay teachers online platform. *Lara K. Dick, **Amanda G. Sawyer**, and Margaret A. MacNeille* (USA). (LO)
[2]	Comparative study on statistical contents in Chinese and Japanese mathematics textbooks. ***Xinqi Zhang** and Masataka Koyama* (Japan). (SO)
[3]	The implementation of a reformed mathematics curriculum: Mathematical processes in practice. ***Anna Klothou** and Charalampos Sakonidis* (Greece). (SO)

[5]	Financial education in the Romanian mathematics curriculum: Policy and implementation in elementary textbooks. ***Daniela Căprioară*** (Romania)*, Annie Savard, and Alexandre Cavalcante* (Canada). (SO)
[6]	Formative evaluation of a tool for representing ideas in mathematics curriculum design: A Delphi study example. ***Ellen Jameson** and Lynne McClure* (UK). (SO)
[7]	Images of mathematics curriculum and pedagogical influences. ***Laxman Luitel** and Bal Chandra Luitel* (Nepal). (SO)
[8]	A participative approach to designing a new mathematics course for all college and university students in the Philippines. ***Catherine P. Vistro-Yu*** (Philippines). (SO)
[9]	A comparison of U.S. and Chinese geometry strands through the lens of van Hiele. ***Lili Zhou**, Jinqing Liu, and Jane-Jane Lo* (USA). (SO)
[10]	Curriculum proposal from El Salvador for improving math learning, description, structure, first results and effectiveness. ***Francisco Antonio Mejia Ramos*** (EI Salvador). (SO)
[11]	A course design for mathematical modeling in high school based on STEM education. ***Shengkui Su**, Lin Miao, and Qinghua Chen* (China). (SO)
Posters	
[12]	Investigating third level lecturers awareness of second level curriculum reform four years on. ***Fiona Faulkner**, Cormac Breen, Michael Carr, and Mark Prendergast* (Ireland).
[13]	Mathematical curriculums for five-year junior college programs in ChineseTaiwan. ***Yu Jr Tsai** and Shao Ying Li* (China).
[14]	The curricular statute of the discrete mathematics discipline in the Brazilian systems analysis and development public technological course. ***Jefferson Biajone** and Vinicio de Macedo Santos* (Brazil).

- Session 1 (Tuesday July 13) 19:30~21:00 Beijing time (90 minutes), only one long oral presentation[1];
- Session 2 (Friday July 16) 21:30~23:00 Beijing time (90 minutes), six short oral presentations[2—7];
- Session 3 (Saturday July 17) 14:30~16:30 Beijing time (120 minutes), four short oral presentations[8—11];
- Poster Session (Saturday July 17) 13:00~14:00 Beijing time (60 minutes), three posters[12—14]

The authors came from 13 countries — Brazil, Canada, China, El Salvador, Greece, Philippines, Ireland, Japan, Nepal, Romania, South Korea, UK, and USA — representing the different parts of the world. In the next section 3, we will classify and summarize the all 14 presentations into the theme of four topics at TSG-40.

3. Summary of Presentations in Theme of Four Topics at TSG-40

3.1. Topic 1: mathematics curriculum policy

We had four presentations related to the theme of mathematics curriculum policy.

Klothou and Sakonidis[3] examined six primary school teachers' practices concerning four mathematical processes adopted after their involvement with piloting a reformed mathematics curriculum in Greece. Analysis of the data revealed contradictions in teachers' teaching practices which can be attributed to local recontextualization procedures activated during the implementation of the reformed curriculum. Căprioară et al.[5] focused on the introduction of financial education in the school curriculum. As the introduction occurs in many ways depending on educational policies and systems, they showed to what extent the Romanian mathematical curriculum for the primary level corresponds to the concepts derived from the definitions of financial education. The recent mathematics curriculum requires teaching a lot of financial concepts. So, they insisted the elementary school teachers play an important role though they have not been trained to teach financial learning, even if they are currently being asked to do so.

Tsai and Li[13] showed the arrangement of mathematical curriculum in five-year junior college programs which combines with compulsory education and higher education in Chinese Taiwan. No matter what schools are, achievement gap caused by the system of mathematical curriculum in compulsory education can be clarified effectively after analyzing mathematical curriculum guidelines. They suggested this may help teachers to understand the contents students are learning in class, and moreover, teachers can find some proper strategies to assist interdisciplinary students to learn mathematics effectively. Biajone and Santos[14] presented research on the statute of the discrete mathematics (DM) course curriculum production in terms of objectives and contents for the system analysis and development (SAD) undergraduate course offered by 134 public technological colleges and universities in Brazil. Developed in 2018, they investigated the DM discipline constitution at the undergraduate level according to what contents and purposes are needed for the SAD course and its prescribed curriculum under the perspective of curriculum policy cycle and history of disciplines.

3.2. Topic 2: mathematics curriculum development and analysis

Mathematics curriculum development and analysis was an important theme at TSG-40. We had six presentations related to the theme.

There were two presentations of comparative study in the theme. Zhang and Koyama[2] compared the statistical contents in Chinese and Japanese mathematics textbooks as a part of intended mathematics curriculum. The similarity and difference were reflected on the structure of statistical contents and means of data analysis. There were deficiencies in problems, plans and conclusions of the statistical investigative cycle in China and Japan. Therefore, they suggested that we can use mathematical history materials of statistics to help students promote statistical thinking process. Zhou et al.[9] compared the geometry standards in U.S. Common Core State Standards of Mathematics (CCSSM) and Chinese Compulsory Education Mathematics Curriculum Standards (CMCS) through the lens of van Hiele levels. By examining the van Hiele level distributions of the learning expectations and major topics, they investigated how CCSSM and CMCS propose the development of the geometric thoughts of students. Implications of this study and suggestions for future revisions for both standards were discussed.

Cho and Kim[4] analyzed the nature of mathematics and the goals of mathematics education represented in 10 Korean mathematics curricula (from the 1st to the 2015 revised curriculum) to find out how the concept and meaning of mathematics have changed over time. They conducted semantic network analysis by keywords of each curriculum to identify the word change trend by extracting the frequency and degree centrality of each word, and matrix charts among words. On the other hand, Luitel and Luitel[7] assessed the beliefs about the mathematics curriculum and its pedagogical influences in classroom aiming to improve the teaching and learning environment. They followed metaphorical approach to represent the beliefs of mathematics curriculum. The knowledge constitutive interest, transformative learning theory and social constructivism were considered the major theoretical lenses. The moments and situations they experienced during their own teaching and learning activities has represented through multiple genres.

Ramos[10] showed the mathematics curriculum in El Salvador. Since 2016, El Salvador in cooperation with JICA has developed a new mathematics education policy. The proofreading strategy based on El Salvador students' needs, the rearrangement of contents in the courses of study, and the approach to specific classes were essentially explained. The implementation based on a 'student-centered approach' and a suitable 'teacher support' based on some specific formative assessment statements were briefly presented as well. Finally, some findings of the first years of implementation and apparent success were shown. Su et al.[11] focused on the strong correlation of mathematical modeling literacy among multiple disciplines in high school. They have built a progressive course system including mathematical modeling basic courses (M), innovation practice courses based on school-enterprise cooperation (I), research-based learning advanced courses (R) and STEM higher-order courses (S), jointly constituting the MIRS course. On this basis, they illustrated the implementation of the MIRS course through four course cases.

3.3. Topic 3: mathematics curriculum, teacher, and teaching

Mathematics curriculum, teacher, and teaching were also an important theme at TSG-40. We had three presentations related to the theme.

Dick et al.[1] studied on identifying the quality of teacher created mathematics curriculum. Teachers Pay Teachers claims to be "the world's most popular online marketplace for original educational resources." The Teachers Pay Teachers (TpT) website offers more than five million free and paid resources and has over seven million teacher users. Despite the growing popularity of websites such as TpT, the mathematics education community knows little about the quality of these curricular resources. In their presentation, they sought to address this lack of knowledge for elementary mathematics. They shared results from a research study that compares 500 free vs. 500 paid elementary mathematics activities each with the highest rating found on TpT.

Vistro-Yu[8] described and analyzed the design process that went into the development of the new mathematics course for the general education curriculum (GEC) required of all students at colleges and universities in the Philippines, beginning SY 2018-2019. The new GEC was conceptualized in 2013 to accompany the new K-12 mathematics curriculum. Entitled “Mathematics in the Modern World” (MMW), this new course was envisioned to help provide for the holistic development of the Filipino student in tandem with courses from other disciplines. Proposals for a more systematic curriculum development process were offered. Faulkner et al.[12] made a further analysis of the transition of a second level curriculum reform to higher education in Ireland. At ICME-13, an initial study was presented by the authors investigating third level mathematics lecturers’ awareness of the second level reform. The findings determined that although many lecturers were mindful of the concept of Project Math, they were not aware of the changes in full and how that affected their own course content, teaching, and assessment strategies. This study was a follow-up to the original, and comparisons were made with the 2015 data to see if the situation had changed.

3.4. Topic 4: mathematics curriculum and student learning

Although the relationship between mathematics curriculum and student learning was an important theme, there was one presentation related to the theme at TSG-40. Jameson and McClure[6] discussed some contributions of a Delphi study conducted for the formative evaluation of such a tool, the Cambridge Mathematics Framework. A panel of curriculum researchers responded to questions arising from the design, theoretical framework and methodology. Their presentation focused on the panel’s responses regarding the contributions of motivation to mathematical thinking and doing. The panel assigned motivation lower priority in total for consideration in the design work, but also expressed the highest levels of professional disagreement about it.

4. Future Directions and Suggestions

The above-mentioned paper and poster presentations are classified into four topics of TSG-40 at ICME-40 as follows. The presentations[3,5,13,14] are related to the theme of Topic 1 which includes policy issues related to mathematics curriculum in different education systems, and the process of curriculum decision-making, curriculum changes, curriculum policy, and education changes viewed from a historical perspective. The presentations[2,4,7,9,10,11] are related to the theme of Topic 2 which includes curriculum design and development in different education systems, explicating and comparison of diverse ideas and practices in curriculum development, textbook design, and changes in curriculum development in different system contexts. The presentations[1.8,12] are related to the theme of Topic 3 which includes perspectives on the process of improving mathematics education by reform of curriculum and teaching, and the challenges of developing, implementing, and evaluating change in the content objectives and teaching of mathematics. The presentation[6] elated to the theme of Topic 4 which includes curricular impact on students' learning and the challenges of reforming the curriculum to improve students' learning.

Many of the papers presented at TSG-40 are descriptive. As future directions and suggestions in the research and development on mathematics curriculum, it would be valuable to consider the design process, the process of implementation and assessing the effects on students, and to take a more critical perspective on the comparative work.

Acknowledgments

As the Chair and Co-chair of TSG-40, we want to thank and acknowledge our organizing team members Gulseren Karagoz Akar, Shelly Dole, and Ruilin Wang. Indeed, TSG-40 wouldn't be possible without their dedicated efforts in the process of planning and implementing TSG-40 held worldwide on-line style in three sessions of July 13, July 16, and July 17, 2021. Thanks also go to all our presenters who took the time to help peer review submitted papers and joined the on-line sessions from across the world.

Topic Study Group 41

Research and Development on Textbooks and Resources for Learning and Teaching Mathematics

Sebastian Rezat[1], Jana Visnovska[2], Guorui Yan[3], Moneoang Leshota[4], and Hussein Sabra[5]

ABSTRACT This chapter gives an overview of the themes that grounded the work of Topic Study Group 41 at ICME-14, and an account of the congress sessions, in which the contributions were reported and discussed. The chapter authors were the members of the TSG-41 organizing team, chaired by S. Rezat and co-chaired by J. Visnovska. We highlight the directions for the continuation of the work of this TSG in the areas of (a) production of detailed accounts and justifications of the principles used in resource design, (b) resource design and evaluation for the opportunities to teach, (c) exploration of the supports the students require to navigate the creation of their own learning trajectories, and (d) development of analytical tools for determining the specific ways in which teaching resources could contribute to teacher support needs within broader systemic improvement efforts.

Keywords: Mathematics textbooks; Curriculum resources; Digital resources; Teaching resources; Instructional design.

1. Themes and Description of TSG-41

The efforts of Topic Study Group 41 (from here on TSG-41) focused on explorations of the issues related to the contents, design, development, use, and implementation of print and digital resources for teaching and learning of mathematics. The resources included extend beyond the print and digital school textbooks, and include teacher manuals, professional development materials, student learning and assessment materials, and a variety of online resources.

Directly linking to, and building on, the earlier work of TSG-38 at ICME-13 (Fan et al., 2017; Fan et al., 2018) the aim of TSG-41 at ICME-14 was to bring to the foreground and examine various theoretical and methodological approaches used to design, analyze, and empirically study mathematics learning and teaching resources and their use in diverse geographic regions and contexts. The pre-congress call for contributions for TSG-41 highlighted three broad leading themes of (1) role and effects,

[5] Cérep, University of Reims Champagne Ardennes, France. E-mail: hussein.sabra@univ-reims.fr

(2) design and development, and (3) use and implementation of mathematics resources. The aim was to attend to resources across their creation, use, and effects, with attention paid to the changes introduced by the emergence of digital resources. Each of the three themes in the call included illustrative questions.

Theme 1: The role and effects of print and digital textbooks and other resources in mathematics classrooms.

- What teaching and learning resources are available in mathematics classrooms in different countries? What role do they play in mathematics teaching, learning, and assessment? What are the current effects of the use and implementation of these resources on student learning?
- How is the role that the resources play affected by the digitalization of information and communication and the growing availability of digital and online resources? What are the effects of modern ICT (particularly internet) on students' use of learning resources?
- How does the availability and use of digital resources affect student behavior, learning, and relationships to the subject of mathematics?

Theme 2: The design and development of print and digital mathematics textbooks and other resources.

- What are the theoretical foundations that guide the aspects of development and design of mathematics textbooks and other resources, such as the selection and progression of tasks, development of student competencies, considerations of and supports for envisioned teacher learning or change of practice, features of interactive elements and feedback in digital resources?
- What do we know about designing resources for supporting specific pedagogical intentions for mathematical learning (e.g., project-based, inquiry-based or problem-based learning) and for supporting mathematical learning in environments with blended agendas (e.g., integrated, STEM, multiliteracies)?
- What are the key differences in features and contents between print and digital resources that result from the affordances of digitalization? How do we conceptualize interactions between resource designers and users? Specifically, what is the role of teachers and students in developing textbooks and other teaching and learning materials?

Theme 3: The use and implementation of print and digital mathematics textbooks and other resources and related interactions among resources, teachers, and students.

- What are the influences on the use and implementation of textbooks and other resources? How are teachers supported in their interaction with and the implementation of textbooks and other resources?
- How do teachers adopt and adapt new resources in their professional work?
- How do teachers' individual resources interact with collective resources, and how could we model such relationships?
- What are the consequences of the use of particular resources for the teaching of mathematics, and for teacher knowledge and professional development?
- What resources do students use for learning mathematics and how do they use them?
- How do students, as well as their teachers, interact through resources?

2. Organization of TSG-41 Sessions

Being the group that deals with research on textbooks, TSG-41 received comparatively high number of submissions. After the review process, 40 contributions were accepted, of which six were presented as long oral presentations, 20 as short oral presentations, eight as posters, and six author teams withdrew their submissions due to the ICME-14 date changes and transition to a hybrid congress mode in 2021.

2.1. Oral presentations

In addition to submitted contributions, TSG-41 engaged three top scholars as invited speakers and discussants, tasked with providing direction for the work of the group.

The ICME-14 congress assigned each TSG three sessions, two 90 min long, and one 120 min long. We included one invited talk in each session, and gave all long oral presenters time for an individual presentation.

Aiming for fruitful experiences online as well as on site, the organizing team sought creative ways of fostering discussions and collaborations, in which authors of all accepted short and long oral presentations could actively take part. Therefore, in the lead up to the congress, thematic small groups of paper authors have met online to discuss their respective work and co-create a pre-recorded 5 min video update on the issues and questions that stood out in their combined contributions.

Subsequently, the congress TSG blocks were shared between three 20-minute discussant contributions, six 10-minute long-paper presentations, and seven 5-minute pre-recorded reports from small group pre-congress debates. Moreover, we arranged $10 + 15 + 20$ minutes of discussions (scheduled respectively at the end of each presentation block), as well as opening and closing remarks from the organizing team. The list of oral presentations is given in Tab. 1, while the list of all accepted paper contributions that reflects the pre-congress collaborative work in small groups is given in Tab. 2 (each long oral presentation appears in both tables with the same numbering).

Tab. 1. List of invited talks and long oral presentations

Paper and author(s)	
Invited discussant contributions	
[1]	Textbooks as teacher support for engaging students in active knowledge organization. ***Susanne Prediger*** (Germany).
[2]	Digital mathematics curriculum resources: Towards design principles of educative materials for students and teachers. ***Birgit Pepin*** (The Netherlands).
[3]	Instructional materials as tools for instructional improvement. ***Paul Cobb*** (USA).
Long oral presentations	
[4]	Identifying educative features in scripted mathematics lesson plans. ***Moneoang Leshota*** (South Africa).
[5]	Learning to design resources for teachers. ***Jana Visnovska*** (Australia), *José Luis Cortina* (Colombia), *and Pamela Val* (South Africa).
[6]	Elements of a theory of textbook design. ***Sebastian Rezat*** (Germany).
[7]	Didactic considerations regarding the iterative development design of dynamic digital tools. ***Anatoli Kouropatov***, *Regina Ovodenko, Michal Fraenkel, Maureen Hoch* (Israel).
[8]	Teaching and learning with dynamic textbooks: studying student uses at scale. ***Vilma Mesa*** *and Saba Gerami* (USA).
[9]	Investigating the use of mathematics textbooks by students in Shanghai and England: a comparative study. ***Yi Wang*** (China) *and Lianghuo Fan* (China/UK).

Tab. 2. List of papers presented in groups

Paper and author(s)	
Group 1	
[10]	An analysis of data and probability tasks in US and Chinese elementary mathematics textbooks. ***Xiang Gao*** (China).
[11]	Constructing a textbook analysis framework of statistics and probability areas in elementary math. ***Shiqi Lu*** *and Wenbin Xu* (China).
[12]	Learning to design resources for teachers. ***Jana Visnovska*** (Australia)*, José Luis Cortina* (Colombia)*, and Pamela Val* (South Africa).
[12]	The effect of the curricula on textbooks for the teaching of probability and statistics. ***Gergely Balazs Wintsche*** (Hungary).
[13]	Mathematics Education according to the textbook: opportunities to learn investigated. ***Marc van Zanten*** (The Netherlands) *and Marja van den Heuvel-Panhuizen* (Norway).
Group 2	
[7]	Didactic considerations regarding the iterative development design of dynamic digital tools. ***Anatoli Kouropatov****, Regina Ovodenko, Michal Fraenkel, Maureen Hoch* (Israel).
[4]	Identifying educative features in scripted mathematics lesson plans. ***Moneoang Leshota*** (South Africa).
[14]	A comparative study of bidirectional connections in U.S.A. and Chinese high school mathematics textbook problems. ***Shuhui Li*** (USA).
[15]	Translations of function representation in different textbooks. ***Yang Shen*** *and Bao Jiansheng* (China).
Group 3	
[16]	A comparative study of problem solving in Chinese and U.S.A. primary mathematics textbook. ***Suijun Jia*** (China).
[17]	A comparative analysis of tasks contexts in mathematics textbooks in China and Singapore. ***Yao Li*** *and Lianchun Dong* (China).
[18]	A comparative study of mathematical inquiry activities in textbooks in China and Singapore. ***Hongwei Ran*** *and Lianchun Dong* (China).
[6]	Elements of a theory of textbook design. ***Sebastian Rezat*** (Germany).
Group 4	
[8]	Teaching and learning with dynamic textbooks: studying student uses at scale. ***Vilma Mesa*** *and Saba Gerami* (USA).
[19]	The elements of textbooks that Indonesian mathematics teachers use as they adopt student-centered instructional approach. ***Dewi Rahimah*** *and Jana Visnovska* (Australia).
[9]	Investigating the use of mathematics textbooks by students in Shanghai and England: a comparative study. ***Yi Wang*** *and Lianghuo Fan* (China).
Group 5	
[20]	Sesamath resources and collective work from mathematical laboratory to classes in Arabic environment. ***Karima Sayah*** (Algeria).
[21]	Promoting the teaching and learning of mathematics through visualising connections in post-16 resources. ***Dominic R. Oakes*** *and Sofya Lyakhova* (UK).
[22]	Comparing naming systems used by Chinese and Ukrainian teachers: exploring teachers' resource system. ***Maryna Rafalska*** (France)*, Chongyang Wang* (China)*, and Luc Trouche* (France).
Group 6	
[23]	Toward systematic support for preservice teachers' learning of productive resource use. ***Ok-Kyeong Kim*** (USA).
[24]	Analysing teachers' individual and collective resources through the lens of their digital resources. ***Katiane de Moraes Rocha*** (Brazil).
[25]	Student understanding of textbook visual representations of natural and fractional numbers: a collaborative international research. ***Everaldo Silveira*** (Brazil) *and Arthur B. Powell* (USA).
[26]	How expert mathematics teacher design curriculum based on textbook use: a case study in Beijing. ***Guorui Yan*** (Hong Kong SAR, China).
Group 7	
[27]	Long-term use of a digital mathematics textbook with integrated digital tools: investigating the influence on students' achievement and self-efficacy. ***Maxim Brnic*** (Germany).
[28]	The relationship between mathematical examples in Malawian grade 1 primary school mathematics teachers' guide and the goals of outcome-based education. ***Lisnet Mwadzaangati*** (Malawi).
[29]	Career mathways: a teaching & learning intervention to show the relevance of mathematics in careers. ***Niamh O'Meara****, Olivia Fitzmaurice, and Patrick Johnson* (Ireland).

2.2. Contributed posters

Posters in this TSG are listed in Tab. 3.

Tab. 3. List of posters

Poster and author(s)
[30] The extent of creative reasoning opportunities and aspects of cognition demand in textbooks in Nepal: a case of high school mathematics textbook. *Deepak Basyal and* ***Mohan Thapa*** (Nepal).
[31] This is the way I use textbooks and other resources for design mathematics lessons: A case of teaching the area of circle. ***Ya Cheng*** (China).
[32] Educative curriculum materials: Teachers' continuous training in the step by step of the materials designing process. ***Pauli Diniz*** (Mozambique).
[33] About textbooks on mathematical logic and theory of algorithms for prospective mathematics teachers. ***Vladimir I. Igoshin*** (Russia).
[34] The presentation of core knowledge acquisition process in junior middle school mathematics textbooks. ***Tianzhuo Jiang*** *and Shuwen Li* (China).
[35] The presentation of linear function in Chinese school mathematics textbooks. ***Na Li*** (China).
[36] A comparative study on fractions in primary school's mathematics textbooks of China and the United States. ***Fulin Liu****, Yiming Cao, and Dengfeng Liang* (China).
[37] A comparative study of "figures and geometry" in junior middle school mathematics textbook by PEP edition and Kangxuan edition. ***Yihan Wang****, Meiyue Jin, and Jiadi Zhang* (China).

3. Contributions to the Themes

3.1. Theme 1

The three contributions to TSG-41 in group 7 were related to Theme 1 (the role and effects of print and digital textbooks and other resources in mathematics classrooms), and particularly related to the question of how the availability and use of digital resources affect student behavior, learning, and relationships to the subject of mathematics. Brnic[27] reported on the long-term effects of a digital textbook on secondary students' achievement and their self-efficacy, where, so far, no significant effects were found for either construct. O'Meara et al.[29] investigated how Irish textbooks include examples, which show the relevance of mathematics in careers. Finding the lack of such examples in the textbooks, the authors created other materials that show the relevance of mathematics and tested them in a pilot study. Mwadzaangati[28] analyzed Malawian primary level mathematics textbooks in order to identify how the examples in these textbooks contributed to the goals of outcome-oriented education. The starting point of all three papers was that textbooks still appear to be the dominant resource used in classrooms across the world. While the paper by Mwadzaangati[28] focused on the contribution of the textbooks to achieve the goals of the official curriculum, the two papers by Brnic[27] and O'Meara et al.[29] focused on alternatives to the traditional textbook and explored the affordances of other resources for enhancing the learning of mathematics.

3.2. Theme 2

Papers in Groups 1, 2, and 3 contributed to Theme 2 (the design and development of print and digital mathematics textbooks and other resources). Rezat[6] raised the need for the theoretical foundations capable of guiding the development and design of mathematics textbooks and other resources. He offered a preliminary attempt at systematizing the empirically evaluated design principles and features of mathematics textbooks, and at forming a structural theory of textbook and curriculum material design.

Some contributions within this theme could be regarded as being related to the design of particular opportunities to learn that mathematics textbooks and other resources come to embody (or capture, or represent). Design research provides a methodological framework that aligns theoretical considerations in the design process with empirical evaluations of the design aims. Two papers exemplified these design processes, while using different methodological approaches. Kouropatov et al.[7] described the iterative design process of three digital resources related to transformations of functions. The paper demonstrated how mathematical and didactical considerations must go hand in hand with empirical evaluations in the design process to develop resources that have the desired learning effects. Similarly, Lisnani and Sariyasa[6] described the design and testing of a digital resource, in which they leveraged comics for learning integers.

A number of contributions to TSG-41 did not bring accounts of design principles or the design process but analyzed and evaluated the opportunities to learn as they were provided in mathematics textbooks (both historical and those currently in use). These papers used comparative analysis to highlight specific design features of textbooks from different countries, different historical periods, or different pedagogical approaches. Using a post-design perspective, such analyses may unveil the design principles and decisions as manifested in the resource from an a posteriori perspective, thus deepening our understanding of resource design. In particular, the contributed studies analyzed comparatively textbooks in China and the U.S.A. (Gao[10], Jia[16], Li[14]), China and Singapore (Li and Dong[17], Ran and Dong[18]); textbooks with different approaches in China (Shen and Bao[15]) and in the Netherlands (van Zanten and van den Heuvel-Panhuizen[13]), and textbooks from different historical periods in Hungary (Wintsche[12]). Finally, Lu and Xu[11] focused on the construction of a framework for analyses of this kind.

Alongside the majority of studies that explored designs from perspective of learning, researchers and designers remain aware that textbooks rarely teach students directly. As a result, the notion of textbook designs, which would not only provide opportunities to learn for students, but also *opportunities to teach* for teachers, surfaced

---

[6] *Teaching and learning integers through ICT-based SI UNYIL comics*. Short paper. The paper was not assigned a discussion group, but the authors were able to attend TSG-41.

within the discussions related to this theme. Visnovska et al.[5] reported on the processes of developing resources that would be in service of teachers (as opposed to teachers having to be in service of the resource). They called for the design of the features that would contribute to teachers' re-claiming the agency over both the meanings and decisions associated with mathematics teaching. Similarly, Leshota[4] analyzed educative features in scripted mathematics lesson plans from South Africa and explored the opportunities that the materials presented for the teachers' learning and teaching.

3.3. *Theme 3*

Papers in groups 4, 5, and 6 contributed to Theme 3 (The use and implementation of print and digital mathematics textbooks and other resources and related interactions among resources, teachers, and students). Within this theme, several authors foregrounded the supports for teachers' use and implementation of textbooks and other resources. Kim[23] combined five components, that prior research identified as key for teachers' productive use of resources, into a framework and explored its usefulness with the U.S.A. pre-service teachers who learned how to use resources. Oakes and Lyakhova[21] used interviews, surveys and questionnaires to identify the extent to which postgraduate level resources were seen to support making mathematical connections and whether the users thought that this was improving their teaching and learning. Rafalska et al.[22] explored the linguistic and cultural supports, aiming to develop a deeper understanding of cultural differences in resource systems of teachers from China and Ukraine. Rahimah and Visnovska[19] analyzed an Indonesian textbook from the perspective of the kinds of supports it provided, or failed to provide, for teachers' implementation of a student-centered teaching approach.

Within the scope of investigations of teachers' resource systems and documentational trajectories, Sayah[20] explored how one Algerian teacher adopted and adapted the French Sésamath resources in their professional work, and how these resources fostered the collective work of this teacher. Rocha[24], in turn, analyzed the interaction of the individual and collective resources in the case of one French mathematics teacher, and Similarly, Yan[26] documented how one Chinese expert teacher used the textbook as a resource in her curricular design.

Additional papers explored students' use of curriculum resources and what sense the students were making of the presented content. Wang and Fan[9] surveyed Chinese and English secondary students' use of mathematics textbooks, highlighting striking differences in the perceived purposes for and uses of the textbooks. Mesa and Gerami[8] tracked U.S.A. university students' viewing of a digital textbook in real time and collected students' written narratives about their textbook use and reported on the methodological challenges faced in analyzing this type of data. Silveira and Powell[25] reported on the methodology developed for explorations of elementary students' understanding of visual representations of natural numbers and fractions in select Brazilian and U.S.A. textbooks.

4. Conclusion and Outlook

A number of ideas discussed within TSG-41 appear to be worth carrying forward in the research of future TSG participants.

Many contributions to TSG-41 had shown that textbook and resource designs differ, at times profoundly, for instance in different countries. It is certain that these differences contribute to how teachers can teach and how and what students get to learn and accomplish in mathematics classrooms. However, it is rarely clear which of the documented differences are to be attributed to specific design assumptions, principles, and processes, as those are rarely explicit, and often remain hidden from our views. In other words, for those of us whose research involves resource design, there is a need for more explicit sharing of the accounts and justifications of the principles that guide our current designs, as well as of processes that guide our theoretical and empirical evaluations of these principles in different cultural and institutional contexts.

The latter requirement calls for deeper empirical substantiation of the effects of textbook and resource design. While understanding differences in textbook and resource design as well as particular values and intentions and ways in which these are used to drive designs is important, it is also necessary, and still not common, to investigate whether or to what extent these values and intentions get realized when the textbooks are used in classrooms. Prediger's discussant contribution offered an inspirational example from the KOSIMA project of how research can be structured to intentionally contribute to the production of such accounts. She illustrated how ongoing cycles of empirical evaluations of both the task design and teacher supports were essential in the production of mathematics education resources that positively contributed to students' learning. This links to the need for the pursuit of analytical notions such as resources for teaching, teachers' resources, and opportunities to teach, which were brought up in several paper contributions and small group discussions during TSG-41.

In addition to the design work that is conducted by resource designers and by teachers, Pepin's discussant contribution drew attention of the role of students as designers of their own learning trajectories and thus as co-designers of curriculum. Accordingly, connectivity, in terms of making the connections among mathematical ideas within mathematical curricula explicit to the students, becomes a critical feature of curriculum design, as it plays a role in supporting students in navigating the resources needed for their own curriculum trajectories.

Finally, Cobb's discussant contribution focused on the role that textbooks and other resources (i.e., instructional materials) play within the broader concerted efforts at instructional improvement, especially when attempts are made to orchestrate these at the systems level. Drawing on the MIST project data, Cobb illustrated that the quality of instructional resources made a considerable difference in student achievement scores, even when teachers used the cognitively demanding tasks in somewhat proceduralized ways. This insight is important given that textbooks which are not composed of well-sequenced mathematical tasks of high cognitive demand are still widely available to schools and teachers. It should be concerning that textbooks of this kind directly contribute to portraying students in ways, which do not represent their capacity for mathematical learning, and they do so at scale. Cobb hastened to stress that in order for teachers to thrive while using high-quality teaching resources, teachers must be adequately supported in this use. How textbooks and other resources could be designed to better support teachers' work is worth of concerted research efforts.

To conclude, we would like to extend an invitation to researchers of textbooks and other curricular and instructional resources to join in the events specifically dedicated to this work, including the 4th International Conference on Mathematics Textbook Research and Development (ICMT 4) in Beijing (China) in October 2022, and the next iteration of this TSG (i.e., TSG3.12) at ICME-15 in Sydney (Australia), July 2024.

Topic Study Group 42

Research and Development in Assessment in Mathematics Education

Abid Sohail[1] and Caroline Long[2]

ABSTRACT TSG-42 provided a forum to share and discuss research and development in the field of Assessment in Mathematics Education. Many interesting and outstanding questions about the nature of interrelationships among assessment and teaching and learning of mathematics, were asked. Recent research has demonstrated the wide range of theoretical and methodological resources that can contribute to assessment in mathematics, including the use of technology. The papers in TSG-42 included reporting on a particular assessment topic or theme, providing the details of an empirical study, giving an exposition of particular assessment practice, or a reflecting on classroom-based assessment.

Keywords: Assessment; Formative assessment; Summative assessment; Large-Scale assessment, Assessment cycle.

1. Objectives

As teachers, practitioners, academics and researchers it is our prime responsibility to conceptualize, debate and formulate learning and assessment systems that prepare our future generations for opportunities and challenges that they may encounter. Assessment is a wide-ranging, multidimensional and vital process integral to teaching and learning. The purposes of assessment can be summarized as being formative, directed at the improvement of teaching and learning, and summative, where the focus is on evaluation of current proficiency, comparability, or evaluating the functioning of an education system as a whole. Various types and formats of assessment support these purposes. Each type of assessment with a well-defined purpose provides specific and useful information to improve standards and quality of teaching and learning. Also, this specific and useful information is beneficial for research. In classroom-based assessment, the interactive teaching, learning and assessment cycle is managed by the teacher, adhering to the perspective provided by policies, procedures and norms of the institutes or states. The assessment cycle may be specifically formulated for a particular cohort of students. In large-scale assessment, this cycle is somewhat extended and generalized to reflect the perspectives and processes which are applicable across countries rather than specific to a certain context. Large-scale assessments have the potential to provide comparative information about a country's curriculum and teaching

[1]Examination Board, Aga Khan University, Karachi, Pakistan. E-mail: abid.sohail@aku.edu
[2]The University of Johannesburg, Johannesburg, South Africa. E-mail: clong@uj.ac.za

practices generally. The purpose of such assessments, the design and development of instruments and the interpretation of results are factors that affect individual countries and influence internal assessment practices. In the 21st century, we have seen new trends and developments in the field of mathematics assessment, including the assessment of the set of skills that encompass creativity, collaboration, communication and problem-solving. New models have been introduced, many of which have encompassed computer-based testing. Also, in this century, the use of Item Response Theory and Rasch Measurement Theory has influenced the design of tests and the analysis and interpretation of results. For this TSG-42, we invited research based on the recent trends and developments in the field of mathematics assessment which cater to the needs of the 21st century. The research papers, presentations and discussions were such that they were beneficial, communicable and accessible to all the stakeholders, would inform a range of assessment practices, and therefore would contribute to making the teaching and learning of mathematics meaningful. Contributions included studies covering (but not limited to) the following themes:

- Theoretical, philosophical and ethical perspectives and debates concerning the assessment of mathematics proficiency;
- Alternative perspectives, models and practices of assessment;
- Classroom-based assessment (formal or informal assessment);
- Teachers and assessment. What is the role of the teacher in classroom-based assessment? What is the impact of high-stakes assessment? How does the phenomenon of "teaching to the test" play out in various contexts?
- Students and assessment. How do different types of assessment affect student learning and motivation? What is the role of feedback in a learner's life? What is the impact of standardised assessments on learning?

What to test? How is a cognitive focus or cognitive development focus accommodated in a testing programme? How is extended problem solving assessed?

- Test design, construction and administration (theoretical, technical and practical components). How do the underlying assumptions of classical test theory, item response theory and Rasch measurement theory affect the design of testing programmes?
- Technology and computer-based assessment;
- Large scale assessment (perspectives, benefits and limitations);
- Validity and reliability: whether or not a test may report dimensions and types of validity and reliability.

The statement that assessment drives learning was illustrated by many thought-provoking presentations at the conference.

2. Sessions

In TSG-42, there were 45 contributions in total 3 sessions. Sessions 1 lasted 90 minutes. There were 9 short oral presentations of 10 minutes. In the second time slot of 90 minutes, there were 6 long oral presentations of 15 minutes of duration. In the third time slot of 120 minutes, there were 2 long oral presentations of 15 minutes of duration and 9 short presentations. The details are as follows (Tab. 1).

Tab. 1. List of papers presented

Paper and author(s)
Session 1
[1] Students' difficulties in the management of algebraic expression highlighted in large-scale assessment. ***Federica Ferretti*** (Italy).
[2] In-service teachers marking students' answers containing derivation errors. ***Alberto Arnal-Bailera***, *José M. Muñoz-Escolan, and Antonio M. Oller-Marcén* (Spain).
[3] Investigating teachers' awareness of the reasons for students' math errors at primary school level. ***Valentina Vaccaro*** *and Eleonora Faggiano* (Italy).
[4] Cognitive load reduction in math items: performance, gender and socioeconomic status. ***Emiliano Augusto Chagas*** *and Mauricio Urban Kleinke* (Brazil).
[5] Expressions of mathematical proficiency in students' mathematical work. ***Priscila D. Corrêa*** (Canada).
[6] Structural features in classroom level standardized mathematics achievement results. ***Timothy Sibbald*** (Canada).
[7] Philosophical insights into PISA and mathematics education policy issues. ***Ian Cantley*** (UK).
[8] A unique item format to assess attentiveness to students' mathematical ideas. ***Ya Mo***, *Laurie Cavey, Michele Carney, Tatia Totorica, and Patrick Lowenthal* (USA).
[9] Developing preservice elementary teachers' capacity in the design of authentic mathematics assessment. ***Kim Koh***, *Olive Chapman, and Shimeng Liu* (Canada).
Session 2
[10] Evaluating mathematics teachers' professional learning in a PLN: a complex systems perspective. ***Xiong Wang*** (Canada).
[11] Validity of assessments in mathematical textbooks: a study of beginning of primary school level textbook assessments. ***Grapin Nadine*** (France).
[12] Are the stakes the same? A comparison of three types of large-scale assessments in Alberta, Canada. ***Richelle Marynowski*** (Canada).
[13] Factors related to mathematics teachers pedagogic discretion, specifically when evaluating parabolic sketches. *Shai Olsher and Kawthar* ***Nakhash Khalaila*** (Israel).
[14] Assessment based on gamification in Hungarian secondary mathematics classes. ***Marta Barbarics*** (Hungry).
[15] I know all about this mathematical topic, but I cannot answer this question' moment, can I have a clue please? ***Anne D'Arcy-Warmington*** (Australia).
Session 3
[16] Investigating the treatment of missing data in an Olympiad-type test — the case for selection validity. ***Caroline Long***, *Johann Engelbrecht, and Vanessa Scherman* (South Africa).
[17] Mathematics assessment practices of primary school teachers in France. *Nathalie Sayac and* ***Michiel Veldhuis*** (France).
[18] The role of formative assessment experiences in the teaching and learning of mathematics. ***Adri van der Nest***, *Caroline Long, and Johann Engelbrecht (*South Africa).
[19] Assessing math in teacher training; what to learn from our students' research. ***Willem van der Vegt*** (The Netherlands).
[20] Transformative assessment system in mathematics education: engaging mind, body and soul. ***Basanta Raj Lamichhane*** (Nepal).
[21] Analysing students' errors in solving context-based problems in Marwa assessment. ***Ummy Salmah***, *Uki Rahmawati and Bungkus Dias Prasetyo* (Indonesia).
[22] Raw scores or rasch measures? Lessons from Rasch analysis of secondary one mathematics test. *Hairon Salleh,* **Foo Kum Fong**, *and Koh Wei Xun* (Singapore).
[23] Research on the level division of mathematical logical reasoning literacy based on solo taxonomy theory. *Hua Wu,* ***Junhan Liu***, *and Fengqi Zhai* (China).
[24] Quality of mathematical reasoning in a Philippine senior high school's pre-calculus examinations on conic sections. ***Vitus Paul L. de Jesus*** (Philippines).
[25] The Results of large-scale assessment as tools for mathematics activity design. *Alessandro Gambini and* ***Roberto Capone*** (Italy).
[26] Research on the assessment system combining standardization and non-standardization in the mathematics education of top talents. ***Jianren Niu***, *Li Lai, Chaodong Chen, Zhirong He, and Liang Yang* (China).

3. Posters

The presenters from different regions of the globe also shared their learning experiences through poster presentations. These posters provided a chance to look at different practices and innovate ideas from/for practitioners and researchers. These were 10 posters. The details of the posters are as follows (Tab. 2).

Tab. 2. List of posters presented

Paper and author(s)	
[27]	Existing assessment practices: a detrimental factor for the value of cognitive diversity in mathematics classroom. ***Shiva Datta Dawadi*** (Nepal).
[28]	Vertically equating the PSM3 and PSM4. ***Jonathan D. Bostic****, Gabriel T. Matney, Toni A. Sondergeld, and Gregory Stone* (USA).
[29]	Contents-specifics in teachers' assessment of non-cognitive skills in mathematics education. ***Enomoto Satoshi****, Iwata Koji, Sasa Hiroyuki, Nakagawa Hiroyuki, and Aoyama Kazuhiro* (Japan).
[30]	A case study of the assessment process in Japanese math classes. ***Shigeki Kitajima*** (Japan).
[31]	Impact of the standardized test in the classroom: a proposal from the socio-epistemological theory of educational mathematics. ***Beatriz Elena Martínez Díaz*** *and Ricardo Arnoldo Cantoral Uriza* (Mexico).
[32]	Semi-automated assessment for mathematical proficiency: the ultimate time-saver for extensive feedback and reliable grades? ***Filip Moons*** *and Ellen Vandervieren* (Belgium).
[33]	Standardized testing administration time differences on problem-solving outcomes. *Toni A. Sondergeld, Gregory E. Stone, Jonathan Bostic, and Gabriel Matney* (USA).
[34]	Development of mathematics items with dynamic objects for computer-based assessment using tablet PC. *Fumiko Yasuno, Keiichi Nishimura, Seiya Negami, and Yukihiko Namikawa, Jin-ichi Itoh* (Japan).
[35]	Making classroom assessment happen in novice teachers' class through assessment techniques design. *Xiaoyan Zhao and* ***Lingchun Kong*** (China).
[36]	Training and e-assessment of mathematical courses by Xpress-tutor. ***Philip Slobodsky****, Mariana Durcheva* (Israel), *and Alexander Ocheretovy* (Russia).

4. Way Forward

The field of research in mathematics education assessment is broad and exciting. Submissions were received from countries across the globe. The range of papers included research focused on large-scale studies and national studies, on both primary school, high school, and tertiary levels, but what was most interesting is the number of papers dealing with alternate type assessment.

Included in the large-scale assessment were philosophical insights into PISA (Northern Ireland)[7], a comparison of different types of large-scale assessment (Canada)[12], and an investigation into the handling of missing data (South Africa)[16]. We regard the scrutiny of large-scale assessments both for what they can reveal to education systems, and for their limitations, as important themes to be taken up at future conferences.

Highlights of the papers focused on primary school included assessment practices specific to the primary school (France)[11,17], and the validity of the textbook assessments (France)[11]. Focused on the high school were papers on specific mathematical topics. It was most interesting to listen to papers that pushed the boundaries of conventional assessment, and included a number of factors apart from the merely academic that impacted on achievement. A study looking at engaging mind, body and soul, emanated from Nepal[20], a focus on mathematical reasoning emerged from the Philippines[24], and the focus on context-based problems emerged from Indonesia[21]. While the focus on standard assessment and the improvement of this type of assessment is needed, the investigation of assessment which is not in the main stream is most important for the future. We envisage more papers that are looking at alternate forms of assessment, and that assess what has not been assessed previously. Gert Biesta, originally from the Netherlands, challenged the education community to not only value what can be measured. In the case of many of the papers in ICME-14, there is the attempt to measure what is valued, though this is not always easy.

At the tertiary level, the design of authentic assessment was presented (Canada)[9], as well as the assessment of mathematics teachers professional learning (Canada)[10]. A further study looked at the assessment of mathematics in teacher training (Netherlands)[19]. Poonam Batra, working in teacher education in India, stated that if we want change in our educational systems, we have to empower the teachers, and enable professional teacher agency. How assessment practices can assist this is a good question.

Overall the tendency for research in mathematics education assessment is to broaden its scope to include innovative and all-encompassing characteristics. This trend we value as we look to the future. On the other hand, the improvement of standard assessments to ensure validity and reliability should remain a focus on this topic specific group.

As for meaningful engagement with teaching and learning, the role of technology is critical. In future, technology will not only be a tool of learning and teaching rather it will become a part of the process. Henceforward, besides looking at other important aspects, types and functions of assessments, the role of technology in assessment needs our attention.

We look forward to welcoming an equally diverse range of papers that both improves existing practices and offer new practices.

Topic Study Group 43

Research and Development in Testing (National and International) in Mathematics Education

Ivan Vysotskiy[1], Julia Tyurina[2], and Anastasiia Demchenckova[2]

1. Aims of TSG-43

The group based on topics related to the testing as an important aspect of evaluation and also its links in the reform of the mathematics curriculum at the national and international level. The presentations are studies on several interconnected topics.

1) What are the results of development and research of the testing with mathematics content and mathematics competency, their connection?
2) How effective is the use of the LMT measures as a way of comparing teachers' international mathematical knowledge based on various concepts of the necessary knowledge, and hence views on the possibility of measuring them.
3) How typical characteristics of each country can influence the organization of their educational system.
4) What is the evaluation of mathematics education and how examination of the new mathematical knowledge can guide the teaching behavior development along the scientific and rational directions.
5) What is the role of mathematics in educational policies?

1.1. Organizing team

Representatives from different countries were involved in TSG-43 as chair, co-chair, moderators and speakers: China, Japan, the Russian Federation, United States, Brazil, Slovakia, and Norway, that highlights co-thinking and common views not only national, but also international collaborative community of people acting in mathematical education.

The organizing team of the TSG consists of

Chair: Ivan Vysotskiy (Moscow Centre for Continuous Math Education, Russia)
Co-chair: Fumi Ginshima (National Institute for Educational Policy Research, Japan)

[1] Moscow Centre for Continuous Math Education, Moscow, Russia.
E-mail: i_r_vysotsky@hotmail.com
[2] Moscow Centre for Continuous Math Education, Moscow, Russia.

Members:

Richard T. Houang (Michigan State University, USA)

Maria Isabel Ramalho Ortigão (Rio de Janeiro State University, Brazil)

Lidong Wang (Beijing Normal University, China)

1.2. Other participants

Besides these team members, participants also include:

Ekaterina Kuksa (Moscow Centre for Continuous Math Education, Russia)

Tibor Marcinek (Central Michigan University, USA)

Jiangong Dong (Wuhu Institute of Educational Science, China)

Joaquim Pinto (Universidade de Aveiro, Portugal)

Bruno Damien da Costa Paes Jürgensen (State University of Campinas, Brazil)

Yu Fu (Beijing Normal University, China)

2. Sessions and presentations

There were 6 high quality presentations in TSG-43. The ICME organizing committee granted the TSG 2 sessions for presentations, but one of them wasn't presented (Tab. 1). Thus, during the hybrid conference only 5 papers were presented.

Tab. 1. List of the presentations

Paper and author(s)	
[1]	On the eighth-grade mathematics achievement and its effect factors — based on seven areas study. *Chunxia Qi* (China), *Ruilin Wang* (China), *Qi Huang* (USA), *and* ***Yu Fu*** (China).
[2]	International comparisons of teacher knowledge: the case of the LMT measures. ***Tibor Marcinek*** (USA), *Arne Jakobsen* (Norway), *and Edita Partová* (Slovakia).
[3]	PISA assessment of Brazilian students' mathematical literacy. ***Maria Isabel Ramalho Ortigão*** (Brazil).
[4]	On composing distractors for multiple choice problems. ***Kuksa Ekaterina*** (wasn't presented) (Russia).
[5]	How Chinese design mathematics test. ***Jiangong Dong*** (China).
[6]	Reflections on large-scale assessment and the formatting power of mathematics. ***Bruno Damien da Costa Paes Jürgensen and*** *Mara Regina Lemes De Sordi* (Brazil)

In the first 90-minute session, the Chair of TSG-43, Ivan Vysotskiy, introduced the rest of the Team, described the format of the session and conveyed greetings to all participants from the organizers of the Congress and PC, called on the participants to the most informal discussion possible. As a rule, each presentation took 20–10 minutes, followed by a 10-minute collective discussion. Throughout the two days, TSG-43 reviewed all the research related to the topic of testing, discussed the problems that arise during the preparation, testing, and discussed possible solutions.

The majority of the work can be summarized across five connected themes. As part of the work, researchers consistently, step by step, revealed the main topic of research and development in testing (national and international) in mathematics education.

We give a brief overview of the presentations as follows.

2.1. Session 1

First talk[1] given by Fu was on the work collaborated by Qi, Wang and Huang. They tried to design math test and questionnaire for 170748 eighth grade students from seven areas in Chinese mainland. The results showed an inextricable relationship of two parts of the test — mathematics content, and mathematics competency. The mathematics content includes three areas: number and algebra, shape and space, statistics and probability. The mathematics competencies consist of 4 components: knowing, understanding, grasping and application. Eight-grade students achieved high scores, and their pass rate was 92.4%. However, their level of application was lower than the level of knowing, understanding, and grasping. Among all the four components in questionnaire survey, teaching representation had the greatest impact on students' performance, teaching methods and mathematics representation were the second while thinking tendency had a negative effect on students' performance. They also confirmed that development of tools in test booklet and the influence factor in the questionnaire need to be further explored.

The talk[2] given by Marcinek was on his work collaborated by Jakobsen and Partová. It draws on the body of international research conducted in relation to the measures of the mathematical knowledge for teaching developed as part of the Learning Mathematics for Teaching project at the University of Michigan (the LMT measures). There are various conceptualizations of the knowledge teachers need in the work of teaching mathematics. Which means there are different views on feasibility of measuring such knowledge. There were made comparisons between Slovak and Norwegian primary teachers. Three layers of studying were used — Technical layer, Local layer, Global layer. The similarities helped to compare translation-related issues while differences helped to model the issues that likely exist in education systems around the world. The possibility to design LMT forms with close psychometric properties does not imply the meaningful comparisons of teachers' MKT. Local layer provides the most useful information to researchers and constitutes the most important contribution of LMT adaptation literature. Such comparisons might be especially hard to interpret if countries with differences in curriculum, grade bandings, teacher education and certification are compared.

Ortigão[3] presented the results of an investigation focused on analyzing PISA Mathematics items based on Differential Item Functioning (DIF) analysis, to compare results between Brazil and Portugal. Based on descriptive analysis were differences in cognitive skills between the assessed groups. Typical characteristics of each country can influence the organization of their educational system. Knowing these features based on items that favor certain groups, in addition to perceiving the incidence of patterns, is undoubtedly the great contribution from DIF (the identification of items that disregard one of the main assumptions of the IRT) analysis to educational assessment.

2.2. Session 2

On the final session, the participants discussed two topics.

First, Dong[5] called for discussion on the paper of the tests as aspect of evaluation and as an important link in the reform of the mathematics curriculum in middle school. The evaluation of mathematics education includes not only curriculum evaluation but also teaching evaluation, and mathematics testing is an important aspect of the evaluation of mathematics education. The function of testing can be divided into two types — first is to summarize the results of the entire mathematics education stage, to identify the teaching effectiveness or achievement at the end of the whole teaching stage, the other is to gain feedback with purpose to improve the teaching process, to understand the problems and defects in teaching process at the end of each teaching unit. The focus of the study on mathematics evaluation question setting in Dong's paper is on the level of senior high school entrance examination. Improving the quality of question setters and making the tests papers play an evaluation function more scientifically and reasonably is the top priority. Dong suggested certain basic principles for test items setting, and emphasized that the teachers creating the tests questions must firstly understand the structure, and then start from every single question. The new mathematical knowledge has enriched and optimized the mathematical thinking method in the middle school mathematics, further expanded the application space of the knowledge, which will be an important source of original test questions. Examination of the new mathematical knowledge and scientific solving of a certain type of problems step by step, may better guide the teaching behavior development along the scientific and rational directions.

The main goal of another research[6] by Jürgensen and De Sordi was to explore and reflect upon the issues concerning largescale assessments in São Paulo, Brazil, and the market-oriented policies underlying them. It was about the role of mathematics in educational policies, since they have a great impact on teachers, their everyday life in schools and, consequently, on society as a whole and the formation of students. During the research they did Questionnaire answered by 26 mathematics teachers and Interviews with 10 of them on this topic. The state began to adopt differentiated payment of teachers and other state education employees, through a salary bonus according to the achievement of goals set by the government for each school. External and standardized assessments impose a teaching and learning method that does not consider the different realities. Standardization of teaching (in authors' opinion) is flawed. The expense or cost of these assessments is too high in relation to their return. The authors believe that the answers, the results obtained, should change this evaluation system, as it has been in the same way for a long time and they have not observed significant changes. There should have an investment in teacher training and better working conditions to thus develop the skills expected for students, and not just charge in the form of assessment and teacher's penalty through bonuses cancel. More than describing the educational reality, the indicators of quality produced by mathematical models and their subsequent dissemination have altered the work routine of teachers and school teams. Mathematics, in general, goes unnoticed, invisible, in these processes, mainly because it comes "in a package" (Skovsmose and Yasukawa, 2009). Therefore, it is pertinent to open the package and proceed to the questions posed by the authors: "what's in the package?", "Whose package is it?" And "what is done by means of the package?". It is necessary to look beyond technical specifications to reverse this picture and to think of an assessment that addresses the complexity of the educational process (including mathematics) and makes it accessible to the general public. Everyone can and should participate in the definition of what is a "good quality" for education, as long as everyone is involved in this endeavor since its elaboration.

Topic Study Group 44

Mathematics and Interdisciplinary Education

Carl Winsløw[1], Rita Borromeo Ferri[2], Nicholas Mousoulides[3], and Avenilde Romo-Vasquez[4]

1. Aims of the TSG

The preceding TSG on “Interdisciplinary Mathematics Education” at ICME-13 in Hamburg produced, among other things, a conceptual classification of the general notion of “discipline” as well as the terms used to indicate various degrees of interaction between mathematics and other disciplines (Williams et al., 2016).

The present TSG, as the slight change in title suggests, took a more specific point of departure in mathematics in its current educational and societal shapes, viewed as social realities: namely, mathematics as taught from preschool to higher education, and mathematics as a more widely established set of social practices (such as in academic research) viewed broadly to include also statistics and what is sometimes referred to as “applied mathematics”. The main goal of the group was to share studies and in-depth cases of the ways in which mathematics currently interacts — or is supposed to interact with other educational practices, in part reflecting the role of mathematical practices in society at large. We focused in particular on current or potential contributions of mathematical theory and techniques to elucidate the “big” questions which are increasingly emphasized in general schooling in many countries, such as sustainable development, and the roles and nature of digital technologies in modern society. This concerns how school mathematics functions as preparation for general citizenship, and also for more specific professional specializations. In other words, we focused on ways in which mathematics is or could be taught in a “paradigm of questioning the world”, rather than in a “paradigm of visiting monuments” (Chevallard, 2015).

2. Submissions and Sessions

We received 26 submissions from 19 countries (Europe: 9; North America: 7; Asia: 6; Australia 3; Africa: 1). Out of these 26 submissions, 7 were accepted as long oral presentations, 16 as short oral presentations, 2 as posters, and 1 was rejected. These numbers reflect the total number of papers and posters, submitted mainly at the ordinary deadline in 2020, but with two being added at the extraordinary deadline in 2021.

[1] University of Copenhagen, Denmark. E-mail: winslow@ind.ku.dk
[2] University of Kassel, Germany. E-mail: borromeo@mathematik.uni-kassel.de
[3] University of Nicosia, Cyprus. E-mail: mousoulides.n@unic.ac.cy
[4] The National Polytechnic Institute of Mexico, Mexico. E-mail: aromov@ipn.mx

The sessions were initially (for 2020) planned with parallel session for short orals. Unfortunately, at the online conference in 2021, not all accepted contributions could be presented due to the authors' choice of not attending the congress. In the actual congress, we ended up with having 6 long oral presentations (LO) and 6 short oral presentations (SO), see Tab. 1, all followed by an opportunity to raise questions and comments in a discussion with the presenter(s). The three sessions were attended by about 25 online participants and 2–5 onsite participants. Posters were presented at the general poster presentation of the congress.

Tab. 1. List of papers presented

Paper and author(s)	
Session 1	
[1]	Interdisciplinary mathematics education: some reflections from the anthropological theory of the didactic. ***Francisco Javier García*** (Spain). (LO)
[2]	Interdisciplinary Inquiry-Based learning with queueing situations: investigating the questions triggering mathematical activities. ***Yuici Nezu*** *and Takeshi Miyakawa* (Japan). (LO)
[3]	A classroom experience: vector concept. ***Viana Nallely García-Salmerón*** *and Flor Monserrat Rodríguez Vásquez* (Mexico). (SO)
[4]	Students' use of geometric cues in an art studio: scaling of artworks. ***Mehtap Kus*** *and Erdinc Cakiroglu* (Turkey). (SO)
Session 2	
[5]	Posing a generating question within the pedagogy of questioning the world: the case of GPS coordinates. *Lenin Augusto Cepeda,* ***Avenilde Romo Vázquez****, and Luis Ramón González* (Mexico). (LO)
[6]	Mathematics and financial education: how do they intersect together? ***Annie Savard*** *and Alexandre Cavalcante* (Canada). (LO)
[7]	Task design features for integrating covariational reasoning with science. ***Debasmita Basu*** *and Nicole Panorku* (USA). (SO)
[8]	STEM projects as didactical situations in mathematics: theoretical frame to construct algebraic institutional meanings. ***Aitzol Lasa****, Miguel Wilhelmi, Olga Belletich, Jaione Abaurrea, and Haritz Iribas* (Spain). (SO)
[9]	Physcial measurements as an environment supporting primary pupils' reasoning about central tendency. ***Lúbomíra Valovičová*** *and Janka Medová* (Slovakia). (SO)
Session 3	
[10]	Questioning interdisciplinarity within teacher education: a module on the evolution of the COVID-19 pandemic. *Laura Branchetti and* **Eleonora Barelli** (Italy), *Berta Barquero, and Oscar Romero* (Spain). (LO)
[11]	A situation of interdisciplinary mathematics education in context of protection of water resources. ***Thi Nga Nguyen****, Thien Thanh Lam, and Minh Dung Tang* (Vietnam). (LO)
[12]	Transdisciplinary and interdisciplinary mathematics in the international baccalaureate. ***Sarah Christina Phillips*** (Canada) *and Jan Mills* (New Zealand). (SO)

3. Paper Topics

Following the call for papers, the papers were classified as far as possible according to the three subthemes of the TSG:

- Subtheme 1: *Mathematics and the study of nature*: here we consider the ways in which mathematics interacts with teaching and learning of subjects such as physics, biology, chemistry etc.
- Subtheme 2: *Mathematics and technology*: interactions with the study and use

of technology in a broad sense, comprising digital technologies, technological innovation and engineering
- Subtheme 3: *Mathematics and the study of human activity and society*, including business and enterprises, economy, creative fields such as art and music, philosophy, history etc.

The specific contents of the presented papers allow to identify several new tendencies and approaches, as is to some extent reflected from the paper titles listed in Tab. 1. The papers certainly included examples and results corresponding to all three subthemes, reflecting a variety of experimental and emergent practices and concerns in mathematics teaching around the world. At the same time, the challenge of mathematics and other disciplines is considered in wider perspectives than has been traditionally the case in this area of research. In particular, 4 of 12 papers refer to the "paradigm of questioning the world" (Chevallard, 2015) and base their experiments and reflections on associated constructs from the Anthropological Theory of the Didactic, such as "study and research paths" and "ecology and economy" (of teaching designs). The range and originality of interdisciplinary phenomena examined by the papers is impressive, and relates to all grade levels including higher education. It is also clear that despite the variation in institutional constraints across the world, the same phenomena (from water resources to satellite based navigation and art design) are increasingly of importance to all of humanity. Several of the studies involve real life data and activities involving data collection, so that the numerical or geometrical aspect of a phenomenon is not merely shown through a table or drawing in a textbook. As always, researchers and special resources are deployed in such experiments, and the question of sustainability arises. In this respect, some of the papers reflect on the fact that teachers face new requirements and challenges if they wish or need to organize interdisciplinary teaching.

4. Discussion and Areas for Future Research

The discussions at the congress allowed participants to get more insight into research methods and teaching practices from around the world. In all countries, interactions between mathematics and other school disciplines seems to be officially encouraged or even prescribed, at least to some degree. However, in some countries, this impetus has come more recently. Both in such countries, but also in other ones, there are still a number of constraints that can inhibit or weaken students' experiences of such interactions. Teachers' educational background is frequently not geared towards independent inquiry across disciplines, or even towards recognizing mathematical components in questions that involve other disciplines as well. Teachers may also be hesitant to orient their teaching towards such inquiry, for many other reasons — including perceived lack of time. Teaching resources for mathematics are, when it comes to relations with other disciplines, often limited to rather sterile examples made to "illustrate" some mathematical technique. On the other hand, experiments as carried out by the authors of several of the papers, do confirm that these constraints can be modified locally. With appropriate support, teachers can be successful with much more ambitious designs for students' experience of the many ways in which mathematical techniques and models appear in other disciplines and, more generally, in descriptions and solutions of important problems for humans and their societies.

There was a strong agreement among participants in the group that teacher education needs to focus more on interdisciplinary learning and teaching of mathematics in school. At present, few if any teacher education programs are geared for interdisciplinary teaching. One reason for this is that teachers need to study more than one discipline to gain some depth in view of the interdisciplinary setting. The study of several disciplines for being a teacher at secondary school is not included in the teacher education programs of most countries, with some exceptions like Germany and Denmark, where two subjects must be studied. But even teachers who studied two disciplines may not teach more interdisciplinary subjects, it does make it easier to combine the two subjects studied, such as mathematics and geography, in the lessons. Doing a project with colleagues from other disciplines makes sense for the learners, but is difficult to implement as a common element in everyday school life. Whether two disciplines are studied or a project is implemented with colleagues, teachers should be made aware of the importance of this interdisciplinarity. Learners benefit especially if they also experience the interrelationships of, for example, the STEAM disciplines on a metacognitive level. This could mean, on the one hand, that teachers have designed their learning unit in terms of the cross-link approach (Borromeo Ferri et al., 2019). One can speak of cross-linking, if at least two (scientific) disciplines are combined during one lesson/project or within the whole lesson-unit/project and are reflected with learners on a metacognitive level (Borromeo Ferri et al., 2019).

It becomes obvious that besides the challenge of interdisciplinarity, there is always the question of which methods can be used in the classroom. Inquiry-based learning, for example, touched upon in several papers presented in this group, is often a promising approach. Reflectively, however, the question should also be asked whether all disciplines are suitable for interdisciplinary work? Which ones fit together particularly well? These questions are useful with regard to the development of interdisciplinary learning environments for specific issues. However, it is important to note that it is through interdisciplinary work that different perspectives should be required of learners, to develop their critical engagement with a topic. Critical engagement or thinking is again one of the central four skills described in the 21st Century Skills, the 4 Cs: Creativity, Critical Thinking, Communication, and Collaboration (e.g., Rotherham et al., 2010). However, creativity, communication, and collaboration can also be promoted and fostered when it comes to issues that learners can solve in an interdisciplinary learning environment.

Furthermore, there is still a research desideratum for more studies that also explore the effects of interdisciplinary learning, for example regarding motivation, or performance in mathematics. If different effects of interdisciplinary learning were investigated more systematically, then one would have a good basis for impact on educational policy including the necessary changes in teacher training.

The topic of interdisciplinarity is becoming more and more prominent in mathematics education, especially for the reasons mentioned above, such as the promotion of 21st Century Skills for the present and future generations. During ICME 14, in the TSG on mathematical modeling, the topic of interdisciplinarity was alo discussed in a separate session in a panel. Real-world problems, which do not necessarily have to be very complex, require solutions from different disciplines. The focus on interdisciplinarity in mathematics learning is interesting for many research areas in mathematics education. The clarification of basic concepts, such as mono-, multi-, inter-, trans- and meta-disciplinarity, has already been well elaborated by Williams et al. (2016). Based on these terms, each research area that focuses on the topic of interdisciplinarity could now work out specifics regarding the topic area in terms of research questions and finally also regarding the practical implementation.

The dialogue between the papers and their authors should continue. The shared character of both constraints and potential resources makes it evident that more, and more international, research is needed in this area — research that goes beyond the local and national contexts considered in the vast majority of studies, here and elsewhere. We also note that only a few of the papers presented here involve, for instance, physics education researchers among the authors. As already mentioned, collaboration between teachers from different disciplines is most evidently needed at schools in order to realize truly interdisciplinary experiences for students. So perhaps more collaboration of researchers from different didactical horizons — not only from mathematics education — is equally needed to engage more efficiently with the issues at the international level?

Topic Study Group 45

Mathematics for Non-specialists/Mathematics as a Service Subject at Tertiary Level

Burkhard Alpers[1] and Mitsuru Kawazoe[2]

ABSTRACT This contribution describes the themes and programme of the topic study group on mathematics for non-specialist/mathematics as a service subject at ICME-14 and outlines directions of future work.

Keywords: Mathematics for non-specialists; Service mathematics.

1. Working Team, Themes and Questions

The working team for Topic Study Group 45 consisted of the following team members: Burkhard Alpers (Germany, Chair), Mitsuru Kawazoe (Japan, Co-Chair), Marta Caligaris (Argentina), Olov Viirman (Sweden), and Jing Zeng (China). This TSG dealt with the specialties of mathematics as a service subject, i.e. mathematics education provided as service in application study courses. The latter comprise all kinds of study courses in natural sciences, engineering, business and economy where more advanced mathematical terms and models are used but also study courses where mainly statistical methods are applied as in medicine and social sciences. The main educational goal of service mathematics consists of enabling students to understand and use the mathematical concepts, models and procedures as they are needed in their application study courses as well as in later job profiles. Essential questions related to the didactics of service mathematics are:

- Which understanding and competencies are needed in application subjects (like mechanics, national economics, experimental pedagogic) in order to understand the terms and development of models and to work on tasks successfully? How can this information be used to specify a curriculum for a specific study course? By which suitable learning arrangements (e.g. application problems and projects) can such competencies be acquired by students?
- How can mathematics be made relevant for students in application study courses such that students experience mathematics education as integral part of their study course and are thus motivated to undertake the necessary efforts?

[1] Department of Mechanical Engineering, Aalen University, Aalen, D-73430, Germany. E-mail: burkhard.alpers@hs-aalen.de

[2] Faculty of Liberal Arts, Sciences and Global Education, Osaka Metropolitan University, Sakai, Osaka 599-8531, Japan. E-mail: kawazoe@omu.ac.jp

- What are the mathematical transition problems when students enter university in an application study course and what are suitable measures to overcome them?
- What is the influence and role of technology in service mathematics courses? How does the existence of technology embodying mathematical concepts and procedures change the goals of mathematics and the ways of teaching and learning?
- Who teaches service mathematics and how do different backgrounds influence the teaching practices? What are suitable boundary conditions for successful teaching?
- What are promising research designs in service mathematics and how can different roles be integrated: mathematician, mathematics educator, application specialist?

Some of these questions were tackled in the paper and poster contributions to this TSG which will be outlined in the next section.

2. Program Overview

The topic study group's programme consisted of three sessions for paper presentations as well as a small part of the overall poster session. Because of the worldwide Covid-19 pandemic, most participants attended online via a video conferencing system which worked quite well for presentation and discussion. In the video meetings about 14–18 participants attended and there was a lively discussion on topics addressed in the presentations.

The following papers (Tab. 1) were accepted for the conference all of which except for the one by Lehmann[6] were presented at the paper sessions:

Tab. 1. List of papers presented

Paper and author(s)	
[1]	Mathematics as a service subject: historical development and major players from a European perspective. ***Burkhard Alpers*** (Germany).
[2]	A practice report on mathematical modelling education for humanities and social sciences students. ***Mitsuru Kawazoe*** (Japan).
[3]	Flexible content, instruction, and assessment in a university-level quantitative reasoning course. ***Deependra Budhathoki****, Gregory D. Foley, and Stephen N. Shadik* (USA).
[4]	A small-scale implementation of inquiry-based teaching in a single-variable calculus course for first-year engineering students. ***Olov Viirman*** *and Irina Pettersson* (Sweden).
[5]	Sometimes mathematics is different in electrical engineering. ***Jana Peters*** *and Reinhard Hochmuth* (Germany).
[6]	Which mathematics competences are relevant for engineering education? — a mixed methods study. ***Malte Lehmann*** (Germany).
[7]	The attitudes of lecturers and students towards puzzle-based learning: the case of differential equations. ***Farzad Radmehr*** (Norway/Iran), *Faezeh Rezvanifard* (Iran), *and Michael Drake* (New Zealand).
[8]	Can we make mathematics interesting for engineering students? modelling tasks in an ordinary differential equations course. ***Svitlana Rogovchenko*** (Norway).
[9]	Teaching materials on calculus as seen from application to engineering. ***Satoru Takagi****, Kesayoshi Hadano, and Sei-ichi Yamaguchi* (Japan).

The paper by Alpers[1] served to set the scene by giving a historical overview of the development of didactical thinking about the provision of service mathematics. Particularly during the last two decades the topic received more and more attention in research and in communities of practitioners but the area is still under-researched and many open questions need to be investigated. The other papers dealt with mathematics education for non-mathematics majors in different types of study courses. Only Kawazoe[2] and Budhathoki et al.[3] were concerned with mathematics education in a non-engineering study course whereas the other papers investigated aspects of mathematics teaching in engineering where mathematics is well acknowledged as being a fundamental subject. Kawazoe[2] described a concept for making mathematics education more relevant for students of social sciences and psychology where students perform modelling activities in groups. Since the concept has been in use for about a decade, long-term experience and necessary modifications could be reported. The paper by Budhathoki et al.[3] described an entry-level course on quantitative reasoning for non-STEM majors where students were given many opportunities for collaboration in problem solving. Since the course content was not fixed, the instructor could flexibly react to students' needs. The students who had rather negative prior experience reacted positively to this form of education.

The remaining papers were all related to teaching mathematics in engineering study courses. Viirman and Pettersson[4] described a small-scale implementation of inquiry-based teaching in a first-year calculus course where students investigated application problems in group sessions. Since this involved the meaningful usage of concurrently learnt mathematical concepts, students gained a better and deeper understanding of those concepts. The authors used commognitive theory as a framework for their research. Peters and Hochmuth[5] addressed differences in mathematical practices between the usage of mathematics in application subjects and the development of theory in the proper mathematics education classes. They used the Anthropological Theory of Didactics as a theoretical framework for their analysis and made suggestions for dealing with students' problems resulting from the differences. Lehmann[6] investigated how first-year engineering students solved physics problems using the theoretical concept of epistemic games for analysis. He found out that higher mathematical content knowledge was a good predictor for success in physical problem solving. Moreover, the students' problem solving behaviour developed more into the direction of schematic work ("recursive plug and chug game") where they tried to use a well-known schematic algorithm for problem solving which he related to the schematic use of mathematics in their mathematics education.

The next two papers[7,8] addressed the problem of making differential equation courses more relevant and interesting for engineering students. Radmehr et al.[7] investigated the effects of puzzle-based learning on the attitudes of lecturers and students where a puzzle is a non-standard, open question with an entertaining component. Based on a questionnaire and interviews the authors found out that a majority of students enjoyed working on this kind of problems and thought that this work improved their understanding and ability to solve realistic problems. Rogovchenko[8] tried to make mathematics more relevant to engineering students by introducing assessed modelling tasks in a differential equations course. Using the framework of activity theory, she found some contradictions between teachers' and students' goals where teachers strived for deeper understanding whereas students were predominantly interested in getting better grades. Conflicts between students occurred due to different backgrounds, work preferences and mathematical skills. Finally, Takagi et al.[9] developed teaching materials on calculus where they started with an application which made the subsequent concept relevant to the students and enabled them to attach practical meaning to those concepts. They illustrated their approach by providing example applications for introducing partial derivatives and double integrals.

The following posters (Tab. 2) were presented at the poster session.

Tab. 2. List of posters presented

Poster and author(s)	
[10]	Peer-assisted learning in less structured courses: a case study in a first-year course on mathematical modelling. ***William Man Yin Cheung*** (Hong Kong SAR, China).
[11]	Implementation of projects about scheduled in software r in a linear algebra course for students of business computing career at the University of Costa Rica. ***Luis Eduardo Amaya*** (Costa Rica).
[12]	On the mathematical knowledge, skills and related information technology needed to pave the way for students' career development. ***Jiao Liu*** (China).

Cheung's poster[10] investigated the effect of peer-assisted learning on increasing the interest and "sense of belonging" of non-mathematics majors in a course on mathematical modelling. The poster by Amaya[11] was concerned with using the statistics programming language R to get business computing students more interested in linear algebra topics, and Liu's poster[12] described her ongoing work on adapting the mathematics teaching of vocational students to their real needs using spreadsheet technology.

3. Future Directions and Suggestions

A more comprehensive overview of the state of the art in the didactics of service mathematics can be found in the report (Alpers, 2020) which shows that research on this topic has gained considerable momentum. Yet, as can be seen by comparing the questions stated in the first section with the results of TSG-45 presented in the second one, there are still many areas worth further investigation. Since there are many application study courses with special needs and requirements, there is still a plethora of research questions to be tackled in the decades to come.

Topic Study Group 46

Mathematical Competitions and Other Challenging Activities

Boris Koichu[1], Peter Taylor[2], Ingrid Semanišinová[3], Yijun Yao[4], and Sergei Dorichenko[5]

ABSTRACT The joint focus of TSG-46 on mathematics competitions and other challenging activities is devised in recognition of the fact that all students benefit from studying mathematics through challenging activities but some students do not like to compete. This group gathered mathematicians, teachers, mathematics educators and mathematics education researchers and served as a stage for presentations and discussions related to the following themes: (i) Organizational formats for challenging students mathematically, (ii) Research on students' experiences with mathematically challenging activities, (iii) Characterizing and theorizing mathematical challenge, and (iv) Competition problems as impetus for mathematical research and discoveries.

Keywords: Mathematical challenge; Competitions; Characterization of tasks; Discovery.

1. Background and Agenda

The mathematics competitions movement emerged more than a century ago as a means to engage bright schoolchildren in mathematical activities that would be more challenging than activities traditionally included in regular mathematics curricula. There is overwhelming evidence that all students benefit from studying mathematics through challenging activities, though there are some students within every age cohort who require more mathematically advanced tasks than others do in order to be adequately challenged. In addition, it is well known that many students who enjoy feasible for them mathematical challenge, do not like to compete with other students. Hence, the joint focus of TSG-46 is on mathematics competitions and other challenging activities, within or beyond a mathematics classroom.

The TSG-46 at ICME-14 built upon the work of the previous ICMI-initiated forums, such as the 16th ICMI Study "Mathematical challenge in and beyond the

classroom", DG-16 at ICME-10, DG-19 at ICME-11, TG-34 at ICME-12, and TG-30 at ICME-13.

In spite of the essential work done in these forums, it still needs to be acknowledged that the mathematical challenge is an elusive notion. For instance, ICMI Study 16 suggests the following conceptualization of challenge:

> "…we will regard challenge as a question posed deliberately to entice its recipients to attempt its resolution while at the same time stretching their understanding and knowledge of some topic. Whether the question is a challenge depends on the background of the recipient; what may be a genuine puzzle for one person may be a mundane exercise or a matter of recall for another with more experience" (Barbeau and Taylor, 2009, p. 5).

This definition puts forward the expectations of the proposers of a challenge regarding actions of its (potential) recipients, but is rather silent about the recipient actual intentions and actions. Accordingly, the following queries are still open and require our attention as a community:

- Why and under which circumstances are our students inclined to accept or not the requests to invest intellectual effort in doing mathematical tasks with which their teachers attempt to challenge them?
- What are characteristics of the mathematical tasks that have a chance to be perceived by the students as engaging and feasibly challenging?
- What is the role of a competitive aspect of a mathematical challenge?
- How can tasks that are initially designed for the use in competitions be used in a regular classroom or in a teacher preparation workshop?
- What are the relationships between engaging students in challenging activities and fostering their creativity and mathematical habits of mind?

These and such queries have been at the heart of the discussions at TSG-46. As in the previous ICMEs, TSG-46 at ICME-14 gathered mathematicians, teachers, mathematics educators and mathematics education researchers and served as a stage for discussions related to the pivotal aspects of the group work: mathematical challenge, competitions, challenging activities connecting school mathematics and mathematics as a research area.

2. Submissions and Presentations

The initial Call for Papers attracted 16 high-quality submissions of different formats. Unfortunately, the changing the year and the format of the conference due to the COVID-19 pandemic did not enable some of the authors to participate in the Congress. Eventually, 11 presentations have been delivered during three 90-minute sessions. Of note is that the group, though small, remained truly international and consisted participants from 8 countries, as follows: Bulgaria, Colombia, Hungary, Israel (2), Portugal, China, Slovakia, and USA (3).

The time of the sessions was distributed between whole-group discussions (45 minutes), two invited talks (IT), one long oral presentation (LO, 45 minutes including

Q&A), and 7 short oral presentations and a poster (SO, 15 minutes including Q&A). See Tab. 1.

Tab. 1. The list of presentations

Paper and author(s):
Session 1
[1] What competitions can tell us about theories in mathematics education. ***Maria Falk de Losada*** (Colombia). (LO)

[11] Competitions promoting the mathematical science. ***Valorie Lynn Zonnefeld** and Ryan Glenn Zonnefeld* (USA). (Poster)

3. Thematic Overview of the Presentations

3.1. Organizational formats for challenging students mathematically

In line with a well-established tradition, TSG-46 at ICME-14 served as a stage for presenting unconventional formats of competitions and out-of-school activities aimed to challenge students mathematically. He and Lin[9] presented Shanghai Grade 11 Mathematics Competition, which encourages students to use various types of calculators, including graphical calculators. Examples of problems from this competition convincingly show that calculators can be used not only as technical scaffolds but as valuable tools for promoting students' mathematical creativity (e.g., by means of devising computational algorithms) and tools for developing conceptual understanding.

Zonnefeld and Zonnefeld[11] overviewed several types of thematic competitions, including a Math Bee, data-analytics competitions and March Madness competition, in which students design algorithms to select teams for a basketball tournament. Cho[3] described the "I Love Math Day" conducted annually on February 14 in an urban school in New Jersey. The "I Love Math Day" is a celebration that playfully recognizes student long-term mathematical problem-solving effort in small teams.

Bora[10] introduced "Pósa Weekend-Camps" — two-day-long mathematical workshops, in which more than 1500 Hungarian 6–11 grade students have taken part since 1988. A characteristic feature of these camps is that the problems chosen are organized in threads and form a rich network. In this way, students explore mathematics while experiencing a mix of discovery learning and guided learning.

3.2. Research on students' experiences with mathematically challenging activities

Students' experiences with competitions and other challenging activities were in the focus of two presentations[6,7]. In these presentation, organizational formats of challenging the students were described as contextual information, and empirical research was put forward.

Ferreira[7] analyzed the reactions of a class of 6th graders in Portugal on "Math Trail" consisting of a sequence of five stops along a predetermined path from a school to a city center and back to school. At the stops, the students were offered mathematical tasks combining intellectual, social and physical dimensions. The data for the tasks were gathered through direct observation of the environment at the stops. Overall, students' reactions on the entire experience were positive though some of the tasks appeared to be too cognitively demanding for them.

Roan and Czocher[6] presented a post-hoc analysis of pre- and post- survey data from two rounds of the "Challenge Using Differential Equations Modeling" (SCUDEM) competition for high-school and undergraduate students. In the SCUDEM competitions, teams of three work for a week on a modeling problem of their choice. At the competition site, teams are offered an additional modeling issue related to the problem they have handled, and then give a 10-minute presentation of their findings, which is followed by immediate feedback. The analysis revealed profound differences between expectations of students, researchers and problem designers in relation to the gains of the competition. For example, whereas researchers and designers expected the competition to be appreciated as an opportunity to engage in modeling and as a chance for recognition, the participants valued most the experience in modeling and teamwork skills.

3.3. Characterizing and theorizing mathematical challenge

In her invited talk, Leikin[4] considered mathematical challenge embedded in a task as a complex function of the task characteristics, didactical settings in which the task is approached, classroom socio-mathematical norms and mathematical potential of the students who cope with the task. In particular, she focused on such task characteristics as conceptual density, the task's openness, and the complexity of mathematical concepts, mathematical connections and logical relationships required for solving the task.

Semanišinová et al.[2] reported a novel method of analyzing competition tasks by means of "formal concept analysis". The method was illustrated by its application to two multiple-solution problems from the Slovak correspondence mathematical competition. The fine-grained analysis of students' solutions revealed that while expert solution spaces were wide enough for both problems, the collective solution spaces varied. In conclusion, the scholars advocated for the choice of competition tasks that would be less dependent on the knowledge of particular mathematical concepts or specific solution methods.

Parasha et al.[5] introduced a notion of "dialogical challenge", that is, a mathematical challenge associated with collective argumentative activity towards deciding which of contradictory solutions to a problem is right and why. By means of three examples, they argued that a dialogical challenge is two-dimensional: the first dimension is related to understanding and validating the solutions, and the second one — to inventing an argument that would be convincing to the peer students.

Finally, a long oral presentation of Falk de Losada[1] was devoted to theoretical analysis of competition problems by means of the conceptual apparatus suggested by Duval's theory of semiotic registers. She provided illuminating examples of the competition problems that can be solved by changing a semiotic register. Based on these examples, Falk de Losada argued that mathematical thinking is more than representations and treatments, and mathematics is more than a language to be learned, but rather an elastic medium that supports the search of novel and unanticipated connections.

3.4. From competition problems to mathematics discoveries

The invited talk of Bankov[8] elaborated on mathematics competition problems as intellectual products, which can serve as impetus for mathematical discoveries. A classic competition context of "cutting a polygon" was unfolded in the lecture. Inspired by a beautiful problem from the 1968 Saint Petersburg Mathematics Olympiad, Bankov considered a series of follow-up questions and problems, some of which are within the reach of a bright school student, some — require profound mathematical knowledge, and some are still open.

Interestingly, one of the open questions mentioned in the lecture deserved special attention at the summarizing discussion of the group when one of the participants (Sergei Dorichenko) offered an idea for how the question can be answered. The vivid discussion of the Dorichenko idea, which has been formulated on the spot, expressed greatly the creative spirit of TSG-46.

Topic Study Group 47

Mathematics Education in a Multilingual Environment

TSG-47 Working Team[1]

1. Introduction

Around the world, mathematics education is taking place in multilingual environments, including classroom situations. The environments can be affected by historical and ethnic diversity, and by colonialism, migration, refugee contexts and/or globalization. Research on issues in such environments are growing, and the "problematique" arising is of wide relevance for teachers and students all over the world. The aim of TSG-47 was therefore to examine issues that arise in conducting research on mathematics education in multilingual environments. The following four themes were addressed:

1. Mathematics teaching strategies in multilingual classrooms;
2. Theoretical foundations for the notion of resource in multilingual classrooms;
3. Multilingual students' agency in mathematics classrooms;
4. Design based research in multilingual mathematics settings.

The cooperation in the organizing team worked well over the years to prepare for the conference. We had a thorough review process and ended up with 16 long oral presentations, seven short orals and two posters. The presenters came from all over the world, showing that multilingual issues in mathematics classrooms are studied "everywhere". Multilingualism is studied from different theoretical perspectives and methodologies, such as: semiotics (Raja and Pugalee, 2016), design research (Prediger and Uribe, 2021), code-switching (Hao and Yap, 2022), translanguaging (Ryan, Källberg and Boistrup, 2021), and variation theory (Essien,2021).

2. Sessions and Papers Presented

The TSG met mainly on zoom, but there were Chinese participants on place in a lecture hall. The technique worked well except for a few of the presenters, they had problems

getting access to the zoom platform. It didn't work to create zoom rooms, so, we had to do that our selves.

The time span from 2020–21, due to Covid-19, made presenters withdraw from the conference. At the time of the conference, a few of the papers presented had already been published, in longer more developed versions, elsewhere. The posters were not presented.

All the presentations are listed in Tab. 1, including two invited presenters: Susanne Prediger[6] and Richard Barwell[10].

Tab. 1. Presentations in TSG-47

Paper and author(s)
Session 1
[1] Code-switching: proposing linguistic relativity as lens in multilingual mathematics education research. ***Lester Cu Hao*** (Philippines).
[2] Practices and functions of colloquial Arabic use to generalize patterns in multilingual classrooms. ***Dibih El Mouhayar*** (Lebanon).
[3] Localised instructional mathematics application programmes: providing access into mathematics in multilingual classrooms. ***Evalisa Miriamu Katabua*** (South Africa).
[4] Fostering mathematics teacher development through experiential learning in multilingual communities. ***Catherine Paolucci*** (USA).
[5] Study on difficulties of math word problems in English-international baccalaureate in Japanese high school. ***Mitsuhiro Kimura*** (Japan).
Session 2
[6] Activating multilingual resources in a superdiverse covariation classroom — a design research study. ***Ángela Uribe*** *and Susanne Prediger* (Germany).
[7] Examining equitable participation and positioning in multilingual classrooms: tasks, language(s), and norms. ***William Carl Zahner*** (USA).
[8] The importance of students' first language as a sense-making resource in multilingual mathematics classrooms. ***Sally-Ann Robertson*** (South Africa).
[9] Exploring the enablement of mathematical proficiency in grade four English second language mathematics classrooms. ***Faith Lindiwe Tshabalala*** (South Africa).
Session 3
[10] Language positive classrooms: an example. ***Richard Barwell*** (Canada).
[11] Towards a framework for understanding the choice and use of examples in teacher education multilingual mathematics classrooms. ***Anthony Essien*** (South Africa).
[12] Impact of an online course of teaching mathematics to emergent bilinguals on teacher perspectives. ***Ji Yeong I*** (South Korea).
[13] Language-related barriers to mathematics learning: an alternative diagnosis. ***Mun Yee Lai*** (Australia).
[14] The problems of bilingual mathematical learners when using mathematics in Arabic. ***Madiha Hassan Mohamed Abd El-Rahman*** (Egypt).
[15] A student may speak with an accent, but no student thinks with an accent in mathematics. ***Clarence Alan Zollman*** (USA).

The organizing team shared the leading of our presentations. Session 1, chaired by Eva Norén, was held at 14:30–16:30 Beijing Time, July 13th; Session 2, chaired by Anthony Essien, was held at 19:30–21:00 Beijing time, July 14th; Session 3, chaired by Eva Norén, was held at 21:30-23:00 Beijing time, July 17th.

All sessions included discussions. The discussions were hold in positive manners. The TSG ended with discussions on how to take results from studies further, and how we could cooperate in the future.

Topic Study Group 48

Mathematics in a Multicultural Environment

Florence Glanfield[1], Anthony Fernandes[2], Qin Jing[3], and Peter Kajoro[4]

ABSTRACT TSG-48 examined historical, current, and emerging trends as well as issues and experiences in research with/in/on multicultural environments, across four themes: theoretical perspectives, methodological perspectives, emergent perspectives, and knowledge mobilization perspectives.

Keywords: Multicultural environments; Mathematics education; Theory; Methodology; Emergent; Knowledge mobilization.

1. Description and Themes

1.1. Description

Mathematics education occurs in multicultural environments in all countries around the world. The aim of TSG-48 was to examine issues, and explore experiences, that arise in mathematics education policy, practice, and research with/in/on multicultural environments. Research, practice, and policies of/in/with mathematics education are affected by history, colonialism, decolonization, migration, and globalization. There is a growing body of research that is related to Indigenous perspectives, social justice, and equity within these historical and colonial environments. Research in mathematics education arising in such environments is growing and is of wide relevance. Four themes were featured.

1.2. Themes

Theoretical perspectives framing mathematics education with/in/on multicultural environments explored the questions: What theories have been used in conducting research with/in/on mathematics education in multicultural environments and why? What theories have been used to guide the teaching and learning of mathematics

with/in multicultural environments? What are normative assumptions about mathematics education policy, practice, and research and multicultural environments? How might theory help to challenge normative assumptions? How has theory and research developed in the context of multicultural environments contributed to understanding the learning and teaching of mathematics more generally?

Methodological perspectives engaging mathematics education research with/in/on multicultural environments explored the questions: What new challenges have emerged in the methodological perspectives used in recent years? How might they be addressed? What perspectives have informed research with/in/on mathematics education in multicultural environments in recent years?

Emergent perspectives in framing research, teaching, and learning of mathematics education with/in/on multicultural environments explored the questions: In what ways are new perspectives informing the mathematics education research community about teaching and learning mathematics with/in/on multicultural environments? What are the ways in which these emergent perspectives inform teaching and learning of mathematics equitably? What challenges arise for mathematics teachers, mathematics educators, and mathematics education researchers when working with/in students' and families' diverse multicultural environments?

Knowledge mobilization perspectives explored the questions: How might research with/in/on mathematics education in multicultural environments inform curriculum and/or assessment policy? What challenges and opportunities arise in the interaction of mathematics education research with/in/on multicultural environments and the development and implementation of local, national, and international policy? What insights might be developed in the analysis of such interaction?

2. Program Overview

The Topic Study Organizing Team are the authors of the proceedings. Six contributions to the topic study group remained following the cancellation of ICME-14 in 2020 and the move to a hybrid format in 2021. In this section we firstly describe the format of the Topic Study Group sessions and then provide an abstract of the papers that were delivered.

2.1. Format

Two sessions of papers were facilitated during the ICME-14 meeting, on July 16 and July 17. The beginning of each session started with a welcome, facilitated by members of the organizing team. Following the presentations there was an opportunity for all individuals who presented and those who were listeners to dialogue around the ideas that were featured throughout the presentations. There were two long oral paper presentations and four short oral paper presentations. The long oral presentations were scheduled for 30 minutes and the short oral presentations were scheduled for 20 minutes. The first paper in each session was a long oral presentation.

2.2. Presentations

Papers in TSG-48 are presented in Tab. 1. In the table, LO stands for long oral presentation, SO for short oral presentation.

Tab. 1. The list of presentations

Paper and author(s)	
[1]	Conceptualizing a framework for a new (disruptive) form of culturally responsive pedagogy in mathematics/teacher education. ***Kathleen Nolan*** (Canada). (LO)
[2]	Preservice teachers engaging with traffic stop data to examine issues of bias. ***Anthony Fernandes*** (USA). (SO)
[3]	Intersections of indigenous knowledge systems and mathematics education. ***Florence Glanfield*** (Canada). (SO)
[4]	Taking a strengths-based approach to learning and teaching mathematics. ***Marta Civil*** (USA) *and* ***Roberta Hunter*** (New Zealand). (LO)
[5]	Developing concepts for mathematics teaching units with a focus on migrant and minority students. ***Andrea Ulovec*** (Austria)*,* ***Jarmila Novotná****, and Hana Moraová* (Czech). (SO)
[6]	The use of dominant discourse practices in secondary multilingual mathematics classrooms: A comparison of lessons given by two teachers. ***Michael Alexander*** (South Africa). (SO)

A long oral presentation by Nolan[1] explored the question of how school mathematics and mathematics teacher education might be reframed through critical and culturally responsive pedagogies. By synthesizing perspectives offered by Ethnomathematics (EM), Critical Mathematics (CM), Indigenous Education (IE), Language Diversity (LD) and Equity-based (E-b) approaches to research in mathematics education, Nolan conceptualizes a new (disruptive) form of culturally responsive pedagogy (CRdP). As discussed in this paper, CRdP is pedagogically informed by the EM-CM-IE-LD-E-b collective; it is theoretically informed by Nancy Fraser's (2009) three-dimensional approach to social justice and participatory parity; and it is methodologically informed by discourse analysis.

Fernandes[2] reported on how ten preservice teachers, who were mostly White, engaged with local city traffic stop data to examine issues of racial bias. Police traffic stops are a common occurrence in the United States. Racial minorities, especially African Americans, are stopped at rates that are higher than other races. As data becomes more prevalent in society globally, it is important for teachers to be able to analyze and interpret large data sets. At the same time, teachers need to be familiar with issues that affect students they are going to teach. In the United States students of color are becoming a majority in schools, while their teachers come from different backgrounds and have different life experiences. An analysis of the pre- and post-reflections demonstrates that the preservice teachers associated the disproportionate traffic stops to actions of individual police officers rather than acknowledge racial bias in policing. The study showed that even though studying data can be an important tool to understand structural inequities, a more comprehensive approach to changing dominant beliefs is needed.

Glanfield[3] asked "In what ways might Indigenous knowledge systems shape mathematical understanding and mathematics teaching practices?" This paper described Indigenous knowledge systems and the ways that mathematics exists within Indigenous cultures. The paper illustrated the ways in which Indigenous knowledge systems have the potential to contribute to establishing and building inclusive, and equitable, classrooms. For example, one such aspect of many North American Indigenous knowledges is "we are all related." This aspect points to the ways in which teachers can build on student, family, and community strengths for any classroom that is multi-cultural, not just Indigenous cultures.

Another long oral presentation[4] by Civil and Hunter drew on research with teachers, students and parents to show how strength-based approaches can support culturally sustaining practices in mathematics classrooms. Although there has been a substantial increase in literature around teaching and learning of mathematics in multicultural settings we still have a way to go to gain equitable outcomes for all learners. Civil and Hunter illustrated how repositioning teachers from a traditional role as listened to, to that of being listeners, causes dissonance from which comes change towards culturally sustaining pedagogy. Civil and Hunter showed how authentic two way conversations between parents and teachers provide opportunities for learning with and from each other, not just about mathematics but also about their values and ways of being.

A joint paper[5] by Ulovec et al. shared the work of a Czech-Austrian project team. The multicultural nature of society influences education in many countries. Teachers are usually not sufficiently prepared to deal with a multicultural classroom context. Particularly mathematics teachers feel the need for materials supporting them in teaching in multicultural classrooms. Mathematics teachers' pupils with a migrant background often encounter more difficulties than their native classmates in acquiring basic mathematical skills. Many projects have created mathematics teaching materials in different settings, though these did not take multicultural classrooms into consideration. Few projects have created concrete mathematics teaching materials for migrants, but these were rather closed materials, not concepts and strategies to be further developed by teachers. The project team worked on designing concepts for teaching units based on the analysis of various research studies, examples of concrete teaching units based on these concepts, and guidelines on how to use these concepts. These materials will give mathematics teachers a tool that allows them to create their own teaching units fitting their own classroom needs.

Finally, Alexander[6] explored some of the dominant discourse practices used in multilingual mathematics classrooms by comparing two teachers' mathematics lessons on trigonometry in a Nigerian secondary school. Alexander started with an introduction, and then outlined a theoretical perspective on the nature of classroom interactions which informed the study. The research questions were: What dominant discourse practices were used by teachers as plainly demonstrated in their language (verbal and non-verbal) in multilingual mathematics classrooms? How do teachers use language (verbal and non-verbal) to enact practices as reflected in their discourses in the teaching and learning of mathematics in multilingual classrooms? Data gathering techniques for the study included video observations in the classrooms, and written field notes. The data gathering process covered a period of six months. A total of 6 lessons were observed. Exploration of these practices lead Alexander to discuss a number of the relationships between teaching and learning of mathematics in multilingual classrooms. The analysis showed that teacher G used language to make his identity visible, as well as re-voicing and gesturing mathematically while teacher S used language not only to make his identity visible but also stabilise it during the discourses.

3. Future Directions and Suggestions

The presentations in TSG-48 highlight the diversity and complexity of research in multicultural environments. Though there were different foci, we find some underlying themes that point to future directions in research. It is important to take a strengths-based approach when working in a multicultural environment. Students effectively draw on their language and lived experiences in the mathematics classrooms. Current research around trans-language is also a step towards new understanding of learning and teaching mathematics in a multicultural environment. Further, exposing future teachers and teachers to these approaches is key to future research directions.

Providing future teachers with experiences and opportunities to dialogue is an area that needs more research. Discussions around racism, colonialism, and sexism can remain controversial within a mathematics classroom. Research related to curriculum and classroom implementation remains an important future direction in research.

We also noted that, on terms of methodological approaches, the research presented in Topic Study Group 48 was primarily qualitative. We wondered, what quantitative or mixed approaches might be developed to offer other perspectives of mathematics in a multicultural environment in the future?

Topic Study Group 49

Distance Learning, E-learning and Blended Learning of Mathematics

Marcelo Bairral[1], Tracey Muir[2], and Veronica Hoyos[3]

ABSTRACT Topic Study Group 49 built on current and emerging research in distance learning, e-learning and blended learning. Specifically, we pushed the boundaries of what is known through a deeper examination and discussion of recent research and development in teaching and learning through these modalities, with a focus on primary, secondary, and higher education.

Keywords: Distance learning; E-learning; Blended learning.

1. Aims of TSG-49

Our TSG-49 aimed to build on current research and highlight emerging research into how distance learning, e-learning and blended learning were enacted in the context of mathematics education. Participants were invited to contribute papers for the following sub-themes:

1. The emerging work on the usage of such mobile technologies, as cell phones and tablets, for distance learning or blended instruction.
2. Incorporation of social media in online (or blended) technologically mediated courses.
3. Flipped classroom.
4. Developing the role of the faculty/moderator/tutor in online mathematics education.
5. Exploration of the emergence and sustainability of communities of practice in online environments of collaboration and co-construction of resources.
6. Utilization (Web 2.0, Web 3.0 etc.) and designing tasks, resources or environment in e-learning, blended learning, and distance education modalities.
7. Enabling mathematical collaboration in online mathematics education and orchestrating productive mathematical conversations in an online or in a blended setting.
8. Using distance learning, e-learning and/or blended learning in mathematics

[2] University of Tasmania, Australia. E-mail: Tracey.Muir@utas.edu.au
[3] National Pedagogical University, Mexico. E-mail: vhoyosa@upn.mx

pre-service teachers' training, professional development of in-service teachers, and/or to promote the collaboration between teacher education researchers.

9. Assessment and evaluating of the effectiveness of distance education, e-learning and blended learning.
10. Research methodologies and paradigms for studying online and blended mathematics education.

1.1. Submissions

We received 23 submissions from authors of eight countries (Australia, Austria, Brazil, Germany, Mexico, Nepal, Russia, USA). Submissions comprised six long presentations, 10 short oral presentations and 7 poster presentations. During the conference, 16 papers were scheduled, and 10 were presented across 4 sessions.

1.2. Sessions

The four sessions included both short and long oral communications. Each session was facilitated by one of our TSG's co-chairs and were well attended by members of our TSG. Discussion prompts were utilized to promote discourse focused on the implications of the study for online learning in the current COVID-19 context and for mathematics education in general. The final session included identification of emerging research themes and identification of opportunities for future research.

2. TSG-49 Themes

The 10 papers presented during the congress were grouped into 3 themes:

- Flipped classroom and hybrid environments
- Mobile devices, task design and other resources
- E-learning and online professional development: Courses, reflections, and interactions

The papers for each theme are listed in Tab. 1 (on the next page).

2.1. Flipped classroom and hybrid environments

The first two papers focused on flipped classroom and hybrid environments. While the flipped classroom approach may seem easily adaptable to cater for online learning as a result of the COVID-19 pandemic, restrictions meant that there was no opportunity to implement the in-class phase of flipped learning. Rothe's study[1] investigated the importance of the in-class time in a flipped classroom, with results suggesting that students experienced difficulties in achieving higher-order learning goals in the changed scenario. Hoyos et al.[2] presented a paper which described the framework, methodology, analysis, and results of an exploratory study around the implementation of a hybrid learning environment designed to address the teaching and learning of

Tab. 1. The list of papers for each theme

Paper and author(s)	
Flipped classroom and hybrid environments	
[1]	Fostering higher order thinking in the flipped classroom — an analysis of students' proof schemes. ***Jennifer Rothe*** (Germany).
[2]	Hybrid environments of learning: teacher efficiency and potential for student learning by collaboration. ***Veronica Hoyos****, Estela Navarro, Victor Raggi, and Sergio López* (Mexico).
Mobile devices, task design and other resources	
[3]	Designing tasks to improve plane transformation using DGE with touchscreen. *Alexandre Assis and* **Marcelo A. Bairral** (Brazil).
[4]	Using free software to implement verification problems with parameters. ***Ilya Alexandrovich Posov*** *and Dmitry Irikovich Mantserov* (Russia).
[5]	Workshop activity in online courses of mathematics education: insights for learning and assessment. ***Niroj Dahal*** (Nepal).
E-learning and online professional development: courses, reflections, and interactions	
[6]	A reflective practice on an online mathematics class. ***Haoyi Wang*** (USA).
[7]	Case study on the change process of a mathematics teacher in an online professional development course. ***Stefanie Schallert*** *and Robert Weinhandl* (Austria).
[8]	Participants' patterns of interaction within and across social networks in a massive open online course for educators. ***Heather Barker****, Gemma F. Mojica, Karen Hollebrands, and James Smiling* (USA).
[9]	The role of the lecturer in facilitating productive mathematical conversations in online mathematics pre-service teacher education. ***Tracey Muir*** (Australia).
[10]	Transforming numeracy professional development for pre- and in-service mathematics teachers and families through e-learning. ***Leicha A. Bragg****, Chris Walsh, and Tracey Muir* (Australia).

functions. The hybrid environment led to improvements in teacher practice, and refinement or validation of students' conceptions.

2.2. Mobile devices, task design and other resources

The next three papers focused on mobile devices, task design and other resources. Assis's and Bairral's research[3] illustrated designed tasks on GeoGebra with touchscreen and reflected about the design of them to improve plane transformation in High School with students without previous instruction in this content. Posov and Mantserov's paper[4], based on computer-aided assessments, rewrote a condition on a function with a logical expression on its parameters, and then proposed ways to implement it using GeoGebra and Sage. And, Noroj's study[5] identified best ways to engage students in the process of learning and peer assessment by using workshop as a learning and assessment tool for MPhil in Mathematics Education for the course Graph and Network.

2.3. E-learning and online professional development: courses, reflections, and interactions

The other five papers focused on e-learning and online professional development (courses, reflections, and interactions). Wang's paper[6] reported on a reflective practice that examines both qualitative and quantitative datasets in understanding the implemented multimedia distance learning environment at an entry-level math classroom at a large state university in the Midwest and its resulting consequences on the math learning and assessment performance of the students. Schallert and Weinhandl's paper[7] presented a case study approach to examine the different elements of a change process of a secondary teacher within an online course for mathematics teacher training. Barker et al.[8], based on social network and sentiment analyses, examined the discussion forum posts of 159 educators from 46 countries who participated in a Teaching Mathematics with Technology MOOCs for Educators. Muir's study[9] provides an example of an online forum, which highlights how pre-service teachers can be engaged in productive online mathematical discussions, particularly when facilitated by the instructor's and other learners' presence. Bragg et al.[10] presented a multipronged approach to transform the provision of numeracy professional development for educators and families through the design of three open-access resources.

3. Areas for Future Research

In our final presentation session, the participants discussed potential future research topics and publication possibilities. Participants in TSG-49 topics' discussion concurred that further research into the nature, purpose, and significance of online, blended, and e-learning in mathematics education was needed, especially in the context of the deep socio-cultural changes brought about globally by the COVID-19 pandemic.

Finally, methodologies to gather data and to analyze online interaction (among students or teachers) using asynchronous or synchronous tools continue to be a field of interest, as well as investigating more on what ways the affordances and limitations of online tools and apps are influencing the task design and/or math's teaching and learning.

Topic Study Group 50

Mathematics Education in and for Work; Continuous Mathematics Education Including Adult Education

Lisa Björklund Boistrup[1] and Geoffrey Wake[2]

ABSTRACT In this report we give account for how TSG-50 was organised, both in terms of structure, and in terms of content of the area of the TSG. The papers presented are summarized and future directions are suggested, including the relevance of a TSG with this theme also for future ICMEs.

1. Organization and Aim

TSG-50 was organised by the following people:

Chair: Lisa Björklund Boistrup, Malmö University, Sweden
Co-chair: Geoffrey Wake, University of Nottingham, UK
Members:
Pradeep Kumar Misra, Chaudhary Charan Singh University, India;
Maria da Conceição Ferreira Reis Fonseca, Universidade Federal de Minas Gerais, Brasil;
Haixia Si, Hangzhou Normal University, China
Gail FitzSimons, Melbourne University (extra member)

Topic study group 50 at ICME-14 had as its aim to exchange ideas and knowledge with regards to two related themes: mathematics in and for work, and continuous mathematics education including adult education. The TSG received eight paper contributions and one poster presentation. Present at the TSG sessions were 15–20 people, where also co-authors took part. In our TSG sessions during the conference, we addressed key questions as an overarching organising structure:

- What issues do we need to consider in designing for mathematics education in and for work?
- What role can theory play in our mathematics education research?
- How can we support the learning of mathematics by adults?

[1] Department of Science, Mathematics, and Society, Malmö University, 205 06 Malmö, Sweden.
E-mail: lisa.bjorklund.boistrup@mau.se

[2] School of Education, University of Nottingham, Nottingham, NG8 1BB, UK.
E-mail: Geoffrey.Wake@nottingham.ac.uk

We allocated time according to the schedule below for contributions to facilitate the discussions around the key questions. In the end of each meeting there was time to discuss the questions across the presented papers.

2. Report from the Sessions of TSG-50

Below we give account for the subthemes and papers of the sessions of TSG-50 (Tab. 1).

Tab. 1. The list of papers for each theme

	Paper and author(s)
Session 1: What issues do we need to consider in designing for ME in and for work?	
[1]	Designing for the learning of mathematics for vocational competence. ***Geoffrey Wake*** (UK).
[2]	Construction of mixed training model for rural mathematics teachers in junior middle school. ***Xiaocheng Li****, Guanghui Zhou, Jun Tao, and Dongxue Tu* (China).
[3]	Sociomathematical norms in vocational mathematics education. ***Trude Sundtjønn*** (Norway).
[4]	Infographics about the world of work: an experience with students of vocational education integrated to high school. *Guilherme Guilhermino Neto,* **Lauro Chagas e Sá***, and Maria Auxiliadora Vilela Paiva* (Brazil). (Poster)
Session 2: What role can theory play in our mathematics education (ME) research?	
[5]	Investigating interfaces between mathematics and vocational content: logos and praxis in education. ***Lisa Björklund Boistrup****, Matilda Hällback, and Divo Racheed* (Sweden).
[6]	"Here we are the boss": numeracy practices as resistance tactics of clothing factory workers in Brazilian northeast. ***Maria da Conceição Ferreira Reis Fonseca*** (Brazil).
Session 3: How can we support the learning of mathematics by adults?	
[7]	Re-thinking the assessment of adults' numeracy skills: new challenges, new responses. ***Javier Díez-Palomar*** (Spain)*, Kees Hoogland* (The Netherlands)*, and Isabelle Demonty* (Belgium).
[8]	Moocs for lifelong mathematics learning of adults in India: promises and strategies. ***Pradeep Kumar Misra*** (India).
[9]	Adults' proportional reasoning in a volume scaling situation. ***Linda Marie Ahl*** *and Lars Ola Helenius* (Sweden).

2.1. Session 1, Tuesday July 13th

The subtheme of this session is: *What issues do we need to consider in designing for ME in and for work?*

This theme was focused by the input of three papers and one poster. These looked at issues relating to developing mathematics education (ME) in preparation for, and in, work. These contributions signaled the wide range of issues to be considered, from overall drivers such as qualifications through to learning based on the use of specific tasks.

Wake[1] developed an argument that we need to consider carefully what we consider to be an appropriate form of the learning which we wish to promote. Consequently, he points to how learners need to get an awareness of how mathematics is developed and applied in vocational domains in ways that are sensitive to the idiosyncrasies that may arise in work settings. He also argued that because application of simple mathematics is important there needs to be time and space dedicated to learn how to do this in ways that are authentic to workplace settings. In this sense he emphasized that learning in and for work is primarily about learners who are involved in identity development as they become members of workplace communities and that a mathematics curriculum should support them in this. Li et al.[2] picked up this theme by illustrating a model of teacher training for rural mathematics teachers of junior middle school students. The paper provided insight into how workplace learning, in the case of teachers promoted a range of carefully designed learning modes that involved them in reflection in different stages that involved them in activity that is both school based and online in a mixed model.

Sundtjonn[3] focuses more closely on students' learning whilst working on a task in a lesson on a vocational education programme in Norway. She considers that even though the task being used is carefully designed to provide some engagement in an authentic activity both teachers and students exhibit behaviours that are those we might expect in traditional school mathematics classrooms. Their focus is primarily on getting mathematical solutions without considering the implications in terms of the real world situation. The study points to how strongly traditional sociopmathematical norms are embedded in the lives of teachers and students and to break through the barriers these present it will be necessary to provide teachers with specialized guidance. The poster[4] by Guilhermino from Brazil likewise looked at students' engagement in a learning activity for students on a Biotechnology technical course. This was found to be motivating as students took ownership of the themes they chose to work with and they drew on learning from other parts of their course as they carried out data collection, analysis and communication through the means of an infographic.

The discussion in this theme pointed to the different levels of support needed if we are designing mathematics education for the world of work. At the strategic levels we have to consider carefully the curriculum and qualifications we design through to the support we give teachers with their teaching at the tactical level of implementation and down to the detail of task design at a tactical level. There is much to do if we are to implement learning mathematics for work successfully.

2.2. Session 2, Friday July 16th

The subtheme of this session is: What role can theory play in our mathematics education (ME) research?

Two papers addressed issues of the use of theory in research with a focus on learning mathematics in and for work. Boistrup et al.[5] used the ideas of Chevallard's Anthropological Theory of Didaactics (ATD) to analyse data from collaborative teaching in mathematics and vocational education in the 'beauty' industries (facial make-up and hair). Their analysis considered both logos (knowledge and theory) and praxis (tasks and techniques) in the vocational tasks that students worked on. They reported, and illustrated, how in two tasks that learners worked on, (symmetry in) facial make-up and (angles in) curling of hair, demonstrated how logos from both mathematics and the world of work were needed and the praxis required was mainly from the vocational context. Their discussion pointed to how their use of ATD led them to confirm the work of other researchers who point to how mathematics can help clarify work practices and vice versa, the context of work can help provide insight into, and explain mathematical ideas.

In a more overtly political paper[6] Fonseca reported ethnographic research that explored the practices that were forged in work, school, and daily life activities of students from Youth and Adult Basic Education (YAE), aged 16. With a focus on the numeracy practices Fonseca's analysis Fonseca identified in the workplace tactics of resistance (Certeau, 2011) to oppressive ways of life and production being delineated, established, and developed. These practices were constituted by diverse discursive practices, including numeracy practices, generally marked by the Cartesian rationality used by capitalist logic. Fonseca suggested that their ways of doing mathematics, the workers were cunningly circumventing the distribution of tasks. They used tricks and expertise to improve and speed up the production — and thus make greater collective gains, not per piece made by each.

These two very different approaches to using theory in general suggest that theorizing our research can provide new insights into what are often complex socio-cultural situations.

2.3. *Session 3, Saturday July 17th*

The subtheme of this session is: *How can we support the learning of mathematics by adults?*

A focus on adults learning mathematics was the common thread in the three papers presented in this session. Again, as in the first theme, the contributions provided a glimpse into the diversity of work that might be considered in research in this area, particularly at strategic, tactical, and technical levels.

At a policy level, Díez-Palomar et al.[7] went back to consider exactly what we mean by the term "numeracy", it's history and its relationship with quantitative literacy. They considered how international studies such as PIAAC are used to measure competence in this area across countries and then argued that we now face new challenges as adults are starting to have to consider solving problems that involve big data, social media, and other new e-social technologies that are deeply transforming social interaction. They point to how there are additional demands being made in terms of employability, citizenship, community participation, etc. and such considerations suggest that we need to rethink how international assessments for adults engage with the new "digital" era.

Picking up this theme, Misra[8] explored the potential of Massive Open Online Courses (MOOCs) as a medium for the education of adults in mathematics. Misra discusses this in the context of India, the worlds' second most populated country, where there are clearly challenges in reaching adult learners in ways that meet their needs in relation to societal, institutional, and governmental needs. The paper suggests that MOOCS offer great potential in this area and is optimistic that this approach can be successful in India.

In a final paper in this theme, Ahl and Helenius[9] considered the learning of a specific mathematical concept, that of proportionality in the specific contexts of volume scaling, speed and cost effectiveness. The fresearch was carried out with adult Swedish students in a prison education programme and contrasted with resuts from upper secondary students in Denmark. It was found that, in the case of volume scaling, the secondary schools students performed considerably better than the adult students. It was suggested that preliminary analysis of the other tasks were pointing to similar results. The authors suggest that proportional reasoning experienced in real situations does not seem to provide useful insight into the scientific ideas that were needed in the tasks used here.

3. Main Outputs and Future Directions

The two themes of the TSG, mathematics in and for work, and continuous mathematics education including adult education, are often related and TSG-50 combined them to consider mathematics education from the different contexts of where mathematics is either related to work (e.g. Wake[1], Sundtjønn[3], Fonseca[6], Boistrup et al.[5]) or other important aspects in the lives of adults (e.g. Li et al.[2], Neto et al.[4], Ahl and Helenius[7], Misra[9]). TSG-50 focused on lifelong mathematics learning and was concerned with mathematics education that takes place in formal education settings, such as formalised adult education; semi-formal settings, such as part of vocational education organized for example by employers or by workers' associations; and informal settings, that may be part of the daily activities of adults in and outside work.

TSG-50 viewed mathematics to be inclusive of the formal academic discipline of mathematics and mathematical processes such as modelling and problem solving in addition to many other informal forms of quantitative and spatial reasoning that arise in a wide range of settings and situations.

The discussions in TSG-50 were lively and focused, with both interactions online, as well as with participant on-site. The contributions pointed towards the future, both in the sense of addressing emerging and current issues, and in relation to the need for joint publications within the area. The plan is to have in process at least one joint publication until next ICME. A conclusion was also the need for a TSG such as TSG-50 also at future ICME's.

Topic Study Group 51

Mathematics Education for Ethnic Minorities

Lianchun Dong[1,2]

ABSTRACT Ten papers were presented in TSG-51, involving nineteen contributors from five countries. Four themes were discussed in these presentations: (1) mathematics teaching practices and strategies in classrooms with ethnic minority students, (2) mathematics teacher professional development practices intended to improve the quality of mathematics teachers in ethnic minority regions, (3) ethnic minority students' performances in mathematics learning, and (4) research methodology in mathematics education for ethnic minority students.

Keywords: Ethnic minority; Teaching strategies; Teacher professional development; Learning results; Research methodology.

1. Introduction

All over the world, members of ethnic minorities (EM) face difficulties with the type of education that is offered to them, particularly in mathematics education. Difficulties are very diverse, including low achievement, dismissal of endogenous mathematical knowledge, mismatch of expectations with school goals, methods, and procedures, and even threats to the cultural and material existence of the minorities. Several educational models and strategies have been proposed to address these difficulties, varying broadly according to the historical, political, and cultural context in which each ethnic minority is immersed.

TSG-51 aims to gather researchers and practitioners from different countries who are interested in share their own experiences, reflections, and concerns about mathematics education for Ethnic Minorities. The TSG is envisioned as an open agora to discuss theoretical or empirical issues of diverse nature, adopting a strengths-based approach that goes beyond deficit perspectives, and is sensitive and respectful of the singularity of the contexts, constraints, and stances of each ethnic minority.

[1] College of Science, Minzu University of China, Beijing, 100081, China.
E-mail: lianchun.dong@muc.edu.cn.
[2] Organizing Team of TSG-51:
Chair: Aldo Parra, Aalborg University of Denmark, Colombia
Co-Chair: Robin Averill, Victoria University of Wellington, New Zealand
Members: Aditya Adiredja, University of Arizona, USA.
Lianchun Dong, Minzu University of China, China
Nancy Nui, CEMASTEA Nairobi-Kenya, Kenya

Ten papers were presented in the three sessions of TSG-51. These presentations were given by nineteen contributors from five countries, namely Brazil, China, Colombia, New Zealand, and USA.

2. Main Ideas and Discussions in TSG-51

Four themes emerged in the ten papers (Tab. 1): (1) mathematics teaching practices and strategies in classrooms with ethnic minority students, (2) mathematics teacher professional development practices intended to improve the quality of mathematics teachers in ethnic minority regions, (3) ethnic minority students' performances in mathematics learning, and (4) research methodology in mathematics education for ethnic minority students.

Tab. 1. The list of papers presented

Paper and author(s)
Mathematics teaching practices and strategies in classrooms with ethnic minority students
[1] How does a teacher sustain collective mathematizing among non–dominant students? ***John Griffith Tupouniua*** *and Jodie Hunter* (New Zealand).
[2] The implementation of culturally responsive teaching practices into the mathematics course. ***Hsueh-Yun Yu****, Huey-Lien Kao, and Kuo-Hua Wang* (Chinese Taiwan).
[3] A case study on the application of "situational problems" teaching model in the mathematics education of ethnic primary school students. ***Chang-Jun Zhou*** (China).
Mathematics teacher professional development practices intended to improve the quality of mathematics teachers in ethnic minority regions
[4] Investigation on teacher professional development in minority areas: taking Yao autonomous county of Liannan, Qingyuan as an example. ***Mudan Chen*** *and Ida A.C. Mok* (Hong Kong SAR, China).
[5] Renegotiating recruitment and retention efforts: promoting teacher diversity in mathematics and science classrooms. ***Christine Darling Thomas*** *and Natalie Simone King* (USA).
[6] Investigation and research on mathematical culture accomplishment of primary school mathematics teachers in ethnic minority areas. *Jun Wu and* **Jing Ting** (China).
[7] Preparing the next generation of STEM innovators. Daniela Cabrera, ***Jose David Fonseca****, and Gerardo Lopez* (USA).
Ethnic minority students' performances in mathematics learning
[8] Chinese ethnic minorities students' performance in mathematical problem posing. ***Lianchun Dong*** *and Wei He* (China).
[9] Study on influencing factors of math achievements of ethnic minority senior high school students in Chinese mainland. ***Aoxue Su*** (China).
Research methodology in mathematics education for ethnic minority students
[10] Rethinking ethnography in mathematics education of ethnic minorities. ***Carolina Tamayo*** (Brazil) *and Aldo Parra* (Colombia).

2.1. Mathematics teaching practices for minority students

Tupouniua and Hunter[1] presented their investigation of a teacher's attempt to sustain collective mathematizing among non-dominant students in a classroom that emphasizes collective success. Taking a collectivist stance, they conceptualized the featured classroom as one in which the students function as a single learning organism. They analyzed three roles that the teacher played within a lesson focused on students' engagement with repeating patterns. They also discussed the affordances of the three roles with respect to sustaining three characteristics of a classroom that functions as a single learning organism.

Yu et al.[2] investigated how culturally responsive teaching influenced students' motivations to engage in mathematics learning. They used the approach of action research and the participants are grade eight Bunun students in secondary schools in Taiwan region of China. Followed the culturally responsive pedagogy, researchers designed mathematics learning materials for the participating students. It is found that: (a) students learning motivation had become more positive after experiencing culturally responsive pedagogy of mathematics teaching; (b) culturally responsive pedagogy enhanced students' mathematics capabilities and scores efficiently.

Zhou[3] selected mathematics classrooms from 12 primary schools in Longchuan County, Dehong Dai and Jingpo Autonomous Prefecture in west of Yunnan Province in China, aiming to explore the effects and existing problems of the teaching model of mathematics "situational problems". This three-year study ran from 2014 to 2016, showing that teachers who are culturally sensitive and good at using modern educational methods can use this model to help ethnic students learn mathematics more efficiently and achieve better results. In order to fulfill the effects of this teaching model, attention needs to be paid to we pay attention to the cultivation of teachers' cultural sensitivity and to the improvident of teachers' ability to use modern education techniques.

2.2. Mathematics teacher professional development practices in ethnic minority regions

Chen and Mok[4] adopted the perspective of Mathematics Pedagogical Content Knowledge (MPCK), examining mathematics teachers' professional development in Yao Autonomous County of Liannan, Qingyuan in Guangdong Province. They employed the questionnaire survey and in-depth interview to investigate the current status and teachers' MPCK, and the degree of contribution of different sources to the development of three dimensions of MPCK. They also explored whether characteristic variables have a significant impact on the MPCK development. It is found that hearing the voices of teachers in different contexts and putting forwards schemes for related departments are efficient patterns for accelerating the teacher education development. The implications for education researchers and policy makers were also discussed.

Thomas and King[5] reported evidence-based strategies on how to recruit and retain diverse mathematics and science teachers. Previous studies suggest that many teachers often underestimate the potential of students of color to excel in the STEM disciplines (Brickhouse, Lowery, and Schultz, 2000). These negative perceptions have a tendency to discourage students from realizing their true potentials and perceiving themselves as STEM talent. Although researchers have analyzed various challenges and strategies to decrease the impact of resisting factors, increasing teachers' capacity to create equitable mathematics and science learning spaces within urban settings continues to remain a challenge (Fraser-Abder, Atwater, and Lee, 2006; Kokka, 2016). These realities reify the need to explore innovative ways to prepare and develop culturally competent STEM teachers who can thrive even in the most challenging working conditions. Therefore, Thomas and King attempted to provide potential approaches and solutions so that the relatively homogeneous and static demographic of the teaching workforce (particularly in mathematics and science) can begin to adequately reflect the dynamism and racial and ethnic diversity of U.S. students.

Wu and Ting[6] conducted questionnaire and interview survey of 760 primary school mathematics teachers in ethnic minority areas of Yunnan Province, China. It is reported that mathematics culture accomplishment of primary school mathematics teachers in ethnic minority areas are generally at a medium level. In addition, teachers' mathematics culture accomplishment showed significant ethnicity, gender and urban-rural differences. Based on these findings, Wu and Ting recommended to set up a "primary school mathematics culture" course, establish a primary school mathematics culture teacher community and integrate the national mathematics culture into primary school mathematics teaching.

Cabrera et al.[7] presented a project aimed to address issues of social justice, and the environment in the educational pipeline. To do this, the project incorporated environmental science, math, and cultural elements into hands-on project-based learning activities for 6–12 students in predominantly American Indian and Hispanic communities. Professional development (PD) workshops for the development of a culturally relevant STEM greenhouse project-based learning curriculum was provided for teachers.

2.3. Ethnic minority students' performances in mathematics learning

Dong and He[8] investigated Chinese ethnic minorities students' performance in problem posing tasks. A set of mathematics problem posing tasks in three different situations (respectively free, semi-structured and structured situations) was developed to examine students' performance in mathematics posing. 105 students in year 5 from Xinjiang Uygur Autonomous Region, China participated in this study. It is reported in this study that the number of problems posed by Chinese ethnic minorities students in all three situations is fewer than those by Chinese Han students, but the complexity of the problems posed by Chinese ethnic minorities students in semi-structured and structured situations is not lower than their Chinese Han counterparts.

Su[9] conducted a questionnaire survey of 932 teachers and 1873 senior high students in ethnic minority regions to examine the school factors that impact students' math achievement with the two levels HLM. The results showed: (1) boys' math achievement was significantly higher than girls; (2) students with expectations of learning in mixed classes had a significantly higher math achievements than those who expected to be enrolled in non-mixed classes; (3) SES had no significant influence on math achievement; (4) students' learning strategies and learning self-efficacy had a significant positive impact on their math achievement and learning self-efficacy was the primary factor; (5) teacher job satisfaction had significant positive effects on student math achievement; (6) school location meditated the relationship among the expected mode of class and academic performance.

2.4. Research methodology in mathematics education for ethnic minority students

Tamayo and Parra's presentation[10] aimed to problematize ethnography in research conducted on ethnic minorities. They provoked a movement of deconstruction of the certainties caused by the uses of the method of ethnography, tracing lines of escape to understand that ethnography carries with it a series of assumptions that create limitations of political and epistemological nature for mathematics education research. They argued that some of those limitations end up undermining the possibility of reaching a new understanding of mathematics as a sociocultural practice.

Topic Study Group 52

Ethnomathematics

Gelsa Knijnik[1], Marcos Cherinda[2], Arindam Bose[3], Cynthia Nicol[4], and Aihui Peng[5]

1. Theme(s) and Description

The "TSG-52: Ethnomathematics" examined issues that consider intersections between the areas of mathematics and culture, but also went beyond to create synergies between them. We used "culture" in a dynamic, emergent, living sense to focus attention on both common traditions and understandings practiced by a group as well as how these understandings and practices shift, vary, and change over time. Our goal was to invite provocative critical engagement in the ideas of ethnomathematics research and pedagogical practices. We explored connections between mathematics, culture, community, politics, and social as well as ecological justice using reciprocal relations while going beyond non-essentialized understandings.

As written in the TSG-52 Invitation, we organized our discussions around the following themes and questions (Rosa et al, 2016):

Cultural self-confidence and reclamation: How can ethnomathematics (or ethnomathematical practices and ethnomathematics research) support transformation of educational systems (from exclusion to inclusion) at local and at global levels (toward regaining "cultural self-confidence")?

Decolonizing and indigenizing: To what extent can ethnomathematics support (or challenge) practices of decoloniality (i.e., challenge how knowledge is constructed across time and place)? How can ethnomathematics be engaged in a political/epistemological level with other systems of knowledge, and in a way that respects self-determination and sovereignty?

Indigenous education and teacher education: What role does ethnomathematics play for Indigenous education and what are the social and cultural impacts of these uses for their own communities? What kind of ethnomathematics experiences are needed for indigenous teacher education? What research exists in this area and what have we learned from these experiences?

Critical mathematics education: In what ways does ethnomathematics support a critical mathematics education (as conceptualized by Skovsmose) and the problematizing of mathematics epistemologies and mathematics education?

Heterogeneous cultural groups: What can ethnomathematics offer in working with heterogeneous cultural groups (with varied linguistic, ethnic, caste/race diversity) but with access to rich funds of knowledge?

2. Program Overview (format, participants, presentations, posters, main outputs, etc.)

When the submission process of ICME-14 TSGs ended, 37 papers were submitted to TSG-52 Ethnomathematics. The rigorous review process was conducted from an inclusive perspective. As a result, 38 papers were approved: 21 long presentations, 13 short presentations and 4 posters. Due to the global pandemic and the move of ICME Topic Study Groups to a virtual environment our final program included 12 long presentations and 6 short presentations.

TSG-52 met over three sessions. Our initial session was divided in two parts. The first part was held by the TSG-52 organizing team, composed by Gelsa Knijnik (chair), Arindam Bose, Cynthia Nicol and Aihui Peng. Unfortunately, our colleague Marcos Cherinda (co-chair) could not attend the meeting. The TSG team welcomed everyone and participant introductions included everyone locating themselves on a world map to emphasize the varied places/lands/ and political spaces of our shared work. Following introductions, Gelsa Knijnik opened the session with a tribute to and acknowledgement of the vast and deep contributions of ethnomathematician Ubiratan D'Ambrosio. Participants were invited to offer memories and experiences with the Brazilian educator on the TSG-52 Padlet (a virtual visual bulletin board that formed the virtual hub of our group). In the second part of our first session Arindam Bose, Tata Institute of Social Sciences (TISS), Mumbai, India, presented a paper "Revisiting ethnomathematics: another social turn?" to start the TSG-52 discussion.

Each Session began with an Ethnomathematical Riddle posted on our group Padlet where participants could post their responses and strategies such as this Riddle posted on Day 3.

> *nau maun guru, nau maun guruayeen, nau maun ke dunno chela, nau maun bhaar naiya sahela, bari-bari paar karela.*
>
> A teacher's weight is nine *maun* (1 *maun* = 40 kg approx.), teacher's wife weighs the same, two students together weigh nine *maun*, one boat can bear nine *maun* at a time, how do they cross the river.

Discussion during our first session included comments and questions focused on how students' school math learning elucidates students' everyday math knowledge; on how drawing upon funds of knowledge as a theoretical framework could overcome the mechanism of scaffolding that can rework local knowledges to be replaced by prescribed curriculum knowledge; and on whether too much school math can erase our practical mathematics?

During our second session ten papers were presented followed by discussion that included questions around the need for clarity in language and terms used, the need to reduce academic jargon, the role and relationships of language, land and mathematics, and the search for ethnomathematical studies of Indigenous North and Central South America.

Session 3 involved the presentation of seven papers followed by discussion questions such as: the future direction of ethnomathematics; the diversity of ethnomathematics indicating the varied ways of being and doing ethnomathematics; the possible reconsidering of ethnomathematics as research programs (plural rather than singular), and the implications for teaching with an ethnomathematical curriculum to counter colonial understandings of school math curriculum.

Below are the titles of the papers, with the name of their respective authors, in the order they were presented during Session 2 and 3 of the TSG (Tab. 1).

Tab. 1. The list of papers presented in session 2 and session 3

Paper and author(s)	
[1]	A framework for examining the quality of mathematics teaching for mathematical understanding in ethnic minority cultural contexts. ***Aihui Peng*** (China).
[2]	Ethnomathematics and ethnomodelling research: glocalizing educational systems from exclusion to inclusion at local and global levels. *Daniel Clark Orey and* ***Milton Rosa*** (Brazil).
[3]	The ethnomodelling as a math learning strategy in the Ecuadorian educational system. ***Juan Ramon Cadena Villota*** (Ecuador)
[4]	Ethomathematics as pedagogical and political tool in an Indigenous school curriculum. ***Vanessa SenaTomaz*** *and Ozirlei Teresa Marcilino* (Brazil).
[5]	Mexican American Women talking about Graphs: A focus on their lived experiences. ***Fany Salazar*** *and Marta Civil* (USA).
[6]	Regaining cultural signs through ethnomathematical descriptors: artifacts, sociofacts and mentifacts. ***Ma. Elena Gavarrete****, Milton Rosa, and Daniel Clark Orey* (Costa Rica).
[7]	Perspectives of mathematics by traditional P'urhpécha artists. ***Thomas E Gilsdorf*** (USA).
[8]	A study of the Quechua weaving elaboration process and mathematics teaching in basic education. ***Maria del Carmen Bonilla*** (Peru).
[9]	Math trail activity on Machchhindranath Chariot: cultural perspective on mathematics education in Nepal. ***Toyanath Sharma*** (Nepal).
[10]	Ethnomathematical study on cultural artefacts: anethnographic field to classroom practice. ***Jaya Bishnu Pradhan*** (Nepal).
[11]	Coming together, research and desire in the field of ethnomathematics. ***Wilfredo Alangui*** (Philippines).
[12]	Waka migrations: reclaiming cultural traditions and identity. ***Anthony Benjamin Trinick*** *and Tamsin Meaney* (Newzeland).
[13]	Exploring mathematics in the Eskaya tribe: an ethnolearning theory. ***Fe Reston Janiola*** (Philippines).
[14]	Ethno-mathematics of Banyuwangi culture: bamboo woven. ***Mega Teguh Budiarto****, Rini Setianingsih, and Rudianto Artiono* (Indonesia).
[15]	Towards mathematics curriculum recontextualisation: developing a rhizocurrere with Roma students. ***Georgios Kyriakopoulos*** (Greece).
[16]	An international class in Germany: the need for ethnomathematical considerations. ***Marc Sauerwein*** (Germany).
[17]	Ethnomathematics in Ethiopia using glocal approach: the case of Gebeta playing. ***Solomon Abedom Tesfamicael****, Anne H. Nakken, Tirillo, and Peter Grey* (Norway).
[18]	Ethnomathematics constructs of Ibo society in Chinua Achebes "things fall apart". ***Epsi Deme*** (Nigeria).

3. Future Directions and Suggestions

At the end of the work, the participants showed their satisfaction with what we had accomplished. The variety of topics and the depth of coverage were highlighted. The importance of bringing the papers together in a publication was discussed. In fact, the TSG Team has invited all colleagues who had their papers accepted to contribute to an edited book. This volume work is currently underway with an intended publication date before ICME-15 conference so that copies are available during the conference.

Topic Study Group 53

Equity in Mathematics Education

Jayasree Subramanian[1], Darinka Radovic[2], Constantinos Xenofontos[3], and Changgen Pei[4]

1. Themes and Description

The Topic Study Group TSG-53 on Equity in Mathematics Education built on the longstanding practice that ICME had of addressing social justice concerns in mathematics Education. Themes such as gender, disability, indigenous mathematical knowledge, socioeconomic class, culture and language figure consistently and over the years in the activities of ICME and in 2016, ICME-13 introduced a Topic Study Group TSG (33) on Equity (including gender). TSG-33 already acknowledged the need to go beyond gender as a binary and the need to address disability.

1.1. Aim of the TSG

In its description, TSG-53 brought in caste, religion, and race in addition to socioeconomic status, culture, region, ethnicity, physical and mental disablement as factors that contribute to exclusion in mathematics education, noting that these forms of exclusion are historical, structural, as well as interpersonal and individual and they have lasting consequences for the students in accessing higher education and in pursuing mathematics. Instead of making unqualified declarations such as "mathematics for all", the TSG acknowledged the need for a nuanced understanding that every student should have the opportunity to learn mathematics to the extent they feel it is desirable or appropriate for them, both from the perspective of fairness in mathematics education and from the fact that mathematics plays a central role in the geopolitical and globalized technocentric world in which we are living. Moreover, it also acknowledged the need for the realization that the equity question is integrally linked to a critical understanding of mathematics education that is prevalent in schools across the world and a movement towards a more just and humanizing mathematics education for the learner.

[4]School of Mathematics and Statistics, Southwest University, China. E-mail: cgpeichina@163.com

TSG-53 sought to foreground the following concerns and questions.

1) What are the experiences of religious, racial and ethnic minorities and those from marginalized castes in learning mathematics? How do class, caste, race, culture and ethnicity operate to shape opportunities for the learners in the classroom?
2) How do factors such as migration for labour, continued conflict, repeated natural calamities and so on impact teaching and learning of mathematics? What systemic measures (if any) have been evolved to address these issues?
3) How do we address language diversity in mathematics classrooms? Given that English is emerging as the language of power and possibilities and it is the medium instruction in large number of schools in urban locations, what are the challenges involved in teaching and learning mathematics in a language that is not the home language for the teacher as well as the students?
4) How does family and community membership affect mathematics learning and teaching? In what ways can we leverage children's lived experiences and funds of knowledge as resources for learning and teaching mathematics?
5) What do we know about the experiences of students who are placed in the intersection of several categories? More specifically what does mean to be an African American girl, a rural poor boy, an emerging bilingual immigrant child seeking asylum in a different county, a migrant laborer's child living in a multilingual urban slum, a tribal, Dalit or a transgender student from a low/ middle income family and so on in the context of teaching and learning mathematics?
6) How do teacher education programs acknowledge the existing research on equity issues and introduce measures to address the issues in the preservice and in service training programmes?
7) What are some of the new theoretical frameworks evolved to understand the complex contexts in which mathematics education takes place and how we can transform mathematics education to be more humanizing and just spaces to learn and teach mathematics?

1.2. A brief account of the response to the call for submissions

In response to the call, TSG-53 received a fair number of submissions which together addressed the concerns we foregrounded in the call for submissions, except the second one about the impact of labor migration, conflict and natural calamities on the children's education, in particular their mathematics education. However, the complications created by the COVID-19 pandemic and the online mode of the conference made a difference to what finally could be realized.

2. Program Overview

We, the TSG-53 team members decided that we will have a few invited presentations and arrived at a consensus on the names of the scholars we would invite. We decided to invite Luz Valoyes Chavez from Catholoc University of Temuco, Luis Leyva from Vanderbilt University, and Charalou Stathopoulou from University of Thessaly. Stathopoulou wanted to present an invited paper jointly with Peter Applebaum from Arcadia University which we accepted. Including the invited papers, a total of 36 papers were submitted in response to the call for submission from TSG-53. Of these, leaving out the three invited papers, 32 were accepted to be presented as either long oral presentation or a short oral presentation or as a poster. However, as the Congress was going to be held only in the online mode because of COVID-19 pandemic, several authors were not able to participate. This was mainly because most of the participants did not receive financial support from their respective universities for online conferences; and they were eligible to get the Solidarity Funds from ICME. Indeed, this was also the case for one of the invited speakers. As a result, only 20 papers were presented. Of the 20 papers presented, 3 were invited papers, 9 were long oral presentations and 8 were short oral presentations. One of the invited papers could not be presented in person as the speaker did not receive financial assistance to attend the conference from any source. Given the importance of the theme, we got the speaker to record the presentation and send, which we played. Apart from these there were 3 submissions accepted as poster presentations.

2.1. Format of the presentations

TSG-53 had a total of six and half hours (390 minutes) spread across 4 days. On the first days we had 120 minutes and on the remaining three days we had 90 minutes each. As we were informed that more participants would be able to participate in the time zone in which the 90 minutes presentations were scheduled, we decided to allocate one invited talk to each of the three days of 90 minutes.

The time allocation for the presentations is given in Tab. 1 below:

Tab. 1. Time allocation for the presentations

Type of Presentation	Time for presentation	Time for discussion
Invites Talks (IT)	25 minutes	15 minutes
Long Oral Presentations (LO)	12 minutes	8 minutes
Short Oral Presentations (SO)	5 minutes	4 minutes

To the extent possible we tried to group presentations sharing the same or similar themes together. But this was not always possible. We also grouped a few short orals together and took the questions for them at the end to optimize available time for discussion.

2.2. Major themes, participants, and the presentations

The submission and the final set of presentations remained faithful to the central concerns of the TSG. The following Tab. 2 gives the title and authors of the presentation just to indicate the diversity of issues raised in the topic study group.

Tab. 2. The list of papers presented

Paper and author(s)
[1] A framework for detailing White heteropatriarchy in mathematics education. ***Luis Leyva*** (USA). (IT)
[2] Chavez cultural power and the fabrication of race difference in the mathematics classroom. ***Luz Valoyes-Chavez*** (Chile). (IT)
[3] Challenging the abyssal line between Roma and non-Roma in and out of the (mathematics) classroom through common spaces. ***Charoula Stathopoulo*** *and Peter Applebaum* (Greece). (IT)
[4] Education equity in Honk-Kong: factors that contribute to Hong Kong students' performance in trends in international mathematics and science study (TIMSS) 2015. ***Frederick Koon Shing Leung*** (Hong Kong SAR, China). (LO)
[5] Critical mathematics teacher noticing: exploring pre-service teachers' noticing of power, privilege, and identity using online video. ***Theodore Chao****, Melissa Adams-Corral, Youmna Deiri, and Joanne Vakil* (USA). (LO)
[6] Questioning the idea of inclusion of blind mathematics learners in India using the social model of disability. ***Rossi D'Souza*** (India). (LO)
[7] Disentangled narratives: exploring lecturers and students gendered discourses in an engineering faculty. ***Darinka Radovic*** (Chile). (LO)
[8] Gender issues and consequences for undergraduate mathematics women students. ***Weverton Ataide Pinheiro*** *and Vanessa Franco Neto* (Brazil). (LO)
[9] History of whose mathematics for teaching: raising the caste question in mathematics education in India. ***Jayasree Subramanian*** (India). (LO)
[10] From invisible to domestic gender in mathematics textbooks in India. ***Kishor Darak*** (India). (LO)
[11] Teaching practices in diverse mathematics classrooms of the republic of Cyprus: equitable or not? ***Constantinos Xenofontos*** (UK). (LO)
[12] Microexclusions as a challenge to dialogue among deaf and hearing students. ***Amanda Queiroz Moura*** (Austria). (LO)
[13] Gender differences in student-student interactions. ***Desiree Ippolito****, Weverton Ataide Pinheiro, and Jinqing Liu* (USA). (SO)
[14] Socioeconomic differences delimited by gender: students' perceptions about mathematics in Mexican Schools. ***Itzel H. Armenta*** (Mexico). (SO)
[15] Gender differences on specific issue: the case of misconceptions in operating with percentage. ***Chiara Giberti*** (Italy). (SO)
[16] Support for students with mathematics learning dis/abilities on bridging programmes in New Zealand universities. ***Phil Kane*** (New Zealand). (SO)
[17] Coping with the challenges while promoting social justice in mathematics classroom. ***Ram Krishna Panthi*** (Nepal). (SO)
[18] Adapting tasks between including and excluding students. ***Nina Ines Bohlmann****, Ralf Benölken, and Timo Dexel* (Germany). (SO)
[19] Children, dialogue and mathematics education. ***Ana Carolina Faustino*** (Brazil). (SO)
[20] Teacher candidates' perspectives of means to facilitate equitable learning opportunities during a high school mathematics methods course. *Ruthmae Sears, Marilyn Strutchensy, Brian Lawler, Lakesia Dupree,* ***Caree Pinder****, and Cynthia Castro-Minnehan* (The Bahamas). (SO)
[21] How to increase girls' sustaining interest, performance and career choices in mathematics: a high-quality project-based learning approach. ***Lorraine Minette Howard*** (USA). (Poster)
[22] Rural elementary students' mathematics academic performance in china: what are the influencing factors? ***Xiangyi Kong*** (China). (Poster)
[23] Theoretical framework of gendered mathematical identity. ***Yuriko Kimura*** (Japan). (Poster)

The 23 presentations — 20 papers and 3 posters — came from as many as 14 countries which in itself is remarkable, though there were visible absences — there was no submission from any of the countries from Africa for example. The list of countries consists of Bahamas, Brazil, Chile, China (including Hong Kong SAR), Germany, Greece, India, Italy, Japan, Mexico, Nepal, New Zealand, United Kingdom, and United States.

Gender, race, caste, ethnicity, disability, and sexual orientation figured as a common thread running through the presentations. Most of the presentations were very nuanced, brought in fresh perspectives, introduced new theoretical frameworks and raised important questions. In that sense and in terms of the range and the complexity of the themes addressed, it can be said that the TSG realized a significant part of what it set to realize.

However online conference posed several challenges, one major difficulty being not all the papers that were accepted for presentation could be presented. We missed out on 9 more presentations. Many of the authors could not participate because their institution refused to pay the registration fee for attending an online conference, nor did the speakers get fee waiver from ICME. Another difficulty was the difference in the time zone which limited the number of people who were present in each session and contributed to the discussions. Face to face conferences not only bring everyone together at one place, but they also allow for more participations in the discussions and often these discussions continue even after the presentations for the day is over. Online conference deprived us of the opportunities for such interactions.

3. Future Directions and Suggestions

TSG-53 built on what had been achieved with regards to addressing equity issues in ICME, brought in new perspectives and questions. However, there are several more issues that need to be studied and understood and here is a short list of some of them.

a) Even though TSG-53 complexified gender by engaging with heteropatriarchy and with the concerns of gender queer learners, not all presentations looked at gender beyond the binary. This poses the following challenge to us: Can we, as a community of mathematics education researchers, accommodate research that continue to see gender as a binary? We need more studies to understand how young learners who do not identify with the gender assigned to them at birth, learners who identify as gender queer or as transgender persons, cope with (or fail to cope with) mathematics in school.

b) The COVID-19 pandemic and the lockdown has had a devastating effect on the education of learners belonging to socio-economic margins as well as those who live in remote areas with limited or no access to technology. Learners who are socio economically privileged, have had access to technology and parental support at home too have encountered serious shortcomings with online education. The impact of lockdown and online education on mathematics education for diverse learners and the measures taken by the state and voluntary organizations to address these need to be studied.

c) The consequence of migration for work, increasing urbanization, living in regions that face continued conflict, repeated natural calamities etc on education and on mathematics education in particular, need to be studied and reported. One way to ensure that some of these figure in the Topic Study Group on Equity would be to identify scholars working on these themes and invite them to present a paper in the upcoming TSG on equity.

d) Equity can be explored in relation to several social issues (e.g. social class, race, caste, gender, ethnicity, disability etc.). More intersectional research is needed for understanding how various social issues interact with each other, and how these interactions impact mathematics education.

e) There is a lack of studies approaching issues of equity from cross-national/cross-cultural comparative perspectives. Collaborations between researchers, teachers, policymakers etc. working in different educational settings could shed more light on the cultural specificities of educational policies and practices.

https://doi.org/10.1142/9789811287152_0078

Topic Study Group 54

Social and Political Dimensions of Mathematics Education

Paola Valero[1], Kate le Roux[2], Andrew Brantlinger[3], Murad Jurdak[4], and Xuhui Li[5]

1. Aims of the TSG

The broad focus of TSG-54 is to explore how mathematics education practices, research and policy in current societies connect to power. Since ICME-13, when TSG-54 was run for the first time, unexpected world events have drawn attention to a series of deep changes that constitute a new reconfigured context for education, and mathematics in particular. This is a new geo-economic-political configuration of relations, between humans and between human and non-humans that put at stake their conditions of existence, a landscape termed the New Climatic Regime by Latour (2018). These conditions are manifested in the multiple crises of societies, among those the COVID-19 pandemic.

Thus, at ICME-14 we aimed to build on the advances of ICME-13 in the light of the contemporary world landscape, inviting empirical and theoretical contributions offered from different locations and experiences. The following questions guided our task: (1) How do contemporary national and global economic and political interests relate to the changes in material conditions in which mathematical and mathematics education practices take place? (2) What are the relations between policy and the directions they steer and mathematics education practice and research? (3) How does the meaning of key concepts used in sociopolitical research — such as access, equity, quality, inclusion — emerge in particular space and time configurations? How might these be different in a New Climatic Regime at this time, and why? (4) What do theories and methodologies of sociopolitical research offer to understand the articulation of mathematics education and this contemporary landscape? (5) Which forms of activism and action emerge to question and/or promote mathematics at his time?

1.1. Submissions

For the 2019 review process, we received 32 submissions from 20 countries, distributed as follows by continent (Africa: 3; Asia: 6; Australasia: 1; Europe: 13;

[1]Department of Teaching and Learning, Stockholm University, Stockholm, SE-106 91 Stockholm, Sweden. E-mail: paola.valero@su.se
[2]Academic Development Programme; University of Cape Town, Rondebosch, 7700, South Africa. E-mail: kate.leroux@uct.ac.za
[3]University of Maryland, USA
[4]American University of Beirut, Lebanon
[5]California State University, Long Beach, USA

North America: 3; South America: 6). Of these, 13 were accepted as short presentations, and 19 were invited to develop into long paper presentations. In addition, we invited one long paper. Of the 32 submissions accepted in 2019, 24 formed the final TSG-54 at the 2021 online Congress (5 long papers and 19 short presentations).

1.2. Sessions

We chose to prioritize discussion in our three allocated TSG-54 sessions. Informed by our guiding questions, we wished to explore emerging themes across the contributions, with the aim to further develop our thinking together. Thus, prior to the event, we circulated — with the necessary author permissions — the 24 papers put forward for the 2021 Congress to participants. Then, each of the TSG-54 sessions had three main components: paper presentations limited to five minutes per paper and supported with a one-page slide; individual reflection time on common themes and questions recorded in a shared electronic whiteboard; and plenary time to look at individual whiteboard responses and to discuss ideas to take forward. The final two-hour session also included a concluding discussion, reflecting on the contributions and discussions across all sessions, and thoughts on advancing the ideas. To promote inclusion in the online Congress format, the grouping and ordering of presentations was primarily based on the geographic location of the presenters, with common themes considered next.

1.3. Paper topics

A list of the 24 contributions is included in Tab. 1 (on the next page). In total, authors of 23 of these papers presented at the TSG.

2. Common Themes Explored and to be Taken Forward

Participants offered responses to the guiding questions from different areas of mathematics education: teaching, learning and assessment in school and university mathematics classrooms; teacher education; resources such as textbooks and other online materials; research theories and practices; the nature of "mathematics"; and the positioning of the "mathematical citizen". In spite of such variety, there were identifiable commonalities with respect to:

1) Theoretical approaches, in particular posthuman thought and decolonial thought. This is a visible advance in the last years and a contribution from so-named "global South".

2) Attention to context in which mathematics and mathematics education is practised. This means that people research and write *from* the particularities of context rather than adopting an "external" perspective *on/about* context.

3) Acknowledgement that the problematization of mathematics and mathematics education that aims at reimagining it is not completely new. It is highlighted by and exacerbated in the New Climatic Regime, including the health pandemic. Recognition of

the connectedness of *all* places in their experience of crises, albeit in inequitable ways, and the extent of how crises are being experienced in the "global South", make the problematization relevant for all.

[18]	Interrogating the promise of online mathematics instructional programs. ***Lisa Jean Darragh*** (New Zealand).
[19]	Contextual barriers to the integration of problem solving in the Egyptian mathematics classroom. ***Mariam Makramalla*** *and Andreas J. Stylianides* (UK).
[20]	Teaching critical mathematics: Obstacles from the teacher's perspective. ***Daniela Steflitsch*** (Austria).
[21]	Transition of Mozambique's primary mathematics intended curriculum in post-colonial period: A focus on adaptation from exogenous curriculum. ***Satoshi Kusaka*** (Japan).
[22]	Crests and troughs: The use of trigonometric modeling towards a critical and realistic mathematics education. ***Dale Aldrinn Pradel*** *and Catherine Vistro-Yu* (Philippines).
[23]	Mathematics education, citizenship and the "commons" in our "global" world? *Anna Chronaki* (Sweden), *Eirini Lazaridou and* ***Effie Manioti*** (Greece).
[24]	A southern perspective on sociopolitical mathematics education research in the New Climatic Regime. *Kate le Roux.*

4) Concern for an ethical mathematics education that recognises: (a) multiple mathematical knowledges, ways of knowing and doing mathematics, and being a “mathematical” knower, and (b) “the commons”/“relations”: between the human (body and mind), the non-human, material technology, place, and so on.

Yet substantial work is required to understand the particularities of the role of mathematics and mathematics education in the contemporary landscape, in particular how to conceptualise and enact basic common values, aims and conditions for an ethical and responsible mathematics education. Such work requires the challenging tasks of:

- Troubling the strong and dominant narratives of the “power” of a particular place-based “mathematics” (“Western Mathematics”), for example, the use-value and exchange-value attributed to this mathematics (e.g., Williams, 2012).
- Thinking about the role of mathematics and its “use-value” and “exchange-value” in the New Climatic Regime, in particular in the prevalent conditions of precarity and unemployment (absence of “work”), even more urgent in the context of a post-COVID-19 pandemic world.
- Making space in educational practices, curricula and policies to other forms of mathematical knowledges and ways of knowing that can enrich people’s notions and experiences of mathematics beyond the closed standards of school mathematics.
- Navigating the tension of foregrounding and backgrounding mathematics, that is shifting between a mathematics that is considered objective and fixed, and a sensibility for mathematics in the dynamics of context, diversity and power. This requires exploring the extent to which the mathematics education is open to consider “mathematics” content both as unique and at the same time just one of the many equally important elements entangled in the current predicaments of our times. This is important if the aim of mathematics education is providing tools to live in and understand our complex, wicked world.
- Instantiating how “mathematics” and mathematics education might be something else, if at all possible.

Taking such concerns forward, returns us to the notion of *power* that underpins the work of TSG-54. There is a certainly a need for us to consider what theories of power we are using to understand the contemporary world, and to inform our research, activism and pedagogical action. In particular, as a community we need to understand why and how mathematics and its processes of teaching and learning are conceived as powerful in both a positive productive way of empowering, and also as oppressive, selective and excluding from education and society at large. In other words, we need to continue exploring the power relationships at work in mathematics education spaces and what and how practices instantiate both their positive and negative effects. Important questions remain such as what mathematics and mathematics education become valuable? For whom? How do these become valuable? Where do they become valuable? We also need to consider where and to whom we look (beyond the privilege of academia) for such learnings.

Topic Study Group 55

The History of the Teaching and Learning of Mathematics

Alexander Karp[1]

ABSTRACT This note describes the work of TSG-55, indicating its main organizational stages and the number of reports presented. Brief descriptions of the topics of the presented reports are provided. These may be grouped into several categories: reports devoted to reforms; reports investigating the work of various mathematics educators; reports discussing the history of specific subjects in courses, textbooks, or other handbooks; periodicals, connected with mathematics education; and so on. Lastly, certain conclusions are drawn about the current state of this academic field.

Keywords: History of mathematics education; Reforms; Mathematical journals.

1. Introduction

The Topic Study Group on the history of the teaching and learning of mathematics was formed in 2004 at ICME-10. Since then, this group has worked at all International Congresses. At the Congress of 2021, this group was also active, although the pandemic made it necessary to introduce certain changes into its work. As usual, all submitted proposals were reviewed and evaluated (in this connection, we must note the role of Wagner Rodrigues Valente from Brazil, who was initially chair of the group, but later resigned from participating in its work for personal reasons). At the final stage, when it became clear that the Congress would mainly take place online, all participants were invited to prepare video presentations, which were made available on a specially created website. This made it possible, for example, to become acquainted with presentations that could not be attended due to time differences.

At the Congress itself, three sessions were held, as planned, chaired by Alexander Karp (USA/Russia) and Naomichi Makinae (Japan). In all, eighteen reports were presented; in addition, there was one poster presentation related to the work of the group (Tab. 1 on the next page). Representatives from Belgium, Brazil, China, Croatia, Japan, Nepal, Poland, Russia, Spain and the United States took part.

All participants were also invited to take part in preparing a collection of papers based on the materials of the presentations — the expanded papers were envisioned, substantially greater in size than could be presented at the Congress, but thematically connected with these presentations. From the submitted papers, the best was selected,

Tab. 1. The list of papers and posters presented

Paper and author(s)
Session 1
[1] Pafnuty Chebyshev as a mathematics educator. ***Vasily Busev*** (Russia) *and Alexander Karp* (USA).
[2] Frédérique Papy-Lenger, the mother of modern mathematics in Belgium. ***Dirk De Bock*** (Belgium).
[3] The history of mathematics education of Tatar Nation. ***Ildar Safuanov*** (Russia).
[4] Mathematics and mathematics education in the 18th century Spanish Journal "Semanario De Salamanca". ***Maria Jose Madrid****, Carmen Leon-Mantero, and Alexander Maz-Machado* (Spain).
[5] Gnomonics in mathematics secondary school education on the territories of Poland in the 17th – 20th century. ***Karolina Karpinska*** (Poland).
[6] The beginning of modern mathematics in Spanish primary education. A look through textbooks and curriculum. ***Antonio M. Oller-Marcen*** (Spain).
[7] Approach of an Early-1940s Japanese secondary mathematics textbook to teaching the fundamental theorem of Calculus. ***Shinnosuke Narita****, Naomichi Makinae, and Kei Kataoka* (Japan).
Session 2
[8] Arithmetic textbooks in Croatia in the premodern period. ***Maja Cindric*** (Croatia).
[9] Missing arithmetic methods: "On the rules for the mixing of analogous things". *Bernardo Gomez-Alfonso and* **Maria Santagueda-Villanueva** (Spain).
[10] The calculation in the first commercialized Decroly's games. ***Pilar Olivares-Carrillo*** *and Dolores Carrillo-Gallego* (Spain).
[11] Mathematical activities focusing on Japanese elementary arithmetic and secondary mathematics textbooks in the early 1940s. ***Yoshihisa Tanaka****, Eiji Sato, and Nobuaki Tanaka* (Japan).
[12] Development history and course setting of mathematics department in early universities in Sichuan Province in modern times (1896–1937). ***Hong Zhang*** (China).
[13] A probe into compiling mathematics textbooks by Christian Missionaries in late Qing dynasty. ***Jun Wei Li*** (China).
Session 3
[14] Building an American mathematical community from the Ground Up: Artemas Martin and the mathematical visitor. ***Sian E. Zelbo*** (USA).
[15] The discarding of the rule of three in the 1960s: changes in elementary education in France and Brazil. ***Elisabete Zardo Burigo*** (Brazil).
[16] Mathematics education for young woman during progressive era: historical overview. ***Yana Shvartsberg*** (USA).
[17] David Eugene Smith (1860–1944) and his work on mathematics education. ***Alexei Volkov*** (Chinese Taiwan) *and Viktor Freiman* (Canada).
[18] College entrance exams in mathematics in Russia before the second world war: development, role, objectives. ***Alexander Karp*** (USA).
Poster Session
[19] Historical development of mathematics education in Nepal. ***Ramesh Prasa Awasthi*** (Nepal).

and consequently a collection was prepared, which was submitted to Springer Publishing (Karp, in print).

2. On the Topics of the Presentations

Below, an attempt will be made briefly to describe the topics of the presentations.

As is usual at conferences on the history of mathematics education, considerable attention was devoted to reforms. Oller-Marcén[6] spoke about the first moments of the introduction of the reform movement in Spain in 1965 and the new features that appeared in elementary school textbooks in Spain. Búrigo[15] also spoke about elementary schools: she compared how the same topic — the rule of three — was studied in Brazil and in France during the 1960s, and what changes occurred in how it was studied. Narita et al.[7] — spoke about a far less well-known reform that was conducted in Japan during the 1940s and involved a radical transformation in how calculus was studied.

In effect, the period of reforms also provided the subject for De Bock's paper[2], which was, however, devoted not so much to the topics studied during this period, as to a figure active during it. This paper discussed the work of Frédérique Papy-Lenger, who was extremely important particularly during the late 1950s–1960s. The paper by Volkov and Freiman[17] was devoted to the early work of a reformer from another era, David Eugene Smith, or more precisely, to his reception of the achievements of German methodological thought and his related early publications. An even earlier period was the subject of the paper by Busev and Karp[1]. This paper relied on recently published materials to discuss the work of the outstanding mathematician Pafnuty Chebyshev in mathematics education.

The history of the teaching of one or another section of the school course in mathematics was investigated in several other papers, as has already been mentioned. Gómez-Alfonso and Santágueda-Villanueva[9] spoke about mixture problems in arithmetic in ancient textbooks. Karpińska (Poland)[5] described how students were taught to tell time by using a sundial, which constituted an important part of the course in mathematics at Polish schools for centuries.

Not a little attention, of course, was devoted to a field that has traditionally attracted researchers' attention: textbooks and other means of instruction. Cindrić[8] discussed the first textbooks in arithmetic used in what is today Croatia during the eighteenth century. Li's presentation[13] was devoted to textbooks written for China by Christian missionaries during the late Qing Dynasty period. Tanaka et al.[11] presented to listeners' attention their analysis of certain mathematical activities and associated instruction materials used in the teaching process in Japan during the 1940s. The paper by Olivares-Carrillo and Carrillo-Gallego (Spain)[10] was devoted to games developed by Ovide Decroly and their adoption in Spain.

In the last decade, it has become popular to study journals that are in one way or another connected with mathematics education. Two presentations were devoted to this topic. Madrid et al.[4] analyzed the eighteenth-century Spanish journal *Semanario de Salamanca*, which devoted considerable attention to mathematics. Zelbo[14] investigated an American mathematics journal, *The Mathematical Visitor*, which was published regularly from 1878 to 1881.

Shvartsberg's presentation[16] contained an analysis of the development of mathematics education for women in the United States between the 1890s and the 1930s, when very many changes occurred both in ordinary life and in education.

Zhang[12] devoted her presentation to almost the same period — 1896–1937 — but focusing on Chinese higher education and its modernization during these years.

Karp's presentation[18] was devoted to entrance exams to higher educational institutions in Russia before 1917.

Lastly, Safuanov[3] delivered an overview of the history of mathematics education in Tatarstan, while Awasthi[19] provided a poster presentation on the history of mathematics education in Nepal.

3. Certain Observations and Conclusions

Summing up the outcomes of the work of the Topic Study Group, we might say that we are witnessing the accumulation of new studies that are based on topics and interests that have already become traditional (Karp and Furinghetti, 2016; Karp and Schubring, 2014). The history of mathematics education as an academic discipline is certainly over a hundred years old — even if we date its beginnings to the appearance of the first doctoral dissertations in the United States (for example, Stamper, 1906), although historical studies in mathematics education had already existed in Europe long before that (Schubring, 2014). Nonetheless, it may be said that the social history of mathematics education, which examines what has occurred in mathematics education as part of a broader social process, is still only at the beginning of its development. The tendency to connect what happened in classrooms or during preparation for class with what was happening in the world can be observed in many, although still not all, studies.

It may be said that many periods, processes, and directions still remain uninvestigated, and in addition that even many extant studies remain unknown and inaccessible to an international audience, if only due to a language barrier. The opportunities this state of affairs offers to researchers are all the greater. Currently, we are in a period of collecting materials about what has not been investigated previously, and thereby making use of new sources and developing new approaches to analysis.

The Congress and other international initiatives make it possible to find out about kindred studies being conducted in different countries. One would like to hope that the work of the TSG, as well as the publication of a volume on the basis of its outcomes, will help historians of mathematics education, enriching them with new facts and new ideas.

Topic Study Group 56

Philosophy of Mathematics Education

Bronislaw Czarnocha[1], Maria Bicudo[2], and Paul Ernest[3]

1. Introduction

The philosophy of mathematics education can be traced back to the work of Plato. In his Republic Plato considered deeply the role and purpose of mathematics in teaching and learning. His enquiries were founded on ethics, for questions of meaning and purpose within a social context inevitably bring in the Good. At the same time, he was interested in the epistemology and ontology of mathematics and its relations with the Truth and Beauty. Overall, Plato displayed great interest in the subject of mathematics throughout his philosophical work, and he is an inspirational godfather and patron saint of the philosophy of mathematics education.

Current mathematics education research is mostly concerned with two questions, one epistemological and the second methodological. The epistemological questions ask what is mathematical truth and how do we justify and explain it, and above all, how to we come to know it? The methodological questions concern how we can best and most effectively teach and facilitate the learning of mathematics. Research in the philosophy of mathematics education also addresses epistemological questions of mathematics and its teaching and learning, but it does so more explicitly, more theoretically. In addition, it considers the ontological, aesthetic and ethical issues of mathematics with respect to education and society.

The philosophy of mathematics education is an interdisciplinary area of research that incorporates many questions.

- What are the goals and purposes of mathematics education?
- What can we learn from deep analyses of the methods and means of teaching?
- and learning mathematics, as well as from studying the underlying theories and philosophies?
- What new insights are revealed by the application of deep theoretical approaches including Phenomenology, Hermeneutics, Complexity, Embodiment and Critical Theory within research in the philosophy of mathematics education?

[3] University of Exeter. E-mail: P.Ernest@exeter.ac.uk

- What are the relationships between and, the mutual influences on each other, of the philosophy of mathematics and mathematics education?
- How do the personal philosophies of mathematics and mathematics education of learners, teachers, teacher educators and researchers impact on practice?
- How are the different actors of interest including students, teachers, researchers, theorists, philosophers and mathematicians linked together professionally within the fields of mathematics education research and practice?
- How do mathematics and the philosophy of mathematics impact on the nature, structure and content of mathematics for teaching?
- What do deep analyses of mathematics itself tell us about its structures, processes and fundamental concepts and about their relationships with its teaching and learning?

2. General Information

Due to the pandemic, there were only 14 presentations out of 24 originally submitted. However, all papers accepted to the original conference have been published in the Special Issue of the Mathematics Teaching Journal Online Vol. 12 N 2 at https://commons.hostos.cuny.edu/mtrj/archives/volume-12-n-2/

Also, many of the authors have been invited to contribute to the upcoming volume Philosophy of Mathematics Education: Work in Progress to be published by Springer in 2023.

The presentations were divided in accordance with the 2020 plans, however we had to fill up a couple of important spots in the program. Scovsmose was especially invited to give an introductory talk on Mathematics and Ethics.

Our surviving presentations have arranged themselves loosely along three themes:

1. Philosophical foundations and approaches, and within them we have several presentations touching upon critical mathematics education; we have an example of phenomenological approach (we had several more examples in the original collection) as well as attempts at epistemological clarification.
2. Philosophical problems; formulating and solving philosophical problems. For example, two presentations following Mathematics and Ethics, address the problem of rigor and the problem of imagination. On Friday we have addressed the problem of the algorithm and the problem of appropriation.
3. Philosophy of mathematics classroom. Here we also have a variety of lenses, math classroom epistemologies, digital games or theory-practice divide. Unfortunately, several other articles addressing modern Internet classrooms have also disappeared.

Meeting of TSG-56 took place on

Tuesday July 13, 19:30 – 21:00
Friday July 16, 21:30 – 23:00
Saturday July 17, 14:30 – 16:30

3. List of Presentations

Tab. 1. The list of papers and posters presented

Paper and author(s)
Session 1
[1] Mathematics and ethics. ***Ole Scovsmose*** (Brazil)
[2] Philosophy, rigor and axiomatics in mathematics: intimately related or imposed? ***Min Bahadur Shrestha*** (Nepal).
[3] Imagination in the philosophy of mathematics and its implication for mathematics education. ***Yenealem Ayalev*** (Ethiopia).
Session 2
[4] Towards a philosophy of algorithms as an element of mathematics education. *Regina D. Möller and* **Peter Collignon** (Germany).
[5] Appropriation mediates between social and individual aspects of mathematics education. ***Mitsuru Matsushima*** (Japan).
[6] Philosophical inquiry for critical mathematics education. ***Nadia Kennedy*** (USA).
[7] Towards critical mathematics. ***Theodore Savich*** (USA).
[8] Recognizing mathematical anthropocentrism. ***Thomas Ricks*** (USA).
[9] Curriculum system of the philosophy of mathematics education for normal students. ***Yaqiang Yan****, Suyue Xue, and Junfeng Ma* (China).
Session 3
[10] Research procedures to understand algebraic structures: hermeneutic approach. ***Maria Bicudo*** (Brazil).
[11] $\mathbf{2+2=4}$? mathematics lost between two pitfalls of essentialism and alternative truths. ***David Kolosche*** (Austria).
[12] Does constructivism tell us how to teach? ***Bronislaw Czarnocha*** (USA).
[13] Teachers epistemology on the origin of mathematical knowledge. ***Karla Sepúlveda Obreque*** *and Javier Lezama Andalón* (Chile).
[14] Mathematical education, body and digital games: play the ball in this way so that it goes, it goes further than the floor. ***Maurício Rosa****, Danyal Farsani, and Caroline Antunes da Silva* (Brazil).
[15] Internet, teaching mathematics: weaving the web. ***Marli Regina dos Santos*** (Brazil).

The first two papers in session 1 studied the underlying theories and philosophies. Scovsmose' study[1] based on the theory of four-dimensional philosophy of mathematics: ontological, epistemological, sociological and ethical. Ethical dimension is explored concentratedly here by showing the broad range of social implications set in motion through bringing mathematics into action. These implications are illustrated in terms of quantifying, digitalizing, serializing, categorizing and imagining. Conclusion draws that the philosophy of mathematics can bring mathematical expertise out of the ethical vacuum. Shrestha[2] examined how philosophy, rigor and axiomatic are related. It seems that philosophy has distant but determining impression on the nature of mathematical knowledge, but rigor and axiomatics seems to be more internal to mathematics.

Most studies in this group focused on specific mathematics education, with different research directions. Ayalev[3] considered "imagination" as a subtopic under mathematics education. Besides the argument whether mathematics was invented or discovered, the construct "imagination" was discussed for the learning of Mathematics.

Möller and Collignon[4] discussed algorithms as well as their roles and importance for mathematics educaiton from a philosophical point of view. The framework of (post-)modernism and a constructivist approach were used. As for social and individual aspects of mathematics education, Matsushima[5] identified five appropriation stages from the discussion of a structural model of social constructivism based on a socio-cultural approach in mathematics education. The result of analysis revealed that a gap in appropriation could occur during the process, and that gap could become the source of creativity. Ricks[8] suggested the benefits of post-anthropocentrism for mathematics education considering that anthropocentric perspectives were inaccurate in lieu of many scientific findings about the mathematical abilities of many non-human entities. The ninth paper is the only one start from teacher education. Yan et al.[9] suggested a curriculum system for the philosophy of mathematics education for Chinese normal students. It is expected to provide "readable materials" for direct application in the practice of future teachers. Czarnocha's study[12] focused on the interface between theory and teaching practice of constructivism. The presentation argued that the research tool, constructivist teaching experiment did define the constructivist teaching methodology and through mathematics teaching-research, it could be introduced into mathematics classroom at large.

There are two presentations about critical studies. Kennedy[6] reported that philosophical inquiry could both offer a space for critical reflection on mathematics, for the development of an epistemological approach, and also a space for the deconstruction and reconstruction of beliefs about mathematics as a form of knowledge, about the social value of mathematical practice, and beliefs about oneself as a mathematics learner/thinker. In Savich's study[7], necessary conditions for arithmetic were expressed as material inferential rules using a normative vocabulary of commitments and entitlements. The explicated critical arithmetic is also related to other projects in critical mathematics education.

The tenth, eleventh and thirteenth paper are about mathematics and the philosophy of mathematics. Bicudo's study[10] was about algebraic and hermeneutic procedures. The openness of abstract algebra may happen through hermeneutic procedures. Kolosche's research[11] started from two examples from popular media to problematize the essentialist epistemologies and relativist epistemologies of mathematical knowledge. Obreque and Andalón[13] argued teachers epistemology attributed to the origin of mathematical knowledge under socioepistemological theory of educational mathematics.

The last two papers of this group are of digital technologies. Rosa et al.[14] conducted a study that high school students conjectured a way mathematically to improve their performance in an the electronic bowling game on Xbox One with Kinect. From that they are drawing up on embodied cognition articulated with the conceptions of perception and body-proper arising from the phenomenological view discussed by Merleau-Ponty. The conclusion is students' perception is shown by the acts of being-with, thinking-with and knowing-doing-mathematically-with-Digital-Technologies. Santos[15] proposed a theoretical and philosophical reflection on the nature of the cyberspace to find the possibilities which the Internet opens to the teaching and learning of Mathematics. The process which educators created resources and spaces for pedagogical practice of mathematics on the Internet is explored.

Topic Study Group 57

Diversity of Theories in Mathematics Education

Angelika Bikner-Ahsbahs[1], Ivy Kidron[2], Erika Bullock[3], Yusuke Shinno[4], and Qinqiong Zhang[5]

ABSTRACT This report presents an overview about the themes of the Topic Study Group 57 on the diversity of theories in mathematics education. Main topics, which were addressed, are the networking of theories in theories related to the use of technology, to design research and beyond. The program, format, contributions, discussions and the main results as well as some future implications are presented.

Keywords: Theory; Networking of theories; Axiology; Epistemology; Ontology; Methodology; Ethics.

1. Themes

1.1. General overview of the topic

Mathematics education is a scientific field with many theory cultures. This diversity can be regarded as richness but it also challenges research as well as communication and cooperation in the field. This is specifically the case when different theories are to be included into research. How the scientific community can cope with this diversity with scientific integrity remains an open question, specifically when research results from different theory cultures are used. Researchers working with the networking of theories (Bikner-Ahsbahs and Prediger, 2014) have started to investigate this question by conducting concrete research. The TSG-57 builds on previous lines of thought on the diversity of theories addressed in various conferences (e.g., ICME-12, ICME-13, CERME 6, 7, 8, 9, 10, 11) and wants to continue this discussion (e.g., Kidron et al., 2018). It aims at exploring how the diversity of theories can be used in mathematics education, how this may influence research theoretically, methodologically and epistemologically and how the diversity of theories may impact on the use of theories and research results in school practice. The TSG-57 wanted to collect concrete research

examples addressing diversity of theories in order to obtain typical 'argumentative grammars' (structure of argumentation to substantiate evidence) for qualitative and theoretical research, research on technology-based teaching and learning, design research, research addressing different educational levels and networking of theories. The TSG welcomed also further ideas going beyond the subthemes briefly described below.

1.2. Subthemes

The TSG-57 called for contributing to four subthemes where the notion of "theories" not only means grand theories but also theory elements or theoretical models of a restricted scope addressing specific perspectives or phenomena.

Subtheme 1 addresses the diversity of theories in the digital era — using technology and other resources in teaching and learning: Technology use often requires theorizing tools, instruments, hence semiotic resources in connection with theorizing teaching and learning mathematics. That is, diversity of theories is an issue with respect to the use of technology and other resources. Some case studies of networking theories are also discussed.

Subtheme 2 addresses the diversity of theories for design research: Steps in design research often require different kinds of theories, for example normative theories for justifying aims, descriptive or explanatory theories for conducting design experiments and prescriptive theories for deciding about means for the design of instruction, hence, diversity of theories is relevant to consider.

Subtheme 3 addresses the diversity of theories at different educational levels including teacher education. Different educational levels (e.g., pre-school vs. university and teacher education) may require the use of various theoretical perspectives to capture the complexity and nature of its teaching and learning, for instance in the classrooms or for professional development.

Subtheme 4 addresses the networking of theories, which may investigate the relationship and function of theory elements in concrete research cases focusing on specificities of theories and their usages to gain insight on theory cultures in the field and meta-theoretical knowledge about how various theories can be related in research.

2. Program Overview

The TSG-57 had 14 submissions consisting of nine papers, two posters and three invited presentations (Tab. 1 on the next page). All submissions were accepted. Finally, the sessions had six long presentations and three invited ones of 20 min each, two short presentations of 10 min each and two poster presentations of 10 min each. We arranged the program according to the topics of the contributions rather than according to the subthemes.

Each of the three sessions started with an introduction bridging previous work within and beyond the TSG-57 with the presentations in the sessions and the aims and scope for the discussions. In each session, an invited talk addressed the subtheme of the day informing the final discussion.

Tab. 1. The list of papers presented

Paper and author(s)
Session 1: Why do we need a diversity of theories?
[1] Facing the challenge of theoretical diversity: the digital case. ***Michèle Artigue*** (France).
[2] Role of feedback when learning with an artefact. ***Angelika Bikner-Ahsbahs****, Estela Vallejo-Vargas, and Steffen Rohde* (Germany)
[3] Constructing mathematical knowledge by means of analogy: connecting Fischbein's theory on the role of intuition in mathematics and the theory of abstraction in context. ***Ivy Kidron*** (Israel)
[4] Seeking a "Theory" of networking praxeologies in mathematics education: a meta-theoretical discussion. ***Yusuke Shinno*** *and Tatsuya Mizoguchi* (Japan).
Session 2: Methodological approaches to the diversity of theories in design research
[5] Vertical analysis as a strategy of theoretical work: from philosophical roots to instrumental and embodied branches. ***Anna Shvarts*** *and Arthur Bakker* (The Netherlands).
[6] Configuration of the theoretical-methodological construct «the teaching model» by affinity between theories. ***Ulises Salinas-Hernández*** (France and Mexico)*, and Luis Moreno-Armella and Isaias Miranda* (Mexico).
[7] The holistic instructional design model of the unit knowledge structure of elementary school mathematics based on core competencies. ***Shiqi Lu*** *and Wenbin Xu* (China).
[8] Networking theories and methodology: identifying argumentative grammars in design research. ***Arthur Bakker*** (The Netherlands) *and William R. Penuel* (USA).
Session 3: Reconsidering basic commitments in the diversity of theories, specifically ethics
[9] Mathematics teaching and learning as an ethical event. ***Luis Radford*** (Canada).
[10] How can we classify teachers' paradidactic praxeologies in different institutional settings? ***Tatsuya Mizoguchi****, Yusuke Shinno, and Toru Hayata* (Japan).
[11] Theoretical networking in a large-scale Danish and a large-scale Norwegian intervention study: TMTM and PBG. ***Lena Lindenskov*** (Denmark).

2.1. Session 1: Why do we need a diversity of theories?

The chair, Angelika Bikner-Ahsbahs, and the cochair, Ivy Kidron, introduced the TSG-57. They distinguished the notions of foreground and background theory (Mason and Waywood, 1996), clarified the term "theory" based on the work of Radford (2008, 2012) as well as the notion of the networking of theories (Bikner-Ahsbahs and Prediger, 2014).

In her invited talk[1], Artigue focused on her research about teaching and learning in a digital environment and used two conceptual tools for her reflection on issues of theoretical diversity: the landscape of networking strategies and the concept of research praxeology. She presented two research cases where theory diversity was relevant, studies on the instrumental approach and the documentational approach to didactics.

Bikner-Ahsbahs et al.[2] combined Activity Theory and Instrumental Genesis to investigate the feedback of a digital tool designed for the teaching/learning of integers. Reflection on the way the two approaches are related revealed a layering model, which describes how the students in the study developed their knowing in the activity of teaching/learning negative numbers mediated by feedback.

Kidron[3] presented a case of Networking of Theories, which showed how she linked the two originally separated foci into one comprehensive focus, the focus of constructing knowledge by means of analogy.

Based on the concept of research praxeology (Artigue and Bosch, 2014), Shinno and Mizoguchi[4] showed via three case studies of theory networking that theoretical concepts and the language used differ with respect to the kind of study they undertook, empirical study, design study, and theory development.

The main outcome in the discussion was that networking of theories can be a source of tensions between theoretical discourses, but it can also offer the flexibility to establish new theoretical discourses.

2.2. Session 2: Methodological approaches to the diversity of theories in design research

Yusuke Shinno (a member of the TSG-57 team) bridged Session 1 and Session 2 by recalling tension and flexibility in the networking of theories suggesting a dialectical way of working with different notions of the same term, such as scheme. Session 2 was then dedicated to the networking of theories in design research (Bakker, 2019), its gains and pitfalls, relating it to ontological, methodological and epistemological issues.

Shvarts and Bakker[5] pointed to the need of undertaking historical analyses to inform conceptualizing when comparing and contrasting theories. They called this analysis ‘vertical analysis’. Their aim was to identify the grand theories behind local approaches and their ontological and epistemological philosophical presumptions. Anna illustrated this approach by unpacking the roots of action scheme used in the instrumental approach and compared it with embodied approaches distinguishing finally between enactive and mental schemes.

Salinas-Hernández et al.[6] took the idea of “affinity” as an alternative to networking strategies in order to configure the methodological construct “teaching model” by three theories based on a semiotic-mediating view. After identifying related elements (affinities) between the theories and configuring the teaching model, the authors used a qualitative investigation in physics education to analyse the teaching practice of two teachers of grade 11 with different experience.

Lu and Xu[7] presented a holistic instructional design model for elementary school mathematics based on core competencies. The core competence concept relates to the development of mathematical thinking. The basic theory underlying the model is a thick epistemology including five characteristics: unit knowledge structure, learning psychological process, teaching objectives, learning evaluation, learning activities.

Finally, Bakker and Penuel[8] talked about networking theories and methodology. Acknowledging the networking of theories approach they stressed also the danger of this approach of being tied to epistemological justifications of choices in design research and simultaneously ignoring the relevant role of ontology. Because of the transformative nature of design research there is the necessity to include ontological and axiological aspects into justifications of design choices.

Main result from the discussion was the need for an increasing sensitivity to more comprehensively consider methodological as well as epistemological, and ontological issues in justifications of theoretical choices in transformative research in mathematics education.

2.3. Session 3: Reconsidering basic commitments in the diversity of theories, specifically ethics

In her bridging introduction, Erika Bullock (a member of the TSG-57 team) proposed to take up work from the philosophy of science. She referred to Patterson and Williams (1998) when she argued that there is a normative structure to scientific research holding certain commitments. These philosophical commitments involve theories about:

a) The nature of reality and what really exists (ontology)
b) The relationship between the knower and what is known (epistemology)
c) What we value and how we determine that value (axiology)
d) The strategy and justifications in constructing a specific type of knowledge (methodology), as linked to individual techniques (methods) (Daene, 2018, adapted from Patterson and Williams, 1998)

In his invited talk[9], Radford addressed the issue of ethics for teaching and learning in general. For the theory of objectification, he proposed and elaborated a communitarian conception of ethics that joins responsibility, commitment and care in the teaching and learning of mathematics.

Mizoguchi et al.[10] reported about two case studies of networking theories exploring the role of categorisation in a methodological approach, asking: “What is a theory for” and “How does it function”. They used the two case studies to differentiate the kind of knowledge being achieved, in one case they revealed “descriptive” and the other case “explanatory” theory elements (Prediger, 2019).

Lindenskov[11] talked about theoretical networking in large-scale Danish and Norwegian Intervention studies. As teachers were included in these studies, culture-specific views of teachers on theories, goals and organizations played a significant role making visible the contradictions between researchers and teachers’ view of how theories are meaningful.

What we learned from the discussion was the conviction that key commitments in the use of theories should be reflected and made explicit. Ways to do this are vertical analyses, grounding research in philosophical work and merging commitment and responsibility.

3. Future Directions

Networking theory research has led us in the past years to revisit our epistemological assumptions. The recent interest in ontology can complement the advances made on the epistemological side. There are a number of future directions to think about in discussions on theory use in the different kinds of research genres in mathematics education.

There are certain commitments related to theories (i.e., axiological, ontological, and epistemological) and to teaching and learning of mathematics (e.g., ethical). These commitments seem to be relevant for methodological choices in research that influence what kind of knowledge can be achieved about a certain research object. We ask how these commitments become relevant when various theories are taken up e.g., when theories are networked.

Ethical issues are particularly relevant for classroom design. As design research is a transformative way of doing research and development, where do the decisions for or against a specific learning goal come from and what are the criteria in what directions changes of the design are to be made? Here axiological issues come into play affecting the ontology as well as the epistemology of the research conducted. Beyond that, how far is it necessary or even mandatory to take ethical issues of the teaching/learning into consideration for theorizing and what are the relevant concepts of ethics for that? More generally, what are the pitfalls when such commitments go unnoticed?

Topic Study Group 58

Empirical Methods and Methodologies in Mathematics Education

Christine Knipping[1] and Soo Jin Lee[2]

ABSTRACT In TSG-58 research methods, methodologies, and paradigms related to traditional issues of mathematics education such as instruction, learning, teaching and classroom processes and interactions were discussed. In total twelve papers and two posters were presented and discussed over three sessions. Overall, about 50 scholars participated in this TSG-58.

Keywords: Methods; Methodologies; Paradigms.

Research in mathematics education employs a range of Methods, Methodologies, and Paradigms (M/M/Ps) in the service of key goals. TSG-58 promoted a discussion about diverse strands of M/M/Ps investigating these goals.

1. Methods, Methodologies, and Paradigms in the Service of Key Goals

In the call for TSG-58 six diverse goals central to ongoing research in mathematics education were promoted, but three of them — Mathematics Education and Social Justice, the Role of Culture and Language in Shaping the Teaching and Learning of Mathematics — were not in focus of the submitted papers. Instead, traditional issues as instruction, learning, teaching in general and classroom processes and interactions were explicitly discussed in the submitted methodical and methodological papers of our TSG-58.

1.1. Diverse goals central to ongoing research in mathematics education

TSG-58 was finally organised, in three sessions, around four diverse goals central to ongoing research in mathematics education:

1) Improvement of Mathematics Instruction (e.g., instructional materials, strategies, organization, assessment);
2) Learning of Mathematics;

[1]Faculty 3 - Mathematics and Computer Science, University Bremen, Bremen, 28334 Bremen, Germany. E-mail: knipping@math.uni-bremen.de
[2]Department of Mathematics Education, Korea National University of Education, Cheongju, 28175 Chungbuk, Korea. E-mail: sjlee@knue.ac.kr

3) Teaching of Mathematics (e.g., teacher beliefs, knowledge, decision-making and professional development); and
4) Classroom Processes and Interactions

Each *goal* was addressed using research designs that integrate one or more different Methods, Methodologies, and Paradigms (M/M/Ps). For each *goal*, the contributors of TSG-58 were asked to address the following questions and to discuss which M/M/P combinations help us understand the phenomena at stake in robust and reliable ways.

1) "Suppose you have a hypothesis about this goal. How do you set about evaluating it?" Alternatively,
2) "Suppose you are trying to explain some aspect of individual or group behavior relevant to that goal. How would you characterize and then theorize that behavior?"
3) Or, "How might cultural, historical and political perspectives shape one's understandings of the contingencies related to realizing this particular goal?"

The *goals* of our research clearly in focus, the actual topic of TSG-58 were the different methods, methodologies, and paradigms (M/M/Ps) employed.

1.2. Empirical research methods and methodologies

This TSG was specifically focused on the empirical research methods and methodologies employed to address the four broad goals of research in mathematics education identified above. For our work to be coherent and allow for comparability, each paper identified the specific goal(s) being explored, identified the theoretical frame on which the research design was predicated, and addressed the question of how effectively the research design (M/M/P bundle) addressed the designated goal(s). Participants were asked to

1) Specify the methodology and methods that constitute the research design and identify the particular goal/s that are the focus of the reported research study;
2) Specify the theoretical frame or rationale by which the selection of methodology and methods can be justified, discussing advantages and limitations of methodological choices respectively the identified research goal(s);
3) Further address the appropriateness of the chosen methods in terms of the robustness of the findings generated, their generality or specific domain of relevance, and their capacity to describe, explain or predict phenomena of importance to the field of mathematics education.

The following brief summaries of the papers in our TSG-58 only indicate the theoretical frames, research designs and designated goals of each contribution. Longer papers about the reported research are published elsewhere and indicated to in the references.

2. Program Overview

Tab. 1. List of papers and posters presented

Paper and author(s)
Session 1 (July 13th at 19:30 – 21:00 Beijing Time)
[1] First voyage of the integrated paradigm: The case of an international study on effective mathematics teaching. ***Zhenzhen Miao*** (China)*, and David Reynolds and Christian Bokhove* (UK).
[2] The teaching of mathematical thinking: The conceptualization of a special class teacher in China. ***Na Li*** (China) *and Ida Ah Chee Mok* (Hong Kong SAR, China).
[3] Teaching design of combination from HPM perspective. ***Weiyuan Fan*** (China).
Session 2 (July 16th, 21:30-23:00 Beijing Time)
[4] Understanding the relations between instructional quality and task quality in mathematics classrooms. ***Ann-Kristin Adleff****, Natalie Ross, Gabriele Kaiser, Johannes König* (Germany)*, and Sagrid Blömeke* (Norway).
[5] What is six-questions cognitive model? *Ying Zhou, Xiaofeng Lan, and* ***Tommy Tanu Wijaya*** (China).
[6] Units coordination as a theoretical construct to understand students mathematical activities. ***Soo Jin Lee*** *and Jaehong Shin* (South Korea).
[7] The influence of ICT on the students' science literacy at the national and student level based on ITU IDI Index and PISA2015. ***Zhenrong Xiong****, Ying Zhang, Bo Li, and Na Li* (China).
[8] The effectiveness of teaching mathematics in circle equation by using 5E instructional model in inquiry-based learning. ***Try Kimhor*** (Cambodia). (Poster)
[9] The trend of mathematics teaching method has changed from fragments to systematics. *Yi Lin,* ***Tommy Tanu Wijaya****, and Ying Zhou* (China) (Poster).
Session 3 (July 17th, 14:30-16:30 Beijing Time)
[10] Eye movements and collaborative problem solving: what do long fixations tell about student cognition? ***Markku S. Hannula****, Enrique Garcia Moreno-Esteva, and Miika Toivanen* (Finland).
[11] Examining the phenomenon of interlocutors talking past each other in collaborative proof constructions. ***Ann Sophie Stuhlmann*** (Germany).
[12] Using MRGQAP to analyse the development of mathematics pre-service trainees' communication networks. ***Christian Bokhove*** (UK)*, Jasperina Brouwer* (Netherland)*, and Chris Downey* (UK).
[13] Case study of personalized teaching based on the Q-learning algorithm in the era of big data. ***Lei Wang****, Yong Zhang, Na Li, Bo Li* (China).
[14] Learning research in a laboratory classroom: Advancing methodology and technology. ***Man Ching Esther Chan****, and David Clarke* (Australia).

2.1. Session 1: Teaching

In our first session, Christine Knipping (Germany) and Soo Jin Lee (South Korea) opened the TSG-58 with an introduction. They highlighted the diverse goals of research, listed above, and promoted the diverse strands of the M/M/P bundle as a way to address these designated goal(s), in terms of diverse methods, methodologies and paradigms. As the leaders of TSG-58 they proposed a programme, which is also used in this paper to structure the contributions of TSG-58. The first session started with papers on M/M/P issues around *Teaching*.

Miao et al.[1] reflected on a mixed methods approach as a way of researching teaching in an international setting (Miao and Reynolds, 2018). The title of the submission indicates a quantitative and qualitative methods approach that is designed as a mixed methods comparative approach to gain deeper insights into issues around teaching and learning mathematics.

Li and Mok[2] presented a paper on research issues around teaching of mathematical thinking. Both researchers made overt that understanding (methodologically) teachers' perspectives on mathematical thinking is important to not only describe and analyze their views on the issue, but also the impact on teaching.

In her presentation[3] Fan (China) talked about teaching integrating historical materials into the classroom. Research and methodological issues are related to specific traditions and cultural issues in this paper.

2.2. Session 2: Instruction and learning

In the second session of TSG-58 papers on M/M/P issues were focusing on issues at the intersection of *Instruction and Learning*. How to research learning in the context of specific materials and designed activities were of particular interest in this session.

The presentation[4] by Adleff et al. explored how quantitative research methods can capture and assess the "instructional quality" in classrooms. They also discussed how the "task quality" can be measured and put in relation to the performed "instructional quality" in class (see also Kaiser et al., 2017).

Zhou et al.[5] proposed in their presentation a 6-questions model, which has been developed in China about 10 years ago, combined with technology-based learning media and reflect in how far this cognitive model can foster students' deep learning (see also Lin et al., 2020).

Lee and Shin[6] discussed how far the theoretical construct "Unit Coordination" can be used to understand mathematical activities of students, portrayed as "cognizing subjects" (see also Lee and Shin, 2021).

Xiong et al.[7] also investigated the role of information and communication technology (ICT) in the context of instruction/learning. They wondered what impact ICT developments have on students' scientific literacy.

Two poster presentations, Kimhor[8] and Lin et al.[9], were part of TSG-58. These posters deal with methodical issues around instruction, learning and teaching. The first poster looks into the effectiveness of teaching in the context of inquiry-based learning, based on an instructional model, while the second one proposes a "systematic plan of teaching mathematics", based on the so called "Dick-Carey" model which aims to offer teachers a systematic approach to mathematics teaching. They report in how far mathematics teaching methods have changed in China.

2.3. Session 3: Learning, teaching and the social dimension

In the last session of our TSG-58 even more diverse methodical and methodological facets were brought up and discussed. Students' cognition "as it happens" was looked at, as well as the phenomena of interaction and how these can divert. Also, social networks of peer pre-service mathematics trainees and the methods and theoretical approaches how to research these were presented and discussed. Two further contributions mirrored how diverse and multi-faceted these discussions were. A "personalized teaching intervention" based on a "Q-learning algorithm", conceptualized as a "dynamic optimization problem" was presented and discussed as well as "Learning research in a laboratory classroom", where methodology and technology was designed so that the investigation of social aspects of classroom practice, particularly student-student and student-teacher interactions could be researched.

Hannula et al.[10] discussed how far paper and GeoGebra contexts effect fixation durations in collaborative student activities in geometry. From their observations and categorizations of four different types of long fixations they conclude possible cognitive student activities (see also Hannula and Toivanen, 2019; Hannula, Toivanen and Garcia Moreno-Esteva, 2019).

Stuhlmann[11] investigated students in collaborative proving activities in an undergraduate linear algebra class. Her interactionist methodology and methods allow her to study the diversity of meaning making of students in the same undergraduate class and why it is challenging for the students to come to a consensus during their proving process.

Bokhove et al.[12] the potential of a specific data analysis method (MRQAP) for analyzing longitudinal network data, in order to study the development of peer networks of pre-service mathematics trainees over time (see also Bokhove and Downey, 2018).

Wang et al.[13] presented a personalized teaching intervention, which is aimed to maximize academic performance of students (see also Wang et al., 2013). According to the researchers the latest advances in information technology allow this approach.

Last, but not least, Ching and Chan[14], based on collaboration with David Clarke, presented a multi-theoretic and multimodal research design, implemented in the laboratory classroom at the University of Melbourne (see Chan and Clarke, 2016, 2017). She discussed the complexity of this research design, which focused on student-student and student-teacher interactions.

3. Future Directions and Suggestions

The methodology and methods that constitute the research designs presented in the TSG-58 were not only diverse and multifaceted, but also indicated distinct and specific goals.

For example, *Teaching* was in some contributions not only researched in mixed methods ways, but also with an international comparative focus. Whereas, other research focused consciously on one cultural context only to deeper investigate the rationale of this specific context and historical tradition. Also, related to *Instruction and Learning* different goals were of interest. Established instruction approaches and models were valued in a methodically pragmatic way, i.e. within a new technology-based environment, and when looking at the impact of ICT environments on students' learning. On the other hand, more theoretical stances were taken to better understand mathematical activities of students.

Also *Learning, Teaching and the Social dimension* were studied not only in diverse methodical and methodological settings, but also with different goals. Understanding individual student cognition and academic performance was of interest for some researchers, other scholars focused clearly on the complexity of collaborative settings for students learning, as well as on student-student and student-teacher interactions.

The appropriateness of the chosen methods and theoretical frame or rationale by which the selection of methodology and methods were justified, was overtly discussed in the three TSG-58 sessions. Questions and comments highlighted advantages and limitations of methodological choices respectively the identified research goal(s). This helped to evaluate the robustness of the findings generated, their generality or specific domain of relevance, and their capacity to describe, explain or predict phenomena of importance to the field of mathematics education.

TSG-58 promoted a discussion about diverse strands of M/M/Ps investigating specific goals. Traditional issues as Instruction, Learning, Teaching in general and Classroom Processes and Interactions were explicitly discussed in the submitted methodical and methodological papers of our TSG-58. Extended discussions of Methods, Methodologies, and Paradigms (M/M/Ps) in research in mathematics education, in the service of key goals, will further substantiate the state of our art in the future. But these discussions will have to also include goals of ongoing research in the area of Mathematics Education and Social Justice, the Role of Culture and Language, shaping the Teaching and Learning of Mathematics, which were not in focus of the submitted papers.

Topic Study Group 59

Mathematics and Creativity

TSG-59 Organising Team[1]

1. Introduction

The major goal of this TSG was to gather educational researchers, research mathematicians, mathematics teachers, teacher educators, instructional designers and other congress participants for the international exchange of ideas directed at better understanding of creativity in mathematics and mathematics education. The TSG gathering was framed by the discussion of the two contrasting perspectives on the nature and nurture of creativity: individualistic vs. social.

The following issues were discussed:

- Does it make sense to perceive creativity?
  1. as emerging from the individual or from dialog, brainstorming and co-construction?
  2. as yielding grand intellectual feats or as an everyday occurrence in each of us?
- How is it best to design situations with dense potential for creativity emergence:
  3. by orchestrating diversity or homogeneity in educational settings?
  4. by focusing within the discipline or promoting interdisciplinary?
- How can we best understand and support creativity in teachers, teacher designs and the teaching process? by addressing the mathematics teacher:
  5. as an individual;
  6. as an actor in a homogeneous community of practice;
  7. as an actor in a diverse community of interest including members from outside mathematics education.

2. Organisation of TSG-59

The TSG activities were organised based upon the theme individualistic versus social' perspectives of creativity and the 30 papers and short orals received. Four sessions are designed, among them two sessions (session 1 and session 4) are simulated (due to the on-line nature of the meeting) "round table" activities, and the other two are oral presentations (Tab. 1).

Round Table 2: Creativity in the World
[7] Mathematical creativity of Filipino and Japanese students: a comparative study. ***Lady Angela Mico Rocena****, Ma. Nympha B. Joaquin* (Philippine)*, and Manabu Sumida, Naomichi Yoshimira* (Japan).
[8] An exploration into Chinese high school students' consciousness of enquiring and innovation. ***Yi Chu*** *and Haiyue Jin* (China).
[9] Promoting creativity in the international baccalaureate diploma programme mathematics. ***Deborah Sarah Sutch*** *and Helen Thomas* (The Netherlands).
[10] A survey of mathematics teachers' perceptions on mathematically gifted learners in Thaba Nchu primary schools in South Africa. ***Motshidisi Gertrude van Wyk*** (South Africa).
Session 2: Collaborative Creativity
[11] Social creativity in a constructionist classroom context. ***Chronis Kynigos*** *and Dimitris Diamantidis* (Greece)
[12] Fostering creativity in a diverse classroom of a community college. ***Malgorzata Aneta Marciniak*** (USA).
[13] Collaborative creation between university students from mathematics and music. ***M. Alicia Venegas-Thayer*** (Chile)
[14] Understanding students everyday play experiences when designing games in the mathematics classroom. ***Erik Ottar Jensen*** (Denmark).
[15] Creative design of digital tools for teaching in a mathematics' teachers' community. ***Chronis Kynigos*** *and Dimitris Diamantidis* (Greece).
[16] Creative art processes to deepen geometrical thinking of middle school mathematics teachers. ***Irina Lyublinskaya*** *and Marta Cadral* (USA).
[17] Beyond Sudoku: creating a course for developing deductive and creative skills. ***Jeffrey J. Wanko*** (USA).
[18] Designing games to foster creativity thinking about randomness. ***Theodosia Prodromou*** (Australia) *and Chronis Kynigos* (Greece).
Session 3: Cognitive abilities and development in connection to creativity
[19] Creativity varies from task to task, doesn't it? — a qualitative view on first graders' individual creativity. ***Svenja Bruhn*** (Germany).
[20] "Rethinking the World" with mathematics: the geometric chess from bauhaus as a basis for creating mathematical ideas and materials. ***Torsten Fritzlar*** *and Karin Richter* (Germany).
[21] Inventing growing patterns by primary school students — a creativity provoking task. ***Daniela Assmus*** *and Torsten Fritzlar* (Germany)
[22] The relation between spatial ability and creativity in geometry in primary school. ***Anastasia Datsogianni*** (Germany)*, and Pantelitsa Eleftheriou, Nektaria Panagi-Louka, and Athanasios Gagatsis* (Cyprus).
[23] How long is half a piece of string — the journey continues. ***Bruce Stuart Ferrington*** (Australia).
[24] Strategy-related and outcome-related mathematical creativity in all as compared to that in gifted. ***Roza Leikin*** *and Haim Elgrably* (Israel).

Session 4: Round tables

Round Table 3: Collaborative and Interactive creativity

[25] Inquiry dialogues in mathematics classroom and mathematical representations and their role in learning mathematics. ***Hanna Zdziarska Slabikowska*** (Norway).

[26] Mathematical creativity workshop to review elements of geometry with high school students. ***Matheus Delaine Teixeira Zanetti**, Mateus G. Fonseca, and Cleyton H. Gontijo* (Brazil).

[27] Comparing social creativity among designers with creativity of mathematical digital resources produced. ***Nataly Essonnier*** (Switzerland), *Mohamed El-Demerdash* (Egypt), *and Jana Trgalová* (France).

[28] Expanding possibilities: a metaphor for the co-construction of students' creative acts. ***Ayman Eleyan Aljarrah** and Jo Towers* (Canada).

[29] Developing mathematical group creativity through mathematical modelling. ***Hye-Yun Jung** and Kyeong-Hwa Lee* (South Korea).

Round Table 4: Evaluation of Creativity

[30] Students and their effects on motivation and performance in mathematics. ***Mateus Gianni Fonseca** and Cleyton H. Gontijo* (Brazil).

[31] Research problems and assessment by students. ***Noriko Tanaka*** (Japan).

[32] Establishment of evaluation index system for primary school students' mathematical innovation competency: investigation and analysis based on Delphi method. ***Yanzhi Wang*** (China).

The first session's activities comprised of two "round table" activities respectively grouping the presentations into the following themes: a) cognitive perspectives of creativity, b) creativity in the world. The round tables were preceded by an introductory talk by Roza Leikin[1] outlining the structure of the meetings followed by another by Chronis Kynigos[2] laying out the frame for the discussions with respect to the TSG-59 theme for the ICME-14 conference.

The activities of the second session comprised of paper presentations grouped around the theme "collaborative creativity". Eight papers were presented and discussed focusing on creativity emerging in a classroom context, stimulated by transdisciplinary approaches to mathematics education and manifested during students' design and tinkering with constructionist digital media and games. To stimulate discussion the session was chaired by Suhy.

The activities of the third session involved paper presentations addressing the cognitive abilities and development in connection to creativity. The papers yielded research on mathematical creativity in individuals' grappling with diverse tasks including patterns, spatial ability, iterative halving of a piece of string. To stimulate discussion, the session was chaired by Kynigos.

The fourth session activities comprised of two simulated (due to the on-line nature of the meeting) "round table" activities respectively grouping the presentations into the following themes: c) collaborative and interactive creativity and d) evaluation of creativity.

The TSG concluded in a discussion around the value and the diversity of the two approaches to creativity concluding that it is worthwhile and necessary to pursue both the individualistic and the collaborative perspectives, to employ research and creativity perspectives outside mathematics education to the extent that they inform and enrich the study of creativity in both the teaching and learning of mathematics, both for high-end performers and in an inclusive spirit as a trait inherent in every student. The group agreed more work is needed especially regarding the nature of every-day mathematical creativity in connection to student activity including the understanding of the role of situational and social context. It was also agreed that more work is needed to understand creativity in teacher classroom activity and with respect to their design of resources as tools to inspire and liberate mathematical creativity in students.

Topic Study Group 60

Semiotics in Mathematics Education

TSG-60 Working Team[1]

1. Aims of the TSG

The TSG-60 aimed at exploring the significance of semiotics and the diverse uses of signs in the teaching and learning of mathematics at all levels. The importance of semiotics is reflected in a large body of literature within mathematics education, an overview of which is to be found in the ICME-13 monograph "Signs and Signification: Semiotics in Mathematics Education Research." The goal of TSG-60 was to expand on prior work, addressing the following themes and sub-themes:

- *Themes*

1. Semiotic perspectives within mathematics education;
2. Sign use and mathematics meaning-making processes;
3. Modes of mathematical narrative through different sign systems;
4. Relationships between sign systems (e.g., natural language, diagrams, pictorial and alphanumeric systems) and transformations between sign systems in mathematics thinking and learning;
5. Inventing and generalizing with visual, alphanumeric, and other sign systems;

- *Sub-themes*

1. Semiotics and Technology (e.g., Design of activities and tasks based on visual-kinesthetic interactions; interplay between physical manipulatives and virtual entities, and roles of animation and video as instructional tools)
2. Semiotics in Specific Areas of Mathematics (e.g., Episodes of sign-use in calculus, geometry, algebra, arithmetic, etc.)
3. Semiotics Inside and Outside Mathematics Education (e.g., differences and similarities between semiotic usages in art, linguistics, or cinema, and mathematics)
4. Semiotics in Relation to Feeling and Expression (e.g., gestures, embodiment, more-than-human agencies, affects, aesthetics, and rituals)

[1] TSG-60 Working team:
Chair: Ricardo Nemirovsky, Manchester Metropolitan University, UK.
Co-chair: Christina Krause, University of Duisburg-Essen, Germany.
Members: Suanrong Chen, Yangzhou University, China.
Francesca Ferrara, University of Torino, Italy.
Kazuya Kageyama, Hiroshima University, Japan.

2. Submissions, participation, and sessions

2.1. Submissions and participation

We received, in 2019, 13 submissions from 8 countries (South America: 1; North America: 4; Asia: 3; Europe: 4; Africa: 1). Of these 13 submissions 10 were accepted as paper presentations and 3 as posters. Of the 13 accepted submissions, only 7 papers were able to be presented during the online conference. We list the papers in Tab. 1.

Tab. 1. The list of papers presented

Paper and author(s)	
Session 1: Embodied aspects, gestures, movement	
[1]	Collaborative gestures among secondary students conjointly proving geometric conjectures. ***Candace Walkington****, Min Wang, and Mitchell Nathan* (USA).
[2]	Conceptualization of co-emergent curriculum in a mathematics lesson. ***Kazuma Kageyama*** *and Masataka Koyama* (Japan)
[3]	Can a movement notation be a mathematical notation? ***Giulia Ferrari*** *and Francesca Ferrara* (Italy)
Session 2: Language, meaning making, social factors	
[4]	Semiotic character and issues in the learning and teaching of linear functions in Japan: The influence of terminology. ***Hiroaki Hamanaka****, Masayoshi Yoshikawa, Hisae Kato, and Mitsunobu Kawauchi* (Japan).
[5]	A semiotic lens on learning math in sign languages. ***Christina M. Krause*** (USA/Germany) *and Annika M. Wille* (Austria).
[6]	Semiotic chaining in Linear Algebra. ***Hamide Dogan*** (USA).
[7]	Interference between artifacts in semiotic chains. ***Andrea Maffia*** *and Mirko Maracci* (Italy).
Session 3: Workshop	

2.2. Themes prominent during the sessions

The themes that became prominent during the three sessions can be outlined along five categories:

2.2.1. Gestures, body, and their annotations

Walkington et al.[1] elaborated on the notion of "collective gestures", in reference to gestural actions bodily coordinated among several students, arguing that they can express important mathematical insights emerging from distributed cognition. *Ferrari and Ferrara*[3] shared a notation for body motion stimulated, in part, by the Laban notation, that they propose to enrich research practices.

2.2.2. Co-emergent curriculum

Kageyama and Koyama[2] distinguish between a hypothetical learning, as it can be traced in a mathematical textbook, and the real learning that incorporates spontaneous contributions from interactions among students and teachers. Their case study focused on the word-usage in a mathematics lesson. They characterize the resultant process as a co-emergent curriculum.

2.2.3. Language and mathematical concepts

Hamanaka et al.[4] discussed the influence of the Japanese phrase for "linear algebra" which, as opposed to the English one, does not connote straight lines. *Krause and Wille*[5] elaborated on different semiotic approaches to analyze the use of sign language among Deaf students in the context of a mathematics lesson.

2.2.4. Semiotic chaining

Dogan[6] traced the emergence of signified-signifier pairs and how they facilitate the emergence of new concepts in linear algebra. *Maffia and Maracci*[7] incorporated a Peirceian semiotic perspective to analyze the enchaining process. They introduced the notion of "interference" to characterize how different artifacts interact in the formation of a semiotic chaining.

2.2.5. Abstraction and mathematics

This was the theme of the workshop that took place in Session 3. The inquiry centered on how semiotics may cast light on the concept of abstraction in the context of two selected video episodes. The complexity inherent in this investigation emerged from the use of physical materials and tools and the expression of ideas in Sign Language, all of which seem to reflect a bodily and "concrete" ground for thinking, allowing for the articulation of abstract ideas.

3. Areas for Future Research and Outlook

The topic of Abstraction and Mathematics led to numerous research questions for future work. These included how the word "abstraction", as uttered in different languages, might lead to distinct ways of conceptualizing it, how to complicate the almost automatic association between "material" and "bodily" with "concrete", and how to question the presumption of abstraction as preventing inclusiveness. Other areas for future research are those that were touched only tangentially, or not at all, by the presented papers, such as semiotics in relation to feelings and aesthetic expressions, the relationship between the uses of sketches and diagrams in mathematics and in other disciplines, or the significance of students' inventing mathematical notations.

The group — TSG leaders and participants alike — agreed that it might be worthwhile to work on a joint publication, for example a special issue of a journal in which will be focused on the topics as they emerged during the discussions. Furthermore, a future seminar and or topic conference/symposium has been considered. Potential contributors met shortly after the conference to elaborate on possible outlets and topics for an open call. The endeavor is still in the planning stage as of March 2022.

Topic Study Group 61

International Cooperation in Mathematics Education

Ui Hock Cheah[1], Masami Isoda[2], Arne Jakobsen[3], Bernadette Denys[4], and Jiwei Han[5]

1. Description of TSG-61

From the perspective of international cooperation, mathematics has always been viewed as an essential literacy which is necessary to address the concerns of globalization. High quality mathematics education has thus become a priority of the reform agenda to achieve the United Nations Sustainable Development Goals (SDGs) (United Nations, 2015). While it is a common goal to progress and improve the status of mathematics education, this aspiration is not easily attained for many countries. As a result, there is a demand for countries and agencies to support and collaborate with each other in international cooperation projects. This demand often provides the rationale for mathematics education to be included in various international education cooperation efforts which go beyond merely adopting successful practices of high achieving countries, to seek appropriate technologies and methods to advance mathematics education. Mathematics educators, teachers, government officials and consultants participate at various levels of international education cooperation, namely, (1) International, (2) Governmental, (3) Institutional, and (4) Personal. Projects also vary in scope from nationwide to provincial and school levels to cater for the demands of both mainstream and marginalized groups. Various aims and purposes of international cooperation in mathematics have been noted: (a) Curricular development which encompasses curriculum reviews, textbook resource development, as well as the enhancement of meaningful teaching and assessment approaches, (b) Professional development at in-service and pre-service levels, and (c) Creating communities to enhance mathematics education. While international education cooperation has been ongoing, there remain many issues and challenges to be overcome (Atweh et al., 2008). Emerging trends in response to these concerns include:

- Renewed emphasis on pre-primary and basic education up to the secondary level.
- Reaching out to special groups, for e.g., disabled, poor and gender groups.
- Re-establishment of higher education as an agenda.

[3]University of Stavanger, Norway. E-mail: arne.jakobsen@uis.no
[4]Paris Diderot University, France. E-mail: bernadette.denys@univ-paris-diderot.fr
[5]Northeast Normal University, China. E-mail: hanjw617@nenu.edu.cn

- Emphasis on assessment for accountability.
- Inclusive involvement and expanding the roles of new partners, donor countries. and agencies, and non-governmental organizations.

The discussions in this group were guided, though not exclusively by the following questions:

1. What were the roles of the cooperating agents in the projects?
2. What were the challenges, and the subsequent methods/solutions/strategies and good practices used to overcome these challenges?
3. What were the views of the various cooperating agents in overcoming these challenges? How were differing views about teaching and learning mathematics resolved?
4. How did the project impact on the quality of teaching and learning mathematics?
5. How did the project plan for sustainability and expansion?

2. Paper Presentations

The papers submitted to TSG-61 were reviewed and a total of 16 papers were selected and presented over 300 minutes, in 3 sessions (Tab. 1, on the next page). All the papers were presented using the online mode. At the end of each session, there was a time for question-and-answers which resulted in fruitful discussions on the papers that were presented.

3. Conclusion

ICME-14 marks the first time the topic of international cooperation has been included as a TSG at the ICME. The papers presented in TSG-61 provided informative glimpses and insights into the current state of practice in international cooperation. The papers presented covered four main areas of international cooperation: Curricular development, professional development, developing communities of practice, and improving environment related to mathematics education. The methods in international cooperation that were reported in the papers included the following strategies: The adoption and adaptation of good practice, capacity building of key personnel/faculties, developing and incorporating local ideas, multilateral dialogue among agents to develop strategic approaches, development of new study programs and certification courses, and the development of curriculum and textbooks.

3.1. Areas for future research and discussion in international cooperation

At the concluding session of TSG-61, three suggestions were highlighted for future research and discussion:

1) Papers in TSG-61 described the success stories in International Cooperation. Issues and challenges are not often discussed. For future projects, reports should also discuss what we can learn from the inadequacies and shortcomings of the projects.

Tab. 1. The list of papers presented

Paper and author(s)
Session 1
[1] Adapting lesson study in Thailand through international cooperation. ***Maitree Inprasitha*** (Thailand) *and Masami Isoda* (Japan).
[2] An experience in developing the regional mathematics curriculum standards. ***Kim Hong Teh*** (Malaysia) *and Masami Isoda* (Japan).
[3] Fostering global citizenship in mathematics classrooms. ***Russasmita Sri Padmi*** (Indonesia) *and Gabriel Matney* (USA).
[4] Development of the national mathematics textbook in primary schools in Papua New Guinea. ***Ileen Palan****, Steven Tandale, Gandhi Lavaki* (Papua New Guinea)*, and Masami Isoda, Satoshi Kusaka, and Akinori Ito* (Japan).
[5] The challenges of improving mathematics education through translated textbook. ***Lambas*** (Indonesia)*, Masami Isoda* (Japan)*, and Wahyudi* (Indonesia)
[6] Developing mathematical thinking through robot programming. ***Wahid Yunianto****, Uki Rahmawati* (Indonesia)*, and Masami Isoda* (Japan).
[7] An electronic assessment workshop for 1st & 2nd year mathematics & statistics course lecturers from East African universities. ***James Musyoka*** *and Michael Obiero* (Kenya)*, and David Stern and Danny Parsons* (UK)
Session 2
[8] Understanding narratives: A pathway towards resolving issues and challenges in international cooperation in mathematics education. ***Ui Hock Cheah*** (Malaysia) *and Masami Isoda* (Japan).
[9] APEC lesson study project (2006–2018) for mathematics education and AI era curriculum project (2019–). ***Masami Isoda*** (Japan)*, Maitree Inprasitha* (Thailand)*, Roberto Araya* (Chile)*, and Sofian Tajul Arus* (Malaysia).
[10] Improving quality and capacity of mathematics education in Malawi through collaboration — lessons from a collaboration between University of Malawi and University of Stavanger. ***Arne Jakobsen*** (Norway) *and Mercy Kazima* (Malawi).
[11] Informal international collaboration and its potentialities: The example of GREMA. ***Bernadette Denys*** (France) *and Jannick Trunkenwald* (Algeria).
[12] Capacity development for mathematics teaching in Tanzania: A follow up of impact on participants. ***Calvin Swai*** (Tanzania)*, Joyce Mgombelo* (Canada)*, Andrew Binde* (Tanzania)*, Florence Glanfield, and Elaine Simmt* (Canada).
Session 3
[13] How El Salvador improved student learning achievement in mathematics: A principle methodology of JICA toward achieving SDGs 4. ***Norihiro Nishikata*** (Japan).
[14] The development of mathematics textbooks in Myanmar: Under the CREATE project. ***Takashi Itoh****, Isamu Imahori, and Koji Takahashi* (Japan).
[15] Impact of APEC lesson study project (2006–2018) in Chile. ***Raimundo Olfos*** *and Soledad Estrella* (Chile).
[16] GUATEMATICS in action. A service learning project for mathematics education between Spanish preservice teachers and teachers from rural schools in Guatemala. ***Elsa Santaolalla Pascual****, Belén M. Urosa Sanz, and Olga Martín Carrasquilla* (Spain).

2) International cooperation should also report what we can learn from different cultures. Knowledge flows both ways. For example, what are the differences in mathematics language, terminologies and concepts that are related to culture? What pedagogical strategies have emerged from local cultures?
3) What can we do about the outcomes of international cooperation?

Topic Study Group 62

TSG-62: Popularization of Mathematics

Christian Mercat[1,2]

1. Theme and Description

The Popularization of Mathematics Study Group (TSG-62) gathered for the second time in ICME people using interesting and inspiring mathematics to motivate both young people and the general public.

Because of the pandemic situation, we have seen a surge in the use of digital media aimed at teaching mathematics. This technological shift had a profound impact on the way we teach and, because of the format, a lot of teachers have taught in a manner much akin to popularization. Many teachers have turned into directors of educational video clips and borrowed from the narrative springs of Youtubers. You don't teach the same way using the blackboard in the classroom and short videoclips on the internet. You cannot expect students to stay as calm and focused for an entire hour as in the classroom when you are competing with entertainment platforms with enormous means of attraction. You are compelled to be as appealing as possible and this had an impact on the math popularization scene. Teaching then reached almost the same goals as popularizing:

- Democratize mathematics;
- Set a healthier relationship with mathematics;
- Raise performance in math education;
- Share math beauty, power and pervasiveness;
- Justify taxpayer's money in research and education.

2. Activity Overview

The Topic Study Group gathered 30 people, authors of 11 papers and 1 poster that were presented during three sessions (Tab. 1).

Patrick Vennebush, University of Maryland, USA.

Tab. 1. The list of papers and poster presented

Paper and author(s)
Session 1
[1] Students make interactive exhibition experimental mathematics for the museum of entertaining sciences. ***Maria Shabanova*** *and Mariia Pavlova* (Russia).
[2] Mathcitymap — popularizing mathematics around the globe with maths trails and smartphone. *Iwan Gurjanow,* ***Joerg Zender****, and Matthias Ludwig* (Germany).
[3] Beyond the classroom and curriculum: the annual maths camp at Bahir Dar University, Ethiopia 2013 – 2019. ***Abdu Mohammed Seid****, Yismaw Abera Wassie, Danny Parsons, Haile Yedeg, and Assaye Walelign* (Ethiopia).
[4] Reconsidering the M in STEM: leaders' conceptions of mathematics to empower girls in gems clubs. *Rose Mbewe, Sue Ellen Richardson, and* **Lili Zhou** (USA).
Session 2
[5] Creating access to engaged views of mathematics and teaching through informal learning spaces. ***Lynn Liao Hodge*** (USA)*, Shande King, and Qintong Hu* (China).
[6] Increasing math appreciation using the upper levels of blooms taxonomy. ***Manmohan Kaur*** (USA).
[7] Math + Origami + Puzzles + Magic → the odds are always in favor of fun. ***Violeta Vasilevska*** (USA).
Session 3
[8] Some suggestions on school-based curriculum construction of mathematics culture for middle school. *Junfeng Ma and* ***Yaqiang Yan*** (China).
[9] Mathematical drama: a new form of popularization of mathematics at East China Normal University, China, 2012–2019. ***Xinyu Liu****, Pan Liu, and Jiachen Zou* (China).
[10] Mutual role of mathematics and culture. ***Abolfazl Rafiepour*** (Iran).
[11] Keeping Popularization of mathematics on track: formative assessment. *Elham Ebrahim Zadeh, Hasan Hoseinpoor,* **Einollah Shokrpourrodbari***, and Younes Karimi Fardinpour* (Iran).
[12] On the impact of popularization oriented assessment: creating excitement. ***Younes Karimi Fardinpour****, Akram Bagheri Gheibi, and Gahimeh Kolahdouz* (Iran).

In Session 1, Shabanova and Pavlova[1] presented the Museum of Entertaining Sciences where students made interactive experimental mathematics exhibitions. Joerg Zender et al.[2] introduced the concept of math trails using the MathcityMap system, a sort of mathematical tourism around the globe. Seid et al.[3] presented their annual math camps since 2013. Zhou et al.[4] empowered girls in STEM clubs with leaders' conceptions of mathematics.

In Session 2, Hodge et al.[5] experimented Informal Learning Spaces, for families and novice teachers to engage with mathematics. Kaur[6], from the Benedictine university, Vasilevska[7] gave an overview of various hands-on outreach programs that demonstrate the fun of math with origami, puzzles and magic that reconciliate students with their own abilities in math.

In Session 3, Yan and Ma[8], investigated how culture in mathematics can be infused into math curriculum at the level of middle school. Liu et al.[9] shared their experience of conducting theatrical popularization through grandiose mathematical drama. Abofazl Rafiepour[10] described how Iranian craftsmanship shows the interrelation between mathematics and culture. Finally, formative assessment was promoted as a way to keep mathematics popular by Shokrpourrodbari et al.[11] and exciting by Farinpour et al.[12].

3. Future Directions and Suggestions

There are many different ways of expressions that fall within popularization of mathematics:

1. Art and science (theater, films, visual arts);
2. Fixed, itinerant, and virtual exhibitions for museums, science centers or non-dedicated spaces. Science or mathematical festival or forums;
3. Competitions in mathematics and computer science Mathematical camps;
4. Contact with research mathematics and mathematicians;
5. Inquiry/research-based projects;
6. Math circles/math clubs;
7. Recreational mathematics;
8. New technologies (apps, websites, ...);
9. International exchanges.

Popularization addresses different audiences and target groups tackling unequal access issues, talent, motivation, gender, social, financial or geographical differences, educational opportunities between countries. We witnessed some of this diversity in this Topic Study Group, but common theoretical grounds to unite all these different views into one perspective still needs some work to be done. Let’s hope that next ICME will see such a vivid community share their enthusiasm for mathematics once again in the flesh.

Part VII

Discussion Groups

Discussion Group 1

70 Years' Development of School Mathematics Textbooks in China

The Working Team[1]

1. Theme and Description

The discussion group of "70 Years' Development of Mathematics Textbooks in Primary and Secondary Schools in China" aims to show colleagues around the world the development of Chinese mathematics textbooks, methods in school textbooks research, exploration on practical reform of textbooks, and understanding of mathematics and mathematics education.

2. Activity Overview

The chairs of the discussion group were Haidong Li and Xiaochuan Zhou. Group members included Jinsong Zhang, Lili Song and Guozhong Ding. All team members are from the Curriculum and Teaching Material Research Institute, People's Education Press.

We first discussed the theme "the development and characteristics of Chinese primary school mathematics textbooks" in two reports. The first one was *70 Years Development of Mathematics Textbooks in Primary Schools in China* delivered by Guozhong Ding. The report introduced the primary school mathematics textbooks of People's Education Edition in the past 70 years and summarized several characteristics in the textbooks and some experiences in the compiling and revising progress. Xiaochuan Zhou gave the second report with title *Mathematical Thoughts and Methods of Mathematics Textbooks in Primary Schools in China*. Zhou introduced the mathematical ideas and methods in the primary school mathematics textbooks of People's Education Edition.

---

[1] The working team:
Haidong Li, Curriculum and Teaching Materials Research Institute, People's Education Press, Beijing, China. E-mail: lhd@pep.com.cn
Xiaochuan Zhou, Curriculum and Teaching Materials Research Institute, People's Education Press, Beijing, China. E-mail: zhouxc@pep.com.cn
Jinsong Zhang, Curriculum and Teaching Materials Research Institute, People's Education Press, Beijing, China. E-mail: zhangjs@pep.com.cn
Guozhong Ding, Curriculum and Teaching Materials Research Institute, People's Education Press, Beijing, China. E-mail: dgz@pep.com.cn
Lili Song, Curriculum and Teaching Materials Research Institute, People's Education Press, Beijing, China. E-mail: songll@pep.com.cn

We then showed attendees the development and characteristics of Chinese secondary school mathematics textbooks. To begin with, Haidong Li carried out a report titled *Reform and Development of Chinese Secondary School Mathematics Textbooks in the 21st Century.* Li especially introduced the reform and development of Chinese secondary school mathematics textbooks in the past 20 years, summarized and illustrated the characteristics on secondary school mathematics textbooks of People's Education Edition. Secondly, Jinsong Zhang gave a talk on title *Information Technology and Mathematics Teaching Materials*. Zhang analyzed the purpose, function, methods and effects of integrating information technology into mathematics teaching materials in China. Furthermore, he introduced the interesting cases of information technology integration in secondary school mathematics textbooks of People's Education Edition. Lili Song gave a talk on *Mathematical Culture in Secondary School Mathematics Textbooks*. Song firstly gave an overview of the mathematical culture in various mathematics textbooks, followed by focusing the selection and presentation of mathematical culture materials in secondary school mathematics textbooks of People's Education Edition. She ended up her speech with the theory and practice experience on integration of mathematical culture materials with mathematical contents.

The above five lectures, concerning mathematics textbooks in primary and secondary schools, not only introduced the historical evolution but also the characteristics of mathematical thinking and methods, information technology, mathematical culture throughout the past seventy years of development of Chinese mathematics textbooks.

3. Future Directions and Suggestions

In summary, the following points should be paid attention to in the construction of mathematics textbooks in the future: to strengthen the research paradigm of mathematics textbooks, to promote the quality of mathematics textbooks with more standardized scientific research methods, and to further strengthen the international exchanges in the compilation and research of mathematics textbooks.

https://doi.org/10.1142/9789811287152_0088

Discussion Group 2

The Future of Mathematics Education Research: A Discussion Group

Arthur Bakker[1] and Jinfa Cai[2]

ABSTRACT With help of a review study by Inglis and Foster published in *Journal for Research in Mathematics Education*, Jinfa Cai summarized trends in the past 50 years of mathematics education research. Next, Arthur Bakker presented a recent survey published in *Educational Studies in Mathematics* about the future of mathematics education research. Anna Sfard compared this survey with an earlier survey for ICMI. The presentations were discussed in the whole group, after which Jill Adler highlighted a few points she considered relevant.

Keywords: Mathematics education research; ESM; JRME; Research into practice; Online teaching and assessment.

1. Theme and Description

Mathematics education research as a discipline has been celebrating several milestones. One example is that *Educational Studies in Mathematics (ESM)* and *Journal for Research in Mathematics Education (JRME)* have recently celebrated their 50th anniversaries. Fifty years is a small step for human history but a giant leap for mathematics education research journals. To mark this auspicious occasion, this Discussion Group has focused on the future of mathematics education research.

We have used an international survey — conducted before and during the pandemic — as the basis of the discussion (Bakker et al., 2021). The survey is based on one single question before the pandemic (2019): *On what themes should research in mathematics education focus in the coming decade? During the pandemic (November 2020), we asked respondents: Has the pandemic changed your view on the themes of mathematics education research for the coming decade? If so, how?* We have reported the survey results and also provided a list of research challenges that are informed by the themes and respondents' reflections on mathematics education research (Bakker et al., 2021). In particular, we discussed the impact of the pandemic on the shape of mathematics education and mathematics education research, including increased attention to issues such as online assessment and pedagogical considerations for virtual teaching.

2. Activity Overview

Due to pandemic, the DG was organized both in person and online. On the basis of Inglis and Foster (2018), Jinfa Cai started the DG. Inglis and Foster (2018) analyzed the full text of all articles published in *ESM* and *JRME* (up to 2015). Jinfa Cai quoted the major findings from their analysis, and showed the social turn in mathematics education research. Jinfa Cai has also pointed out the decline of experimental studies in the past two decades in both mathematics education journals. The findings from Inglis and Foster (2018) served as a basis for looking into the future for mathematics education research.

Then, Arthur Bakker reported the results from an international survey (Bakker et al., 2021). The responses from 2019 were summarized in nine themes: (1) Approaches to teaching, (2) Goals of mathematics education, (3) Relation of mathematics education to other practices, (4) Teacher professional development, (5) Technology, (6) Equity, diversity, and inclusion, (7) Affect, (8) Assessment, and (9) Mathematics education research itself. In relation to the pandemic, most respondents considered the importance of their themes to be reinforced. Only few extra themes were added in the 2020 round of the survey. One question raised was whether new theories were needed due to the drastically new situation of large scale emergency remote teaching and online learning.

In 2005, Sfard published results from a survey result on Relations between Mathematics Education Research and Practice. Scholars were invited to reflect on the question of how research has been informing the practice of mathematics education over the last decade. Anna Sfard summarized the findings from the survey and discussed the survey results from Bakker et al. (2021) in terms of teaching, theories, and technology.

The DG were then divided into two groups: one in person led by Jiushi Zhou and one online led by Arthur Bakker and Jinfa Cai. The DG addressed several points, after which Jill Adler addressed the question of what ICMI can learn from the various studies and comments. One point discussed by Adler was the tension between identifying inequity or injustice on the one hand and perpetuating it on the other. For example, it is useful to know about so-called achievement gaps between various student groups to be able to improve education for lower scoring students. However, objectification of differences in terms of gaps can also have negative effects such as reinforcing existing stereotypes (Akkerman et al., 2021). For example, in Sweden Svensson et al. (2014) observed that immigrant parents believed they could never help their children as well as Swedish parents. How do we point to problematic differences in terms of for example gender, race, or ethnicity, without perpetuating the problem? We elaborate on a few directions and suggestions in the following section.

3. Future Directions and Suggestions

The results from the discussion could be summarized into the following three future directions and suggestions. The first is to increase the international collaboration.

While there is an increased international collaboration in the past a few decades, continuous effort is need. Bakker et al. (2021) reported the limitations of their survey:

> The survey results are limited in two ways. The set of respondents to the survey is probably not representative of all mathematics education researchers in the world. In that regard, perhaps scholars in each country could use the same survey questions to survey representative samples within each country to understand how the scholars in that country view future research with respect to regional needs. The second limitation is related to the fact that mathematics education is a very culturally dependent field. Cultural differences in the teaching and learning of mathematics are well documented. Given the small numbers of responses from some continents, we did not break down the analysis for regional comparison. Representative samples from each country would help us see how scholars from different countries view research in mathematics education; they will add another layer of insights about mathematics education research to complement the results of the survey presented here (p. 19).

Through future international collaboration, scholars from different countries can zoom into the critical issues for future research in mathematics education. One theme where we noticed differences in focus was that of equity and justice (commonly mentioned by respondents from North and South America) and diversity and inclusion (more commonly used terms in some other continents).

The second is to improve the contribution of research to educational practice. Both ESM and JRME were founded with a charge to disseminate significant research to improve educational practice in mathematics. Impact of research on practice is a longstanding issue (Cai et al., 2017; Sfard, 2005), and there is discussion whether it is wise to think in terms of impact (Akkerman et al., 2021; Fielding, 2003). Yet participants recognized the continued effort for connecting research and education practices. The participants discussed three possible strategies to make progress of improving the relevance of research to practice: (1) Identify and understand the fundamental reasons for the divide between research and practice in different countries; (2) Identifying successful teaching practice informed by research in different countries; and (3) Examine the successful teacher-researcher partnership in various countries.

The third is to capitalize on aspects of technology for research and practice in mathematics education. Because of the pandemic, lessons have been delivered online and assessments have been conducted online as well. The participants particularly discussed the three issues mentioned in Bakker et al. (2021): (1) The importance of studying the use and influence of low-tech resources in mathematics education such as podcasts, radio, WhatsApp, or WeChat; (2) The need to systematically investigate any possible effect of administering assessments online as researchers have found a differential effect of online assessment versus paper-and-pencil assessment; and (3) The need to rethink social interactions between students and/or teachers in online settings but also study how to engage and motivate students in online settings.

4. Summary

In this changing world, the only thing does not change is change itself. As a discipline mathematics education research is maturing, we need to continuously make efforts for looking into the future: What do we need now and in the future? Akkerman et al. (2021) propose to focus on actuality and generativity. Thus, when the discussion of the future of mathematics education research continues, encouraging and supporting high-quality research that makes a difference for practitioners also continues!

Discussion Group 3

Capacity and Network Projects: Sustainability and Future Directions

The Working Team[1]

1. Short Description of the Discussion Group

This discussion group will be attractive to congress participants interested in creating networks and communities of practice in challenging and disadvantaged education contexts. Discussion will focus on the Capacity and Network Projects (CANP) of the International Commission of Mathematical Instruction (ICMI) supported by the International Mathematical Union (IMU), UNESCO and the International Council of Scientific Unions (ICSU) as well as regional governments and institutions.

Five CANPs have been organised so far. While each CANP differs in its focus, approach and process the goal is to respond to the challenges in mathematics education that have been documented among other reports in UNESCO 2011. The aims of the Discussion Group at ICME-14 include identifying, sharing and discussing common key issues in creating a critical mass to sustain the network and its activities over long term. Through sharing cross-national regional experiences, we expect to deepen and broaden the understanding of lessons learnt in the process of establishing the CANP and taking it forward.

Discussions will be guided by the following key questions:

- What did the CANP do in 2020? How (if at) were your activities impacted by the pandemic? (Focus on one or two innovations/activities).
- What is planned for the CANP in 2021? Why?
- What new questions arise for the mathematics education community?
- What are the similarities and differences in the opportunities and challenges arising in the CANPs?
- What is the impact of CANP on mathematics education in the region? how could the impact be sustained?

---

Chair: Anjum Halai, Aga Khan University Pakistan
Team members:
Moustapha Sokhna & Mamadou Sangare (CANP1)
Yuri Morales and Nelly Leon (CANP2)
Maitree, Khamla and Vu Nhu Thu (CANP3)
Alphonse Uworwabayeho and Veronica Sarungi (CANP4)
Augusta, Gabriela and Maria del Carmen Bonilla Tumialan (CANP5)

2. Planned Structure:

Session I — 90 minutes

Planned timeline	Planned activity	Working format /Responsible person
10 minutes	Introductions	ALL
5 minutes	Purpose of CANP	Chair
50 minutes	Presentation by each CANP (10 minutes each)	Representative of each CANP
25 minutes	Discussion	ALL

Session II — 90 minutes

Planned timeline	Planned activity	Working format /Responsible person
45 minutes	Identifying similarity and differences in opportunities and challenges in CANPs across regions and countries	Small groups working on strategies to build on the opportunities and to address the challenges
30 minutes	Report to the whole group on the small group activity	Representative from each group
10 minutes	Identifying ways forward	Representative of each CANP
5 minutes	Closing	Chair

Discussion Group 4

Revisiting Shulman's Notion of Pedagogical Reasoning: Looking Back and Looking Forward

Ban Heng Choy[1], Jaguthsing Dindyal[1], and Joseph Boon Wooi Yeo[1]

ABSTRACT Pedagogical reasoning is not a new concept. More than three decades ago, Shulman (1987) expounded this idea in his seminal paper, well known for its elaboration of pedagogical content knowledge (PCK). Although the notion of PCK has been quite well-understood, the notion of pedagogical reasoning is still under-theorised. Yet, pedagogical reasoning has been seen as an important component of teaching expertise. If teaching actions are based on pedagogical reasoning, then how do we enhance the pedagogical reasoning of teachers to improve teaching? Or more fundamentally, is there a need to reinterpret the components of pedagogical reasoning in the light of the current contexts of teaching and learning? In this Discussion Group, we discussed these questions. More specifically, we critiqued this construct and proposed possible modifications to the framework of pedagogical reasoning. In addition, we also discussed the issues and challenges related to the development of teachers' pedagogical reasoning.

Keywords: Pedagogical reasoning; Teacher noticing; Resources, orientations, and goals.

1. Looking Back at Shulman's Pedagogical Reasoning and Action

Pedagogical reasoning is not a new concept. More than three decades ago, Shulman (1987) expounded this idea in his seminal paper, well known for its elaboration of pedagogical content knowledge (PCK). Following Shulman (1987), teaching begins as an act of reason and continues as a process of reasoning. He also added that pedagogical reasoning forms the basis for all actions by the teacher. In his model for pedagogical reasoning and action, Shulman proposed that teaching begins with the act of comprehending what must be taught, followed by the transformation of that knowledge for teaching the students, which is followed by actual instruction, and an evaluation of the students' learning. Finally, teachers engage in reflections, which may lead to new comprehensions by the teacher. Although the notion of PCK has been quite well-understood, the notion of pedagogical reasoning is still under-theorised (Loughran et al., 2016). Yet, pedagogical reasoning has been seen as an important component of teaching expertise (Choy, 2016). If teaching actions are based on pedagogical reasoning, then how do we enhance the pedagogical reasoning of teachers to improve teaching? Or more fundamentally, is there a need to reinterpret the

[1] Mathematics and Mathematics Education, National Institute of Education, Nanyang Technological University, Singapore. E-mail: banheng.choy@nie.edu.sg

components of pedagogical reasoning in the light of the current contexts of teaching and learning?

As Shulman (1987) had highlighted, new comprehension does not necessarily follow through from reflection. Hence, we argue that new comprehension of content, student learning, and teaching actions occurs when a teacher has a shift of attention, gaining awareness of new possibilities in teaching and learning (Mason, 2002), or simply when a teacher notice critical aspects of teaching and learning (Choy, 2016). These new insights expand the teacher's current cluster of resources, orientations, and goals (Schoenfeld, 2011; Thomas and Yoon, 2013), which in turn becomes the base from which the teacher make sense of instruction. Moreover, as Choy (2016) has highlighted, productive noticing can take place during planning, instruction, and reviewing of lessons. Consequently, new comprehension can occur during any of the activities of Shulman's model of pedagogical reasoning and action.

Building on ideas from both Shulman (1987) and (Schoenfeld, 2011), we adapted Shulman's model of pedagogical reasoning and action to highlight the dialogic processes involved when teacher notices critical aspects of instruction (Choy, 2016) in order to learn from their own teaching as shown in Fig. 1.

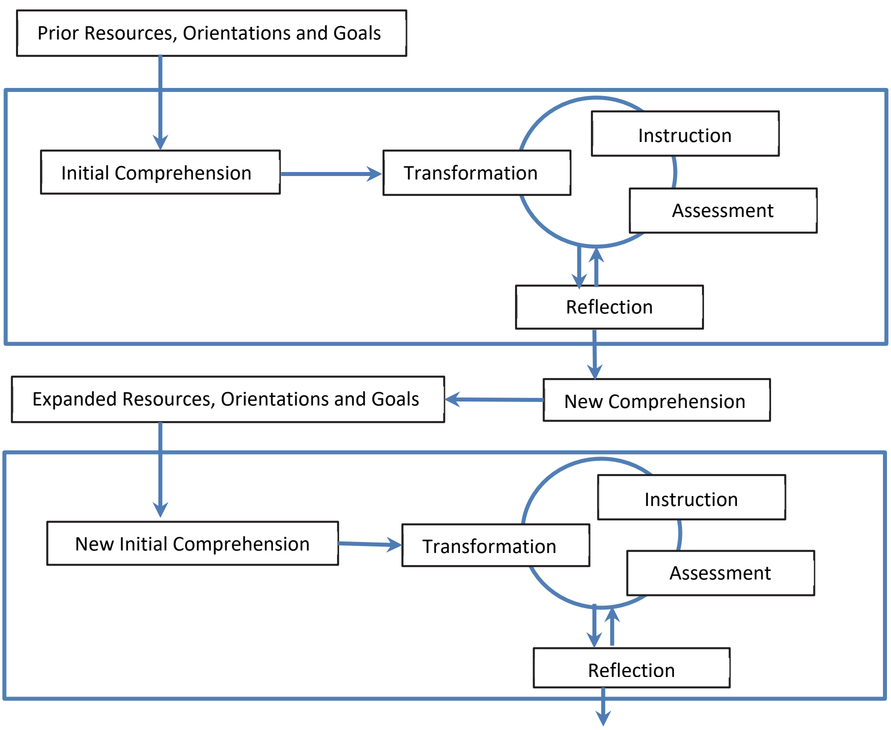

Fig. 1. Adapted model of pedagogical reasoning and action

2. Key Questions About Pedagogical Reasoning and Action

In our discussion group, we got the participants to comment and critique our proposed model, which was developed as part of a larger project. The planned questions and planned activities for the session was summarized in Tab. 1 as shown. However, due to time constraints and the feasibility of discussion, we mainly focused on getting feedback on our proposed model and discussed issues and challenges related to enhancing teachers' pedagogical reasoning. Last but not least, we also briefly discussed the possibility of future collaboration on research related to pedagogical reasoning.

3. Discussion and the Way Forward

To summarize the discussion, participants generally agree that the model strongly resembles what a teacher goes through on a day-to-day basis, and this affords a way to model the teaching activities, while simultaneously focusing on the pedagogical reasoning aspects of a teacher's instructional decisions. Taken as a whole, this model could potentially provide a fine-grained analysis of a teacher's pedagogical reasoning and instructional decisions. It gives a dynamic model of a teacher's pedagogical reasoning and action, which can be used to characterize one's teaching and make teaching more learnable.

Tab. 1. Overview of the planned discussion group activities

Planned timeline	Planned activity	Description
10 minutes	What is pedagogical reasoning and action?	The organisers facilitated the introduction of the participants of this DG and present the key ideas needed in this DG.
20 minutes	What are the components of pedagogical reasoning and what are the roles of each component in teacher education and professional development? What can we say about its relationship to Shulman's notion of pedagogical reasoning?	The participants worked in groups to critique one of the following components: Comprehension, Transformation, Instruction, Evaluation, Reflection, and New Comprehension.
30 minutes		The participants presented their critique and suggest ideas to modify/enhance/clarify the notion of pedagogical reasoning.
10 minutes	What are some issues and challenges with enhancing teachers' pedagogical reasoning?	The organisers summarised the ideas shared by the participants and led a discussion on the issues and challenges.
10 minutes	How can we move forward in our endeavor to enhance teachers' pedagogical reasoning?	The organisers summarised the ideas and discussion to set up possible collaboration opportunities in the future.
10 minutes	Summary and Closing	

However, several issues remain. First, the "individual" components, such as transformation and comprehension, are still perceived as "black boxes". For instance, how do teachers comprehend the materials they need to teach? How do they transform their knowledge into instructional materials? How does their intended design of instructional materials get enacted in the classrooms during instruction? Next, the link between reflection and new comprehension is currently still tenuous. When does a teacher's reflection lead to new comprehension, and why does it not? The mechanisms are perceived to be complex but critical for teacher educators to understand in order to facilitate professional learning. We suspect that teacher noticing (Dindyal et al., 2021; Schack et al., 2017; Sherin et al., 2011) is a useful construct to consider, and in particular, the notion of productive teacher noticing (Choy, 2016; Choy and Dindyal, 2019, 2021) may be helpful for us to understand when reflection leads to new comprehension. Although we do not have any answers to our questions, this discussion group has opened new possibilities for future collaboration and discussion as we continue, as a mathematics education community, to unpack the complexities of teaching practices so that they can be learnable for teachers.

Acknowledgments

The ideas for this discussion group came from a study funded by Singapore Ministry of Education (MOE) under the MOE Academy Fund Programme (AFD 06/17 CBH) and administered by National Institute of Education (NIE), Nanyang Technological University, Singapore. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the author(s) and do not necessarily reflect the views of the Singapore MOE and NIE.

Discussion Group 5

Roles for Mathematicians in Math Education

Solomon Friedberg[1], Patricio Felmer[2], Carlos Kenig[3], JongHae Keum[4], and Jürg Kramer[5]

ABSTRACT This is a report on the ICME-14 Discussion Group entitled "Roles for Mathematicians in Math Education." The discussion took place on July 14, 2021.

Keywords: Mathematicians in math education; Pre-service teachers; In-service teachers; Math education policy; Advocacy for math education.

1. Theme and Description

Mathematicians have played an important role in K-12 math education for many years; for example, mathematicians Felix Klein (the first President of ICMI), Hans Freudenthal, and Georg Pólya have contributed fundamentally. The roles of mathematicians in K-12 math education today are diverse. They include the training of future teachers in the university, the support of in-service teachers (e.g. helping to promote their on-going engagement with mathematics), roles in public policy such as writing or reviewing K-12 math standards and ensuring that there is a close articulation between pre-collegiate math and university-level math, and roles in advocacy for math education. The mathematicians involved in these efforts have a strong professional connection to the work of K-12 math education.

The goal of this discussion group was to take stock of ways that mathematicians are presently contributing to pre-collegiate math education. We also sought to consider what mathematicians can add to the field of math education *as mathematicians* with their specific training and perspectives, and among these, which contributions by mathematicians are the most important. We noted that in the present landscape, with the emergence of many specialists in education and math education, sometimes grounded in other disciplines, there are other voices and other perspectives regarding

math education, and that this diversity of perspectives presents both a challenge and an opportunity. We asked what experiences and structures would be most useful in promoting future cooperation among the different professionals involved in mathematics education and in enabling contributions by mathematicians.

2. Activity Overview

The 90-minute discussion was divided into four roughly equal parts, with the following themes.

- Mathematicians and pre-service teachers
- Mathematicians and in-service teachers
- Mathematicians and mathematics education policy
- Connecting mathematicians and mathematics educators going forward: roles, opportunities, obstacles and potential pathways.

For each part, we posed a series of questions and asked those in attendance to respond. We noted that math education in different countries is organized in different ways, and we welcomed explanations about how it is organized in a specific country and how that affects possible roles for mathematicians in that country.

For Mathematicians and Pre-Service Teachers, the questions were:

- How are mathematicians involved in the preparation of future teachers in your country or region?
- How can the preparation of future teachers in your country or region be improved? What roles can mathematicians play in this? How does their expertise as mathematicians affect these roles?
- Research in math education shows the importance of MKT, mathematical knowledge for teaching. How can mathematicians learn about and support the development of MKT in future teachers?

For Mathematicians and In-Service Teachers, the questions were:

- What is the context in your country for interactions between mathematicians and in-service teachers?
- What roles have mathematicians in your country or region played in the support of in-service teachers? How does their expertise as mathematicians affect these roles?
- Please give specific examples that might be models for others to use.
- What have you learned from these examples? What are best practices for such involvement?

For Mathematicians and Mathematics Education Policy, the questions were:

- How have mathematicians been involved in math education policy in your country or region?
- What has gone right in this involvement, and what could be improved?
- How do the goals of mathematicians in math education policy compare to the goals of other math education professionals in your country or region?

For Connecting Mathematicians and Math Educators in the Future, the questions were:

- What are the most important opportunities or roles? What are possibilities for future engagement?
- What are potential pathways for such engagement in your country? In your region? Worldwide?
- What are lessons learned from past engagement that it would be valuable to keep in mind?
- What role can mathematicians play in math education research?
- How can mathematicians assist, regionally or worldwide, in the domain of math education?

The discussion took place in hybrid format, and was fast-paced and energetic.

3. Future Directions and Suggestions

The involvement of mathematicians in K-12 math education is an important topic, and there is considerable experience with such involvement and also variation in the nature of such involvement worldwide. We hope that the discussion here will serve as a catalyst for more extended interactions in the future. We believe that the thoughtful and sustained involvement by more mathematicians in K-12 math education could be a source of improvements to math education and of support for pre-collegiate math educators.

Discussion Group 6

Variations and Series of Tasks, Crossing the Approaches

Katalin Gosztonyi[1], Charlotte de Varent[2], and Luxizi Zhang[3]

1. Description: Organizers, Aims and Underlying Ideas

This discussion group aimed to extend a discussion led by some young researchers from four different countries for some years about variations and series of tasks. Katalin Gosztonyi wrote her PhD (2015) on the comparison of the Hungarian reform of mathematics education led by Varga (pointing out the importance of structuring problems in series and networks) and the French "mathématiques modernes" reform. Charlotte de Varent, wrote her PhD (2018) on the reciprocal contributions of history of mathematics and didactics to each other. One aspect of her PhD was to point out the importance of small numerical variations in Mesopotamian scholarly context. Luxizi Zhang is working on her PhD (Zhang, 2020) towards an analytic model of "teaching mathematics through variation" from the analysis of teachers' documentation work (Gueudet and Trouche, 2009) in China and France, making profit of the variation theory (Gu et al., 2004) and the notion of didactic variable in the theory of didactical situations (Brousseau, 2002).

We entered variation as sequencing and networking tasks and problems. The "variation perspective" appears as an important issue in various traditions of mathematics education, and at the core of teachers' documentation work. International discussions have been launched on this topic for some years. (In our group, there were meetings such as) the "Series of problems" interdisciplinary historical research project (2012–2019) (Bernard 2015), the first (2018, Budapest) and the second (2019 Lyon) "Variations and series of problems" workshop, and the Varga100 conference (2019 Budapest, https://varga100.sciencesconf.org/). The aim of these discussions was to confront different apparitions of this "variation perspective" emerging in different cultural contexts. We would like to advance towards the elaboration of a common model, or a diversity of models, allowing on one hand to develop analytical tools for researchers, and on the other hand to support teachers' design work. We considered the ICME-14, in the country of the Chinese "variations method" and thanks to the

diversity of the conference's public, a particularly well adapted context for the continuation of this collective work.

2. Activity Overview (Tab. 1)

Tab. 1. 21h30 - 23h, 14th July, 2021

Timeline	Activity	Working format /Responsible person
10 min	Introduction	The coordinators, plenary
20 min	Presentation of the Chinese, Hungarian and French handouts	L. Zhang, K. Gosztonyi plenary
15 min	Analyzing the data, extracting principles with special focus on the structure of the task sequences. Comparing to the participants' teaching traditions	Participants work on the handouts individually
35 min	Sharing the results	Collective discussion
10 min	General conclusions and potential plans for further research	The coordinators, plenary

In addition, a video recorded by Alessandro Ramploud on "Italian adaptation of the Chinese variation" was shared with participants.

3. Questions on Variations Discussed during the DG:

This discussion group aims to extend a discussion on variation activities considered as sequencing and networking tasks and problems. The aim of these discussions was to confront different implementations of this 'variation perspective' emerging in different cultural contexts.

The discussion raised several issues concerning the perspective of variation through this international meeting of traditions on variation studies.

First, participants recalled the difficulty and necessity of classifying varied sets of exercises or problems among different criteria. The discussion started from the question that each participant approaches with his own framework: how to define the variations/how to describe their structure? Underlying questions were asked during the discussion:

1. Do we categorize the series in terms of educational objectives? In terms of expected or resulting effects? In terms of potential/realized interactions? Do we describe them in terms of variation, and/or in terms of problems and numbers used? The possibility of targeting procedural or conceptual variations in problem design was recalled.

Second, participants discussed the description of the tasks given to students in relation to the series, as well as the description of the instrumental context:

2. Are the tasks close together or far apart? How much time is given to the students? How do they interact with the material? Can students also vary the problems? Is the teacher taken into account as a variable and how?

Third, the participants recall that the study is also situated in the present of the teaching situation, they question the existence of interactive variations.

3. Are there also interactive variations, in the classroom, in the moment, and if so, with a final goal in mind or not?

4. Future Directions and Suggestions

In the future, we aim to extend the discussion on variation activities considered as sequencing and networking tasks and problems. We plan to continue to confront different implementations of this 'variation perspective' emerging in different cultural contexts and to advance towards the elaboration of a common model, or a diversity of models. This confrontation seems to us important on the one hand for sharing and developing analytical tools for researchers, and on the other hand to support teachers' design work using variations.

Discussion Group 7

Mathematics Houses and Mathematics Museums Worldwide

The Working Team[1]

ABSTRACT After a fruitful Discussion Group at ICME-13 in Hamburg (Germany) and the establishment of an International Network of Mathematics Houses [INMH] in 2016 (Rejali, et al., 2017), we worked on the structure of the network and discussed cooperations between mathematics houses and mathematics museums worldwide. Enhancing mathematical awareness inside the communities and impact on mathematics education, as well as the challenges, were the aims of this second Discussion Group at ICME-14.

1. Aims

The Discussion Group aims were to introduce Mathematics Houses and Mathematics Museums and similar institutions throughout the world to a public audience and discuss their importance and effect on mathematics education.

They can foster connections and discuss the important impact of promoting teamwork among the members, as well as seeking new ways to cooperate and exchange the successful experiences as well as their particular activities. They can present studies about their programs and discuss the challenges as well. Finally, they can build an official partnership network and announce it to the greater public.

2. Agenda

The agenda was discussions about the following questions in detail:

1. What are the benefits of such institutes for popularizing mathematics and improving mathematics education?

---

[1] The working team:

- Albrecht Beutelspacher, Jestus-Liebig-University Giessen and Mathematikum, Giessen, Germany. E-mail: albrecht.beutelspacher@mathematikum.de
- Christian Mercat, Lyon House for Mathematics and Informatics, Lyon, France. E-mail: christian.mercat@gmail.com
- Ali Rejali, Isfahan University of Technology and Isfahan Mathematics House, Isfahan, Iran. E-mail: a_rejali@iut.ac.ir
- Abolfazl Rafiepour, Shahid Bahonar University of Kerman and Kerma Mathematics House, Kerman, Iran. E-mail: rafiepour@uk.ac.ir
- Yahya Tabesh, Sharif University of Technology, Tehran, Iran. E-mail: yahya.tabesh@gmail.com

2. What are the other roles of Mathematics Houses and Mathematics Museums for the society
3. What are the challenges they face?
4. How can mathematics institutions share activities and cooperate with each other?
5. How can their members benefit from other institutes in other parts of the world?
6. What are the effects of these institutes in mathematics education in the region around these institutes?
7. What is the network [INMH] and what could be its role and what kind of structure would be needed?

3. Discussions

The Discussion Group started with a short welcome statement by Ali Rejali, followed by introducing the Museums of Mathematics by Albrecht Beutelspacher (https://www.mathematikum.de), then Yahya Tabesh discussed the Opportunities for Innovative Multidisciplinary Learning at Mathematics Houses. Albrecht Beutelspacher was the next speaker, who discussed the other roles of Mathematics Houses and Mathematics Museums for the Society.

Abolfazl Rafiepour discussed Challenges facing Mathematics Houses in Iran and also Christian Mercat introduced the French House of Mathematics and explained the challenges (https://prezi.com/p/gcpwtlpucdrg/?present=1), as well. After some discussion between the audience and the speakers, the last speaker was Ali Rejali who introduced his proposal on establishment of an affiliated study group to ICMI with the name of the International Network of Mathematics Houses and Mathematics Museums (INMH) and approved to set up a constitution for this international network.

4. Conclusion

Upon Rejali's proposal, establishment of the International Networks of Mathematics Houses and Mathematics Museum (INMH) as an affiliated study group to ICMI is on the agenda. A constitution will be conducted and will be submitted to ICMI.

Discussion Group 8

Non-University Tertiary Mathematics Education: An Emerging Field of Inquiry

The Working Team[1]

1. Description

The intent of the discussion group (DG) was to gather ICME-14 participants to engage in conversation about non-university tertiary mathematics education (NTME). Over past ICMEs, it has been a tradition to dialogue about educational matters unique to this area. Over time, with both advances, challenges, and opportunities in tertiary mathematics education, as well as increasing attention, it is apparent that NTME is becoming a critical branch of inquiry in mathematics education. Yet, compared to primary, secondary, and university education, historically NTME has received insufficient attention. Consequently, this DG was to provide an avenue to engage a wider group of mathematics educators, network, exchange ideas, and learn more about NTME practices around the world. The meaning of NTME as well as developing this area as a field of inquiry was explored.

2. Activity Overview

The topic was introduced by Kathryn Kozak. We spent the first 20-30 mins watching a short presentation on related practices in the US (presented by Jim Ham) and Europe (presented by Kees Hoogland). The remaining time was relegated to discussion questions, facilitated by David Tannor and Laura Watkins.

The following questions were discussed:

- What is NTME?
- Why should NTME be a field of inquiry? What is special about NTME to warrant inquiry? How does NTME relate (or is different from) to tertiary and secondary education?
- What are (or could be) some important aims of NTME?
- What is the nature of teaching, learning, and research of mathematics at the non-university tertiary level?
- What are some issues, challenges, and/or opportunities related to NTME?

---

[1]The working team:
- Organizers: David Tannor, Kellogg Community College, USA;
- Kathryn Kozak, Coconino Community College, USA;
- Laura Watkins, Glendale Community College, USA

- In light of ICME and our effort toward NTME as a field of inquiry, are we also globalizing (or internationalizing) this area? If so, what would it mean to globalize it? What are some implications/issues that we should be mindful of?

3. Future Directions and Suggestions

The name Non-University Tertiary Mathematics Education (NTME) was coined to aid in conversation about areas of post-secondary education that affect faculty and students unique to this group. It is not clear what exactly defines this group, yet it is understood that there are students and faculty who uniquely reflect this area, and in many ways are different from those typically at the university or secondary levels. Hence, overall discussions were mainly to begin conversation on exploring how to clearly define NTME. It was recognized that the current name has limitations. For example, it is not encompassing or inclusive. Notwithstanding, a model was suggested as a possible guide to examine this field: that is, what is it from students' perspectives; from the perspective staff, faculty, mathematicians, and mathematics educators; and from the viewpoint of society. Given the enormity of students this sector of post-secondary education serves, and an increasing interest to continue to examine mathematics educational matters that affect these students and faculty, DG participants believe NTME is worthy of serious study, and further consideration at future ICMEs either as a discussion group or topic study group.

Discussion Group 9

How do Movements of Bodies and Artifacts Emerge in Mathematics Education?

Anna Shvarts[1], Dor Abrahamson[2], Ricardo Nemirovsky[3], Nathalie Sinclair[4], and Candace Ann Walkington[5]

ABSTRACT The discussion group focused on embodied processes in mathematics teaching and learning. At this discussion group, we aimed to consider the origins of movements performed by students, teachers, and artifacts. We invited group participants to reflect on resources initiating bodily movement and on the agents who perform or share the movement from a theory of dynamic systems, a new-materialist perspective, phenomenological perspective, embodied cognitive science, and cultural-historical approach. We questioned when and how movements become recognized as mathematical activity and discourse; we also discussed the criteria in prompting students to act or suspend enactment and leave room for imagination and articulating prediction of the enactment.

Keywords: Embodiment; Gestures; Artifacts; Embodied collaboration; Theory of dynamic systems; New-materialism; Phenomenology; Embodied cognitive science; Cultural-historical approach.

1. Embodied Interaction: A Variety of Theoretical Perspectives

This discussion group was initiated by an international collective of researchers all concerned with embodied processes in mathematics teaching and learning. Operating from different perspectives that consider bodies as partaking in educational processes, we have been offering theoretical rethinkings of cognitive and affective processes in mathematical practices. Imagine a student who draws the graph of $y = x^2$ on grid paper. From a theory of dynamic systems that Abrahamson uses to argue for his embodied-design framework, this movement emerges as embodied adaptive coordinations in a complex dynamic system bearing agentive, environmental, and task constraints, such as figural features of the paper (Abrahamson and Sánchez — García, 2016). From a new-materialist perspective that Sinclar elaborates in the mathematics education field (de Freitas and Sinclair, 2014), an assemblage of the student with her capacities, the formula, and the paper with the virtual transformation that they imply is actualized towards the graph. From a phenomenological perspective, in which Nemirovsky was engaged for many years (Nemirovsky et al., 2013), objectification of

a formula includes protention and retention of its usage, where the subject joins both the intentional horizon of the paper and the retentional formula usage, in fulfilling her intentionality of drawing a graph by moving the hand along the paper. From an embodied cognitive science perspective that is within Walkington's expertise, movement is driven by cognitive processing of the formula that is extended beyond the scalp in a distributed system of activity that includes both explicit use of embodied resources and implicit embodied associations (Walkington et al., 2019). From a cultural–historical account, represented by Shvarts in the team (Shvarts and Abrahamson, 2019), the student's drawing is mediated by cultural artifacts — the paper and the formula — and expresses an ideal (cultural) form of action, which the student appropriated in a previous collaboration with a more knowledgeable other.

2. Discussion Group Aims and Proceedings

At this discussion group, we aimed to consider the origins of movements performed by students, teachers, and artifacts. We invited the group participants to reflect on resources initiating bodily movement and on the agents who perform or share the movement. We worked on articulating the difference between motion per se and agential movement as well as when and how movements become recognized as mathematical activity and discourse (language, diagrams, gestures).

The session started with an introduction of corresponding theoretical perspectives by each of the organizational team members and continued with discussions in small groups that each applied a chosen perspective to the analysis of a shared one-minute video fragment. This fragment was filmed in November 2006 at an Aboriginal Headstart Daycare in Ontario, Canada. It presented a 4-year-old child, who, in a collaboration with a teacher–researcher, for the first time used a digital application, TouchCounts (Jackiw and Sinclair, 2014), to explore the operation of addition. After diving into the video fragment from different theoretical perspectives and revealing various aspects of embodied interactions between a child, a technological artifact, and a teacher, we discussed our insights jointly at the plenary discussion. Thirty-two researchers from Australia, Brazil, Canada, Chile, Finland, France, Germany, Israel, Italy, the Netherlands, Peru, South Africa, Sweden, UK, and USA joined the conversation.

3. Outcomes and Future Directions

Discussions brought forth the complexity of explicating the sources of the child's mathematical expressions. Different theoretical perspectives highlighted the role of the artifact's design and the teacher's and student's bodily dynamics in triggering and shaping embodied actions. Mathematical expressions coincided with bodily gestures and poses, being indispensable from materially articulated embodied ideas. Despite exploring various theoretical focuses, participants working in different small groups repeatedly noticed that bodily imitation of the adult's gesture apparently guided the student's performance. Mathematically relevant gestures seemed to occur without strict top-down cognitive regulation based on pre-given knowledge, but as a spontaneous emergent dynamical event enabled by material constraints. Those material constraints included cultural guidance by the teacher through gestures and physical forming of the interactional space. The teacher carefully steered the child to alternate between actively manipulating the digital artifacts and suspending the manipulating to predict the artifact's feedback.

Overall, the discussion highlighted a complementarity of various perspectives that evoked different aspects of embodied interaction in mathematics learning, yet revealing a unified phenomenon rather than providing contradictory visions. Further research questions may concern the emergence of a student's awareness of her mathematical expression and the role and form of pre-knowledge in shaping embodied expressions. When and how does a student come to know their own embodied ideas as mathematical? Another direction of future research might focus on the issue of engaging in physical manipulation versus suspending actual manipulation to form anticipation of the feedback from the (technological) environment. What is the potential of embodied theories in explaining mathematical thinking without direct physical enactment? A final direction concerns the political implications of new ways of sensing/making sense in mathematics, such as the visual and the haptic, and how they remain subordinate to the alphanumerical (language and symbols).

The work of this discussion group will be continued at annual and local conferences, such as the Congress of the European Society for Research in Mathematics Education (CERME) and the annual conference of the International Group for the Psychology of Mathematics Education (PME).

Discussion Group 10

Computational and Algorithmic Thinking, Programming, and Coding in the School Mathematics Curriculum: Sharing Ideas and Implications for Practice

Max Stephens[1], Djordje M. Kadijevich[2], Qinqiong Zhang[3], and Haozhe Jiang[4]

ABSTRACT Computational/algorithmic thinking, programming, and coding are emerging areas of importance for mathematics thinking and are increasingly being located in the school mathematics curriculum in countries worldwide. This Discussion Group provided an opportunity to examine these international trends for curriculum, and teaching — in the compulsory years of schooling and in the senior high school years — and the need for appropriate policy responses.

Keywords: Computational thinking; Algorithmic thinking; National curriculum changes; Teaching activities; resources; Policy development.

1. Activity Overview

Participation in this DG involved more than 80 scholars/teachers online and offline.

Prior to the ICME14 Conference a website had been set up by one of the coordinators on which contributions to the discussion from more than twelve people had been pre-posted. Two contributions had been posted by members of the host East China Normal University. One prepared by Haozhe Jiang and Xiaoqin Wang described the current state of readiness among Chinese teachers to introduce computational thinking into their teaching using a PowerPoint in English and Chinese. A second contribution by Han Su — Algorithmic thinking in high school mathematics — An instructional design using the Babylonian method — was made available to participants through the website. Other pre-posted inputs to the DG1 are presented in Table 1 below and provided a structure for the discussion group.

Format: Discussion Group 1 had three components:

1. Selective survey of national curriculum documents
2. Presenting some classroom/teaching activities
3. Identifying some resources to support teachers

Materials for the DG are shown in Tab. 1. For more details see: https://protect-au.mimecast.com/s/q4rSCP7yBls45kKYkSzers7?domain=afrodita.rcub.bg.ac.rs

Tab. 1. Materials for this DG

National Curriculum Documents	Classroom/Teaching Activities	Resources to Support Teachers
Argentina Australia Canada (BC), Coding & CT Canada (O) China England (primary) England (secondary) France Japan South Africa USA	D. Symons and M. Stephens, Australia, Number patterns S. Sardina and M. Stephens, Australia, Sorting activities H. Su, China, AT in high school Q. Zhang and S. C. Wang, China, Sorting + game J. Lu, China, Learning trajectory	Sadosky Foundation, Argentina IDSSP Framework Canada (BC), CT materials: Lighthouse labs, Student sheets, Competencies, Units1&2 W. S. Chang, China D. M. Kadijevich & A. Zakelj, Serbia & Slovenia

2. **National Curriculum Documents** (Coordinated by Max Stephens)

Comments and outputs. The earliest published of the above documents is the English national curriculum published in 2013. Other documents are all relatively recent, giving specific advice for involving computational thinking in the school mathematics programs. What is unknown is the state of readiness of teachers in these countries to undertake specific provisions for teaching computational thinking in their classrooms.

Many countries already have courses for computing, programming, applied computing and algorithmics in the senior high school years providing a transition to university courses in computing and related sciences. The above survey of national documents is focused on the compulsory years of schooling.

Some countries, such as Singapore actively promote computational thinking and algorithmics through intensive teacher development and pilot school programs. There is evidence of a similar trend in China where local educational authorities encourage suitably equipped local schools to implement coding and programming.

Other countries such as Finland have chosen to adopt programming (algorithmics) across different subjects in the school curriculum. Integrated models are not shown is in the official documents above; nor are out-of-school providers that offer weekend courses and study clubs for students in coding and programming in many countries.

Summary. Computational thinking is an emerging and important element of basic education in the national curricula of many countries as shown in Tab. 1. This reflects the prevalence of CT in our social, economic, and scientific environments.

3. **Three Classroom/Teaching Activities** (Coordinated by Qinqiong Zhang and Max Stephens)

Elaborations of these teaching activities are available on the website mentioned above.

3.1. Qinqiong Zhang and Shengchang Wang (Wenzhou University):

This lesson — involving a sorting game for the upper primary school — focused on helping students perceive the different ways to solve a problem through a simulated activity and preliminarily understand computational thinking.

3.2. Duncan Symons and Max Stephens (The University of Melbourne):

How computational/ algorithmic thinking can enrich students' mathematical thinking: Applications of Scratch in number, patterns and geometry in the middle years.

3.3. Sebastian Sardina (RMIT University Melbourne) and Max Stephens (The University of Melbourne):

Five approaches to number sorting activities – where computational thinking is contrasted with human thinking. The YouTube video can be viewed on https://youtu.be/q1TSnkEcQKM An enactment of Bubble sort as shown in the Bubble Sort video: https://www.youtube.com/watch?v=glgnCcjgpek, and also in the general website https://www.cs4all.org/

Comments and outputs. These teaching activities displayed key elements of CT: decomposition, abstraction, pattern recognition, algorithm building and generalization.

4. **Resources to Support Teachers** (Coordinated by Djordje M. Kadijevich)

Comments and outputs. This third component pointed to several resources that may support teachers' professional development and day-to-day teaching activities. These materials are shown in Tab. 1. If we view curriculum as a six-component vector whose dimensions are: goals, content, materials, forms of teaching, student activities, and assessment (Niss, 2016), developing and using good resources to support learning, teaching, and assessments are central issues. The discussion focused on two questions:

1. Are there suitable resources to support teachers' work regarding CT Integration?
2. Are mathematics teachers prepared/equipped to implement this integration?

Preliminary findings revealed that resources rarely focus on CT integration in mathematics. To examine some promising examples, use the hyperlink under Tab. 1. It was also found that various math-related learning activities (not only programming; see Weintrop et al, 2016), comprising and connecting CT stages, are not treated explicitly. In contrast to teachers of informatics, mathematics teachers are reported to have less knowledge and skills to apply CT integration and thus practice CT in their subjects less often (Slovenia). Furthermore, it is usually left to teachers to apply CT key components presented in workshops in subjects they teach (Slovenia, Canada (BC)). These issues generate huge challenges for teacher professional learning.

Summary. The inclusion of CT/AT in school mathematics will entail the search for/presentation of/development of good resources to support work in the classroom. These resources, which aimed at mathematics learning, should include various learning activities. In using resources teachers would not be left to themselves; teacher professional development should support them to do so in effective ways.

5. Future Directions and Suggestions

These elements that are further discussed in Stephens, Goos and Kadijevich (2023):

- *Realize the importance of CT.* Computational thinking is now omnipresent in the sciences, in data analytics and forecasting.
- *Use CT related resources.* Most resources will be on digital platforms, but some activities at all stages of schooling will be *computer-less* or *unplugged*.
- *Resources* provided locally and internationally by educational agencies, private foundations, laboratories, and universities will be essential to support the teaching and learning of CT.
- *Relate CT and mathematical thinking*. Research is needed to elucidate the connections between CT and mathematical reasoning and problem solving.
- *Embedding CT into the mathematics curriculum* will include different dimensions of practice: data *practices*, modelling and simulation *practices*, computational problem-solving *practices*, algorithm design *practices*, and systems thinking *practices*.
- *Develop CT related educational policies*. A key decision is where to split the focus between compulsory education and the later years of schooling where greater opportunities for choice and specialisation can be provided.
- *Building teacher capacity.* Another key policy decision will be determining the rate of change and providing for enhanced teacher professional learning with regard to modes of delivery and assessment.
- *Utilizing in-school cross curriculum models* where teachers of mathematics work in partnership with computer science colleagues.

Discussion Group 11

Teaching and Learning Linear Algebra

Sepideh Stewart[1], Maria Trigueros[2], and Michelle Zandieh[3]

1. Introduction

This discussion group will draw on the experience of three Linear Algebra researchers and curriculum designers to facilitate discussions around the past and future of Linear Algebra education. Linear Algebra is an important area of study for STEM majors. In a survey paper by Stewart, Andrews-Larson, and Zandieh (2019) the authors summarized some advances in many areas of linear algebra education (e.g., span, linear independence, eigenvectors, and eigenvalues). The survey paper also identified areas that need more research (e.g., systems of linear equations, properties of linear transformations, orthogonality, and least squares), and revealed the gaps (e.g., proof).

This discussion group will provide the opportunity to continue to develop and extend the field. Key questions and issues to be discussed are: What do we know from research about the teaching and learning of Linear Algebra? How can research results be used in the teaching of Linear Algebra? What innovative teaching methods have proved some success in the teaching of Linear Algebra?

2. Planned Structure

Planned timeline	Planned activity	Working format
21:30–21:40	Introduction	The organizers will give a brief overview of their research. Attendees will introduce themselves. The plan for the discussion group as well as a set of questions will be presented.
21:40–22:05	(a) Issues on first-year Linear Algebra topics (b) Teaching Resources (application, technology)	The attendees will break up in small groups to discuss: (a) What are some pressing issues concerning the teaching of first-year courses? (b) What teaching resources do you use to help students to understand the concepts better?
22:05–22:30	(c) Linear Algebra proofs, (d) Second courses in Linear Algebra	The attendees will break up in small groups to discuss: (c) What are some issues surrounding teaching linear algebra proofs? (d) What is the nature of second courses in your institution? The attendees will discuss the pertinence and possible contents of the second courses as a group.
22:30–22:50		Group discussion
22:50–23:00	Closing remarks, supporting new researchers, future work	The organizers will close by summarizing participants' views about future research.

Discussion Group 12

The Driving Forces Behind School Mathematics Curriculum Change in Asia

The Organizers[1] and the Working Team[2]

1. Short Description

There are many different driving forces behind every mathematics curriculum change around the world including politics, values, and culture. In recent time, one of the driving forces behind mathematics curriculum changes has been international assessment results. For instance, every four years, after the TIMSS results are released, many officials in various education systems tempting to take some remedial measures to improve their countries' ranking by the next TIMSS. The scope of this Discussion Group is to discuss the root causes of such hasty and sudden decisions. The organizers planned to invite the audience to discuss the ways in which, school mathematics curriculum be altered and adjusted in such ways to keep the balance between local and global situations and to use research findings properly to suit different education systems.

2. 1st Meeting (90 minutes)

- *10 minutes:* Introducing the aim and the rationale of this Discussion Group. Responsible person: Zahra Gooya — Co-organizer.
- *60 minutes:* Opened the floor for participants to discuss the controversial or emerging issues and/or dilemmas they have faced in mathematics curriculum in their countries, focusing on driving forces behind mathematics curricula change/reform in some of the Asian countries. Responsible person: Soheila Gholamazad — Co-organizer.
- *20 minutes:* Discussion among team members & Participants. Responsible persons: Zahra Gooya and Soheila Gholamazad, Co-organizers.

---

[1] Organizers:
- Zahra Gooya, Shahid Beheshti University, Iran
- Soheila Gholamazad, Organization for Research and Educational Planning, Ministry of Education, Iran.

Both organizers have been involved in mathematics curriculum design and textbook writing at the national level in two decades and in this decade, they have been involved in evaluating new mathematics curriculum in Iran.

[2] The team members:
- Anjum Halai — Pakistan/ ICMI EC
- Yudaria Mohammad Yousef — Malaysia
- Ravi Subramanian — India
- Hamid Faizi — Afghanistan

3. 2nd Meeting (90 minutes)

- *50 minutes:* Challenging participants with the identified issues in the 1st meeting to find the relation between local characteristics and mathematics curriculum reform/change. Responsible persons: Team members and participants.
- *30 minutes:* Examining the development of a framework for studying mathematics curriculum changes in Asia. Responsible person: Soheila Gholamazad, Co-organizer.
- *10 minutes:* Planning for the continuation of the next Discussion Group in the ICME-15 and thinking about a possible publication regarding the scope of the current Discussion Group.

Discussion Group 13

Mathematics Education and Teacher Professional Development System in Jiangsu Province

Xiaoyan Zhao[1], Lianhua Ning[2], Jingya Zhao[3], Jiuhong Wang[4], and Guangming Wei[5]

ABSTRACT In this discussion group, a system at various administrative levels for facilitating professional development of mathematics teachers in Jiangsu Province in China were introduced. By means of setting expert mathematics teacher studio, supporting People Educators in mathematics education, strengthening the cooperation between researchers and in-service mathematics teachers etc., a great progress has been made in mathematics education at primary and secondary level in terms of mathematics teachers' capability of providing instruction and doing research. Two specific examples from primary level were given in order to illustrate what happened in schools and classrooms. In the end, discussion was made between the participants and the audiences about how to make a larger group of both domestic and abroad teachers benefit from such teachers' valuable knowledge and experience.

Keywords: Teacher professional development system; Jiangsu Province; China.

1. Education in Jiangsu Province

Jiangsu Province is located in the middle part of the eastern coast of China, which has been considered as one of the provinces with highest educational development in China. In history, the development of Jiangsu is highly associated with its educational culture. In Nanjing, the capital of Jiangsu, there is the official imperial examination center (Jiangnan Examination Hall) for the Jiangnan region during the Ming and Qing dynasties. In addition, Nanjing Normal University is considered as the origin for teacher education in southern China.

For mathematics teacher professional development in Jiangsu Province, a system at various administrative levels has been established. By means of supporting People

Educators in mathematics education, setting expert mathematics teacher studio, strengthening the cooperation between researchers and in-service mathematics teachers etc., a great progress has been made. In this discussion group, it will be shared with examples how these supporting systems helps to supporting mathematics teachers' professional development.

2. Activities Overview

As shown in Tab. 1, this one-hour and half discussion group consisted of five parts. The introductory and closing comments were organized in the format of whole group discussion, and in between three presentations were arranged. Around 40 participants in total took part in the discussion.

Tab. 1. Schedule of the discussion group (21:30–23:00, July 14, 2021)

Planned timeline	Planned activities	Format
21:30-21:40	Introductory comments (organizing the group discussion through the key questions)	Whole group discussion
21:40-22:00	System of and strategies for supporting mathematics teachers' professional development in Jiangsu Province	Presentation
22:00-22:25	Suitable for development: Purport of mathematics teaching wisdom under the condition of large class size	Presentation
22:25-22:45	Expert mathematics teacher studios driven by research-based teacher professional development programme	Presentation
22:45-23:00	Closing comments –summarize the presentations and discussions, and identify follow-up questions to investigate	Whole group discussion

2.1. Teacher professional development system in Jiangsu Province

Lianhua Ning and Minjie Chen explained the effective system established for supporting mathematics teachers' professional development in Jiangsu Province. It includes various forms of teacher training at the provincial, municipal and district (county) levels, aiming at improving teachers' professional knowledge and instructional skills (Duan et al., 2017). In addition, many hierarchical reward approaches have been designed by different administrative areas in order to encourage teachers to pay attention to their professional growth in the long run. Among all these measures, the most innovative three highlights are as follows. The first one is Educator Training Project, which focuses on top expert mathematics teachers. By organizing mentor groups, these selected teachers will get concrete and guidance according to their individuals' needs. The second one is Expert Mathematics Teacher Studio. At the center of these organization is a locally famous expert teacher, and the members are mainly the teachers in the neighborhood. Regular workshops and discussions, academic writing, and many other activities are organized within such studio in order to solve the problems encountered in daily teaching. The last one is Curricula Base

Construction, which support schools as a whole to develop their school-based mathematics curricula.

2.2. *Suitable development: The implications of teaching wisdom in large-size classes*

Jiuhong Wang, the headmaster of Nanjing Tianzheng Primary School, presented the research his expert mathematics teacher studio did about how to provide suitable instruction in large-size classes (Wang, 2017). The presentation is divided into four parts: how they came up with such idea, what suitable instruction looks like, how to construct the teaching system for students' suitable development at school level and practical suggestions for teachers to conduct in daily teaching.

In the mathematics curriculum standards of nine-year compulsory education (MoE, 2011), it is pointed out that everyone should receive a good mathematics education, and different people should get different developments in mathematics. This is a difficult goal to be achieved, especially considering that in Chinese mainland the class size is quite large with 45 students as maximum at primary level. This was why Dr Wang and his colleague chose the research topic of "Providing students with suitable development". This requires teachers to have wisdom to help individuals when solving mathematics problems. To be more specific, more attention is supposed to be paid to excellent students and students with learning difficulties. Meanwhile, make the most of the time and space during classroom teaching. In the end, six suggestions for suitable development and instruction were provided, which refer to learning goals, teaching content, students' cooperation, teachers' support, homework design and classroom assessment.

2.3. *Expert mathematics teacher studios driven by research-based teacher professional development programme*

Guangming Wei, the secretary of Experimental Primary School of Jinling High School, explained the construction of Wei Guangming Elementary School Mathematics Expert Teacher Studio and the longitudinal study the had done. In 2008, the studio was officially established with only 4 teacher members from one school; by 2021, the studio has more than 30 members which are from nine schools of four districts in two cities. Then he presented the fact that over the 13 years, studio members have made significant professional progress. When reflecting the reason why the teachers, including the expert teacher himself, pay attention to and benefit from the activities organized by the studio, it came to the conclusion that research-based programme with a clear and concrete research question to be conducted over years is the key. They have tried to applied many scientific research projects as a manner for promoting teachers' professional growth. In total, they had accomplished or were carrying out five projects, and the funding received was more than 600,000 RMB.

Their research focuses on the core mathematics knowledge teaching theory and practice in primary school (Wei et al., 2020), which can be further divided into three aspects: (1) what are the core mathematics knowledge? (2) How to make the core knowledge and skills standing out during the process of teaching and learning? (3) How to support students to make most of what they have gained by learning the core knowledge and transfer to explore other mathematics content by themselves. It turned out that this research-based teacher professional development programme is not only helpful for teachers' professional growth, but also improve students' learning effectiveness.

3. Future Directions and Suggestions

After the presentations, two major issues referring to the primary school practice were raised and discussed in the discussion group. The first one is how to distinguish and deal with the mathematics content except for the core knowledge. Wei introduced shortly how they divide core and non-core knowledge by applying the mathematical abstraction degree proposed by Lizhi Xu, a famous mathematician and educator in China. Teachers are supposed to pay much more attention to design teaching sequences for core knowledge; as for non-core knowledge, students are given more space to explore and reinvent by themselves under teachers' guidance. Another issue for discussion was raised by a researcher from Australia via Internet. He appreciated the valuable examples and experiences shared by the presenters, and considered such research done by in-service teachers and grounded in practice is precious. Also he and other participants in the discussion group, which are mainly Chinese, noticed that language barrier can be a big problem for teachers to share their practical teaching wisdom. Like Wei and Wang, expert mathematics teachers from other countries and districts probably also have precious and effective knowledge and experience including but not limit to professional development. How to make teachers' voice to be heard worldwide and how to promote teachers from different countries to exchange ideas with their foreign counterparts should be put on the schedule of scientific research and international conference.

Workshop 1

Topological Approach to Game Theory

Giovanna Bimonte[1], Francesco Saverio Tortoriello[2], and Ilaria Veronesi[3]

ABSTRACT We present a laboratory developed in the mathematics activities during the lessons of the research project *Mathematical High School* at the University of Salerno. We consider a continuous location optimization problem, where an optimal location is found in a continuum on a plane, using a topological approach involving the Voronoi diagram and the Delaunay triangulation to find the equilibrium point.

Keywords: Game Theory; Voronoi; Topology; Constructivism.

1. The Research Project

In Italian higher education, the topic of "Game Theory" is not included in the ministerial indications of the mathematics curriculum. Students do not have the prerequisites that enable them to understand and solve multivariable optimization problems.

In order to avoid the impossibility of solving problems of this type using analytical methods, we have chosen to approach them from a geometric point of view. Simple geometry concepts are required, such as the definitions and properties of Euclidean geometry and formulas and solution processes of plane analytic geometry.

Location problems concern the location of resources in a given space. Competitive Localization models also incorporate the fact that some structure is already present in the market and that the new structure will compete for market share. Let us consider a continuous location optimization problem, where an optimal location is in a continuum on a plane. We introduce the Voronoi diagram to solve the location problem, where the number of players is exogenously determined. We use Delaunay triangulation to find the equilibrium point and consider some generalizations of the ordinary Voronoi diagram.

The solution of the problem in the planar case with Euclidean distances and a variety of functions of attraction leads to a finite polynomial algorithm in the number of consumers. Using dynamic geometry software, we construct our case study on the

E-mail: iveronesi@unisa.it

Cartesian plane, we check how the results change as the starting conditions vary and we obtain the solutions without even performing the simple calculations required by the Cartesian geometry to find the equilibrium point.

2. The Laboratory: Voronoi Approach for Discrete Competitive Facility Location Model

The laboratory retraces the activities designed and developed in the Mathematical High School Project, which is an interdisciplinary extracurricular path developed by Research group in Mathematics Education of the Department of Medicine of the University of Salerno (Italy) aimed at overcoming the natural didactic division of knowledge in the various disciplinary fields.

The laboratory deals with competitive location models that relate to the fact that some facilities are already in the market and that the new facility will compete for market share.

There are two main approaches to estimating and analyzing the market share captured by facilities such as retail establishments, restaurants, etc., as a function of their location.

We decided to design the laboratory with the Hotelling approach (Hotelling 1929) and many extensions that assume that customers patronise the nearest facility and consider a class of continuous localization optimization problems that can be solved through the Voronoi diagram (Okabe, Suzuki 1987).

2.1. The basic location model

The Basic Location Model is defined as follows:

Consumers are distributed according to a measure λ on a compact Borel metric space $(S;\lambda)$ with S a compact subset of $\mathbf{R}^2$. A finite set $K = \{1,\dots,k\}$ of retailers have located their facilities on S. A new retailer wants to maximize his market share after locating a new facility, depending only on the “distance” variable.

The activity started asking the participants to divide the space according to the rules mentioned above in the simple case of two facilities, positioning in different configurations (symmetric and asymmetric case, with different distances).

2.2. The topological approach: the Voronoi tessellation

To trace the dominant regions of the players (i.e., their payoffs) in the intent of solving this locational optimization problem, we introduced to the participants the Voronoi tessellation of the space, making some reminders on topology concepts.

The location of the new facility was determined by the maximisation of the distance from other existing facilities and the task of determining this location is the largest empty circle problem.

In computational geometry, a Delaunay triangulation for a given set of discrete points in general position is a triangulation such that no point lies within the circumference of any triangle. The Delaunay triangulation of a set of discrete points in general position corresponds to the dual graph of the Voronoi diagram. The circumcenters of the Delaunay triangles are the vertices of the Voronoi diagram.

Thanks to the software, the participants drew the Delaunay triangulation, they built the circumferences circumscribed to the triangles and then they determined the circle of maximum area fully included in the area S.

The largest empty circle is the one centred in *Voronoi vertex*, so the participants draw the new configuration with the location of the new retailer with the maximum area.

In the laboratory activities the participants explored that the Voronoi problem can be approximated by an isolation game with a measure of distance and the solutions of the isolation game correspond to the Nash equilibrium points obtained by solving the maximum distance problem analytically in multivariable functions.

3. Activity Overview

Various techniques and applications of real cases were actively presented during the workshop and participants were involved in finding solutions to common problems. In the introduction, participants were provided with tools and models useful for understanding the problem of optimal localisation. We then made some reminders on topology concepts necessary for understanding Voronoi diagram construction and Delaunay triangulation. The participants were involved in positional games first on the line and then in the plane.

In the main part of the workshop, participants were presented with various positioning problems in the plane, facilitating discussion and an initial solution based on mere observation. During the workshop, geometric and mathematical models and teaching approaches were discussed, the close correlation between the various fields of knowledge was highlighted through examples of reality problems, underlining how mathematics is the transversal language to interpret the real world.

All problems were illustrated and communicated with the use of technology, in particular with the use of dynamic geometry software. Participants were challenged to formulate the solution of the positioning problem in terms of an optimization problem and then in topological terms.

Participants constructed the set of points and solved the problem of finding the optimal placement point in the plane.

In this way, we induced the topological solution, which coincided with the analytical solution without the use of advanced tools such as optimization in $\mathbf{R}^2$.

4. Future Directions

The activity proposed in the laboratory is part of the broader path of the Mathematical High School Project, which aims to provide students with a unified vision of culture. Still in relation to the topic of the activity presented, some paths that retrace the social experiments known in literature are being tested in the economic field, recalibrated through the use of technologies.

Workshop 2

Linguistic and Logical Methodological Tools to Address Language Diversity in Mathematics Education

Viviane Durand-Guerrier[1], Cris Edmonds-Wathen[2], Faïza Chellougui[3], Judith Njamgong Ngonsap[4], and Jean-Jacques Salone[5]

1. Aim of the Workshop

The aim of the workshop was to share with an international audience the linguistic and methodological tools we are developing in our own multilingual contexts to discuss:

1) the possibility of their generalization;
2) the ways to improve them for wider use;
3) to initiate international collaborations involving a variety of languages.

The main idea underlying this proposal is that in multilingual contexts differing grammatical structures of languages might affect the process of teaching and learning mathematics, whatever the level of instruction. We consider that switching from one language to another in a classroom might be both an obstacle or a resource (Edmonds-Wathen et al., 2016), and that translating even the most straightforward of mathematical statements from a language to another is challenging (Edmonds-Wathen and Bino, 2015). We also consider the issue of translating transcripts for research on language diversity (Chellougui et al. 2016).

2. Organization of the Session

The session held online on July 14th, 2021, 21:30 — 23:00 (UTC+8). After a presentation of the session, we provided two presentations of 15 minutes each about our methodological tools, followed by a ten minutes' discussion. Afterwards, the participants have been invited to fill up an online document with questions and tasks during about 15 minutes. This was followed by the sharing of the results and a collective discussion.

3. Presentation of Our Methodological Tools

3.1. The logical analysis of statements. A tool for dealing with ambiguities in multilingual context

Logical analysis as a tool for didactic research in mathematics education as shown to be relevant. The tool relies on the assumption that objects, properties, and relations are fundamental logical categories involved in mathematical activities, and that quantificational issues play an essential role. Logical analysis in the frame of first order logic (Predicate calculus) with a semantic perspective allow to make visible, and to overcome logical ambiguities, mainly by considering the respective scopes of connectors and quantifiers in vernacular languages. The example of negation in French highlights the relevance of such analysis. First, the French grammar is not congruent with the logical structure, while the Arabic grammar is. This has didactic impact as shown for example in the Tunisian or the Cameroonian educational contexts (Durand-Guerrier, 2020). Second, the substitution principle *salva veritate* does not apply in French regarding negative sentences. Unpacking the logic of statements permits to overcome ambiguities in case where the context does not. This is useful both for a priori analysis of tasks submitted to students, and for interpretation of students' answers. It seems rather clear that in multilingual context, being able to deal explicitly with such ambiguities would open paths for remediation.

3.2. Linguistic methodological tools for multilingual mathematics education research

This presentation focused on two elements: (1) *Representation of multilingual data*. There are no well-defined conventions in mathematics education research for when language data should be presented in the original language and for how and when translations should be made. Interlinear morphemic glossing was presented as a tool to structure data presentation which makes explicit the process of translation, helping show how meaning is being made and providing more information than direct translation alone (Edmonds-Wathen, 2019; Edmonds-Wathen and Bino, 2015). (2) *A functional typological perspective for conceptualizing mathematical language cross-linguistically*. We know that mathematics registers in different languages are different, but not how different they are and the significance of the differences for learners and mathematicians (Edmonds-Wathen et al., 2016). This element discussed how to investigate mathematical expression/mathematics registers in different languages without privileging one language over another (Edmonds-Wathen, 2019). A typological perspective involves classifying languages according to their structural similarities and differences — focusing on syntactic typology, the different ways that languages structure phrases and sentences, and semantic typology, the different ways that languages structure semantic domains such as time and space. The functional typological perspective enables the mathematical concepts, practices, and affordances of diverse languages to be investigated within a broader mathematical frame. It asks:

- What functions are performed by language features that are used in existing school/academic/formal mathematics?
- How are those functions performed in the target language?
- Can the way that those functions are performed by drawn on or extended for the purposes of school mathematics?

4. Summary of Participants Activity

Eight participants from six different countries attended the workshop. After the two presentations, they worked individually on an online shared document with two parts. The first part on participants' relationships with languages revealed that most of the participants speak fluently only their mother tongue (6/8), even if their research leads them to be interested in other languages. English or French are also a teaching language for most of them (7/8). The second part included mathematical questions out of Ben Kilani (2005):

The 2 figures  Fig. I  Fig. II	1/ definition, existence of quadrilateral with perpendicular diagonals that are not rhombus, definition of "not being a Rhombus" for a quadrilateral, and translations of the answer in another language; 2/ Which of these two drawings represents a quadrilateral in which diagonals are perpendicular and all the sides are not equal? (Answers: Fig. I, Fig. II, both, none); a justification was expected.

The following discussion highlighted the grammatical problems of translating from one language to another. Considering than in multilingual educational context, this is likely to arise during mathematical activities, it appears as a challenge for both teaching and research. The activity on the two figures clearly showed that this is at stake even for elementary mathematical statements, which is generally not recognized by teachers.

5. Conclusion and Perspectives

In this workshop, we intended to share with participants our methodological tools for addressing grammatical issues in mathematics education**,** where the focus is generally on lexis. The next step is to explore other multilingual contexts by developing an international network.

Workshop 3

Poly-Universe and Lénárt Sphere: Manipulatives from Hungary

Zsuzsa Dárdai[1], István Lénárt[2], János Saxon Szász[3], Eleonóra Stettner[4], Réka Szász[5], and Szabina Tóth[6]

Tools for Participants: In order to enhance the experience, we recommend participants to have the following tools available during the workshop (they are not required): laptop or tablet, two oranges, colored pens or markers that can mark the oranges, rubber bands, toothpicks, bottle caps.

Hungary has a strong tradition of using games and manipulatives to develop concept building and problem solving in mathematics. This stems from the work of Tamás Varga, but there are constantly new developments in this trend (Vancsó et al., 2018). The workshop presents online adaptations of two such tools: the Lénárt Sphere developed in 1986 by István Lénárt (Lénárt, 1996), and the Poly-Universe set developed in 2009 by János Szász Saxon (Saxon and Stettner, 2019). Both tools are used with 6-18-year-old students and in teacher training.

The aim of the Lénárt sphere is to explore analogies and differences between the plane and the sphere, and get a first-hand experience on comparative geometry education for all levels. (Lénárt and Rybak, 2017). Participants will study basic ideas of geometry on the plane and on the sphere, for example straight lines, and circles. Comparison and contrast make concepts understandable and thought-provoking even for those who are indifferent or hostile towards mathematics. Euclidean monologue transforms into a dialogue, a drama between two approaches to geometry. Besides introducing the Lénárt Sphere with spherical rulers, compasses and protractors, we will work with everyday objects such as oranges and rubber bands, which can be used in online and in person classrooms. Independent investigation and peer discussion prevail over lecture, self-made discovery rather than passive acceptance of definitions. Comparing different geometries may help students understand how relative and human all axioms and theorems of science are, and help them develop tolerance and understanding of those who are different in their cultural or social backgrounds.

[6] Szabó Lőrinc Bilingual Primary and Secondary School. E-mail: t.szabina72@gmail.com

The aim of the Poly-Universe session is to explore the various educational aspects of a tool that originates from art, and which connects multiple subjects and mathematical topics. The novelty value of Poly-Universe lies in the scale-shifting symmetry inherent to its geometric forms and a color combination system. As part of the EU Erasmus + PUSE (Poly-Universe in School Education) project 2017/19 an international team of educators, teachers and students designed tasks for using the tool in mathematics education for primary, middle and high school students and in teacher training (PUSE Methodology book, Saxon and Stettner, 2019). These tasks are visual, hands on and analytic at the same time, so they require both right and left brain functions, and they are centred around motivation, experience, interaction, problem solving and creativity. The tasks are connected to the topics of Geometry & Measurement, Combinatorics & Probability, Sets & Logic, Graphs & Algorithms, Complex & Visuality.

In the workshop participants will have the opportunity to try out and discuss the e-learning platform of the Poly-Universe set, which is an online application for manipulating the set and solving visual mathematics tasks: https://www.puse.education.

Workshop 4

Folding for Fractional Understanding

Bjorg Jóhannsdóttir[1] and Heather Ann Coughlin[2]

ABSTRACT The goal of this interactive online workshop was to introduce paper strips as manipulatives to foster understanding of fractions. Attendees gained appreciation for the versatility of the paper strip to visualize concepts, link fractions to the whole numbers, and build arithmetic algorithms. The operations became alive in the participants' hands.

Keywords: Fractions; Folding; Fractional understanding; Number line.

1. Theme and Description

1.1. *The presenters*

Dr. Coughlin and Dr. Jóhannsdóttir are experienced educators of prospective teachers. Dr. Jóhannsdóttir has a doctorate in Mathematics Education and Dr. Coughlin in Pure Mathematics. Together, they have over 25 years of college teaching and 13 years of teaching in junior high/high schools. Dr. Coughlin and Dr. Jóhannsdóttir are co-directors of the Central California Mathematics Projects, where they design and implement professional development workshops for teachers in Central California.

1.2. *Why fractions and paper strips*

Findings from international studies like PISA and TIMSS indicate that students worldwide struggle with concepts related to fractions (Neagoy, 2017). To improve learning of fractions, the presenters model effective practices, using easily accessible manipulatives: paper strips. During the COVID-19 pandemic, presenters successfully used paper strips in all sorts of activities over Zoom to increase pre-service teachers' understanding of fractions, their properties, and operations with fractions.

The goal of this virtual workshop was to introduce paper strips as manipulatives to foster understanding of fractions. The strips were used to model concrete representations to assist in defining and explaining fractions and make sense of basic arithmetic operations using fractions. During manipulations of the paper strips, familiar concepts emerged, such as common denominator, and equivalent fractions. Using a

[1] Department of Mathematics, California State University, Stanislaus, Turlock, CA 95382, USA. E-mail: bjohannsdottir@csustan.edu

[2] Department of Mathematics, California State University, Stanislaus, Turlock, CA 95382, USA. E-mail: hcoughlin@csustan.edu

paper strip created a tangible way to "extend previous understandings of operations on whole numbers" to fractions, as emphasized in the Common Core State Standards for Mathematics, CCSS-M (California, 2013).

Underlying the manipulations of the paper strips is the definition of fractions as described in the CCSS-M in the United States. "*Understand a fraction 1/b as the quantity formed by 1 part when a whole is partitioned into b equal parts; understand a fraction a/b as the quantity formed by a parts of size 1/b* (California, 2013)." This definition emphasizes thinking about fractions multiplicatively, instead of additively. Students should see 3/4 as three iterations of 1/4, or 3 (1/4). Attendees took part in creative activities they could take back to their classrooms to build students' understanding of fractions.

2. Activity Overview

The format of the Folding for Fractional Understanding workshop was a synchronous, 90 minutes, Zoom meeting. Each participant came prepared with 10 paper strips approximately 2 centimeters wide cut out along the long side of a piece of paper.

2.1. Background

Following the aforementioned definition of fractions, the CCSS-M, developed in 2009 to coordinate and standardize mathematics instruction across the United States, goes on to direct that students need to "*Understand a fraction as a number on the number line; represent fractions on a number line diagram. Represent a fraction 1/b on a number line diagram by defining the interval 0 to 1 as the whole and partitioning it into b equal parts. Recognize that each part has size 1/b and that the endpoint of the part based at 0 locates the number 1/b on the number line. Represent a fraction a/b on a number line diagram by marking off a lengths 1/b from 0. Recognize that the resulting interval has size a/b and that its endpoint locates the number a/b on the number line* (California, 2013)."

This description of a fraction and its representation on a number line attempt to connect fractions to whole numbers in the "marking off" or counting a number of *a* intervals from *0* of size *1/b*. Intrinsic within this definition, *a* and *b* are whole numbers with *b* not equaling *0*.

The presenters shared how they had noticed that this connection of the definition of a fraction to a location on a number line was difficult for some of their prospective teachers. They shared responses to the activity: *Make five fractions using once each of the digits 0, 1, 2, 3, 4, 5, 6, 7, 8, 9. Place the fractions on a number line. Make a visual representation of each fraction.*

The responses sparked discussions on how the prospective teachers appeared to have discrepancies in their understanding of fractions. Many drew circles as fraction diagrams indicating an acceptable understanding of fractions as parts of a whole. However, representing fractions as numbers on a number line was troublesome and showed little connection to the pictorial representation already made.

To bridge this gap in students' understanding, the presenters recommended using paper strips to build the transition from the concrete area model to the number line model. Either long-edge of a paper strip may be marked in ways similar to a number line. Both the paper strip and number line models emphasize how to work with fractions similarly to whole numbers, and they lessen the need for mixed numbers. Additionally, emphasizing improper fractions is unnecessary. For example, showing *5/4* on a number line requires one to begin at *0*, then count out five lengths of *1/4*.

2.2. *Activities*

2.2.1. Addition and subtraction

Participants were asked to visit a place in time before they had learned how to add fractions and heard of a common denominator. Armed with three paper strips and the definition of a fraction, they were to add 1/2 and 1/3, using the instructions; *You need three paper strips of equal length. First paper strip — show 1/2. Second paper strip — show 1/3. "Add" the paper strips. What is your "sum"? Use the third paper strip to determine your "sum."*

Participants began by showing their 1/2 and 1/3 on two paper strips and were asked to "prove" that those were indeed 1/2 and 1/3, by referring to the definition of fractions. Once it had been established, the parts were combined, see Fig. 1. Now the task was to figure out what fraction of a whole paper strip the combined paper strips parts were. When compared to a whole paper strip, it was easy to see that the combined parts were less than a whole strip, and their length was marked on the whole strip, and the remaining piece colored black. The combined length could not be measured by either 1/2s or 1/3s. After sharing ideas and trying different things, one of the participants suggested that we fold the whole paper strip into pieces the size of the black piece. It turned out that the whole strip could be folded that way into six equal parts, see Fig. 2. Now when compared, the combined parts were of the same length as five of the six equal parts, or 5/6 of the whole paper strip.

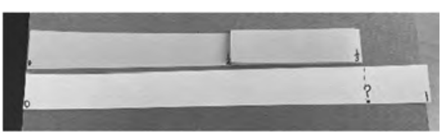

Fig. 1. ½ + ⅓ compared to one whole

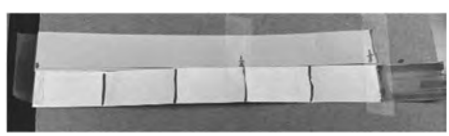

Fig. 2. ½ + ⅓ = ⅚

Participants were asked to subtract (2/3) − (1/2) using a similar process with the paper strips. Adding and subtracting fractions using the paper strips ignited discussions among participants on how these activities paved the way for students' discovery of equivalent fractions and the meaning of a common denominator. This advanced teachers' pedagogy to avoid math tricks and shortcuts, and instead first prioritize conceptual understanding and procedural fluency (Dougherty et al., 2017).

2.2.2. Multiplication and division

Lively discussions arose on how the presented activities could be used in participants' classrooms. This resulted in much less time for the multiplication and division of fractions than planned. For demonstrating multiplication, presenters began with simple problems such as 1/2 times 4/5 and built to more challenging problems. In multiplication the focus is on the definition of fractions, 5/3 is 5 times 1/3. In order to find 5/3 of 1/2, you first need to find 1/3 of 1/2, and then take five such pieces to get the 5/3 of 1/2.

When dividing whole numbers, the fair share model (how many in one group) is more frequently used, but when dividing fractions, the measurement model (how many groups) makes more sense. Using the measurement model, the problem 3/4 divided by 1/4, is asking, how many 1/4 fit into 3/4? The paper strips easily modeled this problem.

3. Future Directions and Suggestions

Being part of ICME-14 was a smooth and fun adventure. Participants from all over the world attended our workshop. It was valuable connecting with colleagues during the difficult COVID-19 times. The organizers of ICME-14 were professional and supplied the support needed to make the workshop successful.

The presenters welcome further exploration of fractions with materials such as paper strips. From here, returning to the paper strips allows students to strengthen their number sense with fractions. Students will have tangible examples to visualize comparing fractions, or answers to situations such as whether the product of a fraction by another fraction will be less than, equal to, or greater than either original fraction.

Acknowledgments

The presenters acknowledge the California Mathematics Project which developed the foundational ideas used in this workshop.

Workshop 5

From the Power of Intuition to the Beauty of Abstraction

Damjan Kobal[1]

ABSTRACT Contrary to the fact that mathematics many ideas, beauty and inspiration are hidden within simple and intuitive patterns, which are easily noticed and 'intuitively understood', mathematics is considered very abstract. Therefore, the motivation for mathematics teaching and learning should be intuitive and the beauty of abstraction will rise from there. As teachers we need to challenge our sensibility for the importance of the intuitive in mathematics teaching and learning. We introduce these challenges by smartly chosen hands-on (and eyes-on) problems. Like some 'graphic puzzles', which are understood in seconds, but are often harder to formulate then to solve. Through examples we explore how understanding, motivation and challenge often lie within intuitive comprehension and how abstraction (especially on the primary level) only follows later.

Keywords: Intuition; Visualization; Deductive reasoning; Abstract thinking.

1. Introduction

This paper is a short overview, a content summary of the Workshop WS3 entitled *From the Power of Intuition to the Beauty of Abstraction*, which took place at ICME-14 on July 14, 2021, 21:30 — 23:00 at T519 and was conducted on-line. About twenty participants were present physically in T519 and on-line. The content was presented and communicated through provided on-line technology, using *PowerPoint*, *Drawboard*, *GeoGebra* and *Web browser*. To support the presented content and to motivate the engagement of participants a special web page (direct link: http://ko.fmf.uni-lj.si/ICME-14/) had been designed (Kobal, 2021). Careful reading of this paper and thorough study of the inter-active materials referenced in this paper might be rewarded with many useful teaching ideas or even with research insights into what is the meaning of 'understanding'. Throughout the content of this paper, we try to challenge the development of critical and creative approach to the technology use. Several samples of exemplary GeoGebra use are presented. Cases where critical teachers will uncover weak or even counter-productive IT use and content neglect will also be considered. With practical and true hands-on and minds-on activity we

[1] Department of Mathematics, Faculty of Mathematics and Physics, University of Ljubljana
Jadranska 19, 1000 Ljubljana, Slovenia. E-mail: damjan.kobal@fmf.uni-lj.si

challenge our reasoning and nourish our intuition to become a valuable predecessor of abstract mathematical thinking.

Presented content is split into five sections. In the first Graphic Puzzles we introduce some intuitive puzzles, which are very easy to understand and often harder to precisely formulate then to solve. In the very short second section Listening to Number Patterns, we intuitively approach some simple mathematical ideas by listening (not by watching). In the third section Basic Examples, we present several elementary ideas where dynamic computer graphic truly helps to motivate and intuitively explain some of the mathematical concepts. In the fourth section titled Motivation vs. Manipulation — Math Rigour vs. Fake News we address some of the dangers of uncritical use of technology. And in the last section with the title Saper Vedere — Saper Raccontare we present a couple of inspiring uses of graphic and intuitive presentations of otherwise very abstract mathematical concepts.

It is worth mentioning that this workshop overview might be hard to follow and understand in every detail for someone, who has not participated at the workshop. Without proper leading, explanations or at least knowledge of the presented ideas, the reader will need to carefully study the interactive animations. Namely, considered ideas and especially prepared interactive animations are designed to speak for themselves and mostly without words, but they do require proper and thoughtful use of its interactive options.

Workshop 6

Exploring the Role of an Online Interactive Platform in Supporting Dialogue in Mathematics Classrooms

Qian Liu[1] and Yuan Zhang[2]

ABSTRACT This is a report of an interactive workshop that was collaboratively designed and implemented by a researcher and a group of practitioners. To share theoretical insights and teaching practices concerning the use of an online interactive platform to support classroom dialogue in mathematics classrooms, this article presents the theoretical and research underpinnings of the workshop, the procedure and main activities, the observed outputs, and reflection and suggestions on designing and organising the hybrid format of workshops in this field.

Keywords: Digital technology; Classroom dialogue; Lesson study; Primary mathematics education.

1. Introduction

There is a growing body of research evidence showing that productive classroom dialogue is beneficial for students' mathematical attainment and mathematical thinking development (e.g. Howe et al., 2019; Mercer and Sams, 2006; Webb et al., 2014). Recently, research interest has been increasingly drawn to the role of digital technologies in supporting classroom dialogue. This is mainly because affordances of digital technologies for learning (e.g., multimodality, interactivity, revisability) are argued to have potential in *opening, expanding and deepening dialogic space* (Wegerif, 2007). Within a dialogic space, multiple perspectives are openly shared, critically and creatively linked and synthesised and new meaning collectively constructed (Major et al., 2018). However, the realisation of any perceived potential of digital technologies requires pedagogical intention and practice. A one-year design-based research with Chinese mathematics teachers in a primary school was conducted with the research interest in optimising the technological potential in classroom dialogue. Based on the iteratively developed teacher professional development programme, a group of four mathematics teachers explored teaching strategies for using an online interactive platform, *Zoomabc (全景平台)* to support classroom dialogue. This workshop was not

[1]Faculty of Education, University of Cambridge, 184 Hills Road, Cambridge, CB2 8PQ, UK.

[2] Hangzhou Yungu School, Hangzhou, Zhejiang Province, China.
E-mail: zhangyuan1976@dingtalk.com

only informed by the related theories including socio-cultural and dialogical theories, but also grounded in the exploratory teaching practices in actual classrooms.

The workshop, bridging dialogic theory and classroom practice, aimed to enrich participants' understanding of the role of online interactive technology in mathematics teaching and learning, from the dialogic perspective. Hence, the workshop introduced Zoomabc and focused on illustrating and explaining its potential affordances for supporting classroom dialogue. The second aim was to share the pedagogical framework derived from the research in conjunction with the teaching strategies exemplified by real lesson cases. In addition, the workshop highlights lesson study as a means to professional development to support the development of dialogic teaching with digital technologies. To systematically analyse and scrutinise and reflect on dialogic teaching practices, a coding scheme, the Teacher Scheme for Educational Dialogue Analysis (T-SEDA) (Hennessy et al., 2021) was introduced. It is worth stressing that the workshop was designed and implemented in a dialogic manner, hoping to draw participants into an open, critical, and ongoing dialogue about the workshop theme.

2. Procedure and Main Activities

Based on the aforementioned aims, Tab. 1 outlines the procedure of the 1.5-hour workshop and its activities.

Tab. 1. The workshop procedure and activities

Duration	Activity	Format
10 min	Welcoming and ice breaking: specifying the workshop's main aims and structure. Inviting participants to share their interests, experiences and expectations related to the workshop topic.	Short presentation Publicly sharing ideas on Padlet
20 min	Introducing the theoretical and research backgrounds of the workshop, the lesson study model and the T-SEDA coding tool. The presentation ends with a brief demonstration of Zoomabc in terms of its technical features and potential affordances for classroom dialogue.	Presentation
15 min	Sharing lesson case one: making two-digit numbers using counters on a tens and ones place value chart. Q & A	Presentation and interaction
15 min	Sharing lesson case two: areas of rectangles. Q & A	Presentation and interaction
20 min	Adapting a short lesson episode 'Areas of Parallelograms'. This activity ends with an open-ended question: what factors should be considered and addressed when attempting to foster classroom dialogue with the use of interactive technologies?	Lesson planning and discussion
10 min	Conclusion with the proposed pedagogical framework. Inviting final comments and questions. Inviting participants to share any ideas and questions on Padlet after the workshop.	Plenary

3. Outputs

This workshop was conducted in a hybrid format, aiming to engage participants from diverse backgrounds. The first 20-minute presentation enabled participants to learn about the theoretical and research backgrounds of the workshop and enrich their conceptual and practical understandings of educational dialogue. Some participants posed questions and shared valuable insights online mainly regarding the disciplinary nature of classroom dialogue in mathematics classrooms.

Given the dialogic approach to the workshop, participants asked questions and proposed alternative teaching approaches related to the shared two lesson examples. They agreed that the use of Zoomabc facilitated students' wider and sustainable participation in dialogue, especially contributing to fruitful opportunities for individual students to express ideas publicly and engage with each other's ideas. However, they pointed out that students' online comments may not be so dialogic and lack criticality, and some comments were not relevant to the contributions (e.g., commenting on writing rather than content).

Facilitated by the interactive activity for adapting the lesson episode and the open question, the pedagogical framework (see Fig. 1) and the accompanying pedagogical strategies were discussed both in this research context and in the participants' own contexts.

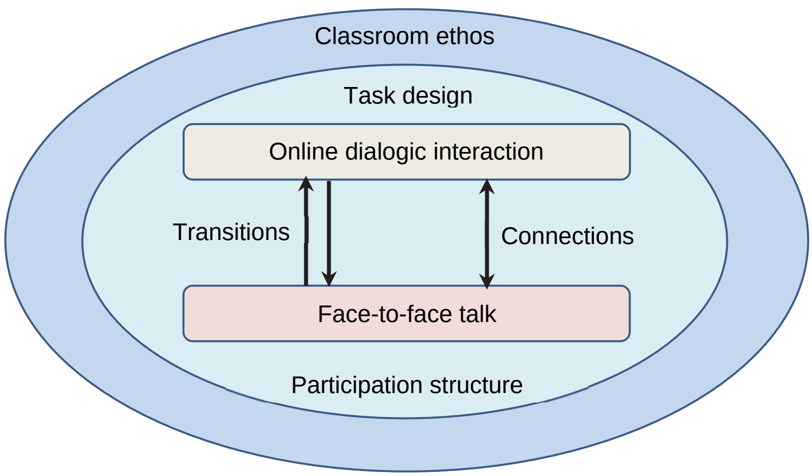

Fig.1. Pedagogical framework for fostering students' dialogic participation supported by using online interactive platforms

4. Reflection and Suggestions

This workshop shared theoretical insights into the role of digital technology in supporting classroom dialogue and focused on the teaching practices concerning the use of Zoomabc, an online interactive platform. Taking the dialogic stance, the workshop enabled participants to share different viewpoints, raise questions, and co-construct understanding and knowledge surrounding this topic.

There are two aspects worthy of our reflection and suggestions. Regarding workshop content, it should be noted that the shared teaching practices and developed pedagogical strategies are situated in the specific context (e.g., the Chinese primary school, technological environment framed by Zoomabc). Hence, applying the strategies to other contexts should be cautious, which requires contextual considerations. The intertwined inquiry between research and practice should be open, diverse and ongoing. Thus, it is hoped that the workshop as a catalyst can stimulate wider interest and encourage researchers from different contexts to further explore and investigate pedagogy for optimising the potential of digital technologies in supporting educational dialogue in mathematics classrooms.

The second aspect relates to the activity formats. To encourage participants' active, critical, and creative engagement, we designed hands-on and interactive activities. The dialogic approach to the workshop enabled us to create and develop an equal, supportive, open-minded, and co-constructive ethos. In corresponding to online interactive platforms, the use of Padlet enabled participants, both in person and online, to have a first-hand and authentic experience regarding how Padlet supported ongoing and cumulative dialogue across time and place. Therefore, future efforts may be needed to strengthen dialogic links between participants who are online and those who are physically present in the hybrid format of workshops.

Workshop 7

Going Beyond the Numbers — Exploring Social Justice in the Mathematics Classroom through Global Connections

Chadd McGlone[1], Hanna Nadim Haydar[2], and Paola Castillo[3]

ABSTRACT By school years, mathematics in the classroom becomes separated from real life. However, if teachers can bring context back into mathematics, like the kids experience outside of school, math becomes real. Beginning class by teaching students a bit about what it's like to live in another part of the world brings class alive. Global Math Stories (GlobalMathStories.org) is a resource that helps educators make cultural and global connections in the classroom. In this presentation, participants learned about the resource and explored the value of making global connections in the classroom.

Keywords: Culture; Global; Pedagogy.

1. Activity Overview

Participants in this workshop consisted of classroom teachers, education leaders, and teacher trainers from multiple countries who were looking for ways to weave local and global cultures into mathematics lessons.

Mathematics comes alive when teachers make global connections in the classroom. Unfortunately, many classroom teachers lack the time and resources to complete the research required to make these connections.

Global Math Stories (GMS) is a free web-based resource (GlobalMathStories.org) that helps classroom teachers make global connections in the classroom. The site consists of approximately 70, one-page stories written by people from around the World, presented in both English and Spanish, called Mate Mundial (mathkind.org/mate-mundial). Teachers may choose to write their own lessons from the stories or use one of the lessons already developed. Each story is supplemented with resources to further explore the culture and social justice questions to look behind the mathematics. Often, after using a story in their classroom, teachers or students decide to write and submit their own story.

[1] Mathkind, Chapel Hill, NC 27514, USA. E-mail: Chadd@Mathkind.org
[2] Childhood Education-Mathematics, Brooklyn College-City University of New York, 2900 Bedford Ave, Brooklyn, NY 11210, USA. E-mail: Haydar@brooklyn.cuny.edu
[3] Mathkind, Chapel Hill, NC 27514, USA. E-mail: Pao@Mathkind.org

In this workshop, participants learned about the site and how to use it to make global connections in their classroom. First, they participated in a mathematical task based on the Wagah Boarder Ceremony. In addition to the analysing the mathematics in the tasks, individuals considered social justice questions associated with the story.

Next, participants explored another story, this time based on the island city of Malé, the capital of Maldives. Working as teams, groups developed mathematical tasks they might create based on the story. Additionally, they explored existing and created their own social justice questions that arise from their exploration.

Before choosing a story to presenting themselves, participants reviewed the role of stories in the mathematics lessons. When mathematical tasks are designed to allow students to make meaningful connections, they develop create a context around which to build mathematical concepts.

Progressing along, participants will pick a story from which to develop a task. They presented the story to the audience and describe how a lesson would progress, complete with a social justice question. Some participants developed actual lessons they would use for their classroom.

Finally, everyone will discuss the benefits of making connections of local and global cultures in the classroom. They will be invited to contribute stories to the site and to share it with educators and authors in their communities.

2. Future Direction

Feedback from participants was universally positive. Future work, generally with culture and mathematics, specifically with Global Math Stories, must include ways teachers can fulfil restrictive, mandated objectives while making cultural and global connections. To that end, the producers of the Global Math Stories website is matching specific objectives to each story so that every story will have one specific, identified objective for every grade level. These objectives will be searchable.

Secondly, the social justice questions and dilemmas associated with each story must be more clearly identified and searchable. Each story contains at least two “extension questions”, but they are not searchable. Future work to strengthen the site must make them searchable.

Finally, future research must be conducted to more clearly identify how making global and cultural connections in the mathematics classroom deepens student understanding of the mathematical concepts being taught.

Lessons that teach include global and cultural connections should not be special, one-off experiences. Rather, they must become part of an integrated curriculum that allows teachers to meet the mathematical objectives set forth by the administration or government. Resources like Global Math Stories are a step toward reaching this objective.

Workshop 8

Math for All: Professional Learning to Help Teachers Reach All Students in the Mathematics Classroom

Babette Moeller[1] and Matthew McLeod[2]

ABSTRACT Persistent differences in mathematics performance between general and special education students underscore the need for improving teachers' preparation to better serve the needs of students with different strengths and needs. Math for All is a research-based, intensive professional learning program designed to help K–5th grade teachers provide accessible, high-quality mathematics instruction to ALL students, including students with disabilities. Using a neurodevelopmental framework (NDF), we analyze the lesson, understand the strengths and challenges of a student, and build adaptations that support the student's access to the lesson. Multiple research studies have demonstrated the efficacy of the Math for All approach.

Keywords: Mathematics; Instruction; Students with disabilities; Accessibility; Lesson planning; Neurodevelopmental framework.

1. Theme and Description

Math for All (Moeller et al., 2012; 2013) is a research-based professional learning program for teachers of grades K-5. The program introduces general and special education teachers to a neurodevelopmental framework (NDF) as a tool to analyze a mathematics lesson or task, including all the demands placed on students as they engage in the activity. This same lens is applied to understanding a student's learning profile in an effort to identify their strengths and challenges. Armed with detailed understanding of the lesson and the student, general and special education teachers collaboratively plan adaptations to the lesson that will increase its accessibility while maintaining the goals and rigor of the mathematics.

At the core of Math for All is the neurodevelopmental framework (Barringer et al., 2010). The NDF parses learning into eight functions — memory, attention, psychosocial, language, higher order thinking, spatial, sequential, and motor — that engage whenever we learn or do anything. Focusing on mathematics learning and instruction, participants learn about the NDF through articles and video case studies

[1] Education Development Center (EDC), New York, NY 10014, USA. E-mail: bmoeller@edc.org
[2] Education Development Center (EDC), Chicago, IL 60642, USA. E-mail: mmcleod@edc.org

during a portion of the workshops. The remainder of each workshop is devoted to helping teachers apply what they learned through adapting a lesson from their mathematics program. General education teachers work with their special education colleagues and experienced Math for All facilitators to engage in a process of collaborative lesson planning to adapt a lesson that they will teach in the near future. During this planning, teams use the NDF to analyze the demands of the lesson, understand their student's learning profile, and develop adaptations that capitalize on the student's strengths and help mitigate the challenges they might face in accessing the lesson.

2. ICME-14 Activity Overview

In our conference session, attendees sampled a portion of the first workshop in which we introduced the NDF and watched a student as she worked on a lesson about building arrays and finding factor pairs of a number, in this case 24. Participants began by watching a recording of the teacher introducing the lesson and then carried out the task using a set of virtual unifix cubes, followed by creating a list of what they had to know and do in order to succeed at the task — move the cubes, count to 24, form a rectangle from the cubes, etc. We next introduced the NDF and asked participants to categorize each of the demands into the eight constructs. Then we observed a focal student, Jashandeep, while she was working with a partner on the same lesson, and we tried to understand something about her strengths and challenges. Finally, we discussed some potential ways that the teacher did or could have supported Jashandeep to be successful.

We concluded our session by sharing research findings (Duncan et al., 2018) which showed that teachers who engaged in Math for All made positive changes to their instructional practices, felt more prepared to meet the needs of all their students, and saw larger increases in student achievement scores than did comparison group teachers.

3. Future Directions and Suggestions

Several components of the Math for All professional learning model make it particularly successful for changing teachers' understanding of individual students' strengths and needs and for improving student outcomes in mathematics: (1) a focus on learning rather than teaching mathematics and the use of a framework informed by learning science to help teachers better understand how students learn; (2) the collaboration between general and special education teachers; and (3) practice-based professional learning that engages teachers in intentional lesson planning and reflection on their practice. We recommend that mathematics leaders incorporate these components in their work with teachers, and encourage further research into what makes professional learning most effective.

Workshop 9

Networking Design Approaches: Around the Teaching of Mathematical Proof

Tatsuya Mizoguchi[1], Ignasi Florensa[2], Koji Otaki[3], and Hiroaki Hamanaka[4]

1. Theme and Description

This workshop is based on part of an ongoing research project regarding the cultural and anthropological study on the development of competencies of mathematical proof throughout of secondary school. The workshop focused on the design of teaching, especially for mathematical proof task. For this, various designs based on different theoretical approaches were compared and their characteristics were considered. The key questions of the workshop were as follows:

(1) How teaching of mathematical proof can be designed with each approach;
(2) What characteristics each approach has in the design process;
(3) How does each approach complement the others?

In the workshop, we considered three different approaches: Study and research paths (with Q-A map) in the Anthropological Theory of the Didactic; Japanese problem-solving lesson model (so called open approach); Substantial Learning Environment. Based on the planned structure shown below, the workshop accessed the above questions by designing teaching for a common mathematical task (Tartaglia's triangle) and then comparing/networking them. There are cultural and theoretical differences in teaching design. In the workshop, we searched for the possibility of new approaches on these problems through collaboration with participants.

The workshop was organized by Japan and Spain jointly. Each organizer was familiar with each theoretical approach. In addition, the workshop was conducted in cooperation with the following prospective contributors (alphabetical order): Yoshitaka Abe (Niigata, University, Japan), Terumasa Ishii (Kyoto University, Japan), Hiroyuki Kumakura (Shizuoka University, Japan), Susumu Kunimune (Shizuoka University, Japan), Takeshi Miyakawa (Waseda University, Japan), Yusuke Shinno (Hiroshima University, Japan), and Yuki Suginomoto (Nagasaki University, Japan).

[4] Hyogo University of Teacher Education, Japan. E-mail: hammer@hyogo-u.ac.jp

Study and research paths [SRPs] are the inquiry-based teaching formats proposed by the Anthropological Theory of the Didactic. SRPs are study processes initiated by an open generating question Q stated to a community of study. These processes include moments of study (search for available and relevant information to answer the question) and research (adaptation of the found information to the specific problem, creation of new solutions) (cf. Florensa, et al., 2021). Problem-solving lesson model is a format widely used in mathematics lessons in Japan. It includes the following phases (although each label may vary): problem posing (comprehension); self-solving, refining and elaborating; and summarizing and developing. Stigler and Hiebert (1999) called it “structured problem solving”. In this workshop, we will provide a template which is arranged so that even beginners can use it (cf. Mizoguchi, 2013). Substantial Learning Environment [SLE] is a keyword of Wittmann’s perspective of the didactics of mathematics as a branch of design science. It means a didactic device or organization which fulfills the following four conditions: (1) representing central objectives, contents and principles of teaching mathematics at a certain level; (2) being relevant to significant mathematical contents, procedures and processes beyond this level, and being a rich source of mathematical activities; (3) being flexible and can be adapted to the special conditions of a classroom; and (4) integrating mathematical, psychological and pedagogical aspects of teaching mathematics, and so it forms a rich field for empirical research (Wittmann, 2001).

2. Activity Overview

The activities of the workshop were implemented as follows:

Activity	Working format/Responsible person
Introduction and overview of the WS	All participants/T. Mizoguchi gave an overview of the workshop.
Introducing the common task	All participants/H. Hamanaka introduced the mathematical background of the common task: regarding Tartaglia’s triangle.
Short keynotes: Theoretical tools and the teaching-designs	All participants/I. Florensa, T. Mizoguchi, and K. Otaki provided short keynotes from three different approaches as follows. SK1: “The theory of substantial learning environments” by Koji Otaki; SK2: “Study and Research Paths: the ATD proposal” by I. Florensa; SK3: “Problem Solving Lesson Format in Japan” by T. Mizoguchi.
Discussing along with the key questions	All participants/I. Florensa, T. Mizoguchi, K. Otaki, and H. Hamanaka
Summarizing: Reflections and further considerations	All participants/I. Florensa, T. Mizoguchi, K. Otaki, and H. Hamanaka

3. Future Directions and Suggestions

This workshop was organised with the aim of networking the design of didactic practice, in line with recent efforts on networking theories (Bikner-Ahsbahs and Prediger, 2014). Of course, this initiative was still in its infancy and there were many challenges ahead. However, through the experience of this workshop, we have been able to clarify what each approach has in common, and conversely, the differences in what each approach intends to contribute.

So, such workshop is very significant for the scientific design of didactic practice. The outcomes of the workshop will be revealed on another paper.

Workshop 10

Challenging Ableist Perspectives on the Teaching of Mathematics: A CAPTeaM Workshop

Elena Nardi[1], Irene Biza[2], Solange Hassan Ahmad Ali Fernandez[3], Lulu Healy[4], Érika Silos[5], and Angeliki Stylianidou[6]

ABSTRACT This short paper outlines the main aims and objectives of the CAPTeaM project and the activities that took place during the CAPTeaM workshop at ICME14 on Wednesday 14 July 2021.

Keywords: CAPTeaM; MathTASK; Ableism; Disability; Inclusion; Mathematics.

1. The CAPTeaM Project

The MathTASK and CAPTeaM projects see engaging school and university teachers with challenges they are likely to face in class as an effective professional development approach. We design situation-specific tasks that emulate these challenges (such as: fostering mathematical reasoning; strengthening classroom management; enriching use of digital resources; and, improving the inclusion of often marginalised groups of learners) and we engage teachers with these tasks in reflective workshop settings. In this workshop, we focused on the last of the aforementioned challenges, inclusion. This is the focus of the CAPTeaM project (Nardi et al., 2018), an international partnership and mobility project between institutions in the UK and Brazil and funded by the British Academy (2014–15, 2016–21).

The CAPTeaM project (**C**hallenging **A**bleist **P**erspectives on the **Tea**ching of **M**athematics) sets out from the assumption that, rather than being the consequence of internal, individual factors, disabled students' oft-reported underperformance in mathematics can result from explicit or implicit exclusion from mathematics learning. The project challenges teaching practices that contribute to such exclusion and that may emanate from ableist[7] perspectives on mathematics. The project's aims cohere

[7] Ableism: "a network of beliefs, processes and practices that produces a particular kind of self and body (the corporeal standard) that is projected as the perfect, species-typical and therefore essential and fully human. Disability then, is cast as a diminished state of being human." (Campbell, 2001, p.44)

with the articles of the United Nations *Convention on the Rights of People with Disabilities* (2006) that both the UK and Brazil have signed up to and the project aims to contribute to a hitherto under-researched, yet growing and highly topical, area of research (Healy and Powell, 2013). CAPTeaM endorses a Vygotskian historical-cultural perspective and elements of embodied cognition (Nardi et al., 2018) and its data consists of written responses and video recorded work on two types of tasks, Type I and Type II, by pre- and in-service teachers of mathematics.

In Type I tasks, participants engage with classroom episodes that evidence mathematical contributions which are made by students with a physical disability (e.g., are visually or hearing impaired), have the potential to shift classroom mathematical discourse towards creatively unexpected turns and may bring learning benefits to all in class. Said episodes are selected from the databases of the Brazil-based (Rumo à Educação Matemática Inclusiva) and UK-based (e.g., Stylianidou and Nardi, 2019) project partners. In Type II tasks, participants engage in small groups with solving a mathematical problem while at least one of them is temporarily and artificially deprived of access to a sensory field or familiar channel of communication. Work on both types of tasks concludes with sharing reflections on the experience and with a brief exposition on the project's hitherto data analysis, findings and plans for the future.

2. The CAPTeaM Workshop at ICME-14

Workshop participants engaged with two tasks, one of Type I and one of Type II. The session lasted 90 minutes and was structured as follows.

Nardi introduced CAPTeaM's aims, objectives, theoretical framework and research design. She outlined the two types of tasks that participants were invited to engage with during the workshop and introduced the first, *André and the pyramid.* In it, participants were asked to consider a mathematical contribution made by André, a blind student: André's description of a square-based pyramid, as an object that can be built from gradually diminishing squares, evokes Cavalieri's (Nardi et al., 2018) description but also diverges from the faces/edges/vertices definition proliferating in textbooks. Participants explored the mathematical affordances of André's proposition and considered the enriching role that such a proposition may play in lessons. They pondered on what constraints and support teachers have for orchestrating the inclusion of disabled learners in mathematics lessons and shared experiences from the very diverse educational contexts each was located in.

Brief findings from data analyses driven by the five themes of *Value and Attuning*, *Classroom Management and Benefit*, *Experience and Confidence*, *Institutional Possibilities and Constraints* and *Resignification* were shared with the participants, before proceeding with engaging with a Type II task. In normal circumstances, this type of task involves the use of several sensory channels, including touch (Nardi et al., 2018). Doing so however is not possible during an online workshop and participants were asked to engage with a COVID-19 pandemic secure adaptation of a Type II task.

This involved working in groups of three (A, B, C), where one participant was A (observer), B could not see, and C could not speak. We communicated a mathematical problem $(354 - 86 = ?)$ to C in a private channel of the chat function on the conference platform. Nardi and Biza collated accounts from the chat and coordinated the discussion of the experience across the entire group. During this, participants shared their experiences of working with limited access to sensory channels. Their coping strategies were then compared with those produced by CAPTeaM participants and the workshop concluded with Nardi outlining project findings so far and mapping current and future CAPTeaM actvities. The workshop concluded with participants asking questions and reflecting on — as well as evaluating — the experience of participating in the workshop.

Throughout the workshop, participants noted substantial differences on inclusion policy and implementation around the globe. Exchanges focussed on how deconstructing the notion of the normal mathematics student/classroom and attuning mathematics teaching strategies to student diversity takes different meanings in different institutional contexts. For example, Nardi and Biza shared the example of a doctoral study in the UK, led by team member Stylianidou, that focuses on exploring and engineering mutual benefits for the mathematical learning of sighted and visually impaired pupils in inclusive elementary mathematics classrooms in the UK, where inclusion is thoroughly legislated but its actualisation supportive mechanisms for teachers is in relative infancy. Other issues, such as mathematical and pedagogical support for specialist teaching assistance staff (e.g., Sign Language interpreters for hearing-impaired/deaf learners) were also raised.

Acknowledgments

CAPTeaM was funded by two British Academy International Partnership and Mobility Grants (2014–15: PM140102; 2016–21: PM160190)

Workshop 11

Simulation Games for Geometry Learning and the Development of Mathematical Language

Angela Piu[1] and Cesare Fregola[2]

ABSTRACT This report describes a workshop on the structure, teaching/learning process, and functions of collaborative simulation games developed to enhance geometry teaching/learning in primary schools. The online participatory workshop entailed observing an ad hoc video about *Cartolandia*, a simulation game on isometries. The video illustrated the structural and dynamic aspects of simulation games based on a dynamic design model developed within a broader research program. The ensuing discussion with the participants covered: the processes of play, teaching-learning, and mathematization suggested by observing the video and engaging with the simulation game; transferring the game to other school settings.

Keywords: Simulation games; Teaching geometry; Research at primary school.

1. Theme and Description

The workshop was focused on simulation games for primary-level geometry learning and the underlying design model developed within the framework of *Simulandia*, a research and teacher professional development project (Piu and Fregola, 2011).

The research program began in 2011 with *Cartolandia*, a simulation game on isometries. Four other simulation games — on the concepts of isoperimetry, equal area, similarities, and angles, respectively — were subsequently experimentally validated (Piu, Fregola and Barbieri, 2016; Piu and Fregola, 2020).

The games are learning environments organized around a model that represents mathematizable aspects of the real world, including a target mathematical concept, via multiple perceptual stimuli. The participating schoolchildren: act out assigned roles and make decisions in light of the possibilities and constraints dictated by the rules of the game; actively handle structured materials, according to the procedural requirements and aims of the game and the associated learning objectives; interact, communicate, and cooperate with their peers, with the teacher mediating as necessary; and reflect on the meaning of their experience.

[2] Human Sciences Department, European University of Rome, Roma, 00163, Italy.
E-mail: cesare.fregola@unier.it

The *Simulandia* games/learning environments have been developed to help primary school students learn key geometry concepts while having fun and acquiring the knowledge/competences required to construct mathematical language.

The theoretical-methodological framework underpinning the design model is informed by: the literature on simulation games; theories and methods from educational science, including the principles of learning by discovery and cognitive load theory (Sweller, 2003; Piu and Fregola, 2020); a semiotic perspective on math learning that emphasizes helping children to attribute meaning to the concepts they are constructing and to the language used to express and share these concepts (Duval, 2017). This implies attending to the patterns of transcoding that underpin the gradual construction of formal mathematical language starting from learners' current everyday language, via an abstraction process that leads to the discovery or definition of geometry concepts (Piu et al., 2016; Vergnaud, 1994).

Research and experimentation with primary pupils and teachers showed that playing *Cartolandia* significantly reinforced children's recall and mastery of concepts: participants in simulation games displayed more robust geometry understanding than peers who took a traditional geometry lesson (Piu et al., 2016).

Based on these results, we developed simulation games on the concepts of similarity, angles, isoperimetry, and equal area, establishing that the structure of the teaching-learning process remained invariant across different games and geometry contents (Piu and Fregola, 2020). All the games share a set of characteristics: rootedness in the literature on simulation games; application of transcoding to the construction of mathematical and formal language suited to the target concepts; the interactional dynamics of children cooperating to solve a complex problem in a simulated real-life scenario; a set game structure and teaching-learning process that facilitate progressive abstraction, representation via multiple semiotic registers (Duval, 2017), and a progressive shift away from the pragmatic language used to describe situations and communicate decisions, discoveries, and outcomes, across the phases of sharing the objectives of the game, initial briefing, play, and debriefing (Piu and Fregola, 2020).

2. Activity Overview

The workshop participants viewed an ad hoc video on the structure and dynamics of *Cartolandia* (Fig. 1, on the next page), a simulation game on isometries for primary school children and teachers.

Participants were briefly introduced to the theoretical-methodological framework underpinning the game's design. They next observed the three-part video, covering: 1) the *Cartolandia* setting (this was to immerse the participants in the experience of the game, and explain its aims and stages; 2) the key interactions among the children during the simulation game; and 3) the debriefing following the game, during which mathematical language is constructed based on the practical experience of playing the game. The final section was narrated by Eledia Mangia, the teacher/researcher who led the game.

Cartolandia is set in a paper city, whose inhabitants learn that a map of the town has been stolen from the city museum. Guided by their teacher, the participants play the role of carto-detectives tasked with retrieving the map, identifying the thief, and reporting to the carto-general on the methods they used to carry out their inquiry.

The children work in a specially designed carto-lab to analyze the carto-carpet — a long sheet of paper with the footprints of all the visitors to the museum — and, later, the visitors' photographs (silhouettes).

In accordance with strict rules, they lay transparent plastic sheets with footprints or silhouettes drawn on them, either over the footprints on the carpet or over the outline shapes of the visitors, to check for matches.

The carto-detectives are invited to discuss the different methods they are allowed to use during the game, and to record their actions on a sheet, so that they can report to the carto-general later. Thus, they are encouraged to invent symbols for the operations they performed with the transparent sheet to match footprints or shapes. They jointly decide how to describe their actions and how they identified the thief, choosing which "code" to adopt in their final report to the carto-general at the end of the game.

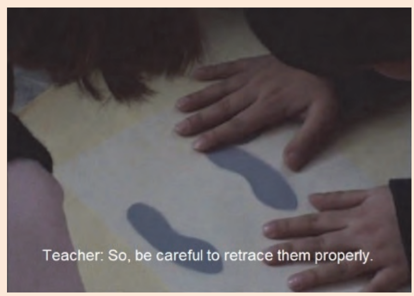

Fig. 1. Cartolandia

The workshop discussion covered the structure/characteristics of the simulation game as well as the teaching/learning processes it elicits. The participants' observations allowed us to explore the three interdependent processes that characterize the design model (and their place within the systemic whole of the simulation game):

- the game process/architecture, which leads to the discovery of concepts via complex problem-solving activities within a simulated scenario with its specific constraints, roles, instructions, and end goal;
- the mathematization process, whereby the children solve the problem via transcoding and the deployment of different semiotic registers, progressively acquiring mathematical language by abstracting, representing, and transforming informal language based on their actions and the rules of the game;
- the teaching-learning process, comprising: opening — eliciting interest/ defining the learning agreement; briefing — presenting the aims/rules of the game; the game itself — experientially and collaboratively discovering

concepts and sharing them with peers via interaction and dialogue; debriefing — systematizing new concepts, facilitating mindful understanding of them, and formalizing them by expressing them symbolically.

Finally, we discussed the feasibility of replicating the simulation game teaching-learning experience in participants' own educational settings, considering differences in culture, teacher training, and methodological approaches to math teaching.

3. Future Directions and Suggestions

Our research program has yielded interesting outcomes, namely: — validation of a dynamic game design model; — identification of the structural constants in the teaching-learning process and its interdependence with a game architecture based on complex problem-solving and the mathematization of reality; — evidence of enhanced understanding and recall of concepts and learning contents. These outcomes are currently being consolidated via experimentation with new games, and extended via investigation of the relational skills of children and teachers from a transactional analysis perspective. In time, this may inform systematic teacher training trajectories and foster the wider deployment of simulation games in schools.

Workshop 12

Developing Quality Criteria for Creating and Choosing Mathematics Learning Videos

Iresha Ratnayake[1], Eugenia Taranto[2], Regina Bruder[3], and Maria Flavia Mammana[4]

ABSTRACT In this report we present our experience in conducting a workshop on using our catalogues for choosing and creating learning videos for mathematics. On the one hand, the participants had an opportunity to use our catalogues to evaluate videos using two different approaches — by being both users and creators. On the other hand, we had an opportunity to obtain feedback from them based on their own experience of working with pre-service teachers in creating learning videos.

Keywords: Mathematical learning videos; Quality criteria; Video catalogue.

1. Theme and Description

In this workshop, we shared the results of a joint project — *Quality of Learning Videos — Mathematics (QLeV)* — between two universities in Germany and Italy. The project aimed to develop quality criteria to create or choose mathematical learning videos. There are many mathematical learning videos freely available on the internet with many videos being uploaded on various platforms. There are, however, many important factors that need to be considered in creating and choosing a learning video. In our project, we suggested some crucial quality criteria to accomplish the intention expressed above. We started with a catalogue developed under the CAKE project (Feldt-Caesar and Bruder, 2018). This catalogue was a general one including quality criteria for digital learning environments. Following this, the current project was designed to develop quality criteria for learning videos from a mathematical perspective (Ratnayake et al., 2020). The result of our collaboration generated two catalogues: (i) quality criteria for creators and (ii) quality criteria for users (teachers). Our catalogues attended to learning situations, expected prior knowledge, accuracy of the content, learner's expectations, pedagogical consideration and design and technical consideration. During this workshop, we shared the two developed catalogues to stimulate discussion with colleagues in the mathematics education research community about ways in which they might be refined and extended. The refinement of the catalogues can in turn contribute to building a shared understanding of the creation and use of high-quality mathematics learning videos.

[4] University of Catania. E-mail: fmammana@dmi.unict.it

2. Activity Overview

We showed a video (chosen from YouTube) explaining some mathematical concepts. After watching the video, a discussion on following questions was conducted.

- What do you think about the video?
- Would you use this in your lessons?
- If so for what purpose?

The participants were thereafter guided to watch the video again and evaluate the video using our catalogue *Quality Criteria for Teachers as Users.* The participants evaluated the video using the catalogue in the internet portal and saved their evaluations. After the evaluation a discussion was conducted on the following questions:

- What can you say about your judgement?
- Did you change your judgement after you evaluated the video using the catalogue? If so why?
- Do you think the catalogue helped you to make a decision?

Subsequently, we discussed the criteria of the catalogue followed by a discussion on the following questions:

1. Are the criteria in the catalogue helpful in evaluating mathematics learning videos?
2. Is the catalogue helpful in choosing a good learning video that you can use in your lessons?
3. Are the criteria understandable?
4. Do you suggest changing any of the criteria? If so, please provide your suggestions.

In the second part of the workshop, we focussed on the creator's catalogue (https://wwwdid.mathematik.tu-darmstadt.de/videoevaluation/) that we propose using in creating a learning mathematics video. First, participants watched a video developed by a pair of pre-service teachers at the University of Catania as a fulfilment of their assessment of a mathematics course. These pre-service teachers followed our catalogue in developing this video. Participants of the workshop used our creator's catalogue to evaluate the video. We then conducted a discussion based on the following points:

1. Are the criteria in the catalogue helpful in evaluating mathematics learning videos?
2. Is the catalogue helpful in creating a good learning video that you can use in your lessons?
3. Are the criteria understandable?
4. Do you suggest changing any of the criteria? If so, please provide your suggestions.

3. Participants and Their Comments

There were ten online participants and some off-line participants from different countries. Most of the participants' pre-service teachers create videos during their undergraduate programmes. Thus, the audience paid more interest on the creator's catalogue and appreciated its features including the ability to use it as a guideline and as a self-and peer- reflection tool.

4. Future Directions

Currently our catalogue — creator's catalogue — is used for the activity called "5 minutes videos" which is a part of the project "Liceo Matematico" at the University of Catania. This is a national-level competition for secondary high school students. Thirteen schools joined the project. These students use our catalogue in creating videos in groups of 4–5 students. The evaluation of the videos will then also be done using the criteria in the same catalogue to choose winners of the competition.

Workshop 13

Beyond Financial Literacy and Financial Mathematics: Conceptualizing Financial Numeracy

Annie Savard[1] and Alexandre Cavalcante[2]

ABSTRACT This workshop engaged participants in an inquiry-based environment to conceptualize the role played by mathematics education regarding financial literacy, both in elementary and secondary schools. Our main goal was to introduce a conceptual framework that allows researchers and teachers to move beyond financial literacy and financial mathematics. The international efforts to incorporate financial literacy in schools have also penetrated the community of mathematics educators in several countries, however the role played by mathematics in this topic has been undertheorized, leaving practitioners without proper support to integrate these concepts in mathematics classes

Keywords: Financial Numeracy; Teaching Mathematics; Money.

1. Brief Introduction to Financial Literacy and Mathematics

The workshop started by presenting to participants a short definition of financial literacy. After that, we asked them to answer this question on Menti: *What is the relationship between Financial Literacy and Mathematics?* We discussed their answers before present to them the concept of financial numeracy.

1.1. Financial literacy

Financial Literacy (FL) has been defined over time as a portfolio of financial knowledge and the behavioral use of it (Huston, 2010; Johnson and Sherraden, 2007). Since 2012, The Organization for Economic Cooperation and Development (OECD) tested 15-year-old students regarding FL. Their international assessment program PISA (OECD Program for International Student Assessment 2016) says:

> *Financial literacy is knowledge and understanding of financial concepts and risks, and the skills, motivation and confidence to apply such knowledge and understanding in order to make effective decisions across a range of financial*

[1] Department of Integrated Studies in Education, McGill University, Montréal, Québec H3A 1Y2, Canada. E-mail: annie.savard@mcgill.ca

> *contexts, to improve the financial well-being of individuals and society, and to enable participation in economic life*. (p. 85).

Four areas of knowledge and understanding are defined: money and transaction, planning and managing finances, risk and reward, and financial landscape.

1.2. Financial literacy into mathematics

Over the last decade, financial literacy has been introduced to many K-12 school curricula around the world (Lusardi and Mitchell, 2014; Suiter and Meszaros, 2005). At the same time, research indicates that mathematical competencies play a major role in developing financial literacy (OECD, 2017). Such competencies promote the modelling of financial situations, the operationalization of financial concepts, and the development of financial mathematics. As a result, financial literacy is now embedded in some mathematic curricula (Savard et al., 2020), such as Australia, some Canadian provinces such as Ontario and British Columbia, and in Romania.

2. Financial Numeracy

Numeracy is more about how people do mathematics in their daily life rather than what do they know about mathematics. Therefore, numeracy is a social practice (Yasukawa et al., 2018). It is a culturally, historically, and politically situated practice. It conveys the values and visions of the world of social groups. Mathematics can be explicit or implicit. In that sense, numeracy comprises more than simple arithmetic operations (Goos et al., 2019). The concept of financial numeracy refers to the intersection of mathematics and everyday practices in the realm of finance (Camiot and Jeanotte, 2016). We believe that financial numeracy involves the wider scope of mathematical concepts, tools and procedures instead of referring to financial mathematics (which is a specific subfield of applied mathematics).

3. Overview of the Activities Proposed

During the workshop, participants were asked to work in team in breakout rooms for analyzing and categorizing a task coming from a mathematics textbook, in grade 7. We use Padlet for sharing their answers.

Look at each question in the situation.

Categorize them in a way that makes sense to you.

As you categorize them, think about the relationships between financial literacy and mathematics.

We had a whole group discussion about their analysis. At the end of their presentation, we presented our categories for analyzing tasks related to financial numeracy.

3.1. A conceptual framework to define financial numeracy

The categories for analyzing tasks are rooted in a framework developed through our collaborative work to conceptualize the role of mathematics in financial education. Through the activity and the discussions that followed, we were able to present a framework of financial numeracy education that encapsulates three dimensions: a) financial concepts as a means to develop motivation for and understanding of mathematics (contextual dimension); mathematics as a way to create models and understanding of financial concepts (conceptual dimension); and c) mathematical and financial concepts in relation to other epistemological systems such as ethics, politics, culture, values (systemic dimension). This framework was developed through research with secondary mathematics teachers from Quebec, Canada (Savard and Cavalcante, 2021). It encompasses the diversity in perspectives in the literature of mathematics education on financial concepts and situations (Cavalcante, 2020), and contributes to the field by systematizing the relationship between mathematics and financial education.

4. Concluding Remarks

This workshop provided a much-needed opportunity for researchers and practitioners in mathematics education to discuss the future of our classrooms now that mathematics teachers are being asked to teach financial concepts. Curricula all around the world are starting to incorporate financial concepts in mathematics in a wide variety of ways, often leading to inconsistencies and mixed messaging about the connections within our discipline and with other disciplines. We have also found inconsistencies related to the grades in which these concepts are being taught and the profile of students being taught. However, the most important challenge currently lies on the preparation of our pre-service teachers to enter the profession with proper knowledge of financial concepts. This challenge was emphasized during our workshop discussions, which led to the creation of a listserv to keep mathematics educators in contact with one another. We hope to provide future opportunities for events to researchers and practitioners interested in this topic through this listserv. To subscribe, please send a message to:
math-financialeducation-l-request@listserv.utoronto.ca

Acknowledgments

We want to thank l'Autorité des Marchés du Québec for their support. Please note that the opinion reflects only the researchers.

Workshop 14

International Mathematics Festival: A Fun and Collaborative Event for Students to Discover "Why" and "What If"

Mark Saul[1] and Cherry Pu[2]

This workshop took the form of a wide-ranging discussion of the opportunities afforded mathematics education by a variety of informal and after-school activities. Participants from six countries and five continents contributed their views and experiences. In addition, students from each of these countries participated in a sample activity, which was then analyzed both by the students and their teachers.

What follows is a summary of the main points made by each contributor.

1. Unlocking Student Potential

Many speakers gave examples of how their activities unlocked students' potential in ways that formal classroom activities may not have. Tatiana Shubin (San Jose State University, USA) talked about her experience with math circles (https://mathcircles.org/home-2/), both in her home institution and on the Navajo Indian Reservation in Arizona. She showed video clips of students saying "I'm confused", but grinning in anticipation of learning something. Another student commented that he "didn't know he was smart" until he was given the opportunity to work non-routine problems in a social setting. Maria de Losada (Colombia, Universidad Antonio Nariño) agreed: "The uniqueness of each young person implies that there are myriad ways to unlock her or his potential for creative thought and engaging in mathematical activity. Solving every new and ingenious problem, preparing an exhibit for a math fair, developing strategies and arguments to prove a certain result, participating in situations that are at once fun and challenging, such as those encountered in a math festival, can all have their appeal to young people. with different preferences coming to light according to the richness of opportunities open to each one."

[1] Ph.D. Consultant, New York, United States. E-mail: marksaul@earthlink.net
[2] Open House Education Foundation, Beijing/Hong Kong, China. E-mail: cherrypu2008@live.com

2. Motivation for Students

At other times, speakers noted that doing mathematics in informal contexts continued to motivate students, even after their potential had been recognized. Often, they remarked that the aspect of mathematics as a joyful experience was something that students learned in and of itself. Hongliang Shi (No. 2 High School of East China Normal University) noted "If students love the subject matter, they take more initiative in the learning process. This is important for students' holistic development." Lynda Phillips (Ridge School, Kumasi, Ghana) commented: "It starts with games, then puzzles. These help the student focus and pay attention to everything they do. Then we can really relate these to the concepts. Gradually they will appreciate the subject, by generating interest and letting them know that math can be fun." Prodipta Hore (Birla Academy, Mumbai, India) noted: We conduct contest for students, and 60 to 70 percent of students sign up for it. Whether they get good scores or not — that's not the question. At least the participation is there. They love it so much that they start participating in it. He further remarked: "Mathematics is not only about numbers. When we teach it to our students, they automatically fall in love with it." Andrey Spivakov (Pelican Study, Russia) likewise commented: "It's simply fun, and keeps members motivated. Our competitions turn games into captivating and unpredictable entertainment." Fanglin Tian (No. 2 High School of East China Normal University) noted: "Math puzzles are great for intellectual development. They can increase students' interest in learning mathematics and broaden students' horizons as well. Therefore, the mathematics and games approach are widely recognized by us."

3. Articulation with Formal Instruction

A number of important points came up linking informal mathematics with more traditional classroom experiences. Hongliang Shi described an effort in his school to produce a classroom-oriented curriculum centered around learning through games, as part of their emphasis on learning based on doing research and developing talent. For the past seven years, he has been developing a mathematics course based on learning through games. The games were used as a gateway to more formal mathematics, expressed in the traditional axiom-and-theorem style. The classroom experience included competition problems and math festival activities, which overflowed 'back' into the informal space. Students developed their own clubs and informal structures to host festivals and administer contests. The enthusiasm was not confined to students: a cadre of five teachers has coalesced around the idea of using informal mathematics to motivate formal learning. A serious point about the relationship between formal and informal education was brought up by Lynda Phillips: "The COVID years have been a challenge. Teachers are overwhelmed, and find it hard to deliver the traditional curriculum. At such times, informal education can fall by the wayside. But even in normal times, parents are concerned about preparing their children for national exams, and may not see the connection between playing games and learning formal mathematics. We have to try to explain to them why we use different approaches."

4. Connections with More General Culture

Aside from linking informal education with the classroom, speakers also made numerous remarks about how informal education contributes to the development of culture more generally. Andrew noted: "High quality 'soft skills' are essential for completing game tasks. That is why our curriculum is geared towards not only learning how to solve math problems, but also developing social skills, such as meaningful discussion and teamwork."

Maria de Losada commented extensively on the effects of her work on more general culture: "We knew we had arrived when a central character in a popular sitcom on Colombian TV was described and singled out as having done well in the math Olympiads…. And yesterday I received an email from a Venezuelan student. Since we were running our summer school online, we opened it up to some Venezuelan students as well as Colombian students. Not only did he thank us for having been in the summer school, but he recounted that he had taken first place in the Venezuelan Math Olympiad for his age group, which was sixth and seventh grades. It's important to understand that things are not normal at all in Venezuela. And the fact that he was able to participate in a school with Colombian students and other Venezuelan students as well. He said it was absolutely one of the most important factors in his being able to do so well in the Olympiad.

5. Connecting Students and Teachers Worldwide

Hector Rosario (CYFEMAT International Network of Math Circles and Festivals) talked about how the network of informal educators keeps expanding. His work in Latin America, where he teamed up with Jeannette Shakeli in Panama, has helped to build networks of informal learning across Latin America. Using the Julia Robinson Mathematics League materials (www.jrmf.org), Rosario and Shakeli explored mathematics with virtual math festivals and circles. Translation of materials into Spanish catalyzed the formation of a community in Latin America that has begun to create its own activities. Rosario described how the use of virtual convening software changed the look of math festivals. Online apps can mimic the experience of playing with manipulatives, and can facilitate communication across vast distances.

The workshop included examples of this phenomenon, as we played clips of students from the six countries involved working together on solving two math puzzles (Wolves and Sheep and Wycoff's Nim). Virtual technology was effective in bringing these students in touch with each other, and their interactions often illustrated some of the points made by their teachers in the conversation. Informal mathematics can forge communities across boundaries, time zones, and oceans. As Tatiana Shubin noted, "Mathematics is the birthright of every human being, and mathematical talent is spread evenly across populations."

The COVID-19 pandemic has changed the world. We have struggled to live with it over the three years it has been with us. One silver lining of the struggle has been that we have found ways to come together without being face-to-face. Indeed, this workshop started out as a face-to-face International Mathematics Festival. Ironically, the COVID-19 pandemic emergency, which has imposed unexpected limits on so many of us, was the occasion for a broadening of the topic of this workshop.

Workshop 15

Mathematics Learning and Mathematics Games

Hongliang Shi[1] and Fanglin Tian[2]

ABSTRACT Investigating the relationship between mathematics learning and games, we find that games and mathematics are very closely related. In our workshop, we give a brief review of the results to our research, and share our experiences about the series of activities. Then we hold a small Mathematics Festival.

Keywords: Mathematics Learning; Mathematics Games; Traditional Chinese Games.

1. Research on the Construction of Mathematics Curriculum from the Perspective of Literacy

1.1. *Improving mathematics literacy*

A new era calls for educational reform, improving education quality, and STEM education has become a hot topic. The goal of education has changed, with more emphasis on morality and comprehensive educations. In-depth study of subject moral education has been carried out, and the pedagogical approach of subject education have become clear.

The aim of our math education is to improve math literacy. It is the internal literacy that people can observe the world with the eyes of math. It is composed of math knowledge and skills, math thoughts and methods, and math abilities and concepts.

1.2. *Cultivating mathematical thinking*

The core of math literacy is thinking literacy. Dewey proposed a five-step method of reflective thinking and wrote in the book *How We Think*. The whole and only purpose of intellectual education is to cultivate thinking habits. Thinking is Power. It emphasizes multiple perspective thinking and integration of Chinese and Western thinking. Therefore, math modeling and math games have become the best carriers for thought training.

[1] No.2 High School of East China Normal University, Shanghai, 201203, China.
E-mail: shihongliang@hsefz.cn

[2] No.2 High School of East China Normal University, Shanghai, 200241, China.
E-mail: tianfanglin@hsefz.cn

The key to improving math literacy is to cultivate math thinking. The learning process of math is a process of acquiring math knowledge, methods, application and internalization, and at the same time a process of continuous cultivation and strengthening of the quality of math thinking. People with high math literacy often receive systematic math education, rich in math knowledge, and often show sensitivity and adaptation to numbers in life and work, and can separate math factors from complicated cases, modes, and perform.

1.3. Math games

Math games promote the growth of modeling awareness and higher order thinking. Learning is the process of continuously solving problems and creating meaning in continuous interaction between individual and the situation. Context is the gradual formation of disciplinary concepts, thinking models and inquiry skills, and the basis for continuous structuring of disciplinary knowledge and skills. Project-based activities should be adopted to improve math modeling literacy in modeling practice. The teaching of project-based learning courses such as “Math Modeling” is often experiential learning, cooperative learning, inquiry learning, and constructive learning, which promotes the transformation of students’ learning styles and evaluation methods, which is favorable to the realization of subject education.

2. Mathematics Learning and Mathematics Games

2.1. Math & games in class

Since the fall of 2014, we set an optional course named Mathematics and Games in senior high school. At School of Excellence in 2015, we invited teachers from Stanford to instruct students. Now there are more and more teachers and students involved in Mathematics and Games. Usually, the classroom mode is as follows: Rules and History → Play and Think (individually or in groups) → Modelling → Solution → Play again.

We did inquiries in the latest three terms. The students were from 10th grade students enrolled in Mathematics & Games. Over half of the students select this course for the reason they like playing games or they love math. They prefer to think while playing. Group discussion is also liked by nearly half of the students. One third students enjoy thinking independently. More than half of the students think modeling is difficult in game research. Acquiring playing skills and understanding the principles rank second and third respectively. Talking about harvest, training thinking ability is placed the first. Students thought they learned some new games, ways of solving problems, some abstract questions can be modeled to solve and they also admire math is wonderful. They harvest rich math knowledge and get more practice. Some students were interviewed. Compared with traditional math class, students think math game class is more fun, and they can experience the principles by playing games, it is more understandable.

2.2. Mathematics festivals in school

In the summer of 2017, we start to cooperate with Julia Robinson Mathematics Festival (JRMF), an educational organization from Stanford. We learn a lot from them, especially the activity named Mathematics Festival. Since 2017, we held our own festivals one or two times a year at our campus. In December 2019, COVID-19 broke out. Then we can't go to campus or play together. JRMF opens webinars about games, and we also joined in.

2.3. Student's club

In 2020, a student club on mathematics and games was built. A student from Grade 10 is in charge of it. Students in the club did a good job. They played many games together and did a lot of research on the games. They also share the games to the old people to help them keep sharp in mind. And they went to the community to share their fruit.

3. Mathematics Festival

Mathematics Festival is quite an important part in our workshop. There are 14 games in the meeting room, located at different tables. Each table has one or two table leaders. They guide the attendees to play games. Attendees are free to move to any game they would like to join in at any time. We had a great time during the Mathematics Festival time. People who joined us showed their passion in Mathematics Games teaching. The Chinese traditional games impress the audience very much.

4. Summary

Math changes thinking, math creates the world! The value pursuit of math education in our school includes: strong foundation-laying — a solid foundation of math knowledge for top innovative talents; empowerment — Cultivate students' core literacy in math and enhance their problem-solving ability; enhancing interest — enhancing the learning interest and academic interest of middle school students; quality improvement — comprehensively improve students' math literacy and enhance their thinking ability.

We will continue to develop and change in math and games. And we will do more research to connect math games and math modelling.

Acknowledgments

Thanks to the Julia Robinson Mathematics Festival for the support of technology.

Workshop 16

Self-Made Automata to Teach Mathematics in Preschool

Oliver Thiel[1] and Piedade Vaz-Rebelo[2]

ABSTRACT The workshop disseminated findings from the European research project AutoSTEM. The project aims to investigate how automata can enrich young children's play to promote a better understanding of Science, Technology, Engineering, and Mathematics (STEM). It aims to provide preschool teachers and other stakeholders of young children's education with tools and materials to build a didactic path, which is simple, replicable, and valuable in terms of (1) promotion of motivation for STEM, especially mathematics, (2) promotion of the development of creative thinking, problem-solving, and comprehension ability, and (3) cultural awareness and transversal values such as recycling.

Keywords: Preschool; Early childhood mathematics; Automata.

1. Theme and Description

Automata are fascinating mechanical toys. They are easy to create in the classroom, suitable for children's age, with simple to complex designs and motions. In the workshop, we presented the "snapping crocodile" developed by the project. We discussed how this mechanical toy could be used to teach mathematics in the early childhood classroom. The goal was to enable ECEC teachers to understand how to use AutoSTEM automata in their teaching practice.

2. Activity Overview

2.1. Presentation of the project's findings

The pedagogical approach developed in the scope of the AutoSTEM project is framed in a play-based pedagogy (Hedges and Cooper, 2018). The AutoSTEM project is distinguished by its potential to approach different disciplines. Besides STEM, it also promotes the development of transversal skills such as problem-solving, creativity and spontaneous cooperation (Thiel et al., 2020). One of the main features of this project is its ability to enhance children's motivation and engagement for STEM learning

[1] Mathematics Department, Queen Maud University College, 7044 Trondheim, Norway. E-mail: oth@dmmh.no
[2] Faculty of Psychology and Education Sciences, University of Coimbra, 3001-802 Coimbra, Portugal. E-mail: pvaz@fpce.uc.pt

(Santos et al., 2020). Another feature is the ability to increase creativity and well-being in the participating children. A clear example of this is the diversity of the products produced by the children, both the automata and their narratives (Bidarra et al., 2020). Another transversal competence is the spontaneous cooperation emerging in the various AutoSTEM activities (Bidarra et al., 2021).

2.2. Making a 'snapping crocodile'

The activity started with the introduction of the materials. The tutor talked about STEM aspects related to the building process during construction, especially mathematics. The following video explains the mathematical content you can teach using the 'snapping crocodile': https://youtu.be/VPfi2g_t5kg. After the attendees finished their automata, they presented their work by holding the automaton up to their camera, so everyone could offer feedback and compliment them.

2.3. Pedagogical concepts and ideas

Finally, the participants tried out the crocodile. They used it to lift light items and reflected on the following questions:

- How is the crocodile related to the curriculum?
- What learning goals can you reach with the crocodile?
- Which learning activities can you carry out with the crocodile?
- How would you structure a lesson with the crocodile?

When constructing the crocodile, several learning goals can be achieved (cf. Thiel, Vaz Rebelo, et al., 2020):

- The children learn about physics and mechanisms, in particular, linkages.
- They develop engineering competencies of analysis and construction.
- They learn mathematical concepts within the construction and assembly process, including patterns, shapes and numbers.
- They learn biology concepts about the animal and its environment.
- Other soft-learning goals can be included, like problem solving and creativity.

Building the snapping crocodile with preschool children offers a playful approach to introducing STEM concepts, such as linkages, geometry, and mathematical patterns. The construction and assembly process allows children to explore shapes, sizes, and center points while discovering the relationship between aesthetics and functionality. Other mathematical topics are the motion of the part and the length and width of the scissor arm that change in relation to each other when the mechanism is in action.

3. Future Directions and Suggestions

The project AutoSTEM was finished in the summer of 2021. All materials that the project has produced are still available on the project's website https://autostem.uc.pt/.

On the website, you will find an online course that helps teachers to learn how to implement our findings in their early childhood classrooms.

Workshop 17

Rich Math Activities for a Primary School Class

Albert Vilalta[1], Laura Morera[2], Horacio Solar[3], and Francisco Rojas[4]

1. Description

Innovamat is a math project that develops materials and activities to teach and learn maths at Primary School. Even though we are only three years old as a project, in 2019/20 more than 350 schools around Barcelona, Spain, are using our program.

According to the Catalan curriculum, which is similar to the NCTM Principles and Standards, we define 4 big math processes: "Problem Solving", "Reasoning and Proof", "Connections" and "Communication and Representation". Our activities always seek those children develop content and skills related to these processes, and this is why our teacher's guides focus on class conversation and materials manipulation. Furthermore, we are developing a self-adaptive app that allows every child to follow his or her own content-practice path. In addition to that, Innovamat is making big efforts to educate Primary School teachers in teaching rich maths from a process point of view, and we organize training sessions all around the country. Last September, more than 2500 Primary School teachers attended our Jornades Formatives (teacher training conferences).

Our didactic team is led by experts from the Universitat Autònoma de Barcelona (UAB). We propose rich activities that are designed in order to encourage teaching and learning math from a rich process point of view. The ideas beneath the project are based on research. Specifically, our main research sources are Morera's thesis (directed by J. M. Fortuny and N. Planas), the research from the Freudenthal Institute for Science and Mathematics Education, the Catalan official curriculum, USA Common Core and Mogens Niss' research. In addition to all that, PhD student Vilalta is working on a thesis to study how children take advantage of the learning opportunities generated in a class by the Innovamat project. Finally, Rojas and Solar, from the Pontificia Universidad Católica de Chile (UC), are going to contribute to enrich the activities and the way we communicate them to teachers, mainly thanks to their research experience in continuing teacher training.

At this workshop, we are going to introduce, perform and analyze three examples of activities from our project. Therefore, this workshop might be especially interesting

for Primary School teachers and any person who wants to know about rich activities and discuss them. The first activity is going to be a geometry activity based on the geoboard. The second one is going to be a numbering activity of productive thinking. The third one is going to be an activity about finding and reasoning patterns. We are going to explain each activity, ask attendants to take part in solving every challenge like if they were students and concurrently we are going to discuss, as teachers, the math didactics and learning opportunities beneath all of it. In addition to that, we are going to project and analyze some short videos from real primary school children working on such activities. We want to focus on the learning opportunities provided by the activities and our classroom management and on how children take advantage of those opportunities (focusing on math processes and contents).

Key questions:

1. Do the proposed activities and class management provide rich learning opportunities from a math process point of view?
2. How do children take advantage of these learning opportunities?
3. How could we make the activities richer?
4. How could we improve the transmission of these ideas to Primary School teachers?

2. Planned Structure

Planned Timeline	Topic Material	Material/Working Format/Responsible Person
00–10 min	Definition of the framework: math processes in the Catalan curriculum.	Computer and projector/Exposition and group discussion/A. Vilalta
10–40 min	Activity 1: Geoboard	Geoboard Computer and projector, paper with geoboard templates/Group discussion/ H. Solar
40–70 min	Activity 2: Productive thinking	Computer and projector, paper/Group discussion/F. Rojas
70–90 min	Activity 3: Patterns	Computer and projector, multilink cubes, paper/Group discussion/A. Vilalta

Workshop 18

The Felix Klein Project — Vignettes in Practice

Hans-Georg Weigand[1], Michèle Artigue[2], Ferdinando Arzarello[3], Yuriko Baldin[4], Bill McCallum[5], Christian Mercat[6], and Samuel Bengmark[7]

1. Theme and Description

The Klein Project aims to present contemporary mathematics for secondary school teachers. The project wants to transfer the ideas of the legendary books of Felix Klein: "Elementary Mathematics from a Higher Standpoint", written at the beginning of the 20th century, into the present. A collection of Klein Vignettes is found on the website (http://blog.kleinproject.org) in different languages: English, French, German, Spanish, Italian, Portuguese, Chinese, Khmer and Arabian. A Klein Vignette is a short article about a single mathematical topic. Vignettes are intended to give teachers a sense of connectedness between the mathematics of the teachers' world and contemporary research and applications in the mathematical sciences. Modern mathematics could be shown in different ways. E.g., if digital technologies give new possibilities in presenting some "old" mathematics — geometry, algebra, calculus — this could be the basis of a Klein Vignette. Klein Vignettes are for teachers, but they should also motivate them to bring ideas presented in the vignettes to the classroom. In some years of experience, we noticed that the vignettes have to be supported by activities in the frame of professional development, and teachers had difficulties with the transfer of the Klein-ideas into the classroom. They had difficulties in creating adequate classroom materials.

2. Activity Overview

The workshop pursued three aims:

- We wanted to give best practice examples of how the idea of the vignettes could be integrated into the professional development of secondary school teachers;

- We wanted to motivate mathematicians to contribute to the Klein project with a new vignette;
- We wanted to motivate especially mathematics educators to think about *Bridging-Vignettes* which bridge the gap between the mathematics explained in a classical vignette and its use in the classroom.

The workshop was attended by 50 participants. It started with a 10 minutes introduction by H.-G. Weigand. Then, M. Artigue and C. Mercat (France) presented a vignette on Entrelacs, its story, and associated resources. They included some practical work of design of entrelacs from selected graphs. Y. Baldin (Brazil) presented material for professional development. She showed innovating didactical sequences while working with Klein Vignettes as teaching strategies in actual classrooms. F. Arzarello (Italy) showed the way from a Klein Vignette to concrete material for the classroom. He reported how he worked with Italian teachers in the frame of a "secret message game". Finally, B. McCallum (USA) gave an example of how a Klein vignette could be adapted into materials for a workshop for teachers on problem-based instruction.

3. Future Directions and Suggestions

There is an ongoing collaboration with other projects like the Snapshots Project (https://mns.co.il) in Israel, the French project "Image des maths" (http://images.math.cnrs.fr), or the project "Mathematical Licei" in Italy. To bring the project ahead, to implement planned projects and to launch new projects, we are looking for cooperation with other projects, we would like to integrate new people into the project team and to motivate others to contribute to the project, writing or translating new vignettes. One main emphasis will be the presentation of contemporary mathematics in classroom situations (Bridging Vignettes), and we want to give examples for this transfer.

Workshop 19

Exploratory Lessons Using Pop-Up Cards and the Making of Cards

Kazumi Yamada[1], Takaaki Kihara[2], and Anri Yamada[3]

ABSTRACT Static figures are used in the learning of the plane figures. In contrast, it is important not only to use a shape with spatial expanse, but also to present the dynamic movement of that shape when a teacher teaches a space figure. There are advantages in pop-up cards creation as teaching materials. While repeating the card making, various questions will arise and you will discover many properties. For example, they are as follows. "In the blueprint, where are the cut lines? Where are the folds? Are there any secrets to these lines?" The lesson to discover such properties exploratively will be described.

Keywords: Pop-up card; Dynamic movement; Space figure; Exploratory learning.

1. Making of Cards as the Teaching Materials of the Space Figure

1.1. Advantages in pop-up cards creation as teaching materials

We have been continuing workshops on ICME-11, ICME-12, and ICME-13 about teaching spatial figures using pop-up cards. Static figures are used in the learning of the plane figures. In contrast, it is important not only to use a shape with spatial expanse, but also to present the dynamic movement of that shape when a teacher teaches a space figure. There are the following advantages in pop-up cards creation as teaching materials. When making a card, a 3dimensional card is completed by trial and error, making cuts in a plane (card) blueprint, and opening and closing a card repeatedly. In this making process, instruction which connected plane figures and space figures is attained. Especially, the pop-up card called "the origami architecture" is effective as the teaching material from this respect. When you open a card that is folded in two from 0° to 90°, the three-dimensional shaped object appears. When you fold this card, this card is returned to its original state. Work of origamic architecture may look at the home page of Masahiro Chatani. http://www.japandesign.ne.jp/IAA/chatani

[3] Paper Architect, Student of Tama Art University

1.2. Introduction of origami architecture

1.2.1. How to make

You can make cards in steps from Step1. to Step 6. Step1. Draw the blueprint of this card with cut lines and fold lines. Step 2. Cut the cut lines with a cutter. Step 3. Crease the fold lines. Step 4. Fold complex places with tweezers. Step 5. Fold the card. Step 6. Open the card to 90°.

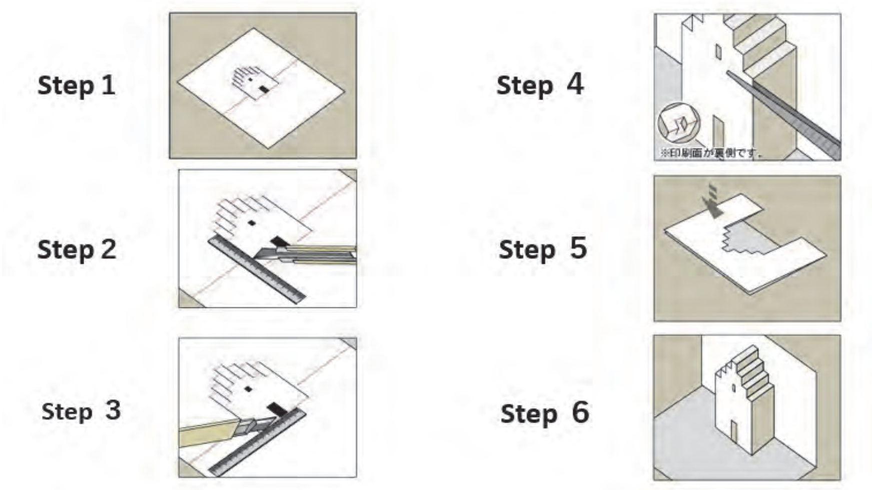

Fig. 1. How to Make

1.2.2. Kihara's collection of works

Mr. Kihara's works can be seen on the Internet.
https://www.facebook.com/media/set/?set=a.127437644000521&type=3.
You can see the cards of the foldable house on
https://www.youtube.com/watch?v=4Q8Nrjlxngg.

Fig. 2. Foldable House

Fig. 3. Foldable Stairs

Fig. 4. Foldable Dragon

2. Exploratory Lessons Using Pop-up Cards

When the card which opened in 180° is being raised to 90° gradually, the blueprint which is one kind of two-dimensional plane figures is changing into a three-dimensional solid gradually. While opening and shutting on a card is repeated, you come to be able to image the continuous movement of the solid and understand the mechanism of the card. The pop-up card is a teaching material effective to bring up the power of the mind operation that dynamically images the transformation of the solid, and to raise the space cognition.

2.1. Basic learning

Let us create the pop-up card as shown in Fig. 6. If you open this card, building blocks as shown in Fig. 5 will appear. For this purpose, you should draw the blueprint of this card on the squares paper. You will notice that you should start by placing building blocks on the squares paper and drawing lines around the bottom and side. As shown in Fig. 7, it is more effective to fill the upward surface of the building blocks.

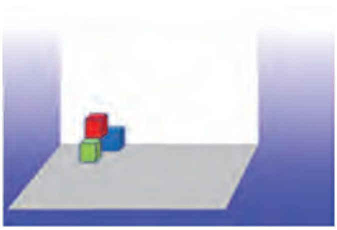

Fig. 5. Building blocks

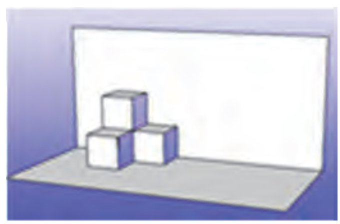

Fig. 6. Pop-up cards

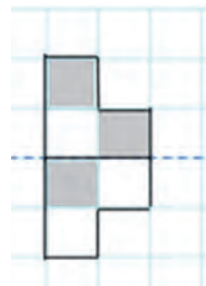

Fig. 7. Blueprint

Through repeated trial and error, you will discover that if you make the cards correctly, you can fold the cards tightly. This is a meaningful discovery that easily checks the correctness of the blueprint.

2.2. Exploratory learning

While repeating the card making by changing the number and position of building blocks, various questions will arise and you will discover many properties. For example, they are as follows. “In the blueprint, where are the cut lines? Where are the folds? Are there any secrets to these lines?” Let us explore the features of the cut lines written in the blueprint (Fig. 10) of the pop-up card (Fig. 8). In this workshop, we will demonstrate a lesson for exploratory discovery of these mathematical characteristics.

Problem Make a work of the origamic architecture such as Fig. 8, Fig. 9.

Think about how to complete the blueprint for this work and pursue your exploration.

Let us examine the regularity of the cut lines. To do this, a teacher should ask the following questions.

Fig. 8. Building blocks

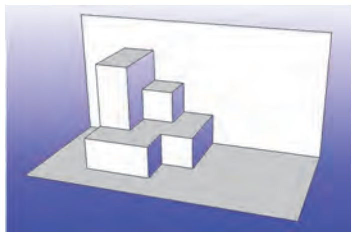

Fig. 9. Pop-up card

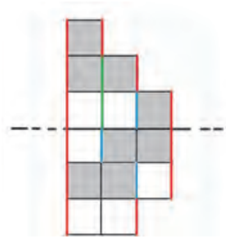

Fig. 10. Blueprint

Question 1: Where are the cut lines that you can easily find?
Answer: The vertical lines of the outer frame are cut lines. These are ① in Fig. 11. Because these parts are parts which be detached from the mount when the card is opened.

Question 2: Where are the adjacent faces that are horizontal and vertical to each other?
Answer: In the squares of the blueprint, it is easier to think that horizontal planes of the work are gray and vertical planes are white. In Fig. 12, when the color of adjacent squares is different, the boundary line is a cut line. Because the square of a white color is a vertical surface, and a gray surface is a horizontal plane, it is necessary to cut it off. These are ② in Fig. 12.

Question 3: Are these all the cut lines? Let us actually make it.
Answer: When the card is opened, if the heights of the adjacent horizontal planes are different, a cut line is required even if the adjacent faces in the blueprint are the same gray. Similarly, if the heights of the adjacent vertical planes are different, a cut line is required even if the adjacent faces in the blueprint are the same white. See Fig.13.

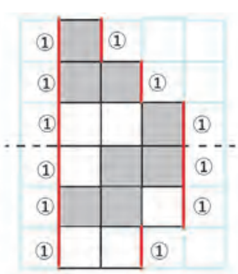

Fig. 11. Question 1

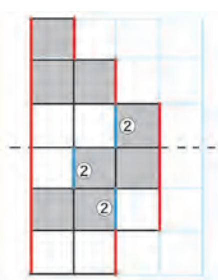

Fig. 12. Question 2

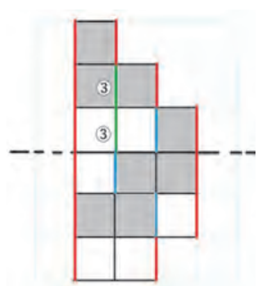

Fig. 13. Question 3

All of the cut lines described above are all cut lines written on the completed blueprint.

Development Problem Find all the blueprints for the card that can be made from the figure of only the outer frame of the pop-up card in Fig. 14.

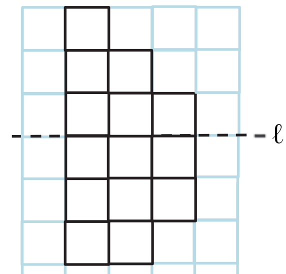

Fig. 14. Development problem

Answer: What is determined only by this figure? It is necessary to discover that the number of grids below the dotted line ℓ of the mount is the number of horizontal planes, and the number of grids above ℓ is the number of vertical planes. It is a surprising discovery that the number of horizontal and vertical planes of the card is determined only by this figure. The top grid of each column of blueprints is always a horizontal plane.

The bottom grid of each column of blueprints is always a vertical plane.

For other planes, the combination of horizontal and vertical planes can be freely determined. You can write all cut lines by using what you learned in "Problem".

3. Activity Overview

We made a presentation using Zoom. We gave the presentation shown in the table below. First, Mr. Yamada gave a lecture on the effectiveness of pop-up cards as teaching materials. Next, Mr. Kihara gave the demonstration of creating pop-up cards. Finally, Mr. Yamada and Miss Yamada made pop-up cards that show the shape of building blocks, and discussed the exploratory approach of various mathematical properties of this blueprint.

Tab. 1. Planned structure

Planned timeline	Topic	responsible person
20 minutes	1. Making of cards as the teaching materials of the space figure 1.1 Advantages in pop-up card creation as teaching materials	Lecture / Kazumi Yamada
30 minutes	Making of pop-up cards	Activity / Takaaki Kihara
30 minutes	2. Exploratory classes using pop-up cards	Activity / Kazumi Yamada, Anri Yamada
10minutes	Question and answer	

4. Future Directions and Suggestions

As mentioned in "2. Exploratory classes using pop-up cards", many mathematical properties are hidden in this type of pop-up cards. The study of exploratory lessons of these properties is profound.

Workshop 20

Mathematical Performance-Based Learning in Hangzhou Yungu School

Jing Yang[1], Fan Zou[2], and Shengwenxin Ni[3]

ABSTRACT Performance-Based Learning is an advanced teaching approach that emphasizes what students can do as a result of instruction. In other words, teachers cultivate and assess students' competencies by requiring them to solve a problem or create something in real-life or simulated scenarios using their mathematical knowledge. Hangzhou Yungu School's math teachers have designed three types of performance tasks: 1) daily-class performance tasks, which are small assignments used in one class, 2) unit performance tasks, which are used during a whole unit of instruction, and 3) multiple-unit performance tasks, which are long-term tasks that last among several related units. Performance tasks focus on competencies acquired in the learning process, assess how well students learn, and guide students to what they can do. Completing performance tasks in mathematics is an excellent deep learning process that meets the expectations of mathematical education. This article presents some cases of the above three performance tasks and provides several suggestions for future research directions.

Keywords: Performance-Based Learning; Mathematics Education; Competency Based Education; Performance Task; Learning process.

1. Theme and Description

1.1. What is PBL?

Performance-Based Learning (PBL) is an approach that teachers let students solve a problem or create something by using their mathematical knowledge in real-life or simulated scenarios. In contrast to traditional paper-and-pencil tests that focus on content knowledge and skills, PBL emphasizes real-world problem-solving, communication, critical thinking, and other transferable competencies. Performance tasks are the most important component of PBL, as they require students to use high-level thinking skills to create or produce something with real-world applications. Research has shown that performance-based assessments provide useful information about student performance to a wide range of stakeholders, including students, parents, teachers, principals, and policymakers (Vogler, 2002). Additionally, performance tasks have been found to propel education systems in a direction that corresponds with how individuals actually learn (Herman, 1992).

[1] Hangzhou Yungu School, Hangzhou, Zhejiang Province, China. E-mail: jing.yang@yungu.org
[2] Hangzhou Yungu School, Hangzhou, Zhejiang Province, China. E-mail: zac.zou@yungu.org
[3] University of Chicago, Hyde Park, Chicago, USA. Email: nswxin@163.com

1.2. Why PBL?

As educators, we seek to cultivate "WHOLE PERSON" with practical abilities and innovative spirits to solve real-life problems. However, traditional paper-and-pencil tests are not sufficient to assess students' learning comprehensively. Effective assessment should not only evaluate learning outcomes but also guide students to "what they can do." PBL offers an integrated approach to teaching, learning, and assessment that is aligned with these goals. For instance, our daily-class performance task "Length Measuring by Eyes and Thumb" exemplifies how PBL emphasizes performance-based assessments that evaluate students' ability to apply content knowledge to critical-thinking, problem-solving, and analytical tasks. The task was designed for 9th graders to estimate the length between two sites using their knowledge of similar triangles, while establishing suitable models to specify the principle (Fig. 1). Throughout the task, teachers provided only hints, with rubrics serving as a guide for students. The task enabled students to learn through hands-on experience and collaboration with their peers, promoting active learning and knowledge application to real-world situations.

Fig. 1. Student's output work of this task

Business and education leaders increasingly recognize the importance of comprehensive assessment in students' learning. For example, Fadel, Honey, and Pasnik (2007) suggest that the workplace of the 21st century will require "new ways to get work done, solve problems, or create new knowledge" (p. 1), and that performance-based assessments will be essential to evaluating these skills. Likewise, higher education faculty value "habits of mind" even more than content knowledge, including the ability to think critically and analytically, to independently draw inferences and reach conclusions, and to solve problems (Conley, 2005). Well-designed performance-based tasks have the potential to measure these cognitive abilities more directly than standardized tests of content knowledge.

1.3. How do we perform PBL?

1.3.1. Macro-plan

To design PBL, we start with a macro plan. First, we examine the curriculum standards set by the Chinese Ministry of Education, which are shared by all Chinese secondary schools. Accordingly, we create a preliminary performance task framework for the three-year middle school teaching program (Fig. 2).

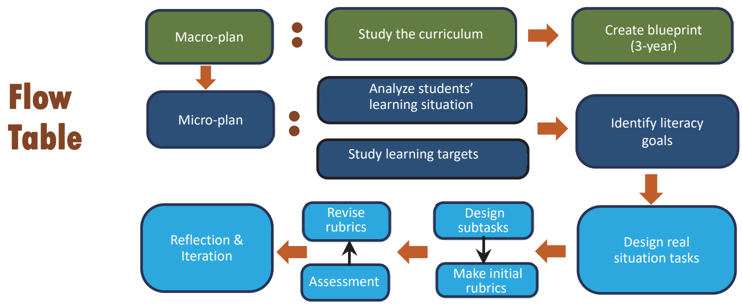

Fig. 2. Framework map

1.3.2. Micro-plan

Next, we design detailed performance tasks for daily lessons, units, or large units according to the framework diagram. We analyze students' current learning progress and goals, identify the competence goals that need to be achieved, and then design practical tasks to match the situation. We develop precise subtasks and make a preliminary rubric. We reflect on and iterate the design after students turn in their assignments. For instance, in the first chapter of the seventh grade of "Zhejiang Education Edition," the curriculum standard requires understanding positive and negative numbers. We designed the performance task of "Stock Market Simulation" accordingly. In Chapter 2, Volume 1, Grade 7, the curriculum standard requires mastering the operation of rational numbers. So, we designed the task of "Shopping Carnival." We help students gain core competency growth by designing specific tasks for corresponding competency goals.

Unit performance tasks play a crucial role in implementing micro-plans. For example, in the Inverse Function unit performance tasks inspired by "Piazza San Marco miracle", students are encouraged to apply their mathematical knowledge to real-world situations. Mathematical problem-solving requires students to apply knowledge, skills and strategies within novel contexts (Lynn et al., 1999). The unit begins with an inspiration video introducing the phenomenon of walking in circles blindfolded towards the tower in the Piazza, which sets the stage for the performance tasks. Students then conduct math experiments in groups, following the teacher's instructions, and participate in individual work, teamwork, and group discussions to achieve a deeper understanding of inverse functions. Throughout the process, the key question "How to explain the phenomenon of walking in circles blindfolded by using mathematical function?" drives students' learning. As it has been revealed, the performance assessment is effective for the teaching concepts and removes misconceptions (Slater,1996). In the second performance task of this unit, students conduct experiments, make conjectures, and summarize their findings to understand the concept of inverse function. They are expected to realize that the product of the radius and the difference in step length does not change, and that it is twice the product of the width between feet and average step length. To promote student engagement, the teacher encourages teamwork and helps students to create an hour-to-hour learning plan. Through this process, micro-plans are implemented step by step, and students are able to develop a deeper understanding of inverse functions and their real-world applications.

1.3.3. Constructing rubrics
