Table of Contents

CONFERENCE COMMITTEE xiii
ORGANIZING INSTITUTIONS xvi
FOREWORD xvii

A - Extended reality technologies in construction

INVESTIGATION OF THE ACCEPTANCE OF VIRTUAL REALITY FOR PLANNING DECISIONS IN EARLY DESIGN PHASES
Daniel Napps, Markus König 1

BUILDING INSPECTOR XR: STREAMLINING SCAN-TO-BIM WITH VIRTUAL AND MIXED REALITY
Christoph Blut, Tristan Kinnen, Jörg Blankenbach, Dirk Heidermann, Felix Schellong 13

THE VALUE OF EXTENDED REALITY TECHNIQUES TO IMPROVE REMOTE COLLABORATIVE MAINTENANCE OPERATIONS: A USER STUDY
Corentin Coupry, Paul Richard, David Bigaud, Sylvain Noblecourt, David Baudry 23

CREATION AND ACCEPTANCE OF LOW-THRESHOLD MOBILE TRAINING ON SUSTAINABILITY IN CONSTRUCTION
Mario Wolf, Jochen Teizer 34

A COLLABORATIVE PLANNING MODEL FOR OFFSITE CONSTRUCTION BASED ON VIRTUAL REALITY AND GAME ENGINES
Mohamed Assaf, Rafik Lemouchi, Mohamed Al-Hussein, Xinming Li 46

PREDICTION OF COGNITIVE LOAD DURING INDUSTRY-ACADEMIA COLLABORATION VIA A WEB PLATFORM
Anthony Yusuf, Abiola Akanmu, Adedeji Afolabi, Homero Murzi 57

TRANSITIONING FROM 2D TO VR IN DESIGN REVIEW – RESISTANCE TO ENGAGEMENT
Shahin Sateei, Mattias Roupe, Mikael Johansson 69

COLLABORATIVE SITE LAYOUT PLANNING USING MULTI-TOUCH TABLE AND IMMERSIVE VR
Mikael Johansson, Mattias Roupé, Mikael Viklund Tallgren 81

APPLICATION OF SMART TECHNOLOGIES FOR ASSESSING USERS' WELL-BEING FOR IMMERSIVE DESIGN STRATEGIES: A STATE-OF-THE-ART REVIEW
Eleonora D'Ascenzi, Vito Getuli, Irene Fiesoli 91

INVESTIGATING THE ABILITY OF IMMERSIVE VIRTUAL ENVIRONMENTS TO FACILITATE OCCUPANT THERMAL STATE DATA COLLECTION INVOLVING FACE MASKS
Girish Srivatsa Rentala, Yimin Zhu 100

SEAMLESS INDOOR/OUTDOOR MARKER-LESS AUGMENTED REALITY REGISTRATION SUPPORTING FACILITY MANAGEMENT OPERATIONS
Leonardo Messi, Francesco Spegni, Massimo Vaccarini, Alessandra Corneli, Leonardo Binni 109

INTEGRATING REAL-TIME OBJECT DETECTION INTO AN AR-DRIVEN TASK ASSISTANCE PROTOTYPE: AN APPROACH TOWARDS REDUCING SPECIFIC MOTIONS IN THERBLIGS THEORY
Xiang Yuan, Qipei Mei, Xinming Li 121

VISUALIZATION OF WEATHER-AWARE AMBIENT HEAT RISKS WITH GLOBAL ILLUMINATION IN GAME ENGINE
Naotaka Sumida, Taira Ozaki, Satoshi Kubota, Dan Hiroshige, Yoshihiro Yasumuro 133

IMPROVING SENSE-MAKING FOR CONSTRUCTION PLANNING TASKS USING VISUAL AND HAPTIC STIMULI IN VIRTUAL REALITY ENVIRONMENTS
Ivan Mutis, Marina Oberemok, Nishanth Purushotham 142

ENHANCING THE REALISM OF VIRTUAL CONSTRUCTION SAFETY TRAINING: INTEGRATION OF REAL-TIME LOCATION SYSTEMS FOR REAL-WORLD HAZARD SIMULATIONS

FUP Best Practice in Scholarly Publishing (DOI 10.36253/fup_best_practice)

Pietro Capone, Vito Getuli, Farzad Pour Rahimian, Nashwan Dawood, Alessandro Bruttini, Tommaso Sorbi (edited by), *CONVR 2023 - Proceedings of the 23rd International Conference on Construction Applications of Virtual Reality. Managing the Digital Transformation of Construction Industry*,

VISIBILITY ENHANCEMENT OF CRANE OPERATORS USING BIM-BASED DIMINISHED REALITY
Roghieh Eskandari, Ali Motamedi 167

ADAPTING BIM-BASED AR POSITIONING TECHNIQUES TO THE CONSTRUCTION SITE
Khalid Amin, Grant Mills, Duncan Wilson, Karim Farghaly 175

SAFETY TRAINING FOR RIGGING USING VIRTUAL REALITY
Rafik Lemouchi, Mohamed Assaf, Mohamed Al-Hussein, Khaoula Boutouhami, Ahmed Bouferguene 184

APPLICATION OF DIMINISHED REALITY FOR CONSTRUCTION SITE SAFETY MANAGEMENT
Alessandra Corneli, Berardo Naticchia, Massimo Vaccarini, Alessandro Carbonari, Francesco Spegni 195

DRIVING SIMULATOR FOR ROAD SAFETY DESIGN: A COMPARISON BETWEEN VIRTUAL REALITY TESTS AND IN-FIELD TESTS
Monica Meocci, Alessandro Terrosi, Andrea Paliotto, Francesca La Torre, Irene Infante 206

ASSESSING IMPACTS OF IMMERSIVE VIRTUAL REALITY BASED DESIGN REVIEWS ON LEARNERS' SELF-EFFICACY
Fadi Castronovo, Seyedreza Razavialavi, Abdullahi Abdulrahman, Mohammed Rayan Saiba, Pablo Martinez Rodriguez 219

COGNITIVE DYNAMICS FOR CONSTRUCTION MANAGEMENT LEARNING TASKS IN MIXED REALITY ENVIRONMENTS
Xuanchang Liu, Ivan Mutis 231

EVALUATION OF COMPUTER VISION-AIDED MULTIMEDIA LEARNING IN CONSTRUCTION ENGINEERING EDUCATION
Anthony Yusuf, Adedeji Afolabi, Abiola Akanmu, Johnson Olayiwola 242

BIM-BASED OPEN LEARNING RESOURCES REPOSITORY FOR THE BENEDICT PROJECT
Marco Bragadin, Caterina Morganti, Pier Carlo Ricci, Emlyn Witt, Kalle Kähkönen, Taija Puolitaival 254

TOWARDS A DIGITAL ERA IN AEC HIGHER EDUCATION: COMBINING THEORY AND TECHNOLOGY TO DEVELOP AND DELIVER ARCHITECTURAL MASTER CLASSES
Aso Hajirasouli, Vito Getuli, Alessandro Bruttini, Tommaso Sorbi, Pietro Capone 266

A FRAMEWORK FOR REALISTIC VIRTUAL REPRESENTATION FOR IMMERSIVE TRAINING ENVIRONMENTS
Caolan Plumb, Farzad Rahimian, Diptangshu Pandit, Hannah Thomas, Nigel Clark 274

EVALUATION OF IMMERSIVE VR EXPERIENCES FOR SAFETY TRAINING OF CONSTRUCTION WORKERS: A SEMI-QUALITATIVE APPROACH PROPOSAL
Vito Getuli, Valentina Fornasari, Alessandro Bruttini, Tommaso Sorbi, Pietro Capone 288

B - Advanced project management and control

ENHANCING COLLABORATION WITH BLOCKCHAIN-ENABLED DIGITAL TWINS: PERSPECTIVES FROM STAKEHOLDERS IN THE BUILT ENVIRONMENT
Nana Akua Adu-Amankwa, Farzad Rahimian, Nashwan Dawood 298

BLOCKCHAIN-BPMN INTEGRATED FRAMEWORK FOR CONSTRUCTION MANAGEMENT
Xuling Ye, Xingyu Tao, Jack C. P. Cheng, Markus König 309

FAST AND SECURE BIM DESIGN USING BLOCKCHAIN: AN EXAMPLE OF MAKESHIFT HOSPITAL PROJECT FOR COVID-19 TREATMENT IN HONG KONG
Xingyu Tao, Xingbo Gong, Moumita Das, Yuqing Xu, Hao Liu, Jack Cp Cheng, Chengliang Zheng 318

INTEGRATING ESG FACTORS INTO CONSTRUCTION PROJECTS: A BLOCKCHAIN-BASED DATA MANAGEMENT APPROACH
Xingbo Gong, Xingyu Tao, Moumita Das, Helen H.L. Kwok, Jack C.P. Cheng 327

A BLOCKCHAIN-BASED SECURE SUBMISSION MANAGEMENT FRAMEWORK FOR DESIGN AND CONSTRUCTION PHASES
Moumita Das, Xingyu Tao, Yuxing Xu, Jack C. P. Cheng 335

ZERO-KNOWLEDGE PROOF FOR TRUSTED CONSTRUCTION MANAGEMENT: A PRELIMINARY STUDY OF ADAPTIVE BLOCKCHAIN BIM IDENTITY AUTHENTICATION
Lingming Kong, Rui Zhao, Fan Xue 343

LEVERAGING SMART CONTRACTS IN BUILDING INFORMATION MODELING (BIM) FOR UNIFIED PROJECT EXECUTION: A THEORITICAL FRAMEWORK.
Oluwatoyin Lawal, Nawari Nawari 352

ISAFEINCENTIVE: TRANSFORMING CONSTRUCTION SAFETY CULTURE THROUGH BLOCKCHAIN INCENTIVES
Mehrtash Soltani, Dohyeong Kim, Akeem Pedro, Jaehun Yang, Si Tran, Doyeop Lee, Chansik Park 360

MULTI-ASPECTUAL KNOWLEDGE ELICITATION FOR PROCUREMENT OPTIMIZATION IN A WAREHOUSE COMPANY
Franck Romuald Fotso Mtope, Sina Joneidy, Diptangshu Pandit, Farzad Rahimian 368

A SYSTEMATIC LITERATURE REVIEW TO IDENTIFY A METHODOLOGICAL APPROACH FOR USE IN THE MODELLING AND FORECASTING OF CAPITAL EXPENDITURE OF HYPERSCALE DATA CENTRES
David King, Nadeeshani Wanigarathna, Keith Jones, Joseph Ofori-Kuragu 380

A VALUE STREAM MAPPING APPROACH TO THE IDENTIFICATION OF LEAN MANAGEMENT OPPORTUNITIES FOR OFF-SITE CONSTRUCTION PRODUCTION: A CASE OF REINFORCED CONCRETE SLABS
Zhe Chen, Zhengting Guo, Fan Xue 388

BAYES THEORY AS A METHODOLOGICAL APPROACH TO ASSESS THE IMPACT OF LOCATION VARIABLES OF HYPERSCALE DATA CENTRES: TESTING A CONCEPT
David King, Nadeeshani Wanigarathna, Keith Jones, Joseph Ofori-Kuragu 398

UNIVERSITY ASSET DIGITALIZATION GUIDELINES: THE PILOT CASE OF POLITECNICO DI MILANO REAL ESTATE
Giuseppe Martino Di Giuda, Elisa Cacciaguerra, Francesco Paleari, Marco Schievano, Stefano Campi, Alessandro Tucci 407

BIM-GIS AND BI INTEGRATION FOR FACILITY AND OCCUPANCY MANAGEMENT OF UNIVERSITY ASSETS: THE UNITO PILOT CASE
Giuseppe Martino Di Giuda, Daniele Accardo, Paola Gasbarri, Silvia Meschini, Lavinia Chiara Tagliabue, Laura Scomparin 419

TOWARDS A FRAMEWORK FOR RAILWAY NETWORK ASSETS MANAGEMENT BASED ON BIM/GIS INTEGRATION
Mattia Mangia, Carla Di Biccari, Mattias Roupé 431

INTEGRATION BETWEEN ENTERPRISE RESOURCE PLANNING AND BUILDING INFORMATION MODELLING
Paola Federici, Daniela Julea, Sara Comai, Kavita Raj, Silvia Mastrolembo Ventura, Giuseppe Rigamonti, Giorgio Paolo Maria Vassena, Angelo Luigi Camillo Ciribini 443

DEVELOPMENT OF AN AUTOMATED WORKFLOW IN THE FIELD OF FIRE PREVENTION USING BUILDING INFORMATION MODELING
Vincenzo Donato, Andrea Bongini, Marco Sparacino 454

DATA-DRIVEN CONSTRUCTION AND OPERATING COST DECISION SUPPORT THROUGH TECHNO-ECONOMIC ANALYSIS: RESIDENTIAL CASE STUDY
Panos Karaiskos, Tulio Sulbaran 466

BUILDING INFORMATION MODELLING (BIM) FOR CONSTRUCTION SUPPLY CHAIN: A SCIENTOMETRIC ANALYSIS
Syed Haseeb Ahmad, Melissa Chan, Wei Yang, Hongyu Jin, Amirhossein Heravi 477

E-PROCUREMENT IN THE AUSTRALIAN CONSTRUCTION INDUSTRY: BENEFITS, BARRIERS AND ADOPTION
Eleanor Hayden, Melissa Chan, David van Kan, Victor Arowoiya, Mohd. Amizan Mohamed 489

A PRELIMINARY INVESTIGATION OF KNOWLEDGE MANAGEMENT TOOLS FOR THE CONSTRUCTION SECTOR
Bartu Kologlu, Deniz Artan 499

IMPROVING BIM AUTHORING PROCESS REPRODUCIBILITY WITH ENHANCED BIM LOGGING
Suhyung Jang, Ghang Lee 508

TOWARDS CONSTRUCTION SAFETY MANAGEMENT MATURITY MODEL IN THE INDUSTRY 4.0 ERA: A STATE-OF-THE-ART REVIEW
Nazi Soltanmohammadlou, Sara Rashidian, Carol K. H Hon, Robin Drogemuller, Sara Omrani 515

INTEGRATED GEOBIM REQUIREMENTS DEFINITION FOR DIGITAL BUILDING PERMIT
Silvia Mastrolembo Ventura, Sara Comai, Francesca Noardo, Kavita Raj, Angelo L.C. Ciribini 526

A SYSTEMATIC REVIEW OF THE IMPACTS OF DIGITALIZATION ON PROJECT MANAGEMENT
Ailin Zerafat, Emmanuel Daniel, Louis Gyoh 538

EVALUATING THE COMPREHENSION OF CONSTRUCTION SCHEDULES OF AN ARTIFICIAL INTELLIGENCE
Tulio Sulbaran 545

MULTI-ROBOT FEDERATED EDGE LEARNING FRAMEWORK FOR EFFICIENT COORDINATION AND INFORMATION MANAGEMENT IN SMART CONSTRUCTION
Xinqi Liu, Jihua Wang, Ruopan Huang, Wei Pan 553

ROBOTIC ASSEMBLY AND REUSE OF MODULAR ELEMENTS IN THE SUPPLY CHAIN OF A LEARNING FACTORY FOR CONSTRUCTION AND IN THE CONTEXT OF CIRCULAR ECONOMY
Jochen Teizer, Kepeng Hong, Asger D. Larsen, Marcus B. Nilsen 564

IDENTIFYING AND DEVELOPING PREREQUISITES FOR TAKT PLANNING IN A BIM-BASED CONSTRUCTION PROCESS
Efraim Ljung, Mikael Viklund Tallgren, Mattias Roupe, Mikael Johansson 574

FCM-ENABLED APPROACH FOR INVESTIGATING INTERDEPENDENCIES OF BIM PERFORMANCE FACTORS IN THE SUSTAINABLE BUILT ENVIRONMENT
Pavan Kumar, Aritra Pal, Yun-Tsui Chang, Shang-Hsien Hsieh 585

A ROBOTIC METHOD TO INSERT BATT INSULATION INTO LIGHT-FRAME WOOD WALL FOR PANEL PREFABRICATIONS
Xiao Han, Cheng-Hsuan Yang, Yuxiang Chen, Alejandra Hernandez Sanchez 594

THE IMPACTS OF DIGITAL FABRICATION ON THE CONSTRUCTION INDUSTRY: A SYSTEMATIC REVIEW
Mehdi Keshtkar, Emmanuel Daniel, Louis Gyoh 605

C - AI, data science and analytics

EFFICIENT DATA CURATION USING ACTIVE LEARNING FOR A VIDEO-BASED FIRE DETECTION
Keyur Joshi, Angelina Aziz, Philip Dietrich, Markus König 616

IDENTIFYING HAZARDS IN CONSTRUCTION SITES USING DEEP LEARNING-BASED MULTIMODAL WITH CCTV DATA
Dai Quoc Tran, Yuntae Jeon, Seongwoo Son, Minsoo Park, Seunghee Park 625

DEEP LEARNING-BASED POSE ESTIMATION FOR IDENTIFYING POTENTIAL FALL HAZARDS OF CONSTRUCTION WORKER
Minsoo Park, Seungsoo Lee, Woonggyu Choi, Yuntae Jeon, Dai Quoc Tran, Seunghee Park 634

DEEP LEARNING BASED POSE ESTIMATION OF SCAFFOLD FALL ACCIDENT SAFETY MONITORING
Seungsoo Lee, Seongwoo Son, Pa Pa Win Aung, Minsoo Park, Seunghee Park 641

PREDICTIVE SAFETY MONITORING FOR LIFTING OPERATIONS WITH VISION-BASED CRANE-WORKER CONFLICT PREDICTION
Peter Kok-Yiu Wong, Synge C. P. Lam, Isabel Y. N. Lee, Felix C. L. Ting, Jack C. P. Cheng, Pak Him Leung 648

LOCALIZING AND VISUALIZING THE DEGREE OF PEOPLE CROWDING WITH AN OMNIDIRECTIONAL CAMERA BY DIFFERENT TIMES
Tomu Muraoka, Satoshi Kubota, Yoshihiro Yasumuro 657

ISAFE WELDING SYSTEM: COMPUTER VISION-BASED MONITORING SYSTEM FOR SAFE WELDING WORK
Syed Farhan Alam Zaidi, Rahat Hussain, Muhammad Sibtain Abbas, Jaehun Yang, Doyeop Lee, Chansik Park 669

COMPUTER VISION-BASED MONITORING FRAMEWORK FOR FORKLIFT SAFETY AT CONSTRUCTION SITE
Muhammad Sibtain Abbas, Aqsa Sabir, Nasrullah Khan, Syed Farhan Alam Zaidi, Rahat Hussain, Jaehun Yang, Chansik Park 676

AUTOMATED EXTRACTION OF BRIDGE GRADIENT FROM DRAWINGS USING DEEP LEARNING
Hakan Bayer, Benedikt Faltin, Markus König 683

PREDICTING MENTAL WORKLOAD OF USING EXOSKELETONS FOR CONSTRUCTION WORK: A DEEP LEARNING APPROACH
Abiola Akanmu, Adedeji Afolabi, Akinwale Okunola 691

UTILIZING 360-DEGREE IMAGES FOR SYNTHETIC DATA GENERATION IN CONSTRUCTION SCENARIOS
Aqsa Sabir, Rahat Hussain, Syed Farhan Alam Zaidi, Akeem Pedro, Mehrtash Soltani, Dongmin Lee, Chansik Park 701

MACHINE LEARNING-BASED CONSTRUCTION PLANNING AND FORECASTING MODEL
Ahmet Esat Keser, Onur Behzat Tokdemir 711

CONCEPT FOR ENRICHING NISO-STS STANDARDS WITH MACHINE-READABLE REQUIREMENTS AND VALIDATION RULES
Sven Zentgraf, Sherief Ali, Markus König 718

TRANSFORMING BUILDING INDUSTRY KNOWLEDGE MANAGEMENT: A STUDY ON THE ROLE OF LARGE LANGUAGE MODELS IN FIRE SAFETY PLANNING
Ori Ashkenazi, Shabtai Isaac, Alberto Giretti, Alessandro Carbonari, Dilan Durmus 729

SCHEDULING OPTIMIZATION OF ELECTRIC READY MIXED CONCRETE VEHICLES USING AN IMPROVED MODEL-BASED REINFORCEMENT LEARNING
Zhengyi Chen, Changhao Song, Xiao Zhang, Jack C. P. Cheng 739

TESTING CHATGPT-AIDED SPARQL GENERATION FOR SEMANTIC CONSTRUCTION INFORMATION RETRIEVAL
Yuan Zheng, Olli Seppänen, Sebastian Seiß, Jürgen Melzner 751

EXTRACTING INFORMATION FROM CONSTRUCTION SAFETY REQUIREMENTS USING LARGE LANGUAGE MODEL
Si Van-Tien Tran, Nasrullah Khan, Emmanuel Charles Kimito, Akeem Pedro, Mehrtash Sotani, Rahat Hussain, Taehan Yoo, Chansik Park 761

MODELLING AND MANAGING BUILT HERITAGE KNOWLEDGE: AN ONTOLOGY-BASED APPROACH FOR MULTI-LAYERED ARCHAEOLOGIES AND HISTORICAL PRODUCTION PROCESS REPRESENTATION
Cassia De Lian Cui, Antonio Fioravanti, Edoardo Currà, Davide Simeone, Stefano Cursi 768

LINKED DATA FOR THE CATEGORIZATION OF FAILURES MECHANISMS IN EXISTING UNREINFORCED MASONRY BUILDINGS
Maria Laura Leonardi, Stefano Cursi, Daniel V. Oliveira, Miguel Azenha, Elena Gigliarelli 781

VIRTUAL HUMAN-BUILDING INTERACTION EXPERIMENTATION ONTOLOGY (VHBIEO): A VHBIEO-BASED METADATA-DRIVEN EXPLORATION
Chanachok Chokwitthaya, Yimin Zhu, Weizhuo Lu 791

CONSISTENCY VERIFICATION BETWEEN COST AND GEOMETRIC INFORMATION BASED ON IFC: APPLICATION ON STRUCTURAL ELEMENTS
Jacopo Cassandro, Claudio Mirarchi, Alberto Pavan, Maria Grazia Donatiello, Carlo Zanchetta 801

SEMANTIC WEB BASED INTEGRATION BETWEEN BIM COST AND GEOMETRIC DOMAINS
Jacopo Cassandro, Claudio Mirarchi, Alberto Pavan, Andrea Zamborlini, Carlo Zanchetta 813

ONTOLOGY-BASED CONSTRUCTION INSPECTION PLANNING: A CASE STUDY OF THERMAL BUILDING INSULATION
Sebastian Seiß, Markus Boden, Jürgen Melzner, Yuan Zheng, Delval Thibaut, Rayan El Chamaa 824

AN AUTOMATED FRAMEWORK FOR ENSURING INFORMATION CONSISTENCY IN PRICE LIST TENDERING DOCUMENT
Chiara Gatto, Maryam Gholamzadehmir, Marta Zampogna, Claudio Mirarchi, Alberto Pavan 837

ENHANCING INTERACTIONS IN AUGMENTED REALITY FOR CONSTRUCTION SITES: INTRODUCING THE ARCHI ONTOLOGY
Karim Farghaly, Khalid Amin, Grant Mills, Duncan Wilson 848

A REVIEW OF COMPUTER VISION-BASED PROGRESS MONITORING FOR EFFECTIVE DECISION MAKING
Roy Lan, Tulio Sulbaran 856

SEMI-AUTOMATED VISUAL QUALITY CONTROL INSPECTION DURING CONSTRUCTION OR RENOVATION OF RAILWAYS USING DEEP LEARNING TECHNIQUES AND AUGMENTED REALITY VISUALIZATION
Apostolia Gounaridou, Evangelia Pantraki, Vasileios Dimitriadis, Athanasios Tsakiris, Dimosthenis Ioannidis, Dimitrios Tzovaras 865

A COMPARATIVE STUDY OF DEEP LEARNING MODELS FOR SYMBOL DETECTION IN TECHNICAL DRAWINGS
Benedikt Faltin, Damaris Gann, Markus König 877

TOPOLOGICAL RELATIONSHIP MODELLING FOR INDUSTRIAL FACILITY DIGITISATION USING GRAPH NEURAL NETWORKS
Haritha Jayasinghe, Ioannis Brilakis 887

INDOOR TRAJECTORY RECONSTRUCTION USING BUILDING INFORMATION MODELING AND GRAPH NEURAL NETWORKS
Mingkai Li, Peter Kok-Yiu Wong, Cong Huang, Jack Chin-Pang Cheng 895

IMAGE SEGMENTATION APPLIED TO URBAN SURFACE AND AERIAL CONSTRAINTS ANALYSIS
Marco Lorenzo Trani, Federica Madaschi 907

GENERATIVE DESIGN INTUITION FROM THE FINE-TUNED MODELS OF NAMED ARCHITECTS' STYLE
Youngjin Yoo, Hyun Jeong, Youngchae Kim, Seung Hyun Cha, Jin-Kook Lee 917

PLANNING ALTERNATIVE BUILDING FAÇADE DESIGNS USING IMAGE GENERATIVE AI AND LOCAL IDENTITY
Hayoung Jo, Sumin Chae, Su Hyung Choi, Jin-Kook Lee 926

EARLY DETECTION AND RECONSTRUCTION OF ABNORMAL DATA USING HYBRID VAE-LSTM FRAMEWORK
Fangli Hou, Jun Ma, Jack C. P. Cheng, Helen H. L. Kwok 933

REFLECTING USERS' PHYSICAL CHARACTERISTICS IN SPATIAL VISUALIZATION
Sumin Chae, Hayoung Jo, Bomin Kim, Jin-Kook Lee 943

GEN AI AND INTERIOR DESIGN REPRESENTATION: APPLYING DESIGN STYLES USING FINE-TUNED MODELS
Hyun Jeong, Youngchae Kim, Youngjin Yoo, Seunghyun Cha, Jin-kook Lee 950

EARLY VISUALIZATION APPROACH TO THE GENERATIVE ARCHITECTURAL SIMULATION USING LIGHT ANALYSIS IMAGES
Bomin Kim, Sumin Chae, Youngjin Yoo, Jin-Kook Lee 958

REAL-TIME GEOMETRY ASSESSMENT USING LASER LINE SCANNER DURING LASER POWDER DIRECTED ENERGY DEPOSITION ADDITIVE MANUFACTURING OF SS316L COMPONENT WITH SHARP FEATURE
Liu Yang, Boyu Wang, Jack C.P. Cheng, Peipei Liu, Hoon Sohn 965

OPTIMAL NUMBER OF CUE OBJECTS FOR PHOTO-BASED INDOOR LOCALIZATION
Youngsun Chung, Daeyoung Gil, Ghang Lee 977

D - Environmental sustainability

INTEGRATING GREEN ROOFS INTO BUILDING INFORMATION MODELING (BIM): A COMPUTATIONAL APPROACH FOR SUSTAINABLE BUILDING DESIGN
Stefano Cascone 988

ENHANCING DISASTER RESILIENCE STUDIES: LEVERAGING LINKED DATA AND NATURAL LANGUAGE PROCESSING FOR CONSISTENT OPEN-ENDED INTERVIEWS
Milad Katebi, Mani Poshdar, Mostafa Babaeian Jelodar, Morteza Zihayat 998

ENGINEERING ANALYSIS IMPACT ON CARBON EMISSION REDUCTION OF AN INFRASTRUCTURE PROJECT: A CASE STUDY OF SEMANTOK DAM PROJECT
Gregorius A. Sentosa, Agung Fajarwanto, Amy R. Widyastuti, Achmad Luthfi Naufal, Ni Putu Pande Dhea, Abdul Rahman Kadir, Muhammad Yunus Amar 1010

SOLAR POTENTIAL AND ENERGY ASSESSMENT DATA IN U-BEM MODELS: INTEROPERABILITY ANALYSIS BETWEEN PERFORMANCE SIMULATION TOOLS AND OPENBIM/GIS PLATFORMS
Carlo Zanchetta, Martina Giorio, Maria Grazia Donatiello, Federico Rossi, Rossana Paparella 1021

IMPLEMENTATION OF BUILDING INFORMATION MODELING BIM FOR ECONOMIC SUSTAINABLE CONSTRUCTION MINIMIZING MATERIAL WASTE IN TERMS OF VALUE ENGINEERING
Aya Ali Shihata, Mohamed Anwar Fekry, Wessam Hamdy Abbas 1033

BUILDING ROOFTOP ANALYSIS FOR SOLAR PANEL INSTALLATION THROUGH POINT CLOUD CLASSIFICATION - A CASE STUDY OF NATIONAL TAIWAN UNIVERSITY
Aritra Pal, Yun-Tsui Chang, Chien-Wen Chen, Chen-Hung Wu, Pavan Kumar, Shang-Hsien Hsieh 1042

SEMI-AUTOMATIC WORKFLOW FOR AIR-CONDITIONING SYSTEM ZONING AND SIMULATION
Yikun Yang, Yiqun Pan, Georg Suter 1049

GOING BEYOND ENERGY CONSUMPTION: DIGITAL TWINS FOR ACHIEVING SOCIO-ECOLOGICAL SUSTAINABILITY IN THE BUILT ENVIRONMENT
Dragana Nikolic, Ian J. Ewart 1061

APPLICATION OF THE INTERNET OF THINGS (IoT) FOR ENERGY EFFICIENCY IN BUILDINGS: A BIBLIOMETRIC REVIEW
Nnaemeka Nwankwo, Ezekiel Chinyio, Emmanuel Daniel, Louis Gyoh 1072

CARBON TRACKING IN THE BUILDING SECTOR: A ‘CABBAGE’ FRAMEWORK
Jiajia Wang, Geoffrey Qiping Shen, Fan Xue 1085

RETROFITTING OF BUILDINGS TO IMPROVE ENERGY EFFICIENCY: A COMPREHENSIVE SYSTEMATIC LITERATURE REVIEW AND FUTURE RESEARCH DIRECTIONS
Elena Imani, Huda Dawood, Nashwan Dawood, Annalisa Occhipinti 1094

E - Advanced techniques for the conservation and management of built assets

A BIM-BASED APPROACH TO THE MANAGEMENT OF HISTORIC BRIDGES
Carlo Biagini, Alberto Aglietti, Andrea Bongini 1105

AS-BUILT DETECTION OF STRUCTURES BY THE SEGMENTATION OF THREE-DIMENSIONAL MODELS AND POINT CLOUD DATA
Nobuyoshi Yabuki, Tomohiro Fukuda, Ryu Izutsu 1117

FIRE SAFETY ENGINEERING: THE COMPUTATIONAL SIMULATION OF THE ESCAPE IN A HISTORIC BUILDING IN BOLOGNA
Stefano Tagliatti, Marco Alvise Bragadin 1125

QUANTIFYING THE CONFIDENCE IN MODELS OUTPUTTED BY SCAN-TO-BIM PROCESSES
Shirin Malihi, Frederic Bosche, Martin Bueno Esposito 1137

CONSTRUCTION OF A PRACTICAL FINITE ELEMENT MODEL FROM POINT CLOUD DATA FOR AN EXISTING STEEL TRUSS BRIDGE
Nao Hidaka, Naofumi Hashimoto, Tetsuya Nonaka, Makoto Obata, Kazuya Magoshi, Ei Watanabe 1147

A BIM-BASED FRAMEWORK FOR FACILITY MANAGEMENT DATA INTEGRATION IN HERITAGE ASSETS
Carlo Biagini, Alberto Aglietti, Luca Marzi, Andrea Bongini 1159

COMBINING LARGE-SCALE 3D METROLOGY AND MIXED REALITY FOR ASSEMBLY QUALITY CONTROL IN MODULAR CONSTRUCTION
Wafa Bounaouara, Louis Rivest, Antoine Tahan 1171

BUILDING'S TWIN RECONSTRUCTION
Cecilia Maria Roberta Luschi, Alessandra Vezzi 1181

F - Digital Twin

A SEMANTIC DIGITAL TWIN PROTOTYPE FOR WORKPLACE PERFORMANCE ASSESSMENT
Alessandro Bruttini, Philipp Hagedorn, Felix Cleve, Vito Getuli, Pietro Capone, Markus König 1193

A SYSTEMATIC REVIEW OF DIGITAL TWIN AS A PREDICTIVE MAINTENANCE APPROACH FOR EXISTING BUILDINGS IN THE UK
Modupe Sobowale, Faris Elghaish, Tara Brooks 1206

PROJECT MANAGEMENT INFORMATION SYSTEM (PMIS) DASHBOARD AS A DIGITAL TWIN TO ENHANCE INFRASTRUCTURE PROJECT DELIVERY: A CASE STUDY OF AMERORO DAM PROJECT
Rizky Agung Saputra, Agung Fajarwanto, Amy Rachmadhani Widyastuti, Sari Gita Wardani, Danang Aris Munandar, Herdy Setiawan, Abdul Rahman Kadir, Muhammad Yunus Amar 1219

HUMAN-IN-THE-LOOP DIGITAL TWIN FRAMEWORK FOR ASSESSING ERGONOMIC IMPLICATIONS OF EXOSKELETONS
Abiola Akanmu, Adedeji Afolabi, Akinwale Okunola 1233

URBAN CENTRES MANAGEMENT: A DIGITAL TWIN APPROACH
Alessandra Corneli, Marianna Rotilio 1245

DIGITAL TWINS FOR SMART DECISION MAKING IN ASSET MANAGEMENT
Chady Elias, Raja R. A. Issa 1255

Foreword

The *International Conference on Construction Applications of Virtual Reality* (CONVR), as one of the world's leading conferences in the areas of immersive realities and digital transformation in AECO Industry, and the local organizing committee are pleased to present the Proceedings of the 23rd International Conference on Construction Applications of Virtual Reality (CONVR 2023) with the overarching theme "MANAGING THE DIGITAL TRANSFORMATION OF CONSTRUCTION INDUSTRY".

The 23rd CONVR was held on November 13-15, 2023, in Florence, Italy and was proudly hosted by the Department of Architecture of the University of Florence.

CONVR 2023 brought together AECO researchers and practitioners from around the globe to report on and exchange the latest development, ideas, improvements and applications stemming from innovative research activities in the following fields: *Virtual Reality (VR) and Augmented Reality (AR), Reality capture and Photogrammetry, H-BIM for heritage management, Simulation and Automation techniques, Computer Vision and Image Processing, Linked Data and Semantic Web for Knowledge Management, Smart Contracts, Distributed Ledger Technologies and Blockchain, Data Science, Machine Learning, and Data-Driven Approaches, Health & Safety, Green and smart buildings, Occupant-centric building design and operation, Building Information Modeling (BIM), Digital Twins, Internet of Everything, Mobile and wearable computing, Construction site management*. Those topics were articulated in eight different areas: *Methodology, Technology transfer, Technology, State of Art, Theoretical Study, Policy and Standardization, Education and Training, Case Study and Application*.

A total of 123 high-quality contributions were accepted after a rigorous review process from 71 esteemed members of the conference's International Scientific Committee. The accepted papers include a total of 374 authors from 32 countries, from Europe, the Americas, Asia and the Middle East.

More than 150 experts attended the conference contributing to enriching the exciting program which included 6 keynote speeches on the first day and 4 parallel presentation sessions on the following days, together with 5 workshop sessions.

The editors trust that this publication is stimulating and inspiring for academics, scholars and industry experts in the field; hoping that this could be a driving force for innovation, growth and global collaborations among researchers and stakeholders. We believe in the significant role that human interactions, networks, knowledge exchange and transfer play in developing high-value and groundbreaking research. This event provides a platform for networking and intellectual exchange of ideas.

We take this opportunity to express our gratitude to the CONVR2023 Technical Organizing Committee as well as our esteemed reviewers and sponsors. The creation of such a broad and high-quality conference program would not have been possible without their involvement and support. We also thank all the authors who dedicated much of their time and efforts to contribute to CONVR2023. We extend our best wishes to you and look forward to seeing you next year for CONVR2024.

INVESTIGATION OF THE ACCEPTANCE OF VIRTUAL REALITY FOR PLANNING DECISIONS IN EARLY DESIGN PHASES

Daniel Napps & Markus König
Ruhr University Bochum, Germany

ABSTRACT: *In recent years, with the increasing digitization of the construction industry, the potential benefits provided by the adoption of Virtual Reality (VR) have been shown especially in interdisciplinary networking among different stakeholders for which effective communication and information exchange methods are crucial. This is particularly significant during early design phases and associated decision-making processes where, despite its positive impact in terms of project's time and cost savings, VR adoption still has to reach its full potential. For this reason, this paper investigates to what extent the acceptance and application of VR has developed and identifies possible integrations in the early planning phases. By conducting a multi-year study with representatives from the construction industry, including qualitative and quantitative survey methods, the current use of VR and the requirements for future applications are determined. The study reveals that VR's importance for design visualization has increased, identifies architects' current requirements and integration barriers. Additionally, these requirements are compared with existing VR possibilities and an approach for exchanging different variants in a building information model will be examined. Based on these findings, VR can be integrated in application-specific contexts and software can be adapted to architects' needs for optimizing the digitization process.*

KEYWORDS: *Virtual Reality, Decision Support, Early Design Phase, Design Visualization, Study*

1. INTRODUCTION

Virtual Reality (VR) has made significant advancements in recent years and is increasingly being employed across various industries to foster innovative solutions. In the construction industry, VR presents novel opportunities and revolutionizes the approach to project planning, design, and realization (Ozcan-Deniz, 2019). For designers, architects and clients, one of the biggest challenges in the construction industry is the difficulty in visualizing a building project in the early design phase. Traditional methods using 2D drawings and 3D models have inherent limitations in conveying an accurate representation or illusory stimuli (Paes et al., 2017). At this point, VR becomes an important factor. By using VR technology, users are able to enter an immersive virtual environment and experience the future building or infrastructure in 3D. Architects are able to visualize their designs in virtual environments, which enables them to improve their understanding of proportions, designs, and functionalities. Developers have the ability to take virtual tours of their future properties, giving them a realistic feel for the space and amenities. Moreover, VR enables improved collaboration between the various stakeholders in a construction project (Davila Delgado et al., 2020). This allows architects, engineers, developers and other stakeholders to collaborate together in the Virtual Reality environment, make modifications, identify problems and develop solutions even before the actual construction process begins. Besides saving time and money, this may also reduce potential errors and miscommunications.

There are different types of VR technologies, each offering unique approaches to allow immersion in virtual worlds. Tethered VR systems are powerful solutions that require a connection to a computer. They incorporate external sensors or cameras to track the user's movements and ensure precise interaction in the virtual environment (Casini, 2022). Established VR companies such as High Tech Computer Corporation (HTC), META, Valve and Windows are already indicating strong growth in the segment over the next few years (Steam, 2022). Standalone VR devices are autonomous items that do not require a connection to an external computer. Instead, they integrate the display, processor, and tracking technology into a single device and offer a certain degree of mobility and ease of operation. By introducing the Apple VisionPro and its release in 2024, there is a potential for the market in this segment to grow even more in the future, as other technologies from the developer have already had a strong impact on the respective sales market. Mobile VR effectively uses smartphones as displays and processing power for virtual experiences. It allows users to plug their smartphone into a VR headset and access a wide range of VR applications or games (Casini, 2022). Available hardware is suitable for both private and professional applications. Unity, for example, is an applied development environment in architecture for the visualization of VR projects (Boeykens & Gawade, 2013). Due to these market trends, developing technologies and fields of application, it is relevant to investigate the actual potentials and evolution of VR acceptance for the construction industry in Germany. Older studies, such as from the United Kingdom, indicate that integration is imminent in large parts of the construction

industry (Bouchlaghem et al., 1996), and even more recent studies simply conclude that the AEC industry in the next few years is changing its previous path toward utilizing (Noghabaei et al., 2020). A study from Australia has adopted a similar approach to investigate the adoption of VR in the construction industry. However, this study is limited by a small sample size and the restriction of participants to the community of two universities in Sydney, Australia. As a result, there is no direct assessment of VR adoption among the stakeholders in the construction sector (Ghobadi & M.E. Sepasgozar, 2020). Country-specific surveys on the status of VR in the construction industry are rare, have been conducted many years ago, and do not include any follow-up studies. There is no specific data available for the construction sector in Germany.

Despite its potential benefits, there are several challenges associated with the use of VR for business purpose. Implementing VR technology in the workplace may be expensive, especially the initial investment in hardware and software. Additionally enquires employees to train and understand how to operate the equipment and navigate in the virtual environments effectively (Prabhakaran et al., 2022). VR technology often collects and stores user data, including personal and behavioral information. Maintaining data security and privacy is crucial to protect sensitive information and comply with regulations. To explore these and other similar potential barriers to the widespread adoption of VR in the construction industry, studies have been conducted in various years involving different target groups in the discipline. The study aims to capture the importance of VR for design visualisation in Germany and will explore the current requirements of architects and barriers for integration. A specially created sample application serves as a visual illustration of the VR possibilities and, in addition to the findings from the study, investigates the exchange of different design variants in a building information model.

The structure of this paper is as follows: Section 2 provides an overview of the research approach, presenting the research methodology and providing a supporting visualization for evaluation. The findings from the conducted studies are presented in section 3. In this regard, a categorization is carried out to investigate the potentials of VR on a topic-related basis. Section 4 discusses the findings and provides suggestions for future research.

2. BACKGROUND

2.1 VR in the construction industry

There are many potential applications for Virtual Reality in the early design phases for construction projects. Besides design presentations, simulations, marketing purposes and construction site inspections the collaborative planning is a significant factor. Simulations, for example, can be used to test specific aspects of a project, allowing for customizations to be made according to the building design. Virtual simulations of sunlight exposure provide insights into the materiality of building components (e.g., on the façade), light reflection and consider shadows on surrounding buildings and streets, while rain scenarios help to capture the direct runoff of rainwater on, around, and adjacent to a building in the early phases. For marketing purposes, the early design phase is less relevant. Instead, investors or potential buyers can be shown the project or building in detail, by a digital tour. VR-based construction site inspections allow for the early evaluation of safety measures as well as safety training and later monitoring of construction progress (Zhang et al., 2022). For many of these applications, a BIM interface is beneficial so that modifications can be made and saved directly in the Virtual Environment. These can be than done in virtual spaces, which enable teams from different locations to collaborate virtually on designs and plans, facilitating decision-making and coordination of work processes (Jensen, 2017).

2.2 Acceptance measurement

In terms of the acceptance of the technology in the construction industry, there is a need to operationalize it. For user acceptance, various models such as David's Technology Acceptance Model (TAM) in the field of innovation (Davis et al., 1989) or Kollmann's Dynamic Acceptance Model which was developed to analyze the acceptance of innovative goods can be utilized (Geldmacher et al., 2019). These are commonly applied in the field of information systems technology. According to the latter, the process of acceptance is divided into three levels:

- Attitude level: This level begins with the awareness of a product, which results in the user's interest and expectations.
- Level of action: In the process, the user makes initial tests and experiences that can result in a purchase and subsequent implementation for appropriate utilization.
- Utilization level: Regular access to the product ensures its continued use.

These levels span from the initial purchase decision to actual usage over time. The levels are interconnected, meaning that successful completion of one level leads to the next, ultimately culminating in the overall acceptance of a product. Therefore, assessing the overall acceptance necessitates examining all these levels. In this context, the potentials of the VR technology have a significant impact as they can positively influence the levels and therefore the overall acceptance.

2.3 Variant Management

In the early design phases, architects have various options for designing individual parts of the building. By using the Variant Management, it is possible to store and retrieve different variants for a specific building component in a digital building model. The methodology is designed to provide architects with decision support. This decision support can be advantageous for a virtual and immersive assessment of a project since different options for construction variants can be explored. The Variant Management encompasses three types of variants: Structure Variants, Function Variants, and Product Variants. Structure Variants refer to building elements related to the structure of the building, such as exterior walls. Function Variants are components that fulfill specific functions (e.g., columns), while Product Variants categorize individual products (e.g., windows) (Napps et al., 2021).

At the initial planning process, building elements must be categorized by an architect according to the three variants in order to ensure to find possible design alternatives later on. This categorization of elements into variants can either be done in a BIM software and provided with additional options (Napps et al., 2022) or based on the IFC data. The approach is performed in a graph-based format. Here, the exported IFC file of the model is transferred to a graph representation, whereby IFC entities are represented as nodes and IFC relationships as edges. Possible options are added to an existing variant in form of an option node, which results in the overall graph as a parallel possible option for an element (Napps et al., 2021). VR visualization allows architects to immersively experience the impact of a variant and how it compares to other stored options. If no options are stored in a model, problem-specific features can be specified for a variant in a separate database to obtain possible solutions from other projects as potential options. By choosing an option from another model, the selected option will be automatically stored as an option node to the graph. The selection of a design option can stem from either a calculation of similarity to other variants or on a specific aspect of investigation. Recently, Variant Management has been used to carefully evaluate design options or alternatives for cost efficiency and assessed alternatives to building components based on their costs to identify the optimal solution for a project (Napps et al., 2023).

3. RESEARCH DESIGN

The research design consists of primary research involving online surveys and expert interviews supported by a literature review to identify the current status and potentials of VR and its use in the early design phases. In order to investigate the current integration and acceptance of VR in the construction industry, a study over several years is conducted, as well as a determination of the acceptance of the technology among potential stakeholders. Acceptance has an important impact, as it is directly related to the usage. An identification of affected actors in the construction industry, the reduction to research-relevant stakeholders and the identification of actual potentials and the operationalization of acceptability is therefore necessary (Fig. 1).

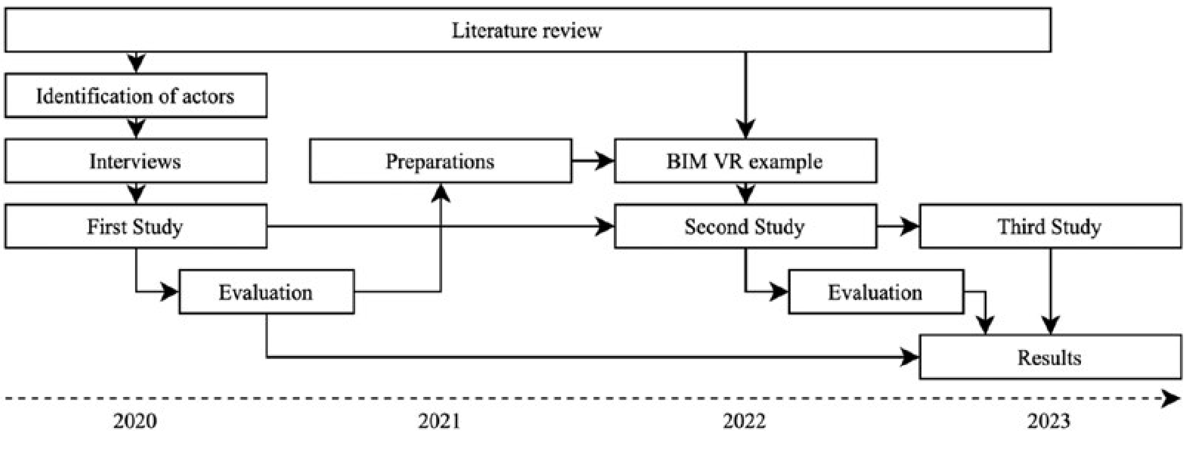

Fig. 1: Research design schedule.

In the construction industry, there are multiple stakeholders working together who might benefit from cooperation and coordination via VR in projects. This includes primarily architects, who have to consider the planning concept, the design wishes and ideas based on the requirements of the clients and on legal circumstances. A planning agency is a service company in which civil engineers, specialist engineers and planners work together. Geographers, geometricians and geoinformatics potentially can come into contact with VR in the planning process, for example, when it comes to generating city or terrain models or data bases. Real estate developers and investors are equally important actors who benefit from early visualization of the project in VR for new buildings, as well as for renovations and modernizations. Municipalities occupy a significant position due to the facts that, on the one hand, they have the primary role in the planning process in Germany, and on the other hand, they are highly significant as contractors for architects and investors (Emmitt, 2010). Of these, smart cities are highlighted, which are characterized by their significantly more innovative character compared to other municipalities. Furthermore, the public benefits from project renderings in VR, as they are able to receive a 3D visualization of the planning through the public participation required by law in Germany (§ 3 Abs. 1 BauGB) and do not have to rely on a planning knowledge of 2D plans and views.

Due to the limitation to the early design phases because of the increased relevance for planning decisions and error minimization (Østergård et al., 2016), not all of the mentioned stakeholders are of equal importance for potential usage and acceptance determination. Therefore, these are to be reduced due to the observation scope. In this context, the decision was made to specifically target architects and also gain insights into the overall sentiment of German cities. This approach allows for capturing aspects from both the supply side (architects) and the demand side (municipalities). Volunteers from the population were also invited to take part in a survey, as the Planning Act in Germany provides that they must be involved in construction projects and plans. For the identification of potentials, different assumptions resulting from research with regard to advantages and disadvantages for the use of VR were analyzed and summarized. These were formulated in various forms into neutral closed and open questions as much as possible.

3.1 Interview

In this research, the integration of interviews and surveys offers a broader and more comprehensive approach to gather data. Whereas interviews have a minor role in this study, they are instrumental in obtaining qualitative data and gaining deeper insights into individual experiences, which subsequently informed the design of the survey questionnaire (Rafidah Biniti Ab, Rahman, 2023). By combining these research methods, the results can be validated and triangulated, enhancing the overall reliability and credibility of the data and the interpretations made.

Table 1: Overview of the interviewees.

	Year	Date	Leading questions	Gender	Country of origin	Field of expertise
Interview 1	2020	7th July	16	female	Germany	PhD and urban researcher in the context of the digitalization of cities
Interview 2	2020	13th July	17	female	Austria	Focus on urban development and public-private partnerships in digital context
Interview 3	2020	16th July	18	male	Switzerland	Software developer for mixed reality and cloud computing
Interview 4	2020	12th August	14	male	Germany	Honorary professor and member of a progressive digitization network
Interview 5	2020	14th August	12	male	Austria	Chief marketing officer of an augmented and Virtual Reality startup
Interview 6	2020	2nd September	10	female	Switzerland	Focus on Digital Real Estate and member of an innovation team

At the outset of the study in 2020, interviews were conducted with specific stakeholders to shape the questions for the study and gather initial insights into the adoption, application, potentials, and barriers of using Virtual Reality in the construction industry. A total of six individuals from different disciplines were selected for expert interviews at various professional levels, which are shown in Table 1. Care was taken to include individuals with technical understanding, as well as scientific and practical knowledge of working with Virtual Reality in the construction industry. The six interviewees were equally distributed among the fields of software development, academia, and urban management and marketing (Tab. 1). All of them had experience with urban-level projects or collaboration with authorities responsible for planning. The experts represented both Germany and other European countries. The duration of the interviews, guided by specific questions, was approximately 60 minutes each. Starting with general topics, the discussions moved on to concrete questions about example projects and the involved actors. Due to partial critical comments on the topic and missing consents of personal data, the experts are anonymized.

3.2 Study

Quantitative research uses standardized surveys to collect data for a large sample size of individual people, groups of people or institutions. The methodology is used to analyze and describe mass phenomena. Online surveys are characterized by their monetary advantage, location independence of the respondents and low temporary effort of collection and evaluation (Mellinger & Hanson, 2021). No related data is stored in the questionnaires, which ensures honest statements and opinions. The questionnaires were initially distributed individually to different groups of persons (Planning and architectural offices) and later by a random principle, e.g., with the help of the inclusion in the newsletter of the Federal Chamber of Architects of North Rhine-Westphalia. The surveys were provided as an online survey and sent via link to the appropriate contacts. Three surveys were conducted over the course of three distinct years, with each survey period lasting approximately six weeks. The initial survey was carried out in July 2020, followed by a subsequent survey in July 2022, and a third in mid of July 2023 (Tab. 2).

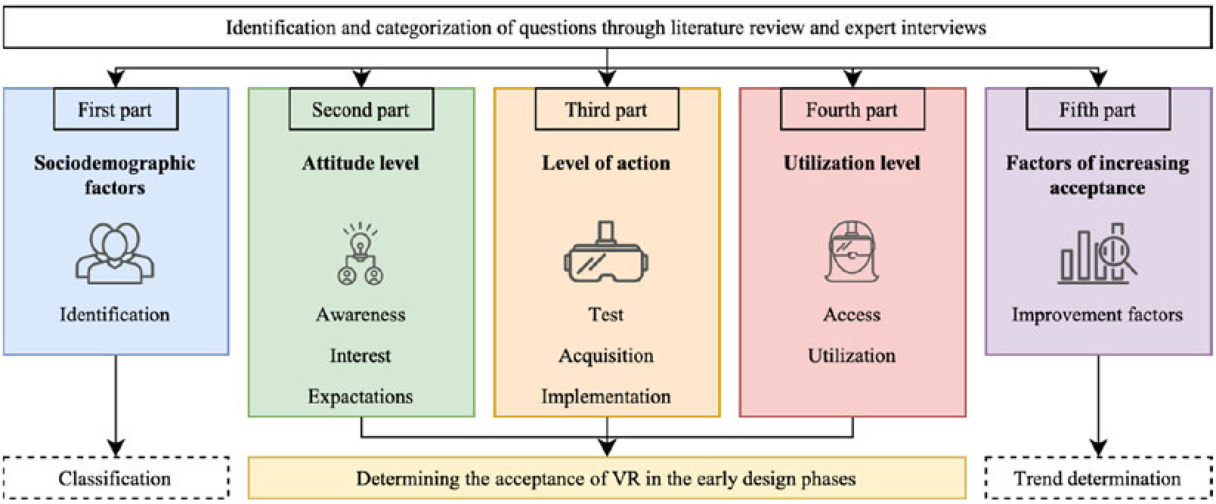

Fig. 2: Structure of the first study according to the acceptance measurement and for the evaluation of trends.

The first study from 2020 was a large-scale study, a deliberate combination of closed (yes/no) questions and open-ended questions was used to capture the situation of Virtual Reality in the construction industry as accurately as possible from different perspectives (Fig. 2). For the first study in 2020, different municipalities and smart cities were drawn from a sample of all German cities. Based on the cities identified, planning offices were selected in each case. Due to the significance of public participation (§ 3 Abs. 1 BauGB) and the benefits identified in the literature, the survey was conducted among both the identified stakeholders in the construction industry and a small sample of the population in Germany. In total, the first study thus consisted of four individual surveys. The sample size was chosen equally for the first three categories (Tab. 3). One follow-up reminder email was sent after half of the survey period.

Table 2: Overview of the studies.

	Year	Questions	Question type	Participants	Country of origin	Estimated duration	Objective
Study 1	2020	16	Mixed	60 + 55	Austria, Germany, Switzerland	12min	Large-scale data acquisition
Study 2	2022	19	Mixed	53	Germany	10min	Data acquisition for comparison
Study 3	2023	9	Closed	11	Germany	3min	Data acquisition for trends

Although the second study was conducted for the use of BIM and Variant Management, it includes a thematic block on VR. Therefore, the second follow-up study aimed to capture potential changes and trends in the adoption and acceptance of VR in the field. The last study was designed to collect final determining factors and is still ongoing. Only single choice questions were used in the third survey to compare most significant factors for the success or failure of VR integration and adoption with the previous ones. Actually, the survey period of the last one has not yet ended. The number of questions varied depending on the study. Overall, the studies were designed with a range of 6 to 16 questions. For the last one, a lower number of questions was used to ensure quick completion by the participants. However, the structure always followed a systematic framework, starting with the general use of VR for projects, followed by exploring advantages and disadvantages, as well as other criteria for measuring the potentials and acceptance. The questions were selected according to the operationalization of acceptance and divided into corresponding categories. In this regard, besides dichotomous and multiple-choice questions, Likert-scale survey questions and question types such as ranking and matrix questions were predominantly employed. A total of (60 (+ 58 participants from the general Population) + 53 + 11) participants were involved in these multi-year's studies, whereby it is to be mentioned that not all respondents answered each question. An overview about these studies is shown in Table 2.

3.3 Experimental realization of the Variant Management in VR

The study was supported with images to enhance participants' understanding of the use of Virtual Reality in the construction industry (Fig. 3). Towards this intent, a building was created which also served as an evaluation example to explore any potential opportunities and barriers in the realization of a project, focusing on the adaptation of a building design in VR. The building information model was created in Autodesk Revit and exported to Unity for visualization in a virtual environment (Fig. 3a). Utilizing the Unity Reflect Review enables design validation before and during a project. For this purpose, various options for building elements were modeled, such as different window variations, doors, and facade options (Fig. 3b & 3c), allowing architects to experience the changes in the building from both the interior and exterior perspectives. This approach aligns with the practical work of architects who evaluate different design variants for a building in early design phases and experience modifications in 3D to gain a better understanding of the effects of different building elements (Fig. 3d).

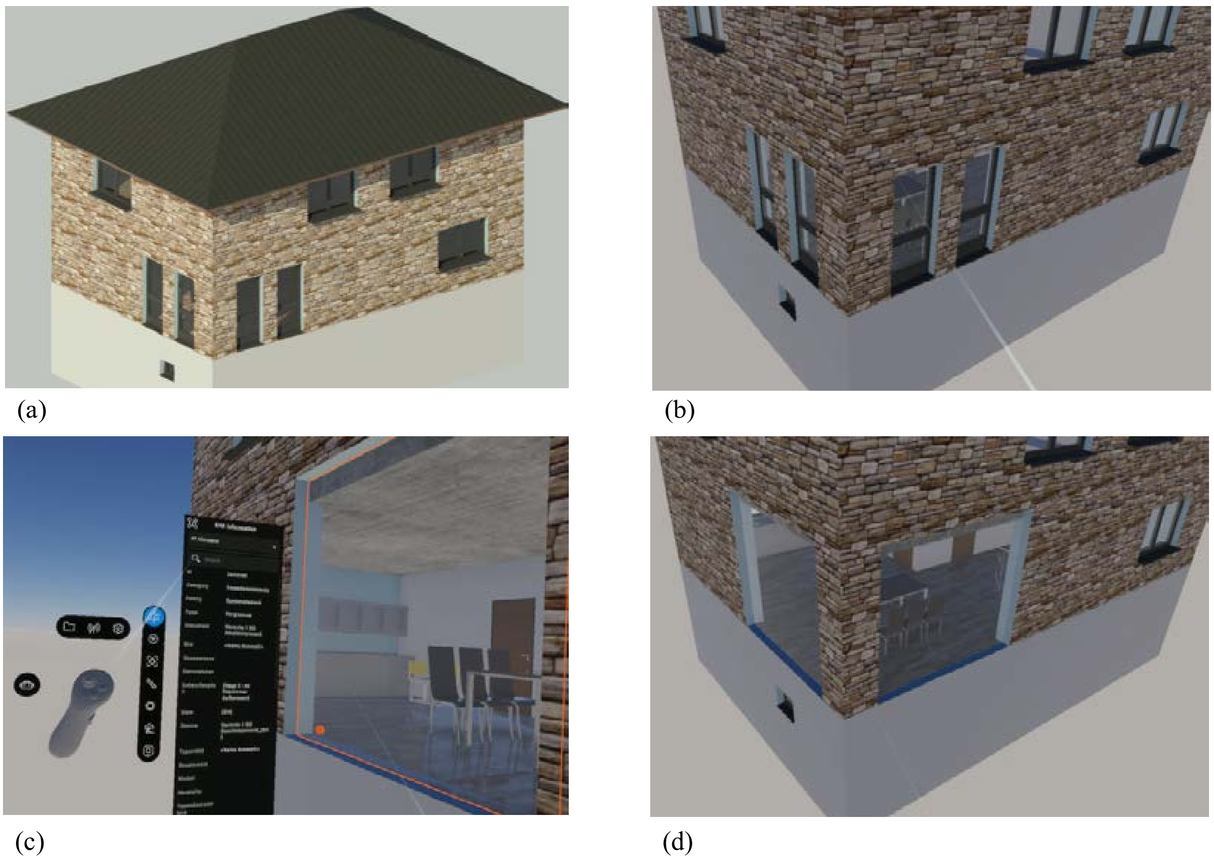

Fig. 3: (a) Building information model, (b) Building design variant in Unity, (c) Checking for stored design options with information and live interaction (Oculus Quest 2), (d) Customization and comparison.

4. FINDINGS

The initial study aimed to explore the current state, potentials, and acceptance of Virtual Reality (VR) in various sectors of the construction industry. To achieve a comprehensive understanding, the study included not only planning offices but also municipalities, smart cities, and segments of the general population in Germany. The subsequent two follow-up studies, however, narrowed their focus to examine planning offices primarily. This decision was driven by the fact that planning offices play a central role in the planning phases, whereas municipalities, smart cities, and the population are more closely associated with the final outcomes of completed projects. The results are categorized in sub-sections to facilitate comparisons of the studies. A total of 182 responses from the studies can be evaluated for this purpose. The three acceptance levels are considered in the discussion.

For the findings, the abstentions were mostly omitted from graphical representation to maintain clarity. The evaluation of the study is divided into three parts. Beginning with an assessment of VR's awareness and integration in the construction industry, it is followed by an exploration of its potentials and barriers. Findings regarding the creation of the VR example project, including various design options and the implementation are shown afterwards. In the discussion, the level of acceptance of VR technology in the construction industry is presented in the context of the demonstrated measurement process.

The response rates for the first study, illustrated in Table 3, range from 28% to 48%. Additionally, 58 individuals from the population participated. Incomplete responses to questions were not included in the response rate and were also excluded from the results. For the subsequent studies, voluntary participation was encouraged among different offices, because the response rate was the lowest in 2020. Based on a large-scale study examining 8,672 surveys and 1,071 online surveys in educational research, a weighted average response rate of 44.1% for online surveys in educational fields was identified (Wu et al., 2022). Different online survey platforms indicate an acceptable response rate between 5% to 30% and values above this correspond to a very good response rate (Chung, 2022; Le Masson, 2023). In the study from 2022, there were several abstentions on some questions, which resulted in the lowest rate for answering a specific question at 41 out of 53 participants (77.3%). All questions for the year 2023 were completed.

Table 3: Response rate of the first study 2020.

	Sample	Incomplete responses	Complete responses	Average time needed	Response rate
Municipalities	50	23	19	approx. 6min	38%
Smart Cities	50	37	24	approx. 7min	48%
Planning and architecture offices	50	16	14	approx. 6min	28%
Population	-	-	58	approx. 5min	-

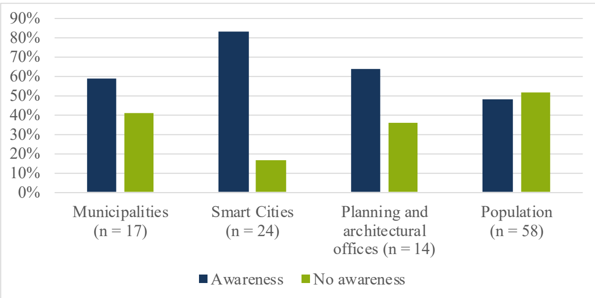
4.1 Actual awareness and integration

The study reveals that both awareness of Virtual Reality for the use in the construction industry and the resulting potential work experiences vary among the surveyed groups. It is evident that the majority of direct planning stakeholders (Municipalities, Smart Cities, and planning and architectural offices) are aware of the application of VR in this context, while the general population is more divided. The division among the public was already suspected during the interviews, as one expert from the scientific perspective believes that citizen participation regarding the acceptance of the technology is currently most advanced, while the software expert is of the opinion that the public is still unaware of it all. However, all interviews indicated that awareness among the population is increasing with a growing number of VR projects, and through the gamification factor, the usage and involvement of the population in projects can be enhanced. Some pilot projects from practitioners can confirm this impression.

Concerning Smart Cities and municipalities, the experts assumed that they are already aware of the technology, but the adaptation processes are challenging. The interviewees with practical background are already familiar with cities that work on projects in VR, but they point out that Smart Cities are likely to take the lead, while other municipalities may wait and observe these developments. However, it is said, that there is a general interest in the topic. It is also noted that larger cities might have a higher interest than smaller towns. Out of 24 respondents, 20 (83.3%) demonstrated the highest awareness of VR technology and its application in favor of Smart Cities, whereas 10 out of 17 municipalities (58.8%) showed awareness of the technology (Fig. 4). Two municipalities did not reply.

Regarding the planning offices, a relatively low penetration of awareness and the resulting integration and application was predicted by the interviewees before the study. First movers would take the lead here, but the technological novelty would not initially revolutionize conventional planning processes. Offices that deal with renderings at a high level are said to experience increased interest, as it enables them to maintain or even improve quality standards. Among the surveyed offices, 9 out of 14 (64.3%) had heard of VR (Fig. 4), and 5 out of 9 (55.5%) had already worked with it (Fig. 5), indicating a high level of awareness and practical experience. Regarding to the work experience, among Smart Cities and municipalities, the percentages were 50% and 30% (Fig. 5). In relation to their previous awareness levels, with municipalities having the lowest percentage of work experience.

The study from the year 2022 depicted that the utilization of VR for the actors within architectural and planning offices is nearly 10% higher than in 2020. According to the 2023 study, this positive trend is not continuing, as 54.5% of these offices report that they have already integrated VR into their everyday work (Fig. 7). This indicates that the level has adjusted to the 2020 level. However, the willingness to use it (71,4% in 2020) continues in a moderate form in 2023 (54,6%).



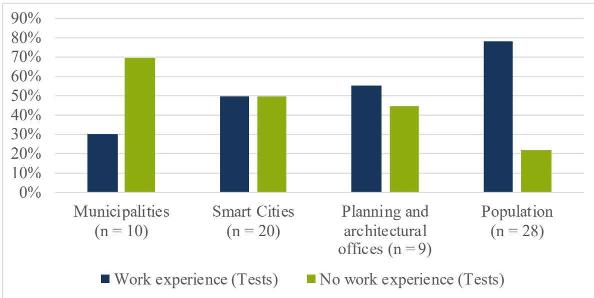


Fig. 4 (left): Comparison of the awareness (2020).

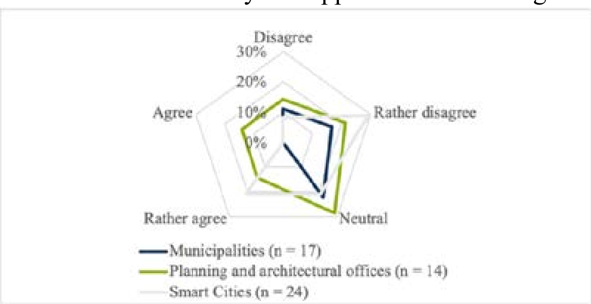
Fig. 5 (right): Comparison of the practical experience (2020).

Interest in the utilization was captured by questions regarding the willingness to incorporate Virtual Reality into the daily work routine and is shown in Figure 7. With the aid of an example integrated into the questionnaire, even participants who were previously unfamiliar with its application could partake in the question. As a result, it becomes apparent that 31.6% of the surveyed municipalities are ready to use VR in the near future, and 63.2% are neutral and do not reject the possibility of potential future adoption. Among Smart Cities, 50% express a willingness to use VR, with no direct rejections. As for the planning firms, 42.9% of the respondents have an interest in its utilization only 2 out of 14 offices do not want to use VR in future. In the year 2022, a highly positive trend was observed regarding the financial benefits derived from the implementation of technology among these actors (Fig. 7). One disadvantage, however, is the readiness of the hardware, which negatively affects the potential utilization. This primarily concerns the urban stakeholders, as five municipalities (26.3%) and six Smart Cities (25%) are not willing to provide hardware for meetings with other stakeholders, while one office (7%) is unwilling to do so (Fig. 7). The experts also perceive the provision of hardware, especially for small offices and small cities, as challenging. Experts in technology hinted in 2020 that with the introduction of Apple's proprietary software, both the general population and the cities and planning offices would benefit since these devices would reach a certain level of maturity and appeal to a broad range of citizens.



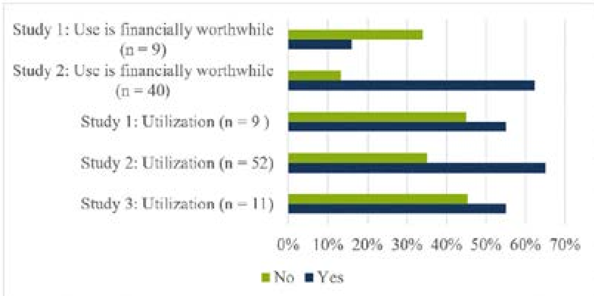


Fig. 6 (left): Comparison of the potential utilization (2020).

Fig. 7 (right): Comparison of the utilization propensity and financially worthwhile for offices (2020-2023).

As the potential utilization is related to the expectations of the technology, these expectations were also collected accordingly. For this purpose, three categories were identified, and the respondents were asked to indicate the extent to which they agree with each statement. Despite some negative remarks, the expectations regarding VR are predominantly aimed at achieving more efficient workflows with other stakeholders, improved communication, and increased public participation. The 2023 results confirm that, but reveal that respondents overwhelmingly agree that the use of VR in the construction industry is neither in high nor low demand. However, most respondents (72,3%) agree that VR representations have a high impact on the construction industry.

4.2 Identified potentials and barriers

The assessed potentials arising from the utilization of VR in the AEC industry are contrasted with the barriers encountered based on diverse experiences, offering a comprehensive comparison. Various response options identified in the literature and the interviews were given to capture the potentials and barriers for integrating Virtual Reality in the construction industry, with multiple responses allowed. The results primarily stem from the extensive study conducted in the year 2020. Trends are being verified with the two additional studies.

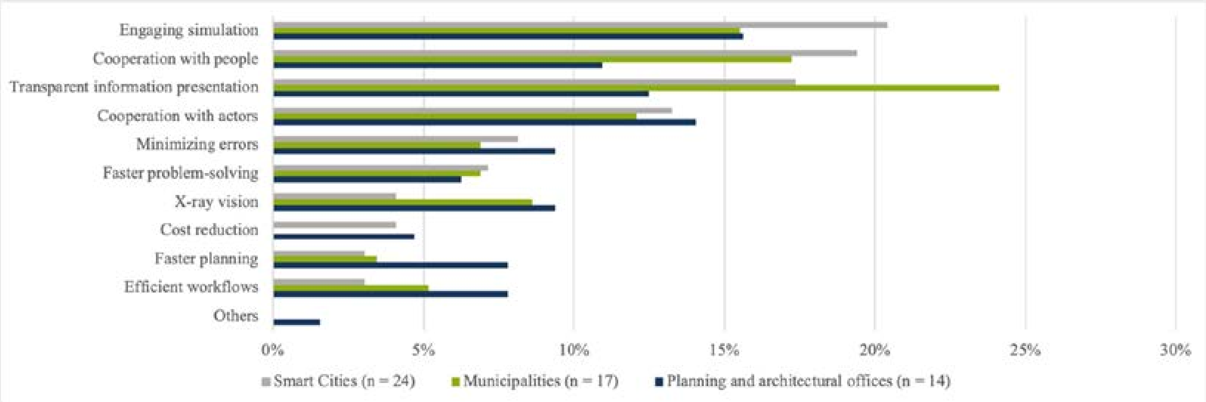

Fig. 8: Results of the first study on the potentials of the use of VR in the construction industry.

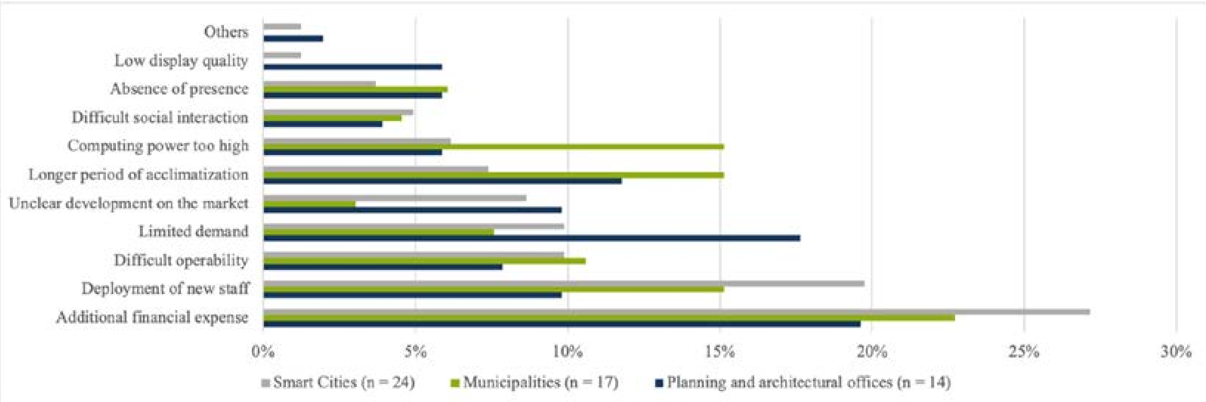

Fig. 9: Results of the first study on the barriers of the use of VR in the construction industry.

The most significant advantage, cited by 71.4% of planning offices, is the ability to create appealing simulations, followed by nine offices (64.3%) that agree to the advantage in better collaboration with other planning stakeholders (Fig. 8). Error minimization gained the greatest advantage among respondents in 2023 (36,4%). As the most significant disadvantage (71.4%), these stakeholders mention the financial burden. The two additional studies also confirm, with the highest number of agreements, the potentials of VR for simulation and collaboration, identified as the greatest potential for planning offices and their respective stakeholders. Additional monetary expense remains the most important barrier factor across the board, even within the study group (Fig. 9).

The three most significant potentials of the municipalities are transparent presentation of information (24.1%), improved collaboration with the population (17.2%), and the creation of appealing simulations (15.5%) (Fig. 8). The most significant barriers are the financial burden (22.7%), followed by the potential need for hiring new personnel, longer adaptation time, and the requirement for high computing power, each cited by 15.2% (Fig. 9).

For Smart Cities, the potentials are in the same three categories but with different weights (Fig. 8). The potential areas are transparent presentation of information (17.6%), improved collaboration with the population (19.4%), and engaging simulations (20.4%). As barriers for the integration of VR in the construction industry, the major concerns are the financial expense (37.3%), the need for hiring new personnel (27.1%), and challenges in operating the technologies as well as a low demand (13.6%) (Fig. 9).

In the study, the indicated potentials, based on the cumulative votes, outweigh the cumulative number of votes for the barriers.

4.3 Practical implementation

During the implementation of the Variant Management for visualization in VR, minor obstacles initially emerged, as saved building options cannot be stored directly in the software environment. Instead, only the selected variant is saved as a Revit file. In consequence, two versions of the designed building had to be saved for the visualization, each with different variants selected. Finally, the visualization is performed with Unity Reflect Review.

Another complication occurred attempting to use the Revit files directly in Unity Reflect Review, as the Unity Engine does not support the Revit format (.rvt). Alternatively, saving the file in the format (.fbx) facilitated the export and import of 3D objects, 2D objects, light sources, cameras and materials between Autodesk software programs and, since 2017, also between Unity. However, the object is displayed generically and in grey because Unity does not recognize the materials from Revit. Manual input of new materials that are recognized by the Unity library does not include all Revit materials and proves to be too time-consuming. Solving the problem is to alternatively use the IFC file for the two models and import it into Unity. A script then allows the BIM metadata to be retrieved and displayed within the object by having the script read the elements' information from the IFC file. It is important that the IFC file comes from the same 3D model referenced by the FBX file.

5. DISCUSSION

The studies have demonstrated that among the examined direct planning stakeholders, there is a predominant awareness of VR for planning processes. Many of these respondents also exhibit an interest in usage, some of which has even slightly increased. They highlight significant expectations of VR for planning tasks, aligning with the identified current capabilities. The results of the first study indicate that several municipalities, half of the surveyed Smart Cities, and the majority of the surveyed planning offices have already worked with and tested VR. While the willingness to acquire suitable hardware was generally portrayed as positive in all studies, the highest barrier, particularly for planning offices, was the financial extra expenditure. In terms of implementation progress in daily operations, a positive trend can be observed from 2020 to 2022. However, the results from 2023 potentially suggest a plateauing. It should be noted, however, that the study does not reflect the total number of offices, so the results from 2023 should rather be understood as a sample for trends. The provision of hardware is accompanied by the already examined acquisition. The willingness to use VR is strongly pronounced among the examined stakeholders, and the potential provision of hardware for meetings with other stakeholders is partially available. Ultimately, the utilization rate over the years demonstrates a significant practical application of VR, even though it appears to be slightly declining in 2023. This trend could potentially be attributed to a lack of demand for VR implementation in projects from contractors (cities and investors), for instance. Regarding the application, some experts see the advantage in the mobile use of VR, as it lowers the entry barrier and in the developments of the products and integration in a broad market. Overall, it can be observed that there was a solid basis for the acceptance of VR in the construction industry for planning decisions, which has continued to grow over the years. The majority of the sampled planning and architectural offices exhibit attitudinal (Level 1) and application (Level 2) behavioral acceptance. However, because utilization (Level 3) depends on certain factors, such as personnel, acquisition, strategic planning and access the acceptance of usability in 2020, is present in less than half of the offices. However, the subsequent studies have shown that the utilization of VR has not declined, which has led to the fact that the third level of acceptance has now also been reached by the majority. Among the smart cities, there was already an overall acceptance in 2020, according to the results of the majority of respondents, whereas the municipalities were not yet able to achieve an overall acceptance at that time, due to a lack of awareness, the resulting lack of test phases and a low willingness to invest. This results in poor values for this actor at all three levels of the acceptance measurement.

While the mentioned potentials and barriers indeed prevail, an individual weighting of factors is not feasible. For instance, a barrier might be so formidable that it cannot be overcome, as exemplified by the purchase of software for small design firms or cities. Nevertheless, the results of the assessment of monetary readiness for the adoption of VR software in comparison to its benefits have demonstrated that numerous architects and engineers have been able to enhance the integration and implementation of VR. By surveying the barriers among the different stakeholders, it was possible to identify factors for increasing the acceptance of VR for the visualization of planning in early design phases, which can be addressed accordingly from the developer perspective as well as the user perspective in further research.

The provided example has demonstrated that visualizing digital buildings in Unity using the IFC format of a model is straightforward, while the exchange of design alternatives with the Variant Management is a bit difficult. In the future, an alternative approach could be explored to better integrate the stored options in this regard. Visualizing projects in the early design phases provides added value for stakeholders, and there is a recognizable public interest in VR visualization of the final product for public information activities and cooperation with other stakeholders.

BUILDING INSPECTOR XR: STREAMLINING SCAN-TO-BIM WITH VIRTUAL AND MIXED REALITY

Christoph Blut, Tristan Kinnen & Jörg Blankenbach
Geodetic Institute and Chair for Computing in Civil Engineering & GIS, RWTH Aachen, Germany

Dirk Heidermann & Felix Schellong
TEMA Technologie Marketing, Germany

ABSTRACT: *Digitalization in the construction industry is increasingly striving to create digital twins in order to continuously exploit optimization potential in the management and utilization of existing buildings. Building Information Modeling (BIM)-based as-is or as-built documentation represents a promising basis in this context, which requires creating a geometric model for example based on point clouds as well as semantic enrichment in a Scan-to-BIM workflow. Conventionally, this is carried out manually by specialists on 2D screens and often is time-consuming and costly. The project "Building Inspector XR" addresses these issues and presents an intuitive solution for BIM-based as-is/as-built documentation using X-Reality (XR). In Virtual Reality (VR), BIM models are created off-site from point clouds and then are verified in Mixed Reality (MR) on-site. By integrating (partially) automated methods and targeting user-friendliness in our solution, Scan-to-BIM can be realized more efficiently and intuitively. In this paper, the focus lies on the innovative aspects of our XR application which encompass VR and MR environments, automation support, modeling schemes in compliance with BIM standards, and the registration of models in reality for MR. Additionally, the paper shows the interconnected toolchain that facilitates an efficient Scan-to-BIM workflow.*

KEYWORDS: *Building Information Modeling, Virtual Reality, Mixed Reality*

1. INTRODUCTION

The global and cross-industry trend of digitalization is increasingly shaping the construction industry as well. As a comparatively less digitalized industry, there is a great need for the development and implementation of digital methods in the construction industry in particular. The linchpin of the digital transformation in the construction industry is the cooperative working methodology Building Information Modeling (BIM). Compared to traditional methods, BIM offers the potential to improve communication and coordination between all construction stakeholders, make management for cost and time more efficient, and achieve higher levels of detail in digital building models by incorporating component-specific semantics in addition to geometry. Although the use of BIM is applicable across the entire lifecycle of buildings, in reality the collaborative working methodology is predominantly used for new structures. For existing buildings, BIM has not yet been applied frequently, although it could create added value for operation and utilization by enabling the resulting digital as-is/as-built models to be used to represent and evaluate the existing condition of the building and, based on this, to plan possible maintenance measures, carry out simulations or organize issue management more efficiently.

For the application of BIM in this context, it is first necessary to capture the existing buildings. In most cases, such an acquisition process is carried out by means of laser scanning (terrestrial or mobile) or photogrammetry. The result of these procedures is a 3D point cloud. The subsequently necessary process of generating a digital building model from the available point cloud is summarized under the term "Scan-to-BIM" and is currently mainly implemented manually on two-dimensional screens using keyboards and mice. Therefore, we identified the need to improve the Scan-to-BIM process, by making it more intuitive in a 3D space using X-Reality (XR). In this paper, we present the project "Building Inspector XR", which includes both a Virtual Reality (VR) and Mixed Reality (MR) application, for the intuitive creation of as-is/as-built BIM models based on existing point clouds.

2. BACKGROUND

2.1 Reality Capturing

As a holistic approach to documenting structures, BIM places more far-reaching demands on building surveying. To meet these requirements, various methods of reality capturing are employed, including photogrammetry, terrestrial laser scanning and mobile laser scanning.

Photogrammetry is a method of deriving geometric information of an object from images (Luhmann, Robson, Kyle, & Boehm, 2014). A distinction is made between mono- and stereo-photogrammetry. While mono-photogrammetry is based on the analysis of single images, stereo-photogrammetry uses pairs of images to measure objects, such as buildings. Using photogrammetry, areas that are difficult to access can be surveyed with a comparatively high information density with Structure from Motion/Dense Image Matching. The respective achievable geometric accuracy is subject to a number of factors, such as the camera technology, the resolution of the individual images, the type of reference point determination (Donath, 2008) and specifically the image scale.

In addition to photogrammetry, laser scanning forms another practical method for building acquisition and is considered the leading technology for the acquisition of 3D spatial information with high density (Lari, Habib, & Kwak, 2011). From a functional point of view, a distinction is drawn between laser scanners with impulse and phase measurement methods. Impulse measurement determines the time of flight of the laser beam, while phase measurement evaluates the phase shift of the reflected signal. While laser scanners with the phase comparison method are characterized by a significantly higher number of recorded points per second, laser scanners with the impulse measurement method offer a significantly higher range. Terrestrial laser scanning is characterized by stationary acquisition of local 3D data of the object from different locations and subsequent registration of the data of all locations relative to each other. In contrast to this, mobile laser scanning continuously acquires 3D data while the object is in motion and registers the data via positional information.

The output of each of these methods is a high variety of 3D points representing the respective surface of the acquired object. These 3D point clouds can be used for further analysis and modeling.

2.2 Scan-to-BIM

In addition to the surveying workflow, the holistic BIM approach to the acquisition, management and exchange of building information also has implications for the processing and modeling of data (Blankenbach, Schwermann, & Becker, 2021). The process of creating or reconstructing as-is/as-built BIM from 3D point cloud data is called Scan-to-BIM. For this process, individual geometric elements such as walls, doors or windows are initially created on the basis of the point cloud data. Additionally, to the geometric model, attributes such as materials, dimensions or further semantic information are linked and documented to the corresponding objects. Subsequently, the resulting BIM model is validated and checked for possible errors or inaccuracies to ensure compliance with requirements and standards. Currently, this process is predominantly handled manually by professionals using (3D) computer-aided design (CAD) or BIM authoring software, such as Autodesk Revit (Autodesk, 2023). While automated solutions for this process are being progressively developed in both research and industry, each of the currently available off-the-shelf Scan-to-BIM software packages presently still requires significant manual user input making the entire process cumbersome and error prone (Son, Kim, & Turkan, 2015).

2.3 State of the art

(Adekunle, Aigbavboa, & Ejohwomu, 2022) compiled a systematic literature review network analysis on the topic of Scan-to-BIM in 2022. According to this, Scan-to-BIM is being researched worldwide with a view to finding more efficient solutions, which occasionally also include the use of VR and AR technologies for information management. However, specific works are not mentioned since the paper focusses to summarize, categorize and analyze the different topological backgrounds and their nationally backgrounds. Therefore, no specific work for modeling in VR or Augmented Reality (AR)/MR is addressed. (Wu, Hou, & Zhang, 2021) and (Alizadehsalehi, Hadavi, & Huang, 2020) show studies that aim to compile various publications related to BIM and XR applications. (Wu et al., 2021) outlines a BIM-XR application as a system combining a BIM database and a human-machine interactive interface for context-aware visualization and interaction. Generally, it highlights that XR can enable modifications and updates to the BIM model and offers intuitive visual representations and interactive experiences within the BIM context. However, the study primarily emphasizes the visualization aspect and does not present detailed approaches for geometric and semantic BIM modeling in VR or MR environments. Specifically, the focus is on AR/MR for post-construction BIM model adjustments, while VR is considered mainly for visualization purposes. (Alizadehsalehi et al., 2020) discuss the benefits of XR technologies for construction project simulation and present a comprehensive overview of XR applications. Nevertheless, while acknowledging the potential of using XR with BIM for interactive visualization, the study focuses on approaches to transform pre-designed BIM models into XR rather than intuitive modeling in VR and MR.

Commercial products such as Enscape (Chaos, 2023) or Twinmotion (Epic Games, 2023a) allow a visualization of 3D models in VR as well as creating images, animations or walkthroughs, however, both require importing previously created models and do not provide the possibility of modeling, except for simple drag and drop functions via the desktop computer editor, in VR. Further XR possibilities, such as the transformation into AR or MR, are also not possible. In comparison to our solution, VR Sketch (VR Sketch, 2023) presents a similar approach. Nevertheless, it lacks comprehensive BIM capabilities, making it incapable of conforming to BIM standards when modeling components. Moreover, the software does not support point clouds. Arkio (Arkio, 2023) offers a platform specifically developed for collaborative design and architectural conception, focusing on free geometric modeling in a VR environment. For this, existing BIM models and 2D plans can be imported as a data basis and the created 3D geometric models can be exported into selected BIM authoring software, such as Autodesk Revit or BIM360. However, Arkio does not provide BIM-specific functionalities to ensure BIM-compliant (as-built) modeling, like complying with existing standards, providing standardized component catalogs or semantic enrichment. Also, Arkio is limited to proprietary file formats and does not contain the option of exporting to the open Industry Foundation Classes (IFC) (buildingSMART, 2019) standard. 3D models can also be created and edited in AR, but this feature is limited to tabletops. GAMMA AR (GAMMA Technologies S.à r.l, 2023) on the other hand offers the possibility to overlay BIM models on construction sites. This integration aids in error prevention and precise component monitoring. Nonetheless, it does not support actual modeling activities. BIM Holoview (BIM Holoview Ltd., 2023) combines VR and AR/MR to enable users to view BIM models using Meta Quest 2 (Meta, 2023) and Microsoft HoloLens (Microsoft, 2023). However, it is limited to Autodesk 3D Revit and Navisworks files, restricting modeling functionalities. Unity Reflect (Unity Technologies, 2023) encompasses the broadest range of capabilities. It allows users to view BIM models in various ways, including VR, AR/ MR, on multiple devices, nevertheless, it does not support the creation of BIM models in real-time.

3. METHODOLOGY

The Building Inspector XR revolutionizes the process of building inspection by harnessing the power of VR and MR technologies. This chapter presents an overview of the process chain involved in the Building Inspector XR, covering its architecture, hardware and software choices, and the functionalities it offers. Through the utilization of point clouds and BIM models, accurate pose tracking, and seamless integration of virtual content into the physical environment, the Building Inspector XR system streamlines the Scan-to-BIM process.

3.1 X-Reality for Scan-to-BIM

The XR BIM system is the foundation of the Building Inspector XR. Fig. 1 illustrates the system's structure, where a point cloud, generated through photogrammetry or laser scanning, serves as the initial data in VR. With the point cloud as a context, the user creates a BIM model, which can be exported as an IFC file for interoperability or brought into MR for on-site enhancement. This seamless interchangeability between VR and MR enables efficient workflows, supporting models based on the IFC building and waterways domain. Choosing the right hardware and software is crucial for the success of an XR system. For the Building Inspector XR system, the Valve Index (Valve Corporation, 2023) and the Microsoft HoloLens 2 were selected. The Valve Index, a tethered VR headset, provides high-quality pose tracking necessary for accurate movements in VR. On the other hand, the Microsoft HoloLens 2 was chosen for its MR capabilities, including accurate pose tracking, gesture-based interactions, and immersive visuals. Software plays a significant role in the Building Inspector XR system, with Unreal Engine (UE) (Epic Games, 2023d) serving as the development framework of choice. UE offers a broad application field beyond gaming, supporting various file formats and a wide range of hardware, including the Valve Index and the Microsoft HoloLens 2. The system leverages relevant plugins to extend its functionalities, such as the Datasmith Plugin (Epic Games, 2023c) for importing IFC files and the LiDAR Point Cloud Plugin (Epic Games, 2023b) for importing point clouds. The open source nature of UE allows for customization and modifications to the core engine functionalities.

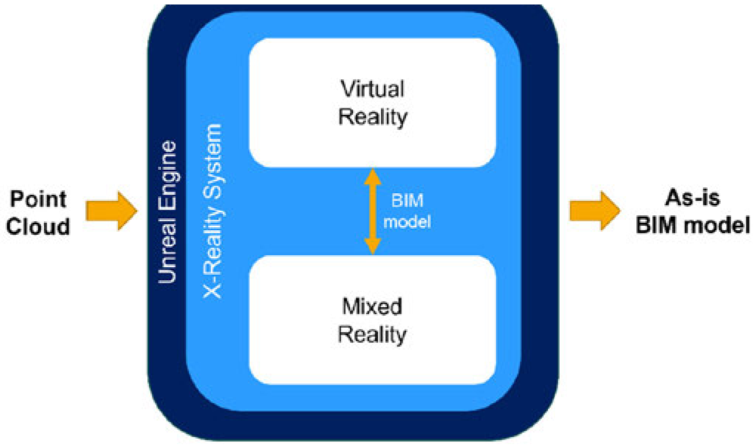

Fig. 1: Architecture of the Building Inspector XR.

The LiDAR Point Cloud Plugin on the one side offers an import interface and on the other side point cloud rendering methods to visualize the point clouds in UE. For starting the modeling process in XR, the initial point cloud can be provided in a couple of different formats, such as XYZ, PTS, LAS/LAZ or E57. Once available in the system, multiple parameters of the LiDAR Point Cloud Plugin ensure that the point clouds are rendering efficiently. We configured the plugin so that the point clouds are visualized with the highest quality possible, while maintaining a high performance. A highly detailed presentation of point clouds is crucial, so that as much information can be derived from the data as possible during modeling. Like this, small details of the environment can be already identified and modeled from the point clouds, enhancing the value of the BIM model, and minimizing additional modeling work later in MR or post processing (Fig. 2).

Fig. 2: Point cloud in VR.

In XR, but especially in VR, rendering performance is crucial for a smooth and realistic user experience. A high frame rate of 90 frames per second (FPS) or higher is recommended to reduce motion sickness and enhance the overall user experience. To address the challenge of rendering large amounts of data, optimization techniques are employed. These include an efficient octree data structure and spatial partitioning. Level of Detail (LOD) systems are used to reduce complexity as objects move farther from the camera, improving performance. The VR system provides intuitive interactions for easy BIM model creation. The VR controllers enable users to access the menu attached to the left controller and interact within it. Over the menu all required functionality to create a complete BIM model is accessible to the user, including geometry and semantic data modeling methods, editing tools and export functionality. The right controller is reserved for the actual modeling process. Teleportation allows instant movement to designated spots in the virtual environment, while fly-mode enables reaching higher locations. Pose tracking allows physical movement within smaller areas, accurately replicated in the virtual environment.

In contrast to VR, the MR system of the Building Inspector XR does not require a complete virtual world (Fig. 3). Instead, it integrates the virtually modeled objects into the physical environment. This is specifically challenging, because the virtual elements modeled in VR need to be placed as accurately as possible in reality, so that they overlay their physical counterparts. Like this, the user can inspect elements, for instance by comparing the modeled with the real situation. Also, details can be added to the BIM elements, for example additional attributes such as material or even further geometric information. This is important, if objects or details were not visible in the point cloud, either because they were covered by other objects during reality capturing or too small so that they are hardly or not visible in the point cloud.

Fig. 3: MR application.

Accurate alignment between the virtual and physical worlds is achieved through pose tracking, which seamlessly integrates the virtual and real elements. The system employs a Visual Simultaneous Localization and Mapping (V-SLAM) algorithm on the Microsoft HoloLens 2 for accurate pose tracking. This algorithm keeps track of the user's pose (position and orientation), thus, of the Microsoft HoloLens 2, keeping virtual objects robustly anchored to a location in reality. To achieve an initial accurate alignment between the virtual objects and reality, a registration method is employed. The Building Inspector XR system utilizes the Kabsch–Umeyama algorithm (Umeyama, 1991), a widely used method for aligning and comparing similarity between two sets of points in multidimensional space. The goal of the algorithm is to find the optimal rigid transformation matrix that aligns one set of points to another set of points. It can roughly be broken down into three steps:

1. Calculate the centroids of both point sets.
2. Transform both datasets to the origin and then calculate the required rotation.
3. Calculate the required translation and scale.

For MR registration, this can be used by defining corresponding points in the virtual world and reality. Optimally, points are chosen that can easily be identified in both spaces, for instance the corners of a door or window (Blut & Blankenbach, 2021). We therefore provide the means for users to actively select corresponding points in the BIM model and in reality. The gesture-interaction system of the Microsoft HoloLens 2 allows easy and intuitive point selection using fingers. And with the spatial understanding of the Microsoft HoloLens 2, points can accurately be placed in reality. Since the points need to correspond to each other, we provide numbered spheres that simply must be placed in the desired spots by drag-and-drop interaction (Fig. 3). Once all spheres have been placed, the user only needs to confirm to perform the instant alignment. This referencing process can be repeated as needed to maintain accuracy.

Once virtuality and reality have been aligned, the user can start the inspection or modeling process. Due to the head-mounted nature of the Microsoft HoloLens 2, the user has both hands free for interactions. We provide a floating menu with the same UI and functionalities as in VR, so that creating a BIM model is as intuitive in both spaces but optimized for the technology. Creating and interacting with objects using Microsoft HoloLens 2 is as easy as using the point or pinch-gesture.

3.2 BIM-compliant as-is/as-built modeling

By combining VR and MR, the Building Inspector XR enables the creation of models completely in 3D space. Furthermore, modeling as well as interactions are carried out intuitively by gestures and voice input. In terms of functionality, we placed emphasis on advanced geometric modeling, linking semantic object data, and compliance with standards for ensuring a standardized BIM model (as-is/as-built model). Within the scope of the associated research project, we focused on the as-is/as-built BIM modeling of building as well as water engineering structures.

The Building Inspector XR offers users three different approaches to geometric modeling, tailored to the complexity of physical objects. The first method is free modeling (Blut et al., 2023). Simpler objects like rectangular walls, floors, or ceilings can be created by specifying just two diagonally opposite points and the software automatically generates a solid object with parallel edges. This method ensures quick and precise modeling. For objects with more intricate geometry, the parametric modeling feature is available. Users input a minimal set of parameters, from which all the necessary geometric information is derived. Step-by-step instructions guide the users through the process. For example, when modeling a ladder, the user only needs to input the base point, height, and width, with adherence to relevant standards such as the German DIN 18799 for fixed ladder systems on structures. The DIN 18799 specifies that the width of a ladder may be between 400 and 600 mm and that the distance between the ladder rungs must be between 225 and 300 mm. Furthermore, it defines that the first and last rungs should be at least 100 mm and a maximum of 400 mm from their respective ends of the ladder. When the user inputs the required parameters, these value ranges are considered. If any value exceeds or is below the permitted ranges, the respective upper or lower limits are set as new modeling parameters to ensure that the modeled object is in accordance with the prevailing standards. Based on the resulting dimensions of the ladder, the two side rails are first created, and then the number and positions of the individual rungs are automatically generated, considering a standard-compliant entry and exit spacing of 200 millimeters.

In cases where manual modeling proves challenging due to the complexity of the object, the Building Inspector XR provides an integrated catalog of pre-modeled components. These components come with essential attributes and can be easily dragged and dropped into the desired positions. This feature significantly speeds up the modeling process, particularly for highly complex objects. For example, a niche bollard can be quickly inserted using this method (Fig. 4). To enhance modeling capabilities further, the Building Inspector XR enables users to selectively cut out areas defined by the user using Boolean operations. This allows for the insertion of additional components or modifications to existing objects.

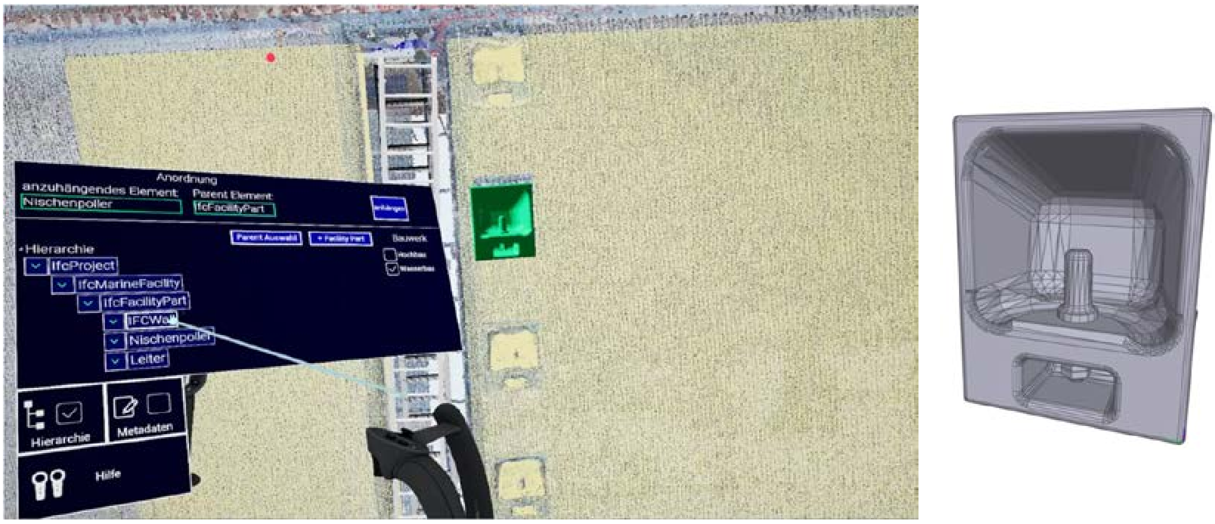

Fig. 4: Placing pre-modeled IFC components in the scene.

A plane fitting algorithm assists users in accurately placing objects on a plane, ensuring proper alignment between components and reducing modeling time. For the detection of surfaces the Random Sample Consensus (RANSAC) algorithm is used. The goal is to find, in several iterations, the area where the largest number of points from the point cloud lie in a plane, i.e., where the distances of all points to the respective plane are minimal, by randomly selecting three points to form a plane in each iteration. Then, the distances of the remaining points to the plane are determined. The plane of the best iteration is stored. RANSAC ensures that outliers are effectively eliminated (Fig. 5).

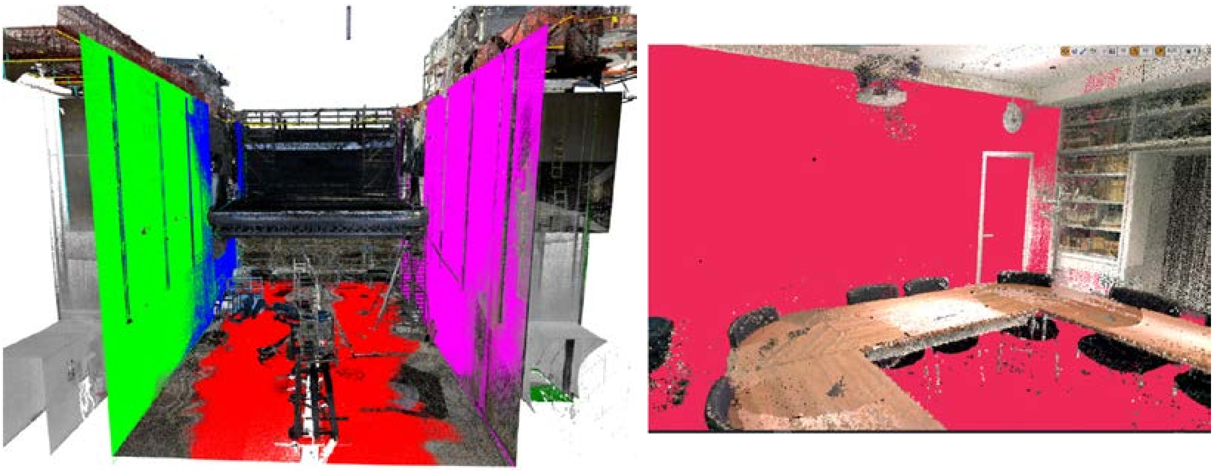

Fig. 5: Detected planes using the plane detection algorithm.

The Building Inspector XR not only focuses on geometry but also emphasizes the assignment of semantic data to objects. By adopting the IFCx4.3 (buildingSMART, 2023) standard as its data model, the software ensures compliance with BIM standards throughout the modeling process. Users can input specific attributes such as name and description for each object, and additional information can be freely assigned using IFC's property sets. The software follows a clear hierarchical structure, enabling users to classify objects, create object-specific properties, and assign components to the IFC hierarchy. Adhering to the IFC hierarchy is crucial for effective BIM implementation. Furthermore, it ensures that modeled objects are correctly classified and organized within the BIM model, facilitating efficient data exchange and collaboration among project stakeholders. The IFC data model is reflected 1:1 already in the application, so that BIM models can easily be exported without loss of data. This was solved by creating the corresponding IFC classes in UE and placing them according to the place in the IFC hierarchy in the UE scene graph. When the user during the modeling process creates a new object, this object can be filled with attributes according to the standard and placed as a parent or child of other objects.

Moreover, the Building Inspector XR facilitates the export of the completed BIM models in the standardized IFC (IFCx4.3 standard) format. The resulting IFC file in STEP Physical Format (IFC-SPF) is readable in any IFC-compliant software, allowing for visualization, editing, and extension of the model using BIM viewer or BIM authoring software.

The integration of water engineering structures into the Building Inspector XR further enhances its versatility and applicability in various construction projects. Users can now model, analyze, and visualize not only buildings but also water engineering elements such as locks, dams, and canals. The inclusion of these new IFC classes demonstrates the commitment to providing a comprehensive XR BIM solution that caters to a wide range of construction disciplines.

4. BUILDING INSPECTOR XR IN PRACTICE

In this section the practical experience with the Building Inspector XR is described. To evaluate the Building Inspector XR, we modeled an office. To obtain the base data for modeling, first, the office and the surroundings of the office were captured with the geodetic terrestrial laser scanner Riegl VZ400 and contained 21 million points (Fig. 6). Subsequently, the resulting point cloud was cleaned from outliers and unnecessary data and exported as a LAS file, since the format proved to work well with the UE LiDAR Point Cloud Plugin. With LAS, importing goes quickly and all data is transferred correctly. On a computer with an AMD Ryzen 9 3900X 12-Core Processor with 3.80 GHz, 32 GB RAM and a M.2 SSD, the LAS file could be imported in less than a second. Importing the same point cloud in E57 format took roughly 20 seconds.

Fig. 6: Point cloud from terrestrial laser scanner of an office in the Building Inspector XR.

A model was created in VR and then later transferred to the Microsoft HoloLens 2. The registration method for aligning the virtual world with reality proved to be efficient, so that the previously modeled objects overlayed their physical counterparts accurately. Three corresponding points were used. The distribution of these three points across the room was crucial, so that an optimal transformation could be calculated. Therefore, we placed on point in the corner of the room, one point on the other side of the room on the corner of a window and the third point on the corner of the door in the wall between the first two points. This provided the maximum distribution of points in the room. The resulting alignment had an accuracy of under 1 cm. After modeling, the BIM model was exported as a IFC-SPF. The created BIM model, i.e., the resulting IFC file then could be loaded without problems in different BIM viewers, such as BIMvision (datacomp, 2023).

The evaluation showed that the Building Inspector XR has a distinct advantage over professional and highly complex BIM authoring software. Inexperienced users could effortlessly create IFC-conforming models using this system. The immersive nature of VR and MR played a significant role in this achievement as it made handling virtual tools and dealing with complex data like point clouds and IFC models much more accessible. Users found the interface intuitive and were able to interact with the models in a natural manner, similar to real-world interactions. The users' experiences revealed that certain modeling tasks, particularly those involving large objects, were most efficiently performed in VR. The flexibility of locomotion in the virtual environment allowed for quicker and more fluid modeling. On the other hand, when it came to adding finer details and object-specific information, the MR application proved to be more advantageous due to its ability to provide better context for these additions. One notable result of the system's efficiency was the ability to model a substantial structure in only a short time. This speed and ease of modeling emphasized the system's capability to create BIM models in a highly efficient manner. Overall, the combination of VR and MR in the XR BIM system demonstrated its potential to empower users, regardless of their experience level, to produce accurate and conforming BIM models in a more intuitive and time-effective way.

5. CONCLUSION

With the Building Inspector XR, we aim to enhance the Scan-to-BIM process by developing an efficient workflow that incorporates VR and MR, ensuring the creation of BIM-compliant as-is/as-built models in a standardized IFC structure, which includes the latest state of the art and thus in addition to building construction also water engineering classes. By transferring BIM to VR and MR, integrating automation, implementing modeling schemes based on BIM standards, and facilitating model registration for MR, we have successfully developed a more intuitive workflow in this context, as users can experience a more immersive and interactive environment for modeling and inspecting existing structures, especially using XR technologies.

For now, we have focused on building and water structure engineering with a selection of elements, therefore, the current capabilities of the Building Inspector XR do not cover all structure types and components but demonstrate the efficiency of our approach. We believe that the Building Inspector XR has the potential to expand its applications in the construction industry. By leveraging artificial intelligence, opportunities to automate modeling tasks can be explored, improving efficiency and reducing human error. In addition to progressively expanding the functionalities of the Building Inspector XR, the inspection aspect, in particular, holds significant promise for further development and extension. To validate and refine the solution, further testing and implementation in real-world scenarios is essential. This would provide valuable insights into the effectiveness and practicality of the Building Inspector XR in real-world construction projects and enable further optimizations and adjustments based on feedback and requirements.

ABSTRACT: *In the Architecture, Engineering and Construction (AEC) sector, data extracted from building information modelling (BIM) can be used to create a digital twin (DT). The algorithms of a BIM-based DT can facilitate the retrieval of information, which can then be used to improve building operation and maintenance procedures. However, with the increased complexity and automation of the building, maintenance operations are likely to become more complex and may require expert intervention. Collaboration and interaction between the operator and the expert may be limited as the latter may not be on site or within the company. Recently, extended reality (XR) technologies have proven to be effective in improving collaboration during maintenance operations, through data display and shared interactions. This paper presents a new collaborative solution using these technologies to enhance collaboration during remote maintenance operations. The proposed approach consists of a mixed reality (MR) set-up for the operator, a virtual reality (VR) set-up for the remote expert and a shared Digital Model of a heat exchanger. The MR set-up is used for tracking and displaying specific information, provided by the VR module. A user study was carried out to compare the efficiency of our solution with a standard audio-video collaboration. Our approach demonstrated substantial enhancements in collaborative inspection, resulting in a significative reduction in both the overall completion time of the inspection and the frequency of errors committed by the operators.*

KEYWORDS: *Virtual Reality; Mixed Reality; Operation & Maintenance; Collaboration; Digital Twin*

1. INTRODUCTION

From all the new methodologies and technologies brought by the latest industrial revolution known as Industry 4.0 (I4.0), some of the most explored in the last years are Digital Twins (DT) and eXtended Reality (XR) technologies (Augmented Reality (AR), Mixed Reality (MR) and Virtual Reality (VR)) (*Gartner Top 10 Strategic Technology Trends for 2023*, 2023; Jamwal et al., 2021). Numerous studies have already proven that these technologies can improve industrial performance, but also building exploitation. A previous work has been done to summarize all these improvements, focusing on the ones brought to maintenance procedures in the Architecture, Engineering and Construction (AEC) sector (Coupry et al., 2021). It has been shown that data extracted from the building information model (BIM) can be used to create BIM-based DT. Such DT can be likened to a centralized database where real-time and static data of an equipment can be gathered and retrieved or used to predict the equipment behaviour and, thus, to compute the optimal maintenance time. Thanks to the centralization offered by a DT, different stakeholders can participate more actively in maintenance procedures, adding equipment-specific information or even checking it before maintenance is needed. In this context, XR devices can be used by on-site operators to display this information in front of the equipment, giving them access to the data needed to perform a maintenance operation.

However, occasionally, the on-site operator may require more specific assistance in resolving certain issues he or she may encounter. The increased complexity of systems and procedures, brought about by I4.0, may necessitate contacting a remote expert. Such assistance may also be required in the case of maintenance work on equipment with which the operator is unfamiliar. With the impact of Covid-19 and the increasing costs of transport, it is now needed to provide new methods for remote collaboration with an expert. XR devices can be used to provide meaningful information on both sides of such a collaboration. Either using virtual representations or shared video,

Corentin Coupry, Paul Richard, David Bigaud, Sylvain Noblecourt, David Baudry, *The Value of Extended Reality Techniques to Improve Remote Collaborative Maintenance Operations: A User Study,* pp. 23-33, DOI 10.36253/979-12-215-0289-3.03

the XR devices provide remote experts with contextual information, such as the position and orientation of the on-site user in relation to the inspected equipment. These devices also provide advanced methods to display information to the on-site user, either through localized annotations or specific data related to the equipment.

Speech communication is the most common method of information exchange during a remote collaboration. Visual cues, such as sharing visual context, are crucial to enhance collaborative performance. Such information can be obtained through 3D reconstructions, which can be static (Kolkmeier et al., 2018; Piumsomboon et al., 2017) or in real-time using depth sensors (Bai et al., 2020; Gao et al., 2016). To scan the, though, specific cameras are typically required. Furthermore, if any changes were made since the last capture, the static models' reliability decreased, which also affected the accuracy of the information shared with the expert. Sharing view has also been explored, either by limiting the expert's perspective to that of the operator (Serubugo, 2018), or by using 360° video, which provides real-time information while allowing the expert to move his vision freely, independently from the operator's (Teo et al., 2019). A 360° camera is thus required, which could burden the on-site operator unnecessarily.

Oral exchange and sharing context are not the only elements required for a good collaboration, visual aid is also important. While some researchers found that the use of annotations (Anton et al., 2018; Fakourfar et al., 2016) can be helpful to share specific location or elements, others observed that sharing gaze (Bai et al., 2020; Piumsomboon, Dey, et al., 2019) can help the collaborators to understand where everyone is looking. Sharing gestures has also been studied and proved to be useful for specific manipulations, such as assembly tasks or localisation issues (Chenechal et al., 2016; Wang et al., 2019). The use of a 3D avatar to show the user's movements and position has also proved to be helpful in increasing performance and decreasing the mental effort of the operator (Piumsomboon, Lee, et al., 2019). A method is proposed by (Grandi et al., 2019), allowing asymmetric collaboration between two users using handheld both AR or VR devices. Even if users could manipulate a 3D model to complete docking tasks, this system allows interactions only with a virtual object, not a physical one. Another work by (Ladwig, 2019) allows a VR user to interact with the 3D representation of a suitcase/machine. Each action performed by the VR user activates a LED to the physical to inform a local user which action to perform. This solution comes closest to using a DT to assist a field operator. (Oda et al., 2015) used so called *"virtual replicas"* to communicate between VR and reality. These replicas are copies of tracked physical machine parts that are rendered accordingly at the correct position in the virtual environment in relation to the machine. Wang et al. have already shown of these virtual replicas can be used to improve remote collaboration by projecting the remote expert gestures to the local operator (Wang et al., 2023). However, projection is not always possible due to lightning issues or narrow operating spaces.

The solution proposed in this work draws its inspiration from all these projects. It consists of a new system where a remote expert and a local operator can both use real-time audio-video feedback and 3D models to interact with each other. The system is using collaboration techniques from both *asynchronous* (checking explanations beforehand) and *synchronous* (physical positions of the operator and the system) collaboration systems. A user study has been conducted on the impact of this solution during a collaborative remote inspection of a heat exchanger. The inspection consists of several manipulations, requiring both one-handed and two-handed operations. The rest of this paper is organized as follows. In Section 2, the framework of our solution is presented. Section 3, describes the user study performed to validate the usability of the solution, followed in Section 4 by the analysis of the results. In Section 5, these results are discussed. Finally, Section 6 presents the conclusions and thoughts on the remaining work to be done on the solution.

2. FRAMEWORK

2.1 Prototype setup

The prototype solution design focuses on binding both audio-video exchange and immersive 3D interactions into a single cross-platform solution. This solution uses MR and VR to connect a local operator with a remote expert for real-time remote interaction. We implemented the solution with Unity3D and C#. Our audio-video exchange protocol is built upon Web Real-Time Communications (WebRTC) library (*WebRTC*, n.d.). The solution consists of a MR client and a VR client, both based on the same application. The Photon Unity Networking (PUN 2) plugin is also used to allow the remote expert to share specific information with the local operator (*Photon Unity Networking*, n.d.). Fig. 1 shows the overall setup of the project. Our solution is developed using the OpenXR norm, allowing our solution to became cross-platform (*OpenXR*, 2016). In Fig. 1, the "BIM-DT" section represents a BIM-based DT. It consists of the shared 3D representation of the physical twin, a history database containing semantic data and the results of previous operations, and a sensor database, where all the data collected from the physical twin is stored (see Fig. 1, red arrow). The BIM-DT also contains a simulation model, with which the VR and the MR user can interact if necessary to simulate specific situations or procedures. This uses data from both databases.

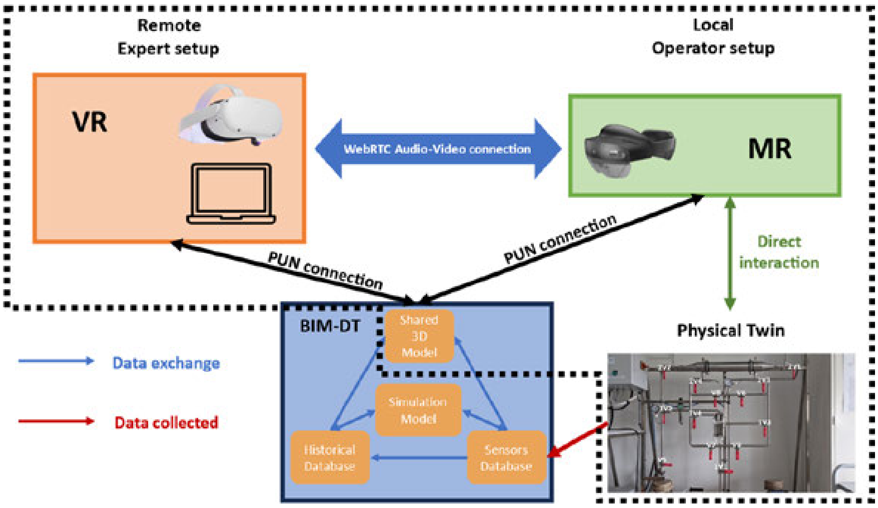

Fig. 1: Schematic representation of the proposed setup consisting of (left) remote expert setup, with VR device and computer, (right) local operator setup, with MR device and physical system, and (bottom center) the BIM-DT.

The local operator side consist of the physical twin of the system (cf Fig. 1 “Physical Twin”), on which the maintenance is performed, and a Microsoft Hololens 2 (Microsoft, n.d.-a) to use the MR client of our solution (cf Fig. 1 “MR”), developed using the Mixed Reality Toolkit (MRTK) provided by Microsoft. The local operator will be referred to as the *Operator* for the remainder of this paper. The remote expert side consist of a Meta Quest 2, wired to a VR-ready laptop PC (Intel Core i9, 32GB RAM, Nvidia RTX 3080), running the VR client of our solution, through Oculus Link connection (cf Fig. 1 “VR”). The rendering capabilities of the PC can manage and host the network connection between the HMDs. The Windows Device Portal (WDP) web server can also be used by the remote expert to record the conversation with the *Operator*, using the Mixed Reality Capture function provided. The PC also host a node-dss server for the WebRTC connection between the VR and the MR clients. The remote expert is also provided with specific documentation on how the maintenance should be performed on the system. The remote expert will be referred to as the *Expert* for the remainder of this paper. The *Expert* and the *Operator* are located in different rooms in the same building during the collaboration. An audio-video exchange is provided between both clients using the WebRTC protocol, which provides peer-to-peer real-time audio and video communication for collaborative applications (see Fig. 3. (blue arrows for *Operator*, red arrows for *Expert*)).

2.2 Information exchange paradigm

2.2.1 3D representation

A 3D model representation of the system is implemented. This model is loaded only on launch, for the VR client, or when a specific QR code is identified, for the MR client, using a specific SDK developed by Microsoft (Microsoft, 2022). Once the QR code is found, the 3D model is loaded in relation to its position. The model is shared between the MR and the VR client and contains the scripts allowing the exchange of information between the two clients, using the PUN plugin. This plugin provides us with a specific feature called *Remote Procedure Calls* (RPCs), allowing each client to call methods on remote clients in the same room. This feature has enabled us to set up an asynchronous interaction system for our solution. The PUN plugin also allows us to create avatars to represent both clients. The avatars used are composed of a white sphere with makeshift glasses, to inform the other client where each avatar is looking. This representation of the users allows for a better communication between them (Piumsomboon, Lee, et al., 2019). In our case, we have decided to use a *God point of view* situation, where the *Expert*’s avatar is on a higher Y-level than the *Operator*’s one, allowing the *Expert* to see where the *Operator* is placed in the physical space in relation with the physical system (Piumsomboon et al., 2017).

2.2.2 Replica paradigm

Our asynchronous interaction system is using the *Replica* method for interactions. Based on the concept of *Voodoo dolls*, brought by Pierce et al, this method consists of creating a reduced copy of a 3D model instead of a direct interaction with it (Pierce et al., 1999). Once the copy has been created, any interaction with it is reproduced to scale on the initial model. In 2015, Oda et al. took up a similar method for exchanging real-time visual manipulations during remote assistance for maintenance procedures (Oda et al., 2015).

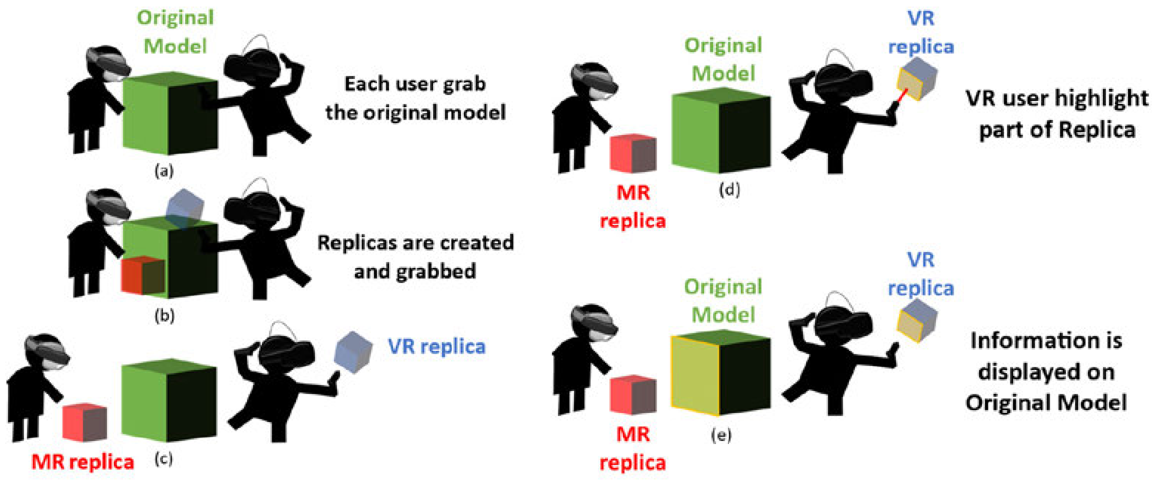

Fig. 2: Schematic representation of our *Replica* interaction system

Our interaction system is based on the same principle: while performing a direct interaction with the shared 3D model (Fig. 2 a), each client creates a *Replica* of the 3D model (Fig. 2 b). This *Replica* can be moved independently from the shared model (Fig. 2 c). Interactions (modified elements, annotations, colour changed…) carried out on the client's *Replica* are specific to it, thus only its owner can see them (Fig. 2 d). If the client wants to share his modifications, he or she needs to *Synchronize* his *Replica* with the shared 3D model, as shown in Fig. 3 (green arrows). Once the synchronization is asked, the modifications of the client's *Replica* are applied to the shared model (Fig. 2 e). If any annotation had already been added to the shared model, these are retained. If the shared model has already been modified and the request is made by the client identified as the *Expert*, its modification takes precedence.

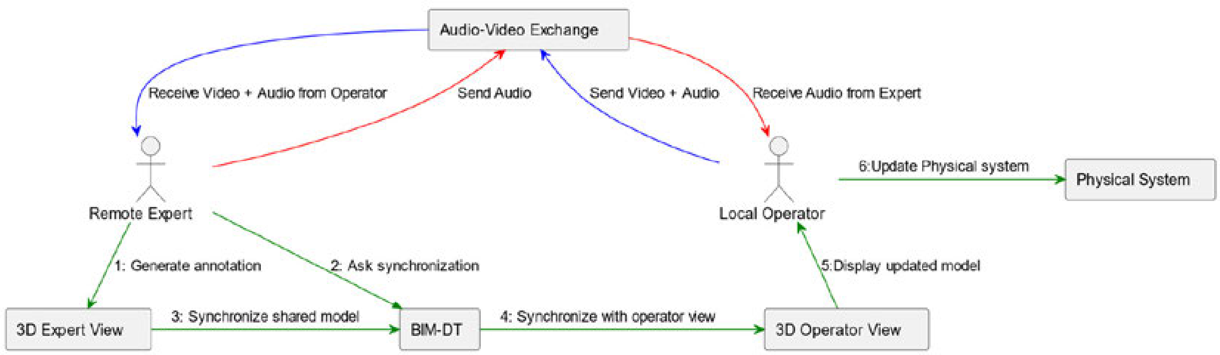

Fig. 3: Representation of the interaction with the *Replica* (green) and the audio-video communication (blue & red)

This method allows both clients to assess different modifications or add several annotations at once before sharing them with the other. It can also allow the client to check the information before sending it, thus avoiding the transmission of incorrect information. If the 3D representation is the digital representation of a Digital Twin, this method also allows both clients to use the DT's simulation engine to observe the impact that a simulated event, such as specific manipulations, can have on the system.

3. USER STUDY

To evaluate our solution, we conducted a user study. Its major purpose is to evaluate the usability of our solution and the impact of the collaboration experience on the performance and resolution time on the *Operator* side. We have decided to make a comparison between two conditions: One using a standard audio-video call, called *Tablet* condition; the other using the MR client of our solution, called *HMD* condition.

3.1 Experimental protocol

A total of 41 participants took part in the study, 12 women and 29 men. They were primarily students and teachers at our school. Participants were asked to sign up using an online form. Only participants with no prior knowledge of the machine were considered. Participants were arbitrarily assigned to one of the two conditions. A presentation of the experiment has been performed prior to commencing the session. For the *Tablet condition*, the *Operator* is invited to use a tablet Samsung Galaxy Tab A. The audio-video call is made via the Teams application (Microsoft, n.d.-b), through the use of a unique account. It has been decided not to use earphones or headphones during the call to simulate an on-site situation, in which the use of this type of device can be difficult due to hearing protection. For the *HMD* condition, the *Operator* is provided with the MR client of our solution. A 5-minute training is performed by the participants to familiarize themselves with the gesture recognition interaction system of the device. Prior to the experiment, to avoid any bias due to a lack of knowledge of the system, it has been decided that the *Expert* would be embodied by a unique actor. The *Expert* is already trained in the use of the VR client, which avoid any issue due to a misunderstanding of the client interaction system.

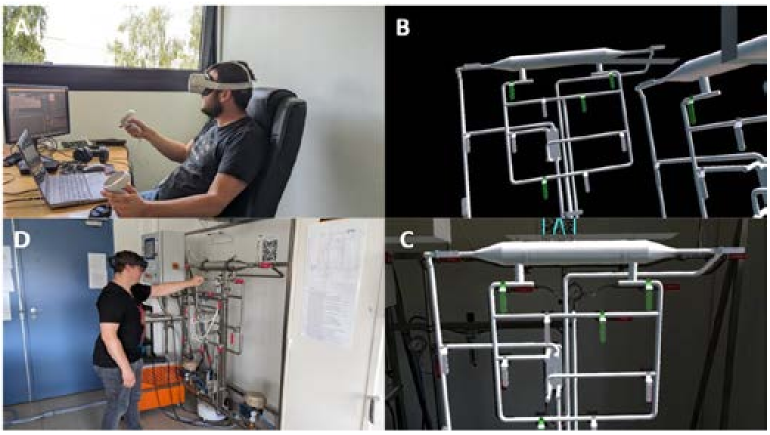

Fig. 4: The *Expert* (a) is moving the valve *2V4* to the *Operator* on his *Replica* (b). The model is synchronized to show the information to the *Operator* (c). The *Operator* can then move the right valve (d).

The *Expert* is provided with a unique inspection plan for both conditions. In the *Tablet* condition, the *Expert* provides vocal instructions to guide the *Operator* to locate the objects he is required to interact with, through detailing the relationships between them. This method proved to be more effective than using visual context (Teo et al., 2019). In the *HMD* condition, the *Expert* use both vocal guidance and the *Replica* paradigm to provide information to the *Operator*, as seen in Fig. 4. During the task performance, the video communication and the participants view were recorded using the in-built system of the device used (record system of Teams for the tablet condition, record system of Windows Device Portal for the MR condition (Karl-Bridge-Microsoft, 2023)).

3.2 Tasks

The scenario simulates an issue with the hot water delivery temperature obtained by the heat exchanger (see Fig. 5). The system is composed of fourteen valves and two different heat exchangers: a shell-and-tube heat exchanger and a plate heat exchanger. This system was chosen for its versatility, as heat exchangers are often found in buildings (HVAC, plumbing systems…). In both conditions, the *Operator* is asked to call an *Expert* to help him identify the issue with the exchanger. Tasks include handling specific valves to alternate between a shell-and-tube heat exchanger and a plate heat exchanger, and to alternate between parallel-flow and counter-flow current, to change the efficiency of the heat exchange. The scenario used by the *Expert* is divided into two parts: *Inspect the system* and *Initial State*. Each part is divided in both *Manipulation* blocks, where the *Operator* is expected to interact with the system, and *No manipulation* blocks, where the *Operator* is invited to give specific information to the *Expert* through descriptions. The *Manipulation* blocks are divided into two types: "*1-handed*" and "*2-handed*" tasks. In the *1-handed* tasks, four operations must be performed, using one hand. In the *2-handed* tasks, only two operations must be performed, but these tasks required to use both hands. Fig. 4 shows an example of interaction in the MR condition. The *Expert* uses the *Replica* paradigm to indicate the correct valve to handle (see Fig. 4 (a) & (b)). Once the valve highlighted, the *Expert* synchronize the system to update the shared 3D model and shows the information to the *Operator* (see Fig. 4 (c)). Then, the *Operator* can move the correct valve (see Fig. 4 (d)).

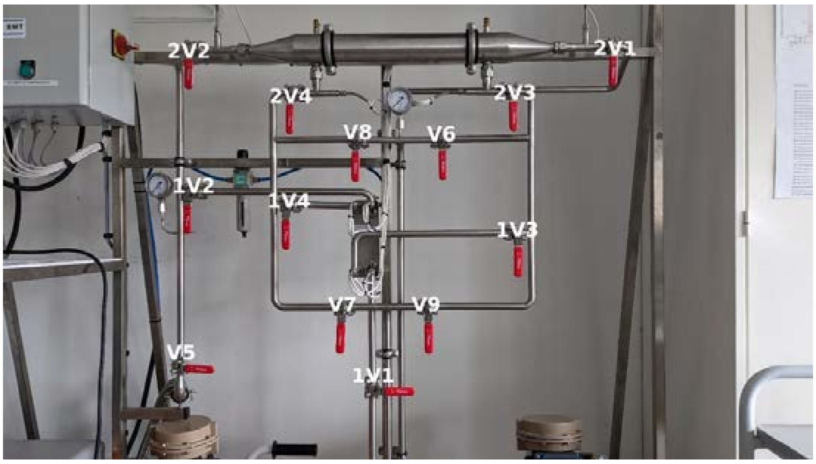

Fig. 5: Physical twin of the heat exchanger with names of the valves.

After completing the *Inspect the system* part, the *Operator* is asked to inform the *Expert* of the hot water outlet temperature obtained. Once the *Expert* has explained the reason for the system's temperature issue and what should be done to correct it, the *Operator* is asked to return the system to its initial state. In this part, the *Expert* can change the order in which the valves are handled in the "*1-handed*" blocks, to avoid a repetition bias with the first part. After completing the *Initial State* part, the *Expert* summarizes the operations conducted by the *Operator* and the conclusion of their common inspection. Then, the *Operator* is invited to end the call with the *Expert*.

3.3 Hypotheses and metrics

In this user study, we stated the following hypotheses:

H_1: The performance time from the completion of the collaborative inspection is faster in the *HMD* condition.
H_2: The number of errors is lower in the *HMD* condition.

To verify our hypotheses, we have used specific metrics. Audio and video of the *Operator* viewpoint were recorded during each experiment for subsequent analysis of the interaction. A timer is started by the test conductor on the *Operator* side at the beginning of the call. For each task, breakpoints are recorded. Errors are also recorded whenever a wrong valve is identified or handled by the *Operator*.

4. RESULTS

Prior to the analysis of the results, we have decided to exclude two participants. One for the *Tablet* condition, where the participant spent most of the experimenting commenting on the relevance of the explanations given by the *Expert*, and one for the *HMD* condition, where the participant had difficulties understanding the purpose of the instructions given by the expert. The following results are thus obtained from 19 participants for the *Tablet* condition, and 20 participants for the *HMD* condition. We performed Shapiro-Wilk (SW) tests on all measurements. For the results non-normally distributed, we performed Mann-Whitney-Wilcoxon (MWW) test on all measurements. For the results normally distributed, we performed a one-way ANOVA test to compare the mean of the samples.

4.1 Completion time

We measure performance time required to complete each experiment. Once the analysis of the overall performance time of the experiment has been analysed, we carry out a detailed analysis of performance times for *1-handed* and *2-handed* manipulations, as well as for phases of the experiment where only vocal instructions were given by the *Expert* to the *Operator* on both conditions.

4.1.1 Global observations

Fig. 6 shows that there is a clear difference in completion time in seconds between the two conditions. The SW test shows that both the *Tablet* condition (W=0.98, p-value=0.96) and the *HMD* condition (W=0.94, p-value=0.267) results follow a normal distribution. For the *Tablet* condition, participants took an average of 763.65 seconds to complete the experiment (SD=76.80). The participants of the *HMD* condition only took an average of 623.55 seconds to complete the experiment (SD=67.70). Because they follow a normal distribution, we use a one-way ANOVA to compare the results. The tests shows that the participants in the *HMD* condition were significantly faster than those in the *Tablet* condition (F (1,37) = 36.6, $p\text{-}value < 10^{-6}$).

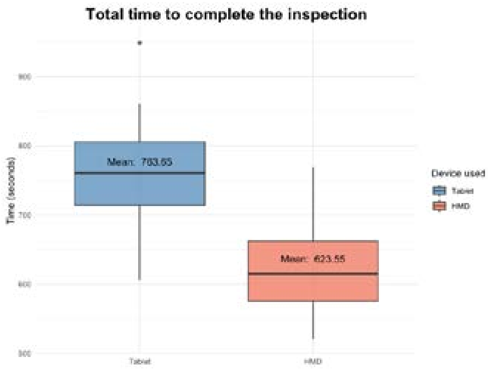

Fig. 6: Total performance time for *Tablet* condition and for *HMD* condition

4.1.2 By task (*1-handed* vs *2-handed*)

Manipulation blocks are divided into two types of tasks. Fig. 7 (a) shows the time difference in seconds between both conditions for the *1-handed* tasks. Neither condition follows a normal distribution (*Tablet*: W=0.9, p-value=0.03; *HMD*: W=0.9, p-value=0.02). The *Tablet* participants spent an average of 193.26 seconds (SD=55.8) to identify and manipulate the valves, while the *HMD* participants only spent an average of 146.43 seconds (SD=26.4). A MWW test is performed and shows that participants using the *HMD* condition were significantly faster than the ones using the *Tablet* condition (W=45, $p\text{-}value < 10^{-4}$).

Fig. 7 (b) shows the time difference between the *Tablet* condition and the *HMD* condition for the *2-handed* tasks. The *Tablet* condition follows a normal distribution (W=0.9, p-value=0.06) for an average time spent of 146.7 seconds (SD=36.1). The *HMD* condition follows a non-normal distribution (W=0.9, p-value=0.01) for an average time of 105.86 seconds (SD=28.4). Thus, we perform a MWW which shows that the *HMD* condition is also faster than the *Tablet* condition (W=49, $p\text{-}value < 10^{-4}$) when the *Operator* should use both his hands to interact with the physical system.

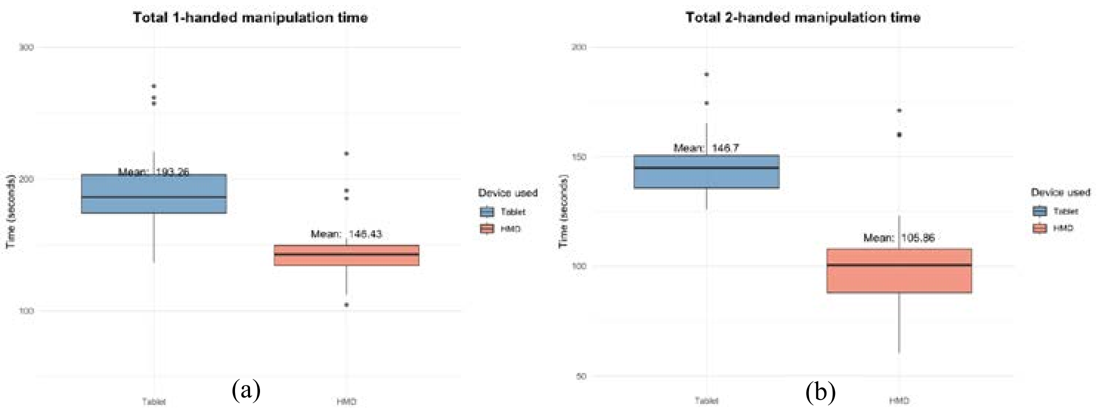

Fig. 7: Total time spent for (a) *1-handed* and (b) *2-handed* manipulation.

4.2 Errors

During the experiment, several types of error have been recorded. A *Simple* error is considered when the *Operator* make an incorrect identification of a valve indicated by the *Expert*, and a *Critical* error is considered when the *Operator* manipulate the incorrect valve. A *Repetition* error is considered when the *Operator* asks for the *Expert* to repeat the information already given. *Simple* and *Repetition* are only considered as one error, while a *Critical* error is considered as two errors, because considered the ones that can worsen the state of the system if performed. Table 1 summarizes these errors and their ponderation.

Table 1: Total and average number of errors for each condition per error type.

Type of errors	Total number for *Tablet*	Average number for *Tablet*	Total number for *HMD*	Average number for *HMD*
Simple (x1)	49	2.45	3	0.15
Critical (x2)	6	0.3	1	0.05
Repetition (x1)	3	0.15	0	0
Total with ponderation	64	2.9	5	0.2

Table 1 shows a difference between the two conditions in terms of errors (58 total errors for *Tablet* condition (Average=3.37; SD=3.02) vs 4 total errors for *HMD* condition (Average=0.25; SD=0.64)). The SW test confirmed that neither condition follows a normal distribution (*Tablet*: W=0.9, p-value<0.03; *HMD*: W=0.4, p-value$<10^{-7}$), thus allowing us to perform a MWW test. The result confirms that there is a significant difference between the total number of errors for both conditions (W=277, *p-value* $<10^{-5}$).

In the *Manipulation* blocks, the *Operator* was invited to use only one or both of his hands to manipulate the valves. Table 2 shows the total and average number of errors in *1-handed* and *2-handed* operations. For the *1-handed* operations, we observe that the *Tablet* condition has a mean of 2.21 errors per participant (SD=2.80), while the *HMD* has a mean of only 0.05 (SD=0.23). A SW test performed on both conditions shows that neither follow a normal distribution (*Tablet:* W=0.8, p-value$<10^{-3}$; *HMD:* W=0.3, p-value$<10^{-8}$). Thus, we perform a MWW test that shows that there is significantly less errors performed on the *HMD* condition (W=314; *p-value* $< 10^{-4}$).

For the *2-handed* operations, the *Tablet* condition has a mean of 1.16 errors per participant (SD=1.21) while the *HMD* condition has a mean of only 0.2 (SD=0.523). As for the *1-handed* manipulations, neither condition follows a normal distribution (*Tablet*: W=0.8, p-value $< 10^{-2}$; *HMD*: W=0.4, p-value$<10^{-6}$). Then, we perform a MWW test to confirm that there is significantly less errors for the *2-handed* operations from the *HMD* participants (W=279, *p-value*$<10^{-2}$).

Table 2: Total and average number of errors for *1-handed* and *2-handed* operations per condition.

Condition	Total number for *1-handed*	Average number for *1-handed*	Total number for *2-handed*	Average number for *2-handed*
Tablet	42	2.21	22	1.16
HMD	1	0.05	4	0.2

5. DISCUSSION

The overall results (Fig. 1) demonstrate a significant difference in performance time, supporting our first hypothesis (H_1). In comparison to the *Tablet* condition, the *HMD* condition is 18,35% faster. We deeply examined both kind of manipulation performed by the participants, *1-handed* and *2-handed* manipulations, separately to establish whether kind of manipulation performance is affected by our solution. We see a significant reduction in the amount of time needed to locate and operate the valves (24,24% for the *1-handed*, 27,84% for the *2-handed*). This reduction can be linked to the obligation to put the tablet down for *2-handed* operations, which may take some time. In the literature, Ladwig et al. found a similar reduction of 30% to locate the correct elements to operate using physical LEDs in comparison with only vocal exchange (Ladwig, 2019).

In a similar way, the effect on the assistance provided to prevent choosing the wrong valve may be observed. Both for the *1-handed* and the *2-handed* manipulations, we see a much-decreased rate of errors in the *HMD* condition (see Table 2). Overall, participants using our solution made 92,58% fewer errors than those using the *Tablet* condition, supporting our second hypothesis (H_2). As shown in Table 1, a more thorough examination of the errors made reveals that there were 93,88 % fewer identification (*Simple*) errors and 83,33 % fewer manipulation (*Critical*) errors. These results are similar to the reduction in errors (89%) observed by Ladwig et al. when using physical LEDs (Ladwig, 2019). Thus, our approach, which uses virtual animations as indicators, makes it possible to avoid misunderstandings and misidentifications during remote support while preventing the need to modify the physical system to support the collaboration.

6. CONCLUSION AND FUTURE WORK

In this paper, we propose a new solution for remote collaboration using a MR client for a local operator and a VR client for a remote expert. This solution aims to help improve remote collaboration during maintenance procedures, using both video communication and 3D models to interact with each other. In our research, we propose a solution allowing both synchronous and asynchronous collaboration using the *Replica* paradigm. We performed a use case to compare our solution with a standard video communication using a video conference program. We stated two main hypotheses that we wanted to investigate about the performance (H_1) and the number of errors (H_2) of the participants.

About the performance time, there was a significant effect of our solution on the total completion time of the participants, hence supporting hypothesis H_1, that the time required to complete the maintenance was decreased by giving the *Operator* contextual visual aids. The fact that *1-handed* manipulations were also quicker proved that our solution has a positive impact on improving the assistance to identify the valves to manipulate, even though the improvement of *2-handed* manipulations was expected due to the free hands provided by the *HMD* condition. In term of identification and manipulation errors, we see a significant reduction for the participants using the MR client. This support hypotheses H_2 that contextual visual aids and using a hands-free device facilitate the *Operator*'s ability to identify and manipulate the equipment they must operate.

In our use case, the *Expert*'s avatar was not on the same height level as the *Operator*. It might be interesting to study the impact that the presence of this avatar might have on the guidance provided by the *Expert*. Some studies have already observed a significant impact of an avatar presence, but without direct interaction of the remote expert with the 3D environment (Piumsomboon, Lee, et al., 2019; Wang et al., 2023).

Furthermore, only the *Operator* side was studied during our use case. It will be necessary to carry out a usability study on the VR client of our solution. The system used for our use case didn't have any usable sensors, so further experiments should be performed to evaluate the simulation model of our BIM-based DT and its impact on the collaboration. The simulation could be used by the *Expert* to perform diagnostic simulations and to test various maintenance operations before guiding the *Operator*, while the *Operator* could use the simulation model on its *Replica* to perform its own diagnostic simulation, and then compare it to the *Expert*'s results.

CREATION AND ACCEPTANCE OF LOW-THRESHOLD MOBILE TRAINING ON SUSTAINABILITY IN CONSTRUCTION

Mario Wolf
Digital Engineering Chair, Ruhr University Bochum, Germany (Corresponding Author)

Jochen Teizer
Department of Civil and Mechanical Engineering, Technical University of Denmark, Denmark

ABSTRACT: *Many recent developments in mixed reality applications are exploited for research on improving training in the construction industry. While immersive technologies offer indisputable advantages over classic paper- or multi-media-based training material, access to this kind of technology is still very limited in the academic world and even less widespread in industry. In this paper, the authors follow the current trend of creating low-threshold micro-learning nuggets, which are easily consumable on mobile devices but can be accessed in every web browser. This is essential to reach the construction trade workforces, which for the most part will own a smart or mobile device, but neither specialized equipment, nor will there be time or patience for a lengthy setup phase before learning content consumption. The learning content aims to give construction workers a clear vision of what some of the fundamental components of a sustainable construction site should look like and what role they play in achieving the said vision. The learning content revolves around the initial idea of DGNB certification (German: German Sustainable Building Council), waste management, certification of construction wood, handling of harmful substances and chemicals and some general health and safety regulations that impact the emission of dust, noise and vibration. The paper describes the general approach of the planning, orchestration of learning material, development of the learning nugget, and deployment, as well as a study for acceptance and user experience.*

KEYWORDS: *DGNB, continuous education and training, micro-learning nuggets, responsible consumption and production, smart and mobile devices, sustainable construction, ubiquitous learning, workforce.*

1. INTRODUCTION

The construction industry plays an important part of the European economy, employing over 13 million people (6.6% of the EU employment) (CEDEFOP, 2023). The sector's related effects in other industries are known, for decades, to be extensive as the entire value chain from sourcing over to fabrication and final installation, maintenance and operation, and reuse of products consume enormous amounts of raw materials and energy. As such, 13.5 million other jobs in supplier industries are directly impacted by construction in Europe. In brief, the entire life-cycle chain in the built environment involves, to name a few resources, substantial plant environments, complex products, purposed machinery, and specialized trades with skilled personnel across industry sectors.

While construction is generally seen as a catalyst for stability in economies around the world, it is also viewed in the public perception as one of the most important areas for the green transition, as it is responsible in large amounts for energy consumption contributing to waste and emissions (Teizer and Wandahl, 2022). Yet, in Denmark, the Renovation Wave and the New European Bauhaus, supporting building and infrastructure facilities in the entire of the Europe Union (EU) in becoming smarter and greener, construction significantly contributes to the green transition through large-scale installations of wind farms (EU 2020b). However, Denmark and other countries have realized that sustainable construction plays a significant role in achieving the 30% emission-reduction goal by 2030 and becoming climate neutral by 2050 (DEA, 2023).

While construction remains one of the least digitalized sectors in the EU, new digital technologies will shape it with increasing intensity. Demand for highly qualified workers is growing steadily, as will the skill needs for medium- to low-skilled occupations to learn and practice sustainable goals (UN 2023b). Job surveys, conducted for example by CEDFOP (2023), highlighted substantial training needs for construction workers. Many workers' skills are not well-utilized, which is especially true of construction's significant migrant workforce. Yet, new and far more complex rules and regulations in the built environment demanding ever stricter compliance of construction materials or products, or their integration into installation and maintenance processes, make it even more challenging for the workforce to keep up with state-of-the-art knowledge and practices. All reasons above call for additional learning tools that can create or attract and retain skilled and tech-savvy personnel.

The following research questions indicate the objectives of this paper:

- While policy makers often force change through top-down approaches, what bottom-up initiatives can be taken to stimulate change by sustainable behavior?
- Who are the suitable recipients and what are the key focus areas of learning sustainable goals?
- How can awareness among the construction and real estate sector's workforce be created with a tool that is simply to use and still actively engaging them in a learning exercise?

2. BACKGROUND

2.1 Policies on climate forcers

The construction and real estate sector is one of the main sources of emissions globally. Typical new construction and renovation processes use various types of equipment, numerous sophisticated raw material or product resources, and a workforce that is highly specialized in their trade discipline. Yet, combined use in inefficient and wasteful building or operation processes, contributes significantly to different forms of waste and pollution, and irreversible consumption of quite significant amounts of energy (Andrade and Teizer, 2023). In the European Union (EU) alone, the sector is responsible for over 35% of the EU's total waste generation and an estimated 5-12% of total Greenhouse Gas emissions (EC, 2022). On a global mission, according to DGNB (2023), a German non-for-profit organization named "Deutsche Gesellschaft für Nachhaltiges Bauen e.V." (English: German Sustainable Building Council), there is further potential for action in the construction and real estate sector as it is also responsible for:

- 30% of worldwide resources consumption,
- 40% of worldwide energy consumption, and
- More than 30% of worldwide carbon emissions.

Consequently, the urgent need for greener construction is being addressed by several world climate agendas such as the European Green Deal, which aims for climate neutrality by 2050 through the green and digital transformation of EU sectors (EC, 2020a).

2.2 Practices in the construction and real estate sector

Three selected examples from Europe, Germany and Denmark point to the significance of the problem and show that the potential impact of bottom-up approaches, for instance, e-learning tools, can be high.

Example from Europe: According to official reports, only 11% of the existing building stock in European Union undergoes some level of renovation each year (EC, 2020b). However, very rarely (1%, weighted annual energy renovation rate) do building renovation works address the energy performance of buildings, and worse, only 0.2% of building renovation projects reduce their energy consumption by 60%. At this pace, the report concludes that "cutting carbon emissions from the building sector to net-zero would require centuries." It is time to act.

Example from Denmark: Avoiding wasteful and energy-consuming construction, less than 3% of the Danish building stock is built newly on an annual basis. The vast majority of Danish projects in the built environment are already renovation efforts to make its buildings more sustainable. Moreover, most of its existing building stock has reached the age for renovation: Over 80% was built before 1990 and over 75% of the total floor area can be attributed to residential buildings (Statisics Denmark, 2019; Wittchen and Kragh, 2016). Additionally, Danish society, and presumably societies around the world, is becoming more and more aware of the negative environmental impact of our living environments. Almost 50% of the annual energy consumption (Nordic Energy Research, 2023) and nearly 12% of annual CO2-emissions can be attributed to households (Statistics Denmark, 2023). By far, the majority of energy usage in a building takes place during its operational lifetime. In this combination lies a vast challenge how can we improve the performance of our building stock on a scale that meets the now urgent and strict energy requirements?

Example from Germany: Construction and demolition in Germany in 2017 caused 220 million tons of waste, 53% of all industry sectors' combined waste (SB, 2023). A fraction of the waste, while its raw material components are valued highly, is typically recycled (Circle Economy, 2022). Note, while this number includes the demolition of bulk material in road infrastructure, the principles of circularity in the construction and real estate sector yet have to arrive in full swing. Subsequently, as part of the Sustainable Development Goals (SDG 12) (UN, 2023), the sector can benefit from responsible consumption and production. The proposed learning tool addresses some of these goals, see italic text:

- *Sustainable management of natural resources, recycling and reuse*
- *Waste reduction*

- Use of natural resources
- *Awareness for sustainable development*

2.3 Sustainability certificates and target group

While the World Green Building Council has many initiatives around the world, for example, LEED and Green Star, DGNB was founded in 2007 and is Europe's biggest network for achieving sustainable buildings. It is a non-profit organization (NGO) that aims to identify and promote solutions for the planning, execution and use of buildings and communities in order to achieve a sustainable future (DGNB, 2020). Pooling and sharing knowledge, translating sustainability into practice, and sensitizing the general public are its key objectives. As of February 26, 2020, DGNB has more than 2100 members that are comprised of 20% architects/planners, 16% engineers, 21% manufacturers, 17% others, 10% project managers/consultants, 9% investors/developers, and 7% building contractors (DGNB, 2020). DGNB, like the other initiatives mentioned, offers expensive certification courses for a wide range of users, incl. practitioners, consultants, and even students.

The representation of the building contractors in DGNB, and moreover, the large number of personnel it employs, including but not limited to laborers and site superintendents, and supposed to be more than any of DGNB's membership, would be the ideal and predominant use group of the proposed learning tool. In Europe, the construction sector as a share of total employment in the European Economic Area varies by country between 4-10% (Statista, 2023).

2.4 E-learning-content creation in construction and engineering pedagogy

The previous sections have shown, policy and practice differ widely. While behavioral change is one approach to create awareness, yet, hardly any learning tools exist that actively engage the personnel at the workplace. While many methods exist to engage the construction workforce with learning (Wolf et al., 2022), *E-learning (EL),* defined as conducting learning via electronic media, typically on the Internet, depends on the self-motivation of individuals to study effectively.

In the context to construction applications, the effectiveness of EL has been widely studied in safety training and construction management (Lee et al., 2014). Ho and Dzeng (2010) reported a positive impact on Taiwanese labor. Bokor and Hajdu (2014) focused in creating interactive content, incl. use of videos, to facilitate better understanding. Likewise, Lu et al. (2023) investigated the learning curves of participants in modular construction. Kim and Santiago (2005) focused on the instructional development process through the impact of educational technology. Clevenger and Ozbek (2013) and El-Adaway et al. (2014) both addressed service-learning concerning evaluating sustainability competences in the engineering curricula. However, their work made not much use of EL. Similarly did Love et al. (2015), while examining collective learning by coaching, not focus on sophisticated technical aids.

A few other teaching methods are reviewed rather in brief to let readers understand the differences what they offer:

- *Game-based learning (GBL)* is where game characteristics and principles are embedded within learning activities that reward and motivate the participant to think critically. In construction, Oo et al. (2016) focused a game on cost estimation and bidding and Sacks et al. (2007) on reducing waste in construction by applying lean principles. Teizer et al. (2020) utilized Internet of Things (IoT) technology in a serious game for the purpose of identifying and eliminating waste during the construction operations. Jacobsen et al. (2021) extended their work to multi-user GBL-experience in Virtual Reality (VR). Few studies exist to GBL with regards to sustainable design and LEED or equivalent concepts; Dib et al. (2012) is one of these. However, Dib et al. (2013), Ayer et al. (2016), Castronova et al.'s study (2017), Dancz et al. (2017), Clark et al. (2021), most of the studies use university students for evaluation. A late criticism, practitioners should be used instead, was raised by Adami et al. (2023).
- *Problem-based learning (PBL)* uses complex real-world problems as a vehicle to promote student learning of concepts and principles as opposed to direct presentation of facts and concepts. It stimulates

finding and evaluating research materials, critical thinking skills, problem-solving abilities, and communication skills. PBL is often practiced in the format of groups, as seen in architectural studios and construction management courses at universities (Williams and Pender, 2002), and life-long learning workshop exercises or seminar series in industry (Duch et al, 2001).

- *Mobile learning (ML)* is education or training conducted by means of portable computing devices such as smartphones or tablet computers. Among studies investigating m-learning technology acceptance (Al-Rahmi et al., 2021), Wolf et al. (2023) investigated construction product quality by utilizing mobile Augmented Reality (AR) technology.
- *Life-long learning (LLL)* is a formal or informal approach to personal or professional learning that is continuous and self-motivated. Froehle et al. (2022) studied civil engineering skills development in LL using semi-structured interviews. Gao et al. (2022) explored the drivers and barriers of LL in construction, Salajan and Roumell (2021) outlined a holistic view of LL for European learning opportunities and promoted clearer links across educational pathways and sectors, incl.
- *Micro-learning and Nuggets (MLN)* focus on learning by creating concise and bite-sized chunks of information. Nugget learning is a subset of micro-learning that focuses on the development of personal nuggets or mini-lessons at the end of each unit (Ploder et al., 2021). While recent research focuses on the emergence of technology for MLN and how it can perfectly address the next-generation workforce's learning needs (Nanjappa et al., 2022), delivery of MLN in the context of construction applications, including sustainability, has yet to be explored in greater detail.

Several other studies in the architecture and civil engineering domain focused on the effectiveness of education, for example, Vorster (2010) and Mostafavi et al. (2013). Yet, they fall short in explaining the role of advanced technology in education and training. These limitations indicate a vast, and still unexplored, opportunity for leveraging technology in learning, as recently shown by Wang et al. (2020) and Wolf et al. (2022).

3. METHODOLOGY

Based on the concepts and related work mentioned in the background section, the methodology section introduces the exact goals and requirements for the training application, was well as the theory behind both the learning and gamification content. Figure 1 shows the general approach, which is derived from the common SCRUM practice in software or product development.

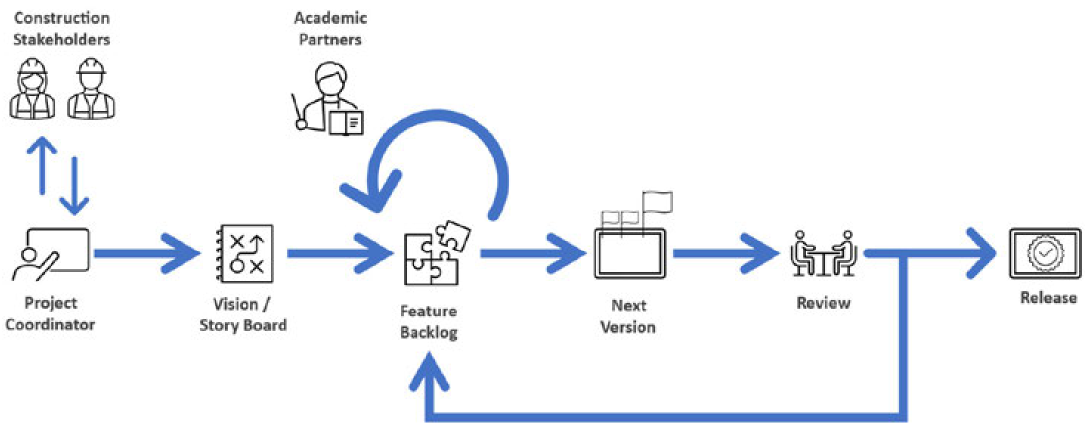

Fig. 1: Development approach for the training application.

The motivation for the training application is based on the needs of stakeholders from the Danish construction sector. A central project coordinator assures the alignment of goals and requirements, as well as providing the solution to the stakeholders after the development. The vision and storyboard are developed with the academic partners after which the iterative development itself starts. A feature backlog is derived from the story board, with each feature being developed as a singular entity. Once enough features are finished, the next version of the training application is released for review with the project coordinator, who keeps contact with the construction sector stakeholders. This loop is repeated until the feature backlog is empty so that every feature from the vision is implemented to sufficient standards. After that, die release version of the application is compiled and provided to the project coordinator.

3.1 Goals and requirements

The goal is to create a learning application that is easily consumable on mobile devices but can be accessed in every web browser if need be. Due to the ubiquitous availability of smart mobile devices and the ease of use of scanning i.e. QR codes, the mobile view is the favorable focus. The target audience is construction workers with basic training and at least prior experience regarding waste sorting on a construction site.

The requirements were to create a fun training, uses gamification elements and transports some core rules for sustainable construction. The five main talking points are: Waste sorting on the construction site, certified wood use, handling of hazardous substances, health and safety regarding dust, noise and vibration exposure and the reduction of energy consumption. The story-board for the training was developed in a virtual whiteboard by both construction experts and academic staff in an evolutionary manner, iterating ideation, creation and feedback for each section after the initial story development. There is no integration into an existing Learning Management System, no user management or login required to use the training, no persistent data storage, especially not on personal information and the final product should be hosted on any regular webserver without special setup.

3.2 Content and structure

The learning content itself is very limited in this context, as the target audience should have prior knowledge in most fields touched upon in this training. It is assumed that the training acts more like a refresher of that long-term knowledge and a reminder of the importance of the acts of each individual.

To minimize the time needed to read texts on the smart device, each section is introduced by an animated character video-narrated by a voice actor. The following take-away messages and key points were chosen for the training.

3.2.1 Introduction

Awareness for the impact of the way most industrialized nations work is one of the main goals of this training application. The introduction therefore lays the foundation by stating that, if scaling Denmark's energy and resource consumption up to the world population, the world's yearly available raw resources would be consumed 420%, or within weeks instead of a full year. Therefore, the goal is to become generally better at reusing, recycling, and recovering, in order to reduce the consumption of raw materials, in this case in the construction sector specifically. As stated earlier, the DGNB certification is a comprehensive tool that creates guidelines for a building's environmental, economic, social, and technical quality. Many clients are demanding DGNB-certificated buildings and it is therefore important that craftsmen not only follow those guidelines but understand their impact. Therefore, the introduction offers a perspective of what can be done in everyday life on the construction site.

3.2.2 Waste sorting

Denmark's goal for 2030 is to re-use, recycle and/or recover a minimum of 70% (weight percent) of raw waste materials. In order to reach this goal, there is a need to ensure efficient and correct material sorting on the construction site. With efficient sorting and reuse, the reduction of the currently excessive consumption is more easily achieved. While providing some background with the animated character videos, the waste sorting section should offer an active exercise in waste sorting as depicted in Figure 2. While most sorting tasks of raw materials seem obvious (metal into the metal container, wood into the wood container, etc.), the edge cases are the important ones to reduce waste and/or problems further down the recycling path. For example, metal buckets with leftover paint belong in the correct waste bin for harmful chemicals, wet sheetrock can not be recycled easily and should be separated from dry sheetrock and reinforced concrete belongs to regular concrete and not to general metal.

3.2.3 Certified wood

For valid certification of a building, every raw material has to be certified too. It is up to the craftsmen to validate those certifications on the material that arrives at the construction site. For the wood sector, Denmark generally uses two internationally recognized systems for FCK and PS3 from forests with Skovbo for the benefit of present and future generations. This quiz offered in this section should put the user into the perspective of a worker tasked with receiving a batch of wood. Before signing the delivery note, the user must identify the correct certification marks or decline the delivery completely. This step in particular is quite harsh in reality and awareness of the importance of correct certification needs to be established as the "higher goal" instead of "just keep working, it's just wood".

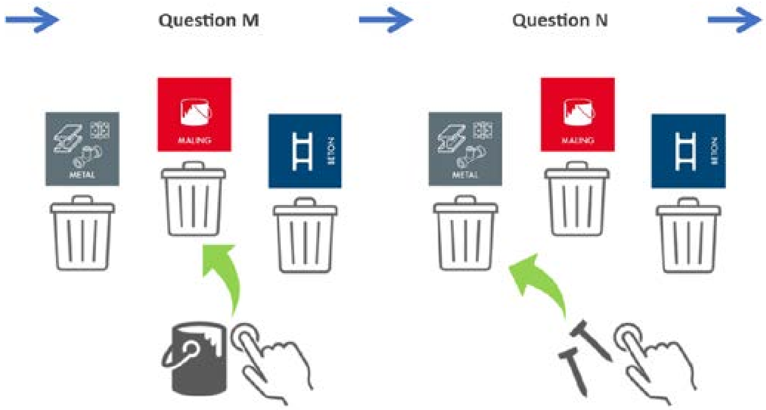

Fig. 2: Sktech of a dragg and drop quiz for waste sorting.

3.2.4 Hazardous substances

While there is great value in being able to reuse materials, if the materials used on the construction site contain chemicals, they usually cannot be used in other contexts where health factors play a greater role. Awareness of the most common harmful substances is essential, as well as which substances are suitable for use on the sustainable construction site. There is a considerable number of valid certifications that can be found on the chemical's containers and, once again, need to be recognized by the skilled craftsmen. The quiz in this section demands the user to judge the sustainability of certain chemicals, like paint for example, based on the packaging and once again to decide whether to accept or decline its use on the construction site.

3.2.5 Dust, noise and vibration

Health and safety play a major role on the construction site. Sustainability also encompasses a safe working environment and the awareness for dangers is one of the most crucial factors in preventing accidents. Especially the awareness of the accumulating severity of seemingly minor hazards like exposure to dust, noise, and vibration are put into focus in this section. Not only is the protection relevant for the workers conducting the operations but also for their coworkers and the surrounding neighborhood. The importance of reducing the noise, dust, and vibration at the source as much as possible and the awareness of restrictions regarding how much and when workers are allowed to apply the mentioned procedures are mediated with easy-to-follow videos and examples.

3.2.6 Energy consumption

Energy consumption is a key metric in every sustainability initiative. In the future, the EU taxonomy will include technical audit criteria for a wide range of activities related to energy supply and consumption on- and off-site construction. It is therefore important that craftsmen prepare for their future tasks, especially since more equipment and machines, incl. hand-held power tools become electric and battery-powered. Likewise, fossil fuel consumption is to be reduced, for example, idling vehicles present a significant waste and contribute to poor productivity. Moreover, excessive energy use to heat temporary office containers plays a critical role during late fall, entire winter, and early spring times, and as such, does cooling during summer times. Lighting of the construction site to ensure sufficiently safe walking pathways and workplaces, or providing a pleasant work desk atmosphere also contribute to energy consumption. While the implementation of Light Emitting Diodes (LED) have substantially reduced the energy needs, yet not all construction sites make use of it, and those who do, can either optimize their use and may at least need to become familiar with the appropriate recycling guidelines.

4. IMPLEMENTATION

In the following paragraph, the tools used to create the low-threshold training are presented, followed by the detailed description of the created content. The main editor for the created training is Microsoft PowerPoint 365, which is enhanced by the use of an E-Learning content management addon called iSpring Max. The latter allows the creation of interactive content and the compilation of the final product into HTML5 plus JavaScript, to be consumed with both mobile devices and PCs. The training could also be compiled into a so-called SCORM (Sharable Content Object Reference Model) package, so that it may be imported into regular learning management systems (LMS) as a separate activity in a more extensive learning path or e-learning course. When deployed as

HTML5, the hosting is identical to any static website, meaning a regular webserver will suffice for hosting and displaying the training.

For media creation, the assortment of applications of the Adobe Creative Cloud were used, most notably the Adobe Character Animator, which allowed the creation of the animated avatar and the voice acting to be conducted separately. The created avatar is depicted in Figure 3, showing some of the animations and the active lip sync.

Fig. 3: The created avatar as used in the Character Animator.

The avatar was chosen based on the stakeholders wishes, but can be switched out very easily if need be, while keeping the animations, triggers and the eye- and body-movement. When switching out the graphical representation, usually, the audio changes too. In that case, the lip-synchronization can be recalculated to match the graphic and audio representations.

Figure 4 gives an overview of the structure and the logic implemented in the training application.

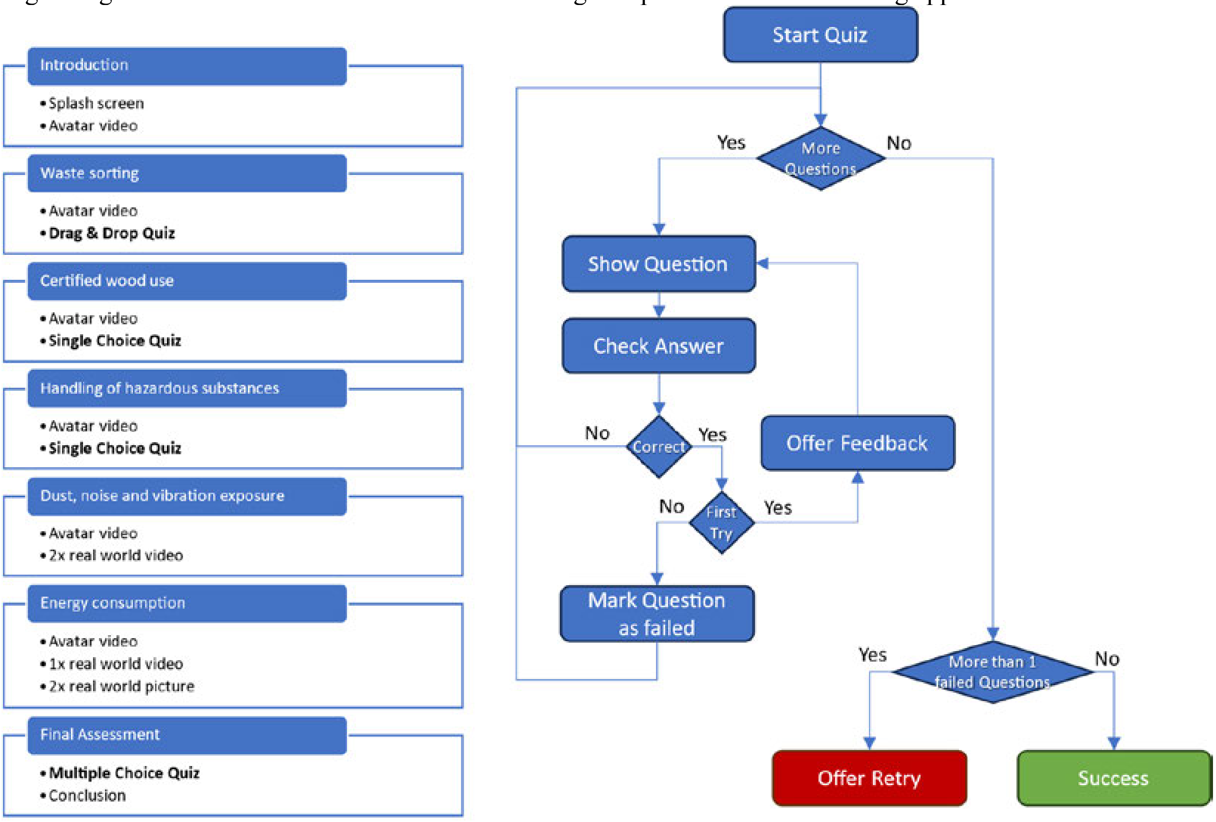

Fig. 4: Structure of the training and implemented quiz logic.

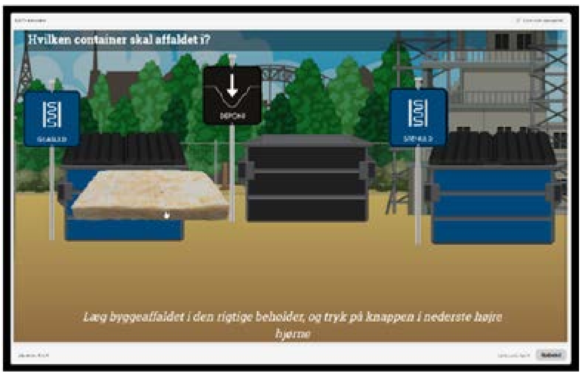
The initial introduction is done with a splash screen, followed by an avatar video. A splash screen is omitted in the sections, as an avatar video represents both the switch to another section, as well as providing background information and an introduction to the topic. Quizzes in the following description are all uniform in their way of providing feedback and explanation right after confirming in the answer and offering a second try, in case the given answer was wrong. After a second wrong answer, the question is marked as not successful. Each quiz only allows a single question to be answered not successfully, with unlimited attempts for each quiz. When finishing a quiz successfully, the next section is unlocked.



(a) Waste.

(b) Certification.

(c) Environment.

(d) Health and safety.

(e) Emissions.

Fig. 5: Training challenges: (a) waste sorting, (b) certified wood, (c) hazardous substances, (d) dust, noise and vibration, and (e) energy consumption.

4.1 Waste sorting

After the avatar video, the trainees are presented with the first quiz (Figure 5a). The quiz focuses the correct assignment of material to recycling bins or containers, with narration at the start of the quiz to clarify task and functionality. There are eight questions in the quiz, which are simply solved by dragging and dropping the waste to the correct bin.

4.2 Certified wood

After the avatar video, the trainees are presented with a real-world video, showing a truck delivering construction wood (Figure 5b). The quiz then revolves around the identification of relevant certifications. Several life-like delivery documents are presented and the trainees must choose to either accept or decline the delivery, based on the provided certification.

4.3 Hazardous substances

After the avatar video, the trainees are presented with the third quiz (Figure 5c). There are six different typical chemicals, which are regularly used on construction sites, and the task is to check for the correct certification.

4.4 Dust, noise and vibration

After the avatar video, the trainees are presented with two real-world videos and instructions with narration regarding health and safety regulations (Figure 5d). As Health and Safety Trainings are regularly conducted, there is no quiz in this section.

4.5 Energy consumption

After the avatar video, the trainees are presented with two real-world videos and instructions with narration regarding health and safety regulations (Figure 5e). As health and safety trainings are regularly conducted, there is no quiz in this section.

4.6 Final

The final of the training is a quiz of four questions with a summary of the training at the end.

5. STUDY AND PRELIMINARY RESULTS

According to studies of Wolf et al. (2022) and Adami et al. (2023) practitioners as participants that evaluate the application matter. While the evaluation of the testing with an initial group of dozen practitioners is pending, preliminary comments that both workers and construction site staff left with the authors indicate that the developed application is technically sound to communicate the relevant content to the participants. The participants claimed to have known most, but not all of the content, thus receiving some value from using the application. While neither personal data about the participants nor IP-addresses of their smart devices accessing the application were collected, completion rate and time spent when navigating within application was recorded. Preliminary data indicates that participants stay within the envisioned time span of less than 15 minutes to complete the application. Abortions before ending the application were very low, probably due to the application still being novel. Yet, few participants mentioned that additional or variations of the examples within each module could help make it more attractive or revisit in the future or as part of continuous training short courses that they also recommended. One participant expects that repetitive use of it "makes some of us [workers] change thoughtless behavior". Yet, the authors recommend the application for extensive testing with structured evaluation methods, utilizing, for example, anonymized pre- and exit surveys and/or interviews, and, perhaps, accompanied by behavioral observations of workers on the construction site. In addition, a verbal review meeting with site management staff who also acted as participants, revealed that demographic developments in the construction industry need to consider as well. While smart and mobile devices offers a communication style that attracts younger workforce and subsequently increases the chance that workers accept to participate, offering multiple international languages prevalent in the target country might be required, especially for migrating workforces that are not familiar with the local language. Likewise, the dependence on a voice actor while listen to the application may require a quiet space or headphones to operate it. Overall, preliminary results demonstrate technical feasibility and the workforce seems to accept the delivery method.

6. CONCLUSION

The tools mentioned in the implementation section allowed for a rather quick implementation of the desired training. While the technical and content goals were met, several quality-of-life requirements, which came up during the implementation process, could not be implemented due to restrictions in the frameworks, applications or time constraints. Most revolved around the exact depiction of feedback in the different quizzes or certain behavior regarding user interaction. Some of the preliminary results to a study showed that technology to create an effective learning nugget for achieving sustainability goals in construction exists. This can be used to counter the general trends in the construction workforce that can be named: significant labor shortage in certain trades, often replenished by migrant personnel, joining construction initially with limited skills or awareness. Future work will encompass the creation of multilingual trainings in the now focused field, as well as the creation of a larger scope training, based on multiple micro-learning nuggets, which will allow more room for learning content, media and assessment of learning outcomes.

7. ACKNOWLEDGEMENT

This research has been funded by Realdania and Industriens Fond under the Danish research project "Bæredygtighedssimulator" of the Rådet for Bæredygtigt Byggeri and ConTech Lab.

ABSTRACT: *Accurate process planning is essential for successfully implementing offsite construction projects. New technologies, such as virtual reality (VR), have been proposed as potential proactive solutions that allow users to experience and train on OSC processes to ensure safety and efficiency in an immersive environment. However, current VR applications in OSC projects (VR-OSC) problems are limited to residential projects and target single phases of the OSC implementation. This study proposes a VR framework to train participants on modular bridge construction processes. The developed model comprises several OSC phases, such as fabrication, transportation, and assembly. Furthermore, the study explores the use of collaborative platforms that can be associated with the VR model to ease the model and the developed scenes. The model is tested on a sample of participants that evaluated the performance of the model and provided areas of improvement. The results showed the capabilities of the model in providing an immersive experience for participants and connecting different phases of the OSC projects. Also, the results show that the experiment length and complex controlling buttons are among the areas of improvement. The developed model is expected to facilitate safe and efficient training for complex OSC projects.*

KEYWORDS: *Offsite Construction, Building Information Modeling, Virtual Reality, Game Engines*

1. INTRODUCTION

As the conventional construction method has been argued to provide less productivity compared to other industries, offsite manufacturing and modularization solutions have been proposed to enhance the efficiency of the construction industry (Alsakka et al., 2023; Hussein et al., 2022). Modular construction, as a part of offsite construction (OSC), is the process of assembling fully finished modules in the factory, transporting them to the job site, and installing them in the correct locations (Assaf et al., 2023). However, the efficient adoption of modular construction requires a high level of information technology and digitalization (Ezzeddine & García de Soto, 2021). Hence, various digital solutions and technologies have been adopted in modular construction methods, including computer vision (Alsakka et al., 2023), blockchain (Wu et al., 2022), Internet of Things (IoT) (Li et al., 2022), and immersive technologies (Zhang et al., 2023).

Virtual reality (VR), as a part of immersive technologies, has been used by many researchers to enhance the implementation of OSC techniques. VR can be defined as a simulation of the real world in which participants can interact with the virtual assets and experience different degrees of immersion in the simulated environment (Abbas et al., 2019; Alrehaili & Al Osman, 2022). These degrees of virtual immersion include non-immersive, semi-immersive, and fully immersive VR models (Zhang & Pan, 2021). The virtual scenes in the simulated environments are usually done using game engines (Olofsson, 2018). Through the use of game engines, the interaction rules and conditions are defined using coding scripts (Kumar et al., 2011). This combination of VR and game engines have been used in several research domains, such as health and therapy treatment (Mevlevioğlu et al., 2022), the food and shopping industry (Gil-López et al., 2023), and the construction industry (Boton, 2018).

As the combination of VR and game engines is a promising approach in many industries, OSC also benefited from it. The VR-OSC research has gained massive attention in recent years. For instance, Zhang and Pan (2021) have proposed a VR model of tower crane location planning for modular construction projects. The model was created using the Unity3D game engine and was supported by a graphical user interface (GUI) to facilitate the selection of crane types, layout plans, and camera views. Similarly, Shringi et al. (2023) aimed to develop a VR model to train operators on crane operations in offsite construction. Their model included a safety index that was calculated based on penalties applied to each of the identified risks in the scene. In safety and ergonomics analysis, Dias Barkokebas et al. (2022) combined a VR model with a motion capture system to evaluate workers' ergonomics in OSC factories. The VR model was developed using Unreal Engine, and the data collected through the motion capture technology was analyzed using rapid entire body assessment (REBA) and rapid upper limb assessment (RULA) methods. Similarly, Joshi et al. (2021) proposed a VR safety training model for precast factories for

employees. The model was developed using Unity3D and was used to train the employees on the personal proactive equipment (PPE), stressing processes, and safety measures in the factory. Inyang et al. (2012) developed a VR model to assess safety risks in panelized construction factories. Their model evaluated different layouts of the manufacturing facility, and ergonomic risks were evaluated for each of the selected layouts.

For educational purposes, VR has proven to be an effective tool in educating participants and students on OSC processes (Eiris et al., 2020). For instance, Beh et al. (2022) introduced an educational model to train students on inspection activities of the OSC projects. Game engines were used in their model to develop educational game scenes, including fire inspections, leak inspections, and rain system inspections. Similarly, Sampaio and Viana (2014) created a VR model to educate students on the processes included in the prefabricated bridges. Furthermore, VR-OSC research also targeted the use of VR in evaluating design alternatives and factories/site layouts. For instance, Zhang et al. (2006) have developed a VR model to help participants in evaluating design alternatives in prefabricated construction. Their model assessed many criteria, including production time and cost. Zhang et al. (2021) developed a virtual environment to improve the generated value to the customer in offsite construction facilities. Many other applications of VR-OSC research were found in the literature, including collaborative digital platforms in modular construction projects (Ezzeddine & García de Soto, 2021) and the use of VR in circular economy of OSC projects (O'Grady et al., 2021).

Despite the contribution provided by the previous studies, they lacked the following aspects: 1) all of the mentioned studies have considered the use of VR in OSC residential projects. OSC, especially modular construction, can be employed in many project types, such as bridge construction, which is usually referred to as modular bridges (Lechner et al., 2021). Modular bridge construction includes fabricating heavy steel and concrete modules in manufacturing facilities and shipping them to the bridge to be aligned and installed (Xiangmin & Dewei, 2021); 2) most of the presented studies have tackled the OSC life cycle from a single perspective, such as onsite installation (Zhang & Pan, 2020) and manufacturing phase (Dias Barkokebas & Li, 2021); 3) the developed models have limited accessibility, as the participants needed to be in the lab where the experiment was being held. In light of the mentioned limitations, the current study aims to bridge these limitations by developing a VR model that considers all of the implementation phases of modular bridge construction to train practitioners on different OSC processes and connect various project teams. The objectives of this study can be summarized as follows: 1) review the literature contributions in VR-OSC research; 2) develop a framework of a VR model considering the fabrication, installation, and transportation phases of modular bridge construction; 3) test the developed framework on an actual case study on a modular bridge and gather feedback from participants for improvement; 4) develop a cloud platform to support remote access to the model. The rest of the paper is organized as follows: Section Two summarizes the methodology outline, Section Three discusses the model development in the mentioned phases, Section Four discusses the analysis of the model and provides the areas of improvement, and finally, Section Five concludes the current study.

2. METHODOLOGY SECTION

This section demonstrates the methodology and the tools used in this study. Figure 1 outlines the study framework. As mentioned, the proposed framework aims to provide engaging and efficient training for various OSC processes, improve stakeholders' connectivity and coordination, and assist participants in getting familiar with OSC processes. The proposed framework targets many project teams, such as the factory team, onsite assembly team, and transportation team. The developed model in the game engine is further upgraded to be accessible online for project teams.

The framework combines the merits of BIM modeling and game engines. The framework starts with building a 3D BIM model of the modular bridge construction project. The 3D model was developed based on the statistical system of an example of a modular bridge addressed by Xiangmin and Dewei (2021). Autodesk Revit is used in this step to develop the BIM model. An FBX format is used to export the developed BIM model, with all of the needed information and real dimensions, to the game engine tool. In this study, Unity3D is used as the game engine tool. Unity3D has been used by research scholars in developing serious games and VR scenes due to its efficiency and compatibility with technologies, such as BIM (Zhang & Pan, 2021) and hardware sensors (Jeon & Cai, 2021). After the FBX model is imported to the Unity3D platform, the interactions in the virtual scenes are added using C# programming language. The developed virtual scenes include the following: an exploring scene, a transportation scene, a yard scene, and an onsite scene. The scenes will be further detailed in the following section. To facilitate easy access to the developed VR model and leverage the use of the VR model, web cross reality (WebXR) and Web Graphics Library (WebGL) are used. WebXR facilitates the ability to develop fully immersive virtual models across the web using several types of hardware (Bao et al., 2022). A modular construction case study is also discussed to test the proposed methodology, and participants are then asked to evaluate the designed tool, and the feedback is used to improve the development of the model. The following sections will detail the development of each of the discussed steps.

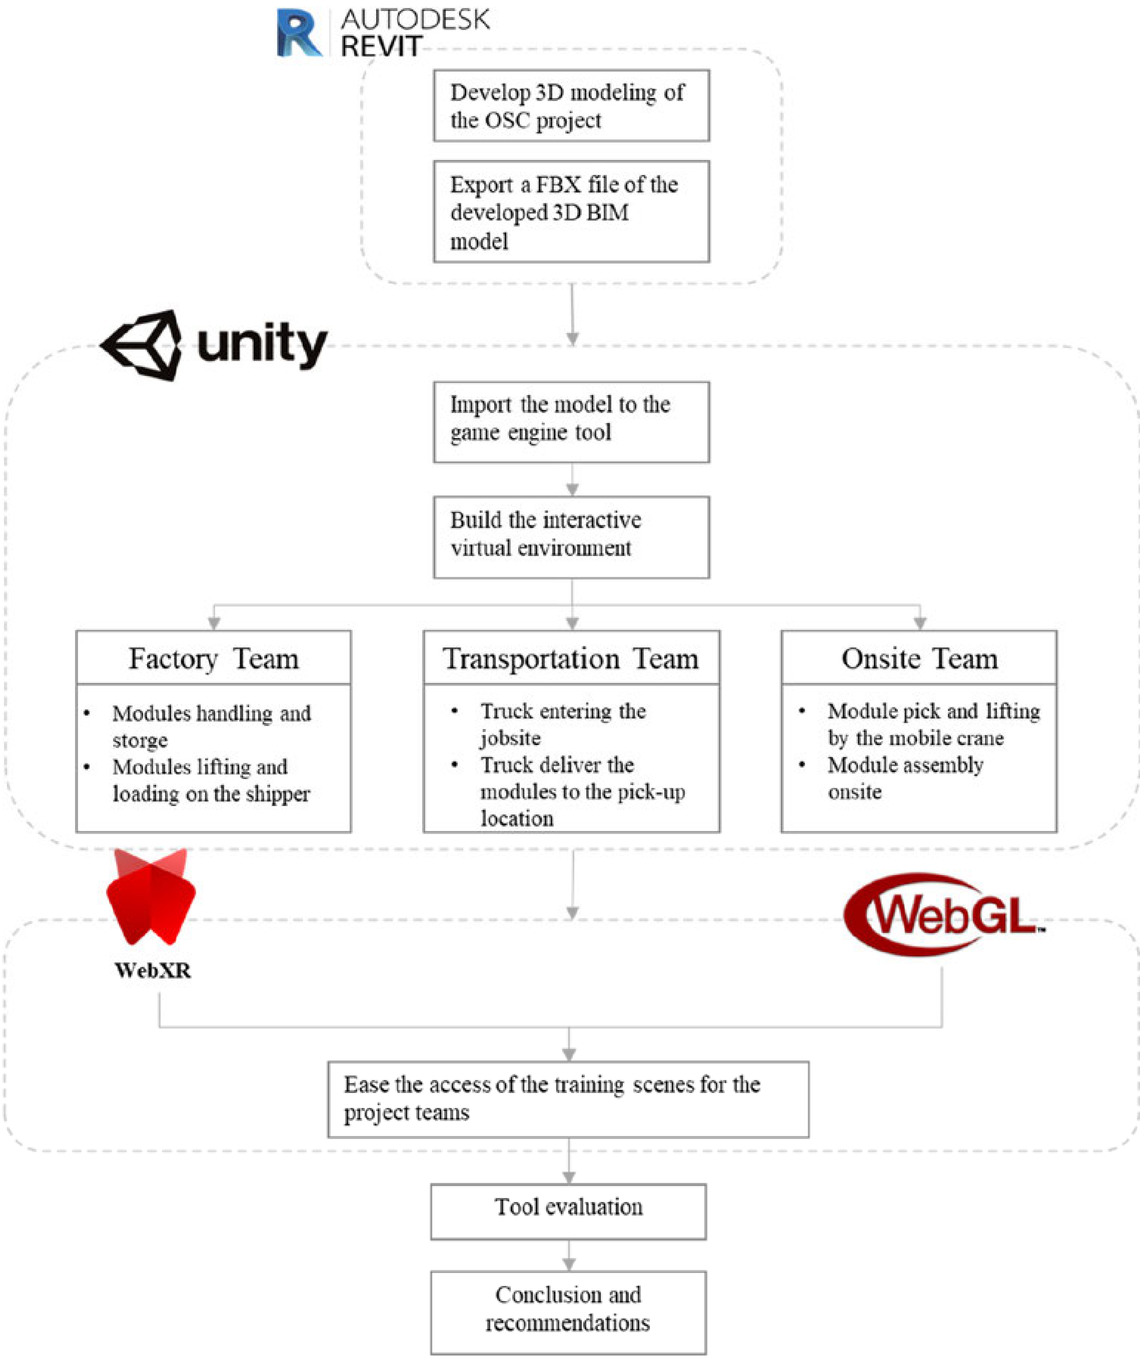

Fig. 1: The study framework

Furthermore, the model testing was performed through two main steps. First, a non-immersive environment is created where the participant can enter any of the developed scenes and test the efficiency of the developed model. This option is valuable when deploying the developed virtual model on the shared cloud. This arrangement allows participants to access the model without the need to have a VR headset and controller. In the second step, the model is then tested in a fully immersive environment. The VR headset and controllers are connected to the virtual model in the Unity3D platform. The controlling buttons are then edited and added to the VR controllers. Participants in the fully immersive model can perform the same tasks using the VR controller. Participants are asked to evaluate the model after the experiment and to provide possible areas of improvement.

Besides the software tools used in the study, a number of hardware tools are also used. The installation of the VR headsets and controllers is shown in Figure 2. The hardware used in this experiment includes the following: 1)

HTC VIVE headset, 2) HTC controllers, and 3) two bases. All of these hardware pieces were connected to the PC and added to the Unity 3D game engine.

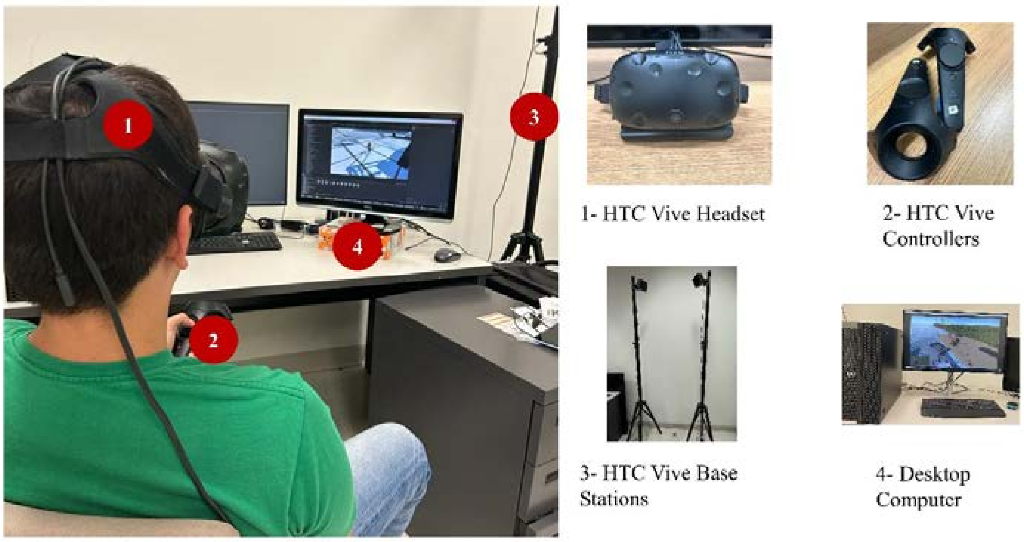

Fig. 2: Hardware used in the VR experience

3. MODEL DEVELOPMENT

In this section, the development of the model is discussed. As mentioned above, Autodesk Revit is used to develop the BIM model, Unity3D is used to develop the virtual interactive scenes, and WebXR is used as the web platform of the model. A case study of a modular bridge is discussed in this section to demonstrate the proposed methodology. It is worth noting that the location, details, and drawings of the case study are remained anonymous.

3.1. BIM model

This section shows the development of the BIM model. The chosen case study comprises the following OSC elements: prefabricated steel modules and precast reinforced concrete slabs. Figure 3 shows the details of the developed BIM model. The shown steel modules are first installed on the bridge, and then the precast slabs are installed on top of the steel modules. The fabrication of the steel modules is beyond the scope of this study. However, handling the steel modules at the factory is included in the developed scenes.

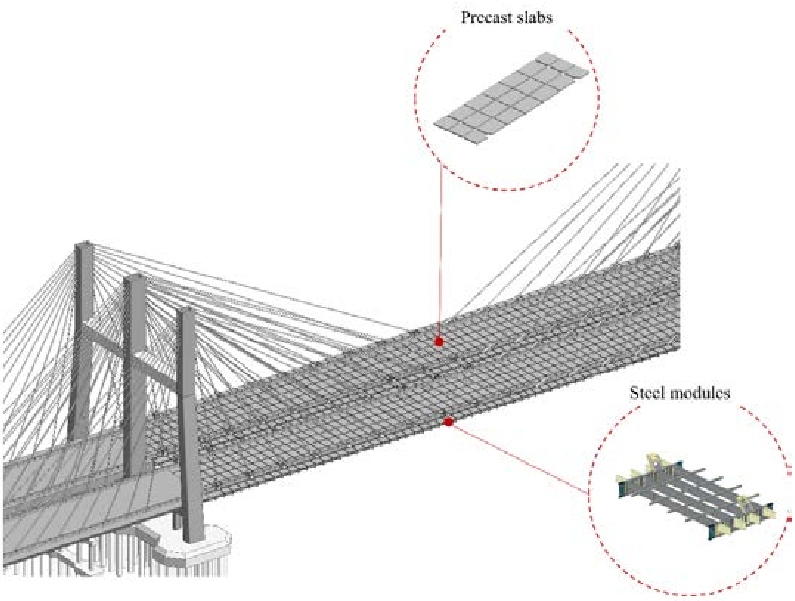

Fig. 3: Developed 3D BIM model.

3.2. Virtual Scenes

This section discusses the development of virtual scenes in this study. The section includes the following scenes: the exploring scene, the yard scene, the onsite scene, and the transportation scene. Further, the graphical user interface (GUI) is used to ease the accessibility of the developed scenes. Figure 4 shows the developed GUI. The user can easily navigate among different choices, including scene selection, scene instructions, and scene options (i.e., audio adjustment).

Fig. 4: GUI of the developed game scenes.

3.2.1. Explore Scene

In the Explore Scene, the participants can walk around the VR model in a fully immersive environment. Figure 5 includes a snapshot of the developed scene. The use of this scene for participants is to get familiar with the project before the actual implementation. In this scene, the location of heavy equipment, material storage, special connections, and safety precautions are included. The participants control a character that moves in the virtual environment to explore the mentioned attributes. Participants can choose different camera views, such as first-person or third-person views. All of the elements in the virtual environment, along with the moving characters, are equipped with colliders, making the experience more realistic. Further, the scene is equipped with sound effects, such as footsteps, to increase the engagement of the participants in the virtual environment.

Fig. 5: Exploring scene of the developed model.

3.2.2. Transportation Scene

This scene includes the transportation of the precast slabs to the pickup point. Figure 6 shows a snapshot of the scene. The scene includes the following: a signaler character to guide the truck, signs for the safe entry of the truck, barriers that separate that truck's movement from other vehicles and elements on the job site, and vehicles moving in opposite directions to make the experience more realistic. Furthermore, the sounds of the moving vehicles are also added to the scene for an engaging experience for the participants. In this scene, participants (in this case, truck operators) are expected to drive the truck from the first location to the pickup location. The truck should be able to lift the slabs and assemble them on top of the steel module in the next scene. The scene also shows the clearance of the truck and surrounding elements. The scene then alerts the participant using a beep sound when the clearance is below a certain value. This is achieved through the physical attributes of the elements and collider functions in Unity3D.

Fig. 6: Snapshot of the transportation scene

3.2.3. Onsite Scene

The onsite scene includes the assembly of precast slabs on the steel module. Figure 7 shows a snapshot of the scene. The scene includes heavy equipment, such as a mobile crane, and heavy vehicles, such as trucks. The scene includes many tasks for the participants, such as moving the mobile crane, manipulating the crane boom, tying the module, lifting the precast element, and assembling. The participant (crane operator in this scene) is expected to install the precast slab in the correct location. To make it easier for the participant, an assistant is provided for accurate precast element installation. For instance, a clearance check algorithm is provided so that the participant would know the distance between the element and the nearest surrounding elements. The participant will be notified when this distance goes below a certain value. Furthermore, participants can also enable an option that assists them with the installation process by indicating the projection area on the below elements.

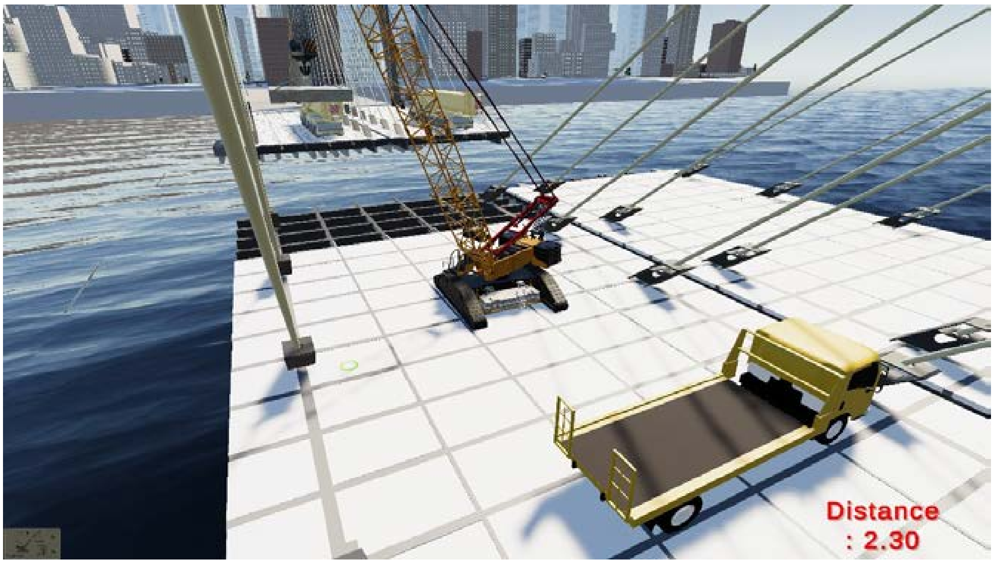

Fig. 7: Snapshot from the onsite scene

3.2.4. Yard Scene

Similar to the onsite scene, this scene targets the handling of the modules in the factory. It is worth noting that in the displayed case study, the factory is represented as a yard where the steel modules were being manufactured. Figure 8 depicts a snapshot of the factory scene. The scene shows how are the steel modules arranged on the yard. The participant is expected to do the same tasks included in the previous scene, but this time with an aim to place the steel module on top of the barge, which later will be shipped to the bridge to be installed. The participant can hook the module and lift it to be aligned on top of the barge. The model provides Various guidelines, such as alerts and the location of the installation. The participant can choose between various points of views, such as the operator view and the barge view. Sounds of the crane engines are also provided to engage the participants in the experiment.

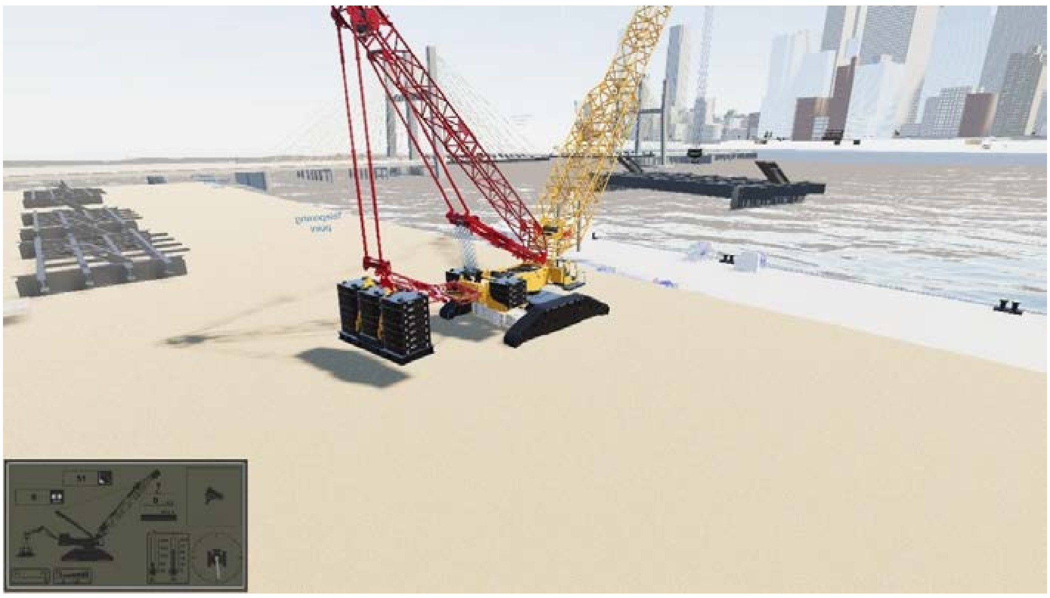

Fig. 8: Yard scene of the virtual model

4. RESULTS AND DISCUSSION

This section discusses the testing of the developed model. A group of researchers from the University of Alberta, where this study was conducted, were invited to test out the developed tool. The testing was performed in both non-immersive and fully immersive environments. In the non-immersive environment, the participant was provided with a demonstration of the keyboard buttons, as shown in Figure 9. The controlling buttons can be adjusted to fit the user preferences. All of the scenes controlling buttons are added in the instructions tab of the developed GUI. The participant should review the controlling button prior to the start of the experiment. On the other hand, in the fully immersive experience, a number of hardware pieces are used, including the VR headset and controllers. As mentioned before, the installation of the hardware is shown in Figure 2. All of the used hardware pieces were connected to the PC and added to the Unity 3D game engine. Further, in the Unity 3D platform, a few add-ons were installed to enable the VR play mode. These add-ons are the XR plugin package and the SteamVR package. The XR plugin package converts the game scene in Unity 3D from regular mode to immersive VR mode after installing the VR headset. In addition, the SteamVR package supports many functions throughout the game scenes, such as teleporting and picking/dropping functions.

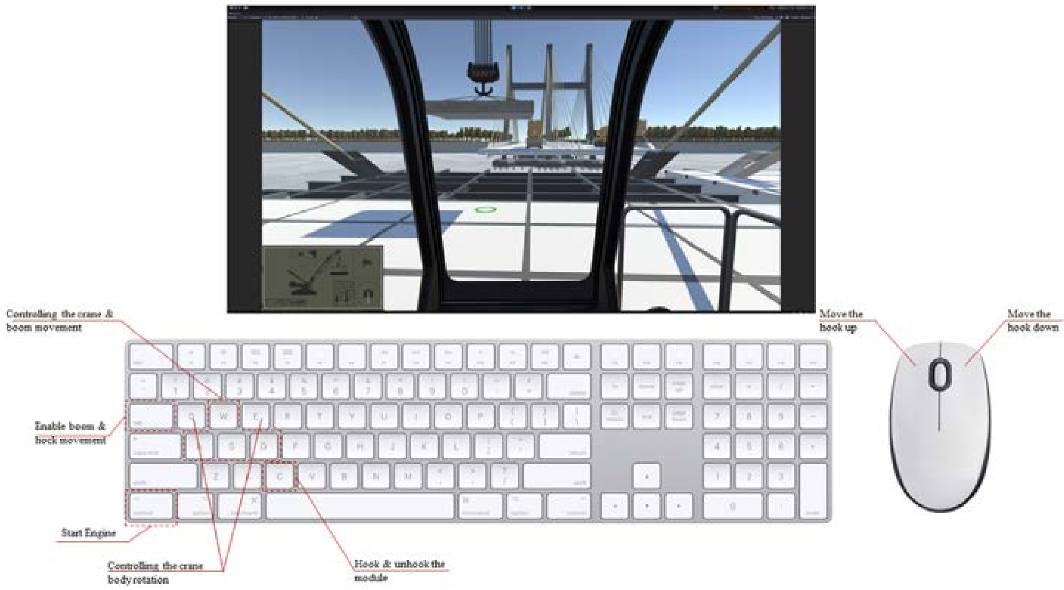

Fig. 9: Instructions of controlling buttons in the developed scenes

Participants were asked to perform tasks in the four discussed scenes. It is worth mentioning that the model was tested using a small sample of VR researchers. The next step in future research is to evaluate the model based on construction and manufacturing professionals' feedback, i.e., workers, truck operators, and crane operators. The tasks that each of the participants needed to complete can be summarized as follows: 1) in the exploring scene, the participant was asked to tour the construction site and identify several elements in the modular bridge, including steel girders, modules, precast slabs, crane locations, and stayed cables. In the immersive reality, the participant controls the movement using the VR controllers and can also teleport easily to different positions with the assistance of teleporting areas and points. When pressing on the VR controller and aiming for a teleporting point, a light is generated in the virtual environment to help the participant navigate to the selected point. This is followed by a list of questions to ensure the participant's understanding of the construction site and factory. The questions range from basic to high-level and detailed questions; 2) in the transportation scene, the participant is asked to drive the truck safely from the starting point to the pickup location. The truck path is determined by barriers and supported by signals, i.e., slow speed signs. Further, participants are also assisted by animated characters, i.e., signalers, that direct them in the right direction. In addition, the participant is also asked to park the truck next to the mobile crane in the specified location; 3) in the onsite scene, several tasks are asked to be performed by the participant. The participant is asked first to turn on the mobile crane engine, move the crane boom, and lower the hook towards the precast slab. Following that, the participant is asked to lift the slab and move to its assembly location. Finally, the participant is asked to install (drop) the slab on top of the steel module; 4) in the yard scene, the participant is asked to perform similar tasks to the previous scene. However, in this scene, the tasks are more complex because of the size of the steel module, which requires more accuracy and precision. The participants are asked for their feedback on the developed model after completing all of the mentioned tasks.

The time spent by the participants in completing the mentioned tasks was 30 minutes on average. Participants reported the high level of immersion experienced and the high level of detail in the virtual environment. It was also reported that sound effects and guidance in the virtual environment have helped participants to be more engaged in the experiment. The participants also reported that the tasks required were clear in the virtual environment and displayed GUI, i.e., clearance check, and module installation assistance facilitated safe and accurate installation. However, participants also highlighted several areas of improvement: 1) the time of the immersive VR was quite long, and participants reported a low level of focus in the last 10 minutes of the experiment (last scene); 2) some of the controlling buttons were hard to follow, especially in the crane scene where the participant needed to control the crane movement, boom rotating, hook movement, and module lifting; 3) the placement of the module was found hard by most participants as it included movement in tight spaces. The collected feedback from participants is used to improve the performance of the developed model. This is part of a continuous study that is currently conducted by the authors. It is also worth noting that the multi-user environment, which enables connections between stakeholders in the VR model, requires further testing by the participants. The cloud application of the model using WebGL and WebXR was also tested. The WebGL plugin was supported by Unity3D. The function of this tool was to build the game scenes in a format that could be deployed online. Figure 10 shows a snapshot of the cloud model. This cloud model was tested across different platforms to ensure its functionality. Furthermore, the model was also supported by the WebXR plugin. This allowed the participants to experience the developed scenes in a fully immersive manner. These tools provide accessibility to the model to multiple stakeholders. The scenes can be easily updated by the designer based on stakeholders' feedback on the cloud platform. It is also worth noting that the authors tested a few scenes of the model due to size restrictions.

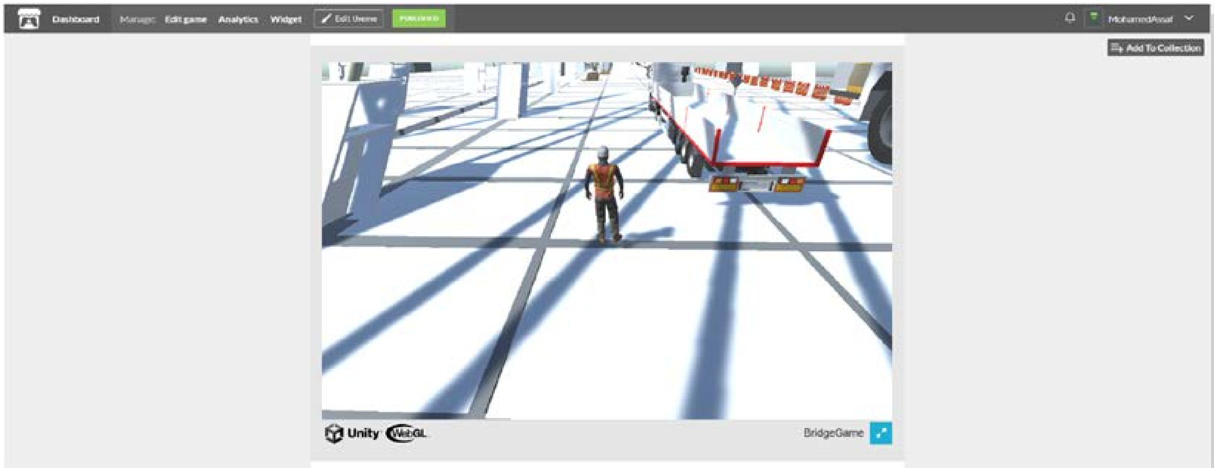

Fig. 10: Cloud platform for the developed model

5. CONCLUSION

This research was motivated by the lack of VR-OSC research when dealing with complex structures, such as modular bridges. Hence, this study contributes by developing a VR model to train participants on the processes included in the construction of modular bridges. The model is supported by a GUI that facilitates the selection of the scene of interest. This includes exploring, yard, transportation, and onsite scenes. The exploring scene allows the participant to walk around the model and explore several elements and connections. In addition, the exploring scene is supported by the steamVR feature that allows participants to navigate among different positions in the scene by pointing the VR controller in the virtual environment to the desired location. In the transportation scene, the participant can maneuver the truck according to a defined path to the pickup point following the road signals and signaler characters. This is supported by sound effects to engage the participant in the VR experience. In the onsite scene, the participant can control the mobile crane to hook the precast slab and place it on top of the steel module. This is also supported by crane and truck sound effects to engage the participant in the experiment. Furthermore, a clearance check between the hooked precast slab and surrounding objects was added to the model. The displayed clearance distance color is turned into red, and a beep sound is played when it goes below threshold to alert the participant. In the yard scene, the participant can control the crane to hook and place the module on the barge. An assistance projection area is displayed to help the participant in placing the module in the correct location on the barge.

The results show the capability of the model to immerse participants in the VR environment. Furthermore, they also showed participants' understanding of the processes through hands-on experience. However, the feedback from the participants showed a lot of areas of improvement, including the duration of the experience and the complexity of controlling the crane in the crane scenes. These areas of improvement are considered future research directions for the current study. The study provides theoretical and practical contributions. Theoretically, the study is considered a basis for a collaborative VR model that can facilitate process planning in OSC projects. Practically, the study provides an advanced VR model that can be used to connect and train OSC practitioners on various processes. Despite the contributions provided by the study, several limitations are included. The sample of participants is considered small compared to the scale of the study. However, this paper is considered a first step in continuous research that explores VR in OSC projects. Furthermore, the study theoretically explores the potential of the WebXR feature that allows easy access to the model. Future studies will be conducted to create access control for the developed model on the WebXR. In addition, the next step in this research will target the use of wearable sensors, such as eye-tracking sensors, to mitigate subjective feedback by the participants.

ABSTRACT: *Web platforms are increasingly being used to connect communities, including construction industry and academia. Design features of such platforms could impose excessive cognitive workload thereby impacting the use of the platform. This is a crucial consideration especially for new web platforms to secure users' interest in continuous usage. Understanding users' cognitive workloads while using web platforms could help make necessary modifications and adapt the features to users' preferences. Users' usage patterns can be leveraged to predict the needs of users. Hence, the pattern of cognitive demand that users experience can be used to predict the cognitive load of web platform users. This could provide insights, generate feedback, and identify areas of modification that are critical for sustaining acceptability of web platforms. Using recurrent neural network, this study adopts electroencephalogram (EEG) data as a physiological measure of brain activity to predict brain signals (cognitive load) of users while interacting with a web platform designed to connect industry and academia for future workforce development. This paper presents a Long Short-Term Memory (LSTM) based approach to develop a model for predicting users' cognitive load via EEG signals. Nineteen (19) potential end-users of the proposed web platform were recruited as participants in this study. The participants interacted with the web-platform in a real case scenario and their brain signals were captured using a five-channel EEG device. The validity of the proposed method was evaluated using root mean square error (RMSE), coefficient of determination (R^2), and comparison of the predicted and actual EEG signals and mental workload. The results revealed the reliability of the model and provided a suitable method for predicting users brain signals while using web platforms. This could be leveraged to understand users' cognitive demand which could provide insights for web platform improvements to engender users' continuous usage.*

KEYWORDS: *Cognitive load, electroencephalogram, industry-academia collaboration, long short-term memory, web platform.*

1 INTRODUCTION

To achieve a balanced blend of theory and practice, as well as adequately prepare students for a rapidly changing industry like the construction sector, collaboration between industry and academia is important. Academia differs from the industry in that the industry is known for practical application of knowledge while academia is known for teaching and research. These differences are complementary in preparing the future workforce for the workplace. Therefore, this necessitates a connection between instructors and practitioners for collaborations in future workforce development. However, there are myriads of challenges plaguing these collaborations of which a prime challenge is instructors' access to practitioners (Chandrasekaran, Littlefair, & Stojcevski, 2015). Since the outbreak of Covid-19, the internet is being increasingly used to connect individuals and communities, for example, to connect instructors to students, and buyers to sellers. The usage of the internet has been growing over the decades, with a transition from mere information sharing medium to workspaces, marketplaces, and even communities (H.-F. Lin, 2009; Schmutz, Heinz, Métrailler, & Opwis, 2009; Wellman, 2004). Dale, Basumatary, Iqbal, Khullar, and Shaikh (2022) used Facebook to connect diverse community users to archived language collections. Maher, Oropello, Roman, and Zeoli (2022) also showed how the internet was used to connect underserved communities to increase health care access and improve care outcomes. Internet-based technologies have also been leveraged to build virtual communities (H.-F. Lin, 2009). Therefore, a web-based platform could be used to connect instructors to different practitioners who are willing and able to provide complementary input in course offerings. Hence, a web-based platform was designed to give instructors improved access to practitioners who could provide complementary inputs in instructors' pedagogical effort and support the preparation of students for the industry. However, during interaction with web-based platforms, there is a risk of cognitive overload. Cognitive overload is an indicator of non-intuitive interface, poor presentation of information which requires more efforts to interact with thereby exhausting cognitive resources. Therefore, to ensure that the web platform for connecting instructors with practitioners has little or minimal downsides, it is important to ensure it has minimal cognitive demand on users.

High cognitive load has been identified as an indication of web usability problem (Albers, 2011) but this is not always the case. Users' performance and success in the use of web-based platforms depends not only on the web platform but also on users. This is because human cognitive resources at a point in time are limited, unstable, and vary from person to person. Also, the perceived cognitive demand for the same activities varies among people (Das, Chatterjee, & Sinha, 2013), for example due to differences in prior knowledge (Seufert, Jänen, & Brünken, 2007), users skill level (Kumar & Kumar, 2016), and amount of cognitive resources available (Tracy & Albers, 2006). In addition, regardless of intrinsic features of a web-based platform that could impact users' cognitive load, other extrinsic factors such as lack of adequate sleep, temporal demand, and stress (Tracy & Albers, 2006) could reduce the amount of cognitive resources available to users at a point in time. Therefore, due to these varying and fluctuating extrinsic factors, a user can experience different levels of cognitive demand on the same web-based platform at different times even when the platform is not changing. Majority of prior studies (Hewitt & He, 2022; F.-R. Lin & Kao, 2018; Mills et al., 2017; Schmutz et al., 2009) focused on detection of cognitive load and the impact of web-platforms' intrinsic characteristics on users' cognitive load with little or no attention on extrinsic factors that are user-dependent which also impact cognitive demand. This represents a major limitation to the generalizability of user experience on the same web platform due to the fluctuation and differences in human cognitive resources. This also accounts for disparities between usability evaluations and real-world scenarios which usually skewed the results of several user testing research. Hence, one-size-fits all approaches cannot meet users' unique and differing needs.

Therefore, to address the dynamism in web-platform usage because of the varying and unstable nature of cognitive resources, adaptive and personalized website design would be beneficial (Desai, 2021). To achieve this, (Adomavicius & Tuzhilin, 2005) recommended leveraging usage patterns to predict the needs of users. A reliable prediction of cognitive load is a fundamental step toward adaptive design (Appel et al., 2019). Hence, the pattern of cognitive demand that users experience can be used to predict the cognitive load of users. This could also help to generate feedback and identify areas of modification that are critical for sustaining acceptability of web platforms. In addition to subjective measures (e.g., NASA TLX), electroencephalogram (EEG) is a growing objective measure of cognitive load in human computer interaction. This has been used by previous studies (Caldiroli et al., 2023; Kumar & Kumar, 2016) to assess cognitive load in web-platform usage. Previous studies (Appel et al., 2019; Herbig et al., 2020) have focused on predicting cognitive load with other physiological measures (such as eye tracking metrics, heart rates, and galvanic skin response) using machine learning. Most previous studies (Caldiroli et al., 2023; F.-R. Lin & Kao, 2018; Mills et al., 2017) focused on using EEG to detect cognitive load in web platform usage. Only a few studies such as (Friedman, Fekete, Gal, & Shriki, 2019; Mills et al., 2017; Yoo, Kim, & Hong, 2023) used EEG for prediction of cognitive load in web platform usage. Mills et al. (2017) leveraged EEG spectral features using partial least squares regression to develop a model to predict cognitive load during interactions with an intelligent tutoring system. Yoo et al. (2023) developed a long short-term memory (LSTM)-based machine learning model to predict the degree of cognitive load using EEG data. The study showed that LSTM had the highest accuracy of 87.1% compared to random forest (64%), AdaBoost (64.31%), support vector machine (60.9%), XGBoost (67.3%), and artificial neural network models (71.4%). Using EEG data for prediction of cognitive load, Friedman et al. (2019) assessed different machine learning predictive models and reported that XGBoost has the highest predictive power compared to random forest, artificial neural network, and simple linear regression models. Therefore, if a web platform is held constant over time, users' cognitive demand can be predicted with EEG signals as they interact with the platform. Hence, this study leverages EEG signals to develop a model for predicting the cognitive demand of a web platform designed for industry-academia collaborations. The results of predicting users' cognitive load could help identify patterns in the usage of the platform which could inform necessary modifications to ensure optimum usability that could influence users' acceptance and intention to use the proposed web-based platform

2 BACKGROUND

The success of new information systems hinged on users' acceptance (Davis, 1985). However, high cognitive load could affect user's satisfaction as well as acceptance of a new web-platform. For example, high cognitive load is an indication of web usability problems (Albers, 2011). Hu, Hu, and Fang (2017) demonstrated that cognitive load can affect user satisfaction with a website. This could affect users' revisit, trust, and loyalty (Desai, 2021). Hewitt and He (2022) showed that difficulty of task to be performed and web page contrast could impact users' cognitive demand and perceived usability. Schmutz, Roth, Seckler, and Opwis (2010) revealed that mode of presentation of information on web platforms impacts users' perceived cognitive load. Examples of other problems associated with web-based platforms which could affect the cognitive load of users include confusing link name or description, horizontal scrolling, and atypical interface design which negate users' mental model (Albers, 2011). The cognitive demand of web-based platforms is crucial because human cognitive resources are limited. Hence, there is a risk of web-platforms requiring more cognitive resources than what users possess, which results in cognitive overload (Albers, 2011). Despite design principles, users of web platforms could be overwhelmed or confused because of information overload and/or excessive obstacles to overcome before locating the right information. Cognitive overload could interfere with mental processing of information which could cause users to exit a web page or even fail to locate appropriate content (Albers, 2011). Other manifestations/impact of cognitive overload on web users include task shedding, increase in frustration, multiple mistakes, lack of attention to detail and disregard of content (Albers, 2011; Kumar & Kumar, 2016). As cognitive demand increases, users' performance plummets (Tracy & Albers, 2006). Hence, the need to assess cognitive load of users as they interact with web-based platforms.

Though originated from psychology, assessment of cognitive load has translated into physiological sensing where objective measures such as EEG are increasingly being used to complement subjective measures (Kumar & Kumar, 2016). The limitations of subjective measures (such as bias and inability to currently recall actual experience or perception) make objective measures (e.g., EEG) growing methods for assessing cognitive load. Through electrodes on the scalp, EEG collects brain signals resulting from cognitive processes taking place in the brain (Kumar & Kumar, 2016). These signals vary depending on the type of activities in the brain and correspond to cognitive load (Mills et al., 2017). By leveraging deep learning techniques, EEG signals can be used to predict cognitive load via real time data from brain signals. Prior studies have demonstrated the efficacy of EEG to predict the cognitive load in different contexts (Moghar & Hamiche, 2020; Salman, Heryadi, Abdurahman, & Suparta, 2018; Yoo et al., 2023) using Recurrent Neural Networks (RNN). RNN are deep learning techniques commonly used for time series forecasting of sequential data (Qin & Bulbul, 2023). However, major downsides of RNN include the time intensive nature of traditional RNN and difficulty in training the models because they are prone to vanishing and exploding gradient problems (Van Houdt, Mosquera, & Nápoles, 2020). To circumvent this challenge, advanced architectures like LSTM are being used in diverse contexts to develop prediction models for time series. For example, in prediction of mental workload during construction task using augmented reality head mounted display (Qin & Bulbul, 2023), stock market prediction (Moghar & Hamiche, 2020), and weather forecasting (Salman et al., 2018). LSTM consists of input layer, output layer and an intermediary LSTM layer (or hidden layer) (Moghar & Hamiche, 2020). The input layer receives data as input, while the output layer determines data that will be output. The hidden layer is made up of memory cells and three gates that are in charge of updating the cell state. LSTM is a gradient-based method used for capturing long-term dependencies in sequential data (Hua et al., 2019). The primary component of LSTM that enabled this capability of LSTM is the memory block (Van Houdt et al., 2020). Memory block (or LSTM cell) is a subnetwork comprising a memory cell (also known as cell state) and three gates (namely, input gate, output gate and forget gate) (Staudemeyer & Morris, 2019). The memory cell retains the temporal state of the neural network while the gates control the flow of information. The input gate manages the inflow of new information into the memory cell using Equation 2 and 3 and updates the memory cell by Equation 4. The amount of existing information which remains in the current memory cell is controlled by the forget gate as illustrated in Equation 1. The output gate regulates the amount of information for computing the output activation of the memory block and how it propagates to the rest of the neural network (Hua et al., 2019) using equations 5 and 6. The structure of the LSTM cell is shown in Figure 1.

$f_t = \sigma(W_f [h_{t-1}, x_t] + b_f)$ ...Eqn. 1
$i_t = \sigma(W_i[h_{t-1}, x_t] + b_i)$ ...Eqn. 2
$\tilde{c}_t = \tanh(W_c[h_{t-1}, x_t] + b_c)$ ...Eqn. 3
$c_t = ft \odot c_{t-1} + it \odot \tilde{c}_t$ ...Eqn. 4
$o_t = \sigma(W_o[h_{t-1}, x_t] + b_o)$ ...Eqn. 5
$h_t = ot \odot \tanh(c_t)$ ...Eqn. 6

Weight matrices for the forget gate, input gate, cell state and output gate are denoted by W_f, W_i, W_c, W_o. In the same order, b_f, b_i, b_c, b_o represent the bias vectors. Elementwise (Hadamard) multiplication is denoted by $\odot$, logistic sigmoid function by σ, and the hyperbolic tangent function by tanh. h_t and c_t represent the hidden state and cell state at time t respectively.

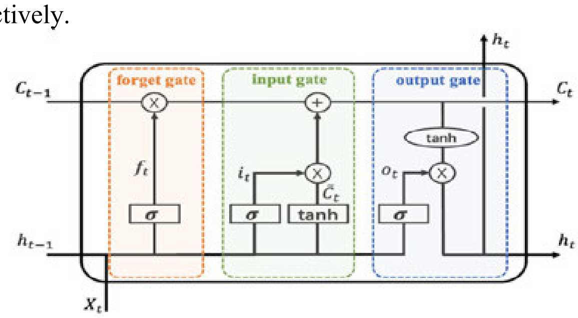

Fig. 1: Architecture of LSTM network.

Mental workload can be estimated from spectral power which represents the brain rhythm's energy (Qin & Bulbul, 2023). A positive relationship existed between cognitive load and theta rhythm power, whereas a negative relationship exist between cognitive load and alpha rhythm power (Gevins, Smith, McEvoy, & Yu, 1997). Hence mental workload can be calculated using equation 7 similar to Qin and Bulbul (2023).

$$\mathrm{MW(t)} = \frac{\theta f\,(\mathrm{t})}{\alpha\, p(\mathrm{t})} \quad \text{......Eqn. 7}$$

MW(t) represents the mental workload at time t; θf(t) and αp(t) are the mean spectral power of theta and alpha rhythm at time t respectively.

3 METHODOLOGY

3.1 Overview of the Web Platform

The web platform in this study is designed to be a collaborative network of instructors and practitioners for future workforce development. The aim of the platform is to improve instructors' access to practitioners who could provide practical supplementary inputs in construction engineering education to aid students' preparedness for the industry. The potential users of the platform are instructors in construction-related programs (such as Building Construction, Architecture, Civil and Environmental Engineering as well as Construction Engineering and Management) and construction industry professionals. The platform was designed by leveraging participatory design, interaction design and user-centered-design principles (Freire, Arezes, & Campos, 2012). Users' input and participation in the design process were ensured through usage research. Usage research was used to elicit pertinent information from end users. The information elicited served as inputs for the design of optimal graphic user interface of the platform. By leveraging heuristics design principles for user interface design (Nielsen, 1994), the platform was designed to be typical to other platforms that potential users are familiar with. This is to ensure that the platform operational procedure is similar to users' mental mode which could enhance ease of use of the platform as well as users' acceptance. To use the platform, an instructor is required to sign up, verify email address, complete profile, submit request for course-support, view recommended practitioners from the platform and select preferred practitioner to meet the course-support request. The course-support requests include site visits, guest lectures, seminars, workshops, and other activities that allow students to interact with practitioners under the guidance of an instructor. The platform was designed using JavaScript programming language. A relational database management system (MariaDB) was adopted with Node.js as server.

3.2 Experimental Design

After a brief introduction of the platform to participants. The procedure of the experiment was explained. All participants provided their informed consent by signing the consent form. The participants interacted with the web-based platform. Each participant was required to sign up on the platform. Thereafter, participants verified their email address before first login. Upon login, the participants were required to complete their profile after which they requested a course-support from practitioners. After a request for course-support, participants viewed recommended practitioners to meet their course support request. Out of these recommendations, instructors made a selection. Every session of the experiment was conducted under similar conditions.

3.3 Participant and Study Approval

Nineteen (19) participants were recruited after the research protocol was approved by the Virginia Tech Institutional Review Board. The participants include both male and female professors (the proposed end-user of the web-based platform) with varying degrees of experience, different job titles and from diverse construction-related academic programs such as civil and environmental engineering, building construction, architecture, and construction engineering and management.

3.4 Data Collection

As participants use the web-based platform, their cognitive load was objectively measured via braai signals using an electroencephalogram (EEG) device called EMOTIV Insight. EMOTIV Insight has five channels, namely AF3, AF4, T7, T8, Pz with semi-dry polymer sensors and two reference sensors (CMS and DRL). The channels are arranged according to the 10/20 international EEG system. EMOTIV Insight has a sampling rate of 128 samples per second per channel for EEG signal with frequency response of 0.5-43Hz, digital notch filters at 50Hz and 60Hz. The device has Bluetooth connectivity which can be connected to a computer or mobile device with Bluetooth V5.0. EMOTIV Insight provides coverage of the frontal, temporal and parietal lobes which are associated with cognitive effort (Kumar & Kumar, 2016). The EEG recording was about ten (10) minutes on average per participant. An overview of the methodology is shown in Figure 2.

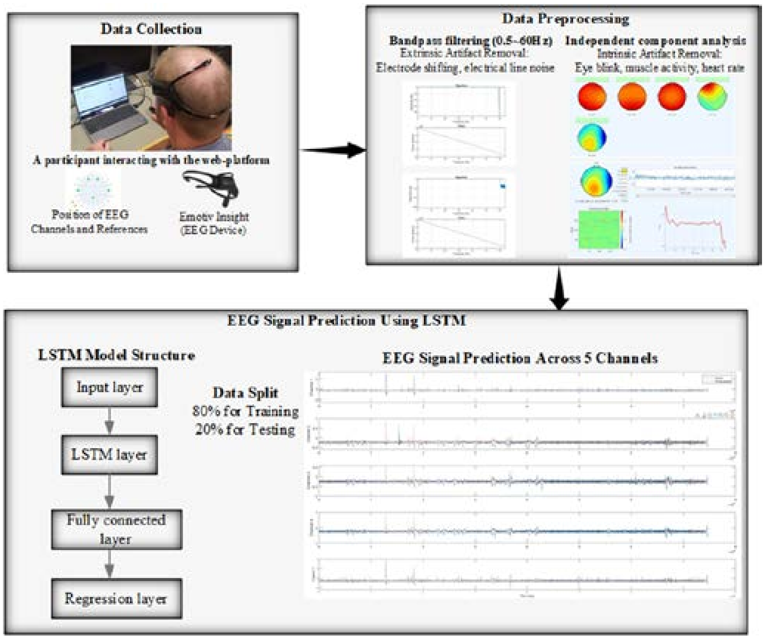

Fig. 2: Overview of methodology.

3.5 Data Preprocessing and Analysis

The raw EEG data collected with the EmotivPRO app was cleaned. Thereafter, the processes highlighted below were carried out.

3.5.1 Artifacts removal

EEG signals are susceptible to diverse categories of artifacts which represent noise/interferences to signals of interest. These artifacts are either intrinsic or extrinsic. Intrinsic artifacts are generated by EEG user's body movement such as blinking and muscle activity. Extrinsic artifacts originate from external factors such as shifting of electrode, noise from electrode wiring and surroundings noise (Jebelli, Hwang, & Lee, 2018). According to Urigüen and Garcia-Zapirain (2015), these artifacts are usually small when the EEG device is used in a somewhat stationary position as it was in this study. Both intrinsic and extrinsic artifact removals were done using EEGLAB. The cleaned EEG data in CSV format were converted to MATLAB file and imported into EEGLAB. The data was mapped and structured using 5-channel location. The extrinsic artifacts were removed using basic band pass filter range of 0.5Hz to 60Hz. As recommended by Delorme and Makeig (2004), Extended Infomax method was used to decompose the EEG data through independent component analysis (ICA). The data was decomposed into 5 components, displayed with scalp heat maps and intrinsic artifacts were rejected.

3.5.2 Data Processing

Five (5) brain wave frequency bands were captured by each of the five (5) electrodes of the EEG device (EMOTIV Insight) used in this study. These frequency bands include Theta (4-8Hz), Alpha (8-12Hz), Low Beta (12-16Hz), High Beta (16-25Hz), Gamma (25-45Hz). The cleaned data for all the nineteen participants from the five (5) channels of the EEG device were used for the analysis. There were 79936 data points on average for each participant for an average recording time of 10 minutes. The data points were split into 80% and 20% for training and testing respectively.

3.5.3 Prediction framework

The preprocessed EEG data was used to train the LSTM network for prediction of EEG signals. Open loop forecasting was adopted because true values of brain signals (representing cognitive load) from EEG were used to train the LSTM network for prediction. Similar to Kingma & Ba (2014), Adaptive Moment Estimation which is an extension of the stochastic gradient descent algorithm was used for optimization with a learning rate of 0.001.

To ensure that the loss is as small as possible an epoch of 250 was adopted for training the model. Root Mean Square Error (RMSE) was used to calculate the loss function to determine the performance of the model. The LSTM layer has 128 hidden units or memory cells to capture and store information over time, which enables the LSTM network to process sequential data effectively. The hidden units determine the amount of information learned by the layer. Both the sequence input layer and the fully connected layer of the LSTM regression neural network have sizes that match the number of channels of the input data.

3.5.4 Mental workload

Because it is not possible to directly measure mental workload from EEG signals, the signals were converted into frequency domain. This conversion enabled the calculation of the average spectral power of particular brain rhythms, hence, the Power Spectral Density (PSD) of the signal was calculated. PSD is a measure of the mean power distribution of a signal over a specific timeframe with the unit showing energy per frequency (Qin & Bulbul, 2023). The mental workload was estimated using equation 7 for both the actual and predicted EEG signals.

4 RESULTS AND DISCUSSION

4.1 Performance Evaluation

The performance of the predictive model was evaluated using RMSE. The RMSE shows the difference between the predicted and actual values of the EEG signals. Table 1 shows the RMSE for all the test participants. The average of the RMSE was 0.0674. The RMSE of the test participants' datasets were very low (<0.037) except for the third participants whose RMSE was 0.1607 which skewed the average of the RMSE to 0.0674. However, the low RMSE of the other test participants' datasets reveal the high predictive power of the LSTM model by indicating marginal difference between the actual and predicted EEG signals. This agrees with Miyamoto, Tanaka, and Nakamura (2022) who posited that the closer RMSE is to zero the better. The high RMSE of the third participant in the test dataset could be attributed to insufficient data points. All other participants had more than 74,000 data points while the third participant had about 58,500 data points amounting to a difference of 16,000 data points. Also, the EEG recording time of the participant was very short and fell below the average duration. This agrees with Pyo et al. (2018) who opined that low RMSE might be because of insufficient data points. In addition, although 58,500 data points seem considerably high, this result reveals that prediction models require large amounts of data for accurate forecasting. This position is also supported by Ettinger et al. (2021), even though there are no fixed number of data points required for predictive models. However, considering other factors such as complexity of problem, desired performance and complexity of model, this result could provide a guide for future research.

Table 1: RMSE for test participants.

Test Participants	1	2	3	4
RMSE	0.0356	0.0367	0.1607	0.0367

The performance of the LSTM prediction model was further assessed as shown in Figure 3 by comparing the predicted and actual EEG signals of the test dataset for the five (5) EEG channels. The comparison reveals that the predicted EEG signals follow a very similar pattern as the actual EEG signals. Although there were minor deviations where the path of the predicted signals did not align with the actual EEG signals, to a large extent, the model was able to accurately predict sudden and subtle fluctuations. However, it appears that the model was able to predict subtle fluctuations better than sudden drastic changes in the EEG signals. Overall, the predictive model can be adjudged reliable especially in predicting subtle fluctuations in the EEG signal. To further show the performance (validity) of the predictive model, scatter plot was used to plot the predicted values and the actual values of the test data set for each EEG channel (see Figure 4).

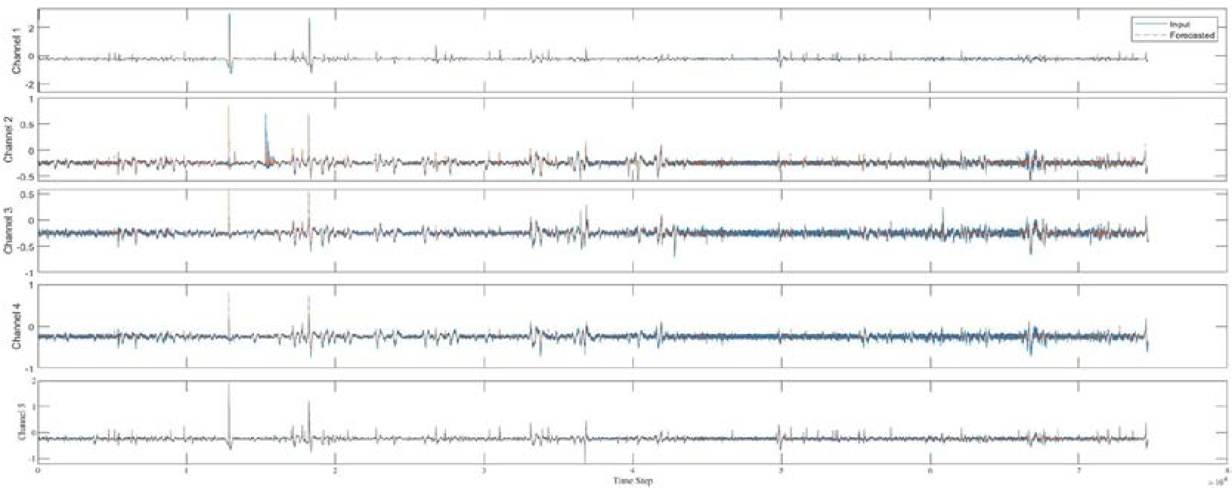

Fig. 3: Comparison of predicted and actual EEG signals for the test dataset across the five EEG channels.

The scatter plots in Figure 4 and the R^2 in Table 2 show that the model was able to explain a significant proportion of the variability in the actual EEG values. R^2 is the coefficient of determination which indicates the goodness-of-fit of the regression model. Given the low RMSE for the test participants and the high R^2 for the channels, it is evident that the model captured the underlying pattern in the data effectively, and the predicted values are very close to the actual values. The model could therefore be considered accurate because as Alexander, Tropsha, and Winkler (2015) explained, RMSE is a useful indicator of a model's practical value. The high R^2 values show that a significant portion of the underlying patterns and relationships in the actual data is accounted for by the predictions made by the LSTM model. This is because according to Chicco, Warrens, and Jurman (2021), RMSE is a measure of the average errors between predicted values and actual values while R^2 explains the amount of variance in the data that the model could explain. Hence, the overall value of a model has been defined by its accuracy and precision and as well as by its effectiveness in elucidating the variability in datasets (Coulibaly & Baldwin, 2005; Qin & Bulbul, 2023). Also, given that the low RMSE values were for the test participants while the high R^2 values were for the EEG channels, it is shown that on the overall for a participant, the model was able to achieve little error between the actual EEG signals and the predicted EEG signals, and for each EEG channel, the model was able to explain a significant portion of the variability in the data for prediction. Hence, the model is able to give reliable prediction of participants' EEG signals.

Table 2: R^2 for each channel.

Channel	AF3	T7	PZ	T8	AF4
R^2	0.9336	0.7683	0.8022	0.7541	0.8854

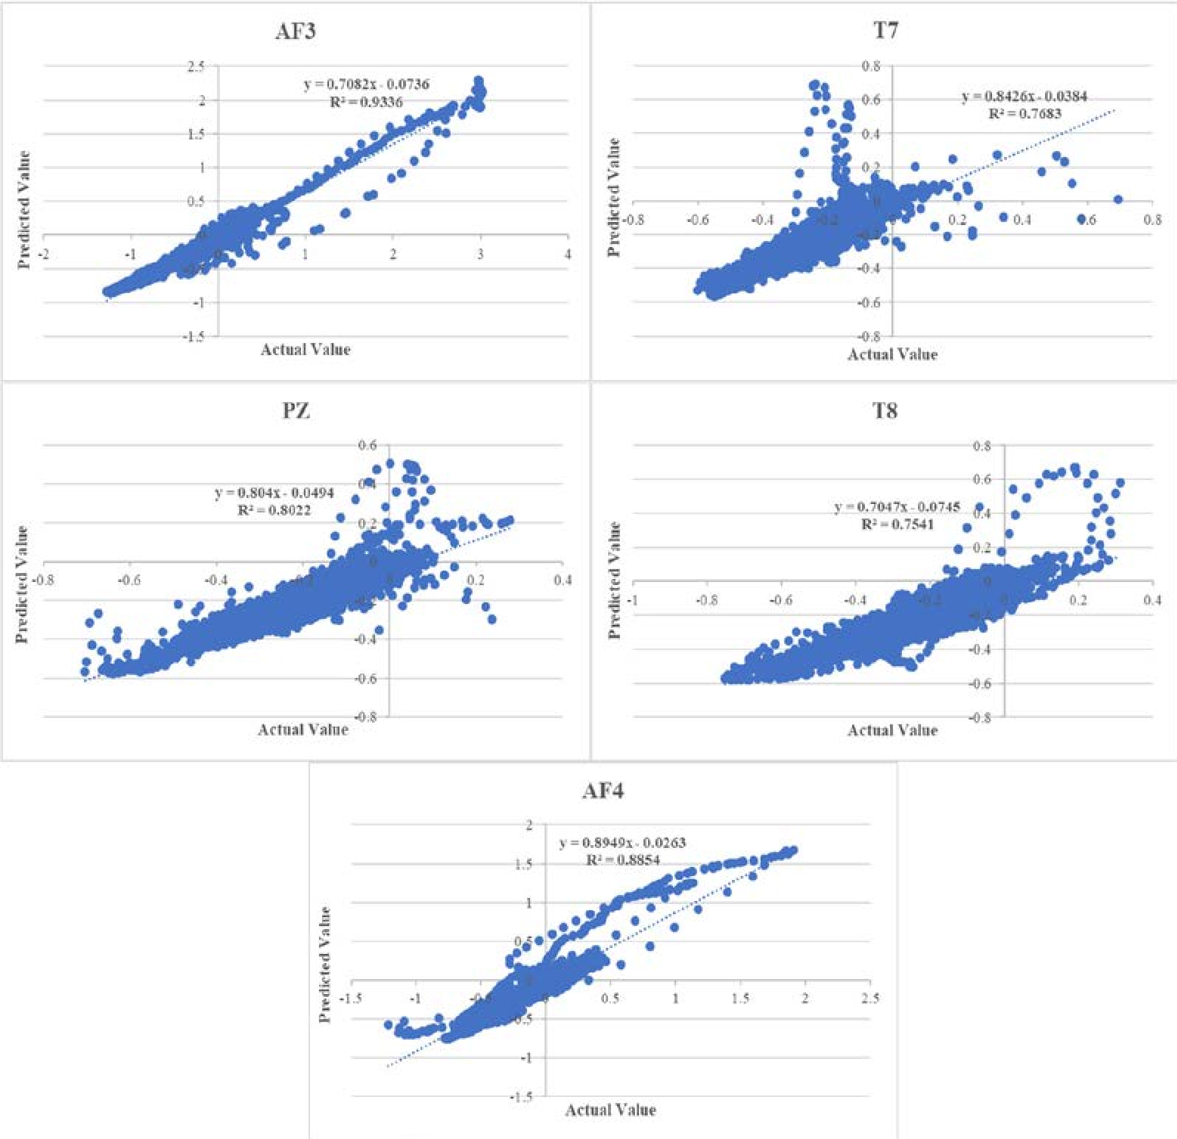

Fig. 4: Scatter plots showing the predicted and actual values for the 5 EEG channels.

As shown in Table 2, the R^2 values are ≥ 0.7541. Channel AF3 has the highest R^2 value, this is followed by channel AF4, PZ, T7 and T8 respectively. The scatter plots show the linear relationship between the predicted and actual EEG signals. Although as shown in Figure 4, there are few data points that deviated from the linear relationship in each EEG channel, a great proportion of both the predicted and actual EEG values fit into the linear relationship. For example, the lowest R^2 value is 0.7541 shows that about 75.41% of variance in the actual EEG signals is accounted for by the predicted signals. According to Coulibaly and Baldwin (2005), R^2 values in the range of 0.8 - 0.9 are considered acceptable and those > 0.90 are considered very satisfactory. Only three EEG channels (AF4, PZ and AF4) fall within this range. However, as revealed by Alexander et al. (2015), RMSE is a more informative indicator of a model's usefulness compared to R^2. This is because, the value of a model should be based on its accuracy and precision and not on its explanatory power of variability in a particular data set (Alexander et al., 2015). Chicco et al. (2021) also noted that R^2 value can be quite low even when dealing with a fully linear model, and the opposite is also true. Therefore, overall, the results show that brain activity of users using a web-based platform can be reliably predicted with EEG signals.

4.2 Mental Workload

Figure 5 shows the scatter plot of the predicted mental workload plotted against the actual mental workload. According to Coulibaly and Baldwin (2005), the R^2 value (> 0.90) was very satisfactory. This shows that the predicted mental workload matches the actual mental workload which further reinforces the efficacy of the LSTM model to learn and predict the cognitive load of users during industry industry-academia collaboration via a web platform. The results reveal that 92.50% of the variance in the actual mental workload can be explained by the predicted mental workload. This provides a reliable prediction of mental workload of users in industry-academia collaboration via a web platform. This potential of LSTM model to predicted cognitive load has been corroborated by earlier studies such as Salman et al. (2018) and Qin and Bulbul (2023).

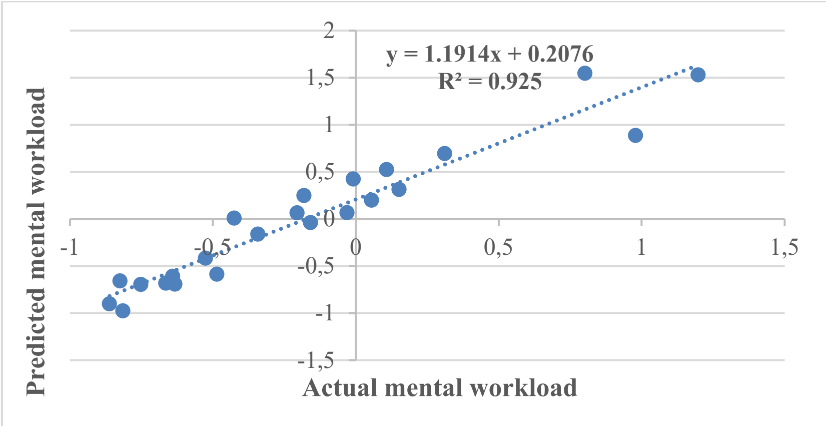

Fig. 5: Relationship between actual and predicted mental workload.

5 CONCLUSION, LIMITATIONS AND FUTURE WORK

Cognitive load is a major consideration in the design and usage of user interfaces because it could influence users' attitude towards the web platform as well as continual usage. Through web platforms, the internet is being leveraged to connect instructors in construction-related programs with construction industry practitioners who could support their pedagogical efforts in preparing students for the workplace. Using LSTM, this study assessed the effectiveness of EEG-based prediction of brain signals (representing cognitive load) as instructors interact with the web platform designed to connect them with practitioners. The results demonstrated the accuracy and reliability of the LSTM model to predict EEG signals as users interact with the web platform. The model was able to predict subtle fluctuations better than sudden drastic changes in the EEG signals. The results showed low RMSE and high R^2 values which indicate that the model's predictions are close to the actual values, and it is explaining much of the variability in the data. The efficacy of the model to predict EEG signals could be leveraged to understand users' pattern of cognitive demand in human-computer interaction. This pattern of users' cognitive demand could provide a better understanding of the cognitive resources expended by users as they interact with the web platform. This is critical because users' cognitive resources and cognitive demand varies due to both intrinsic and extrinsic factors hence a one-time detection of cognitive load might not provide adequate insights. The prediction of EEG signals could be used to understand users' usage patterns and necessary modifications required to enhance interface functionality, navigation, content integration as well as user experience. This is crucial for new web platforms which users are unfamiliar with and which could operate differently from their mental model. Also, the process of users' acclimatization with the platform as well as the impact of learning curve in using the web platform could be better understood through the prediction model. The study has some limitations which should be acknowledged. Although the sample size is adjudged adequate, using a higher sample size could yield better results. Also, LSTM was used in this study, future work could focus on using different network models for comparison of accuracy and reliability. Future work could likewise explore achieving lower RMSE and higher R^2.

TRANSITIONING FROM 2D TO VR IN DESIGN REVIEW – RESISTANCE TO ENGAGEMENT

Shahin Sateei, Mattias Roupé & Mikael Johansson
Chalmers University of Technology, Sweden

ABSTRACT: *Although immersive virtual reality (VR) has been shown to facilitate collaborative understanding of a design, many users remain resistant to its use. Moreover, there is currently a lack of real-world studies investigating why certain users (e.g., architects) are resistant to use VR during design reviews. The aim of this study is to understand the resistance that influence client representatives' and architects' interaction with a VR-system that supports both fully- and non-immersive experiences of the virtual environment. Data were gathered from three VR-workshops, which were part of 3 design review sessions of a new elementary school. Additional data were gathered from four semi-structured interviews with both the architects and client representatives participating in all workshop sessions, the interior architect involved in the project as well as an additional six semi-structured interviews. These additional six interviews involved exterior architects from different firms, who had previously used VR for both informative and design review purposes. The findings suggest that client representatives and the architects had initially been resistant to use VR during the design reviews, but their attitudes changed progressively during the three workshops, in particular that of the architects. The findings also indicate that interactive features in VR (e.g., object manipulation, multi-user) help end users negotiate design requests more efficiently and make informed decision-making. This paper highlights how immersive VR could improve the design review process.*

KEYWORDS: *Virtual Reality, HMD VR, design process, design review, spatial understanding, end-users.*

1. INTRODUCTION AND RELATED WORK

Fully immersive Virtual Reality (VR) has emerged as a potential alternative to traditional information and visualization media (e.g., 2D drawings, 3D models) where users are surrounded by a virtual environment of the building design. This experience of users "stepping into the design" is referred to as an immersive experience (Castronovo et al., 2013; Johansson, 2016). When fully immersed, users can experience the design from a user-centric viewpoint, i.e., an ego-centric frame of reference (Paes et al., 2023), which provides clearer visual cues (e.g., size, shape, location) (Hermund et al., 2017). Enhanced visual cues not only help users better perceive volumetric qualities of the building design than when 2D drawings and 3D models are used (Chowdhury & Schnabel, 2020), but also help users gain a more representative understanding of the final building design (Nikolić & Whyte, 2021). It is important to note here that 3D models viewed on a traditional screen are considered non-immersive VR (Castronovo et al., 2013), e.g., when 3D models are displayed on a computer monitor, projector screen or a multitouch table (Dorta et al., 2016), the users are not immersed even though they do view a virtual environment. In contrast, immersive VR-systems provide either a semi-immersive experience (i.e., experiencing the virtual environment through stereoscopic displays) or a fully-immersive experience (i.e., with head mount display (HMD) and motion-tracking). Studies have also explored how hybrid design environments, (i.e., combining traditional design techniques such as sketching by hand with immersive ones like VR), influence users' understanding of the design. For instance, Okeil (2010) showed how design team members, interacting with available 3D computerized sketching feature combined with a visual understanding enabled by a semi-immersive CAVE system, were able to efficiently explore and iterate on different design ideas. More specifically, by viewing the design that had been drawn in the non-immersive environment, design team members could immediately see the outcome of their design decisions in the semi-immersive environment, resulting in a more rapid cycle of testing and validating of different designs.

In the context of users' interacting with different VR-systems, interactive features in fully-immersive VR such as object manipulation (Wolfartsberger, 2019), multi-user (Truong et al., 2021) and multi-scale (Sateei et al., 2022) have shown to facilitate a mutual understanding of the design between end-users and design team members. For example, the ability to combine multi-user and object manipulation to use task-based scenarios during design review has shown to accelerate decision-making when resolving design issues. Specifically, by enabling furnishment and collaborative review of the virtual environment in real-time, end-users can better understand which layouts support building occupants' work tasks whilst also reducing the overall lead-time of the design process (Roupé et al., 2020). Accordingly, task-based scenarios in VR shift design review from interpreting the design to understanding building occupants' daily work tasks (Nikolić & Whyte, 2021). This understanding of

Referee List (DOI: 10.36253/fup_referee_list)
FUP Best Practice in Scholarly Publishing (DOI 10.36253/fup_best_practice)

building occupants' daily work tasks is then more likely to result in collaborative practices such as Co-design where the end-users become part of the design team (Caixeta et al., 2019; Roupé et al., 2020).

However, although several studies have shown the benefits of using VR in the design process, few have explored end-users' and design team members' engagement in using VR for design review purposes (Maftei et al., 2018). For example, questions remain as to how a collaborative understanding for the design may be facilitated with VR when VR as an information and visualization medium, whether semi- or fully-immersive, is primarily used as a presentation tool by architects (Achten, 2021; Scheer, 2014). One explanation might be the lack of knowledge on how to use VR in workflows where 2D drawings and 3D models are used (Zaker & Coloma, 2018). Another explanation highlighted by the literature is that due to the lack of real-case studies, stakeholders such as architects are resistant to using VR due to not knowing when in the building process to use it. Specifically, there is an initial resistance to using VR in a project setting, and its value in understanding end-users' design preference is often realized too late in the project when time constraints arise (Belek Fialho Teixeira et al., 2021). Therefore, the focus of this study is twofold: 1) to understand client representatives' and architects' resistance to engage with VR-systems with support for both fully- and non-immersive experiences of the building design and 2) how architects and client representatives collaborate to resolve design issues when VR is used in a design review context.

1.1 Clients' and architects' use of VR for design review

Studies have explored the advantages of using VR in the context of design review and from a client perspective. One example is that end-users such as client representatives seem to become less reliant on the design team for their interpretation of the design (Kim et al., 2016), which could help reduce decision-making time during design review (Liu et al., 2020). Another example is a study by Liu et al. (2020) where they found that semi-immersive VR did not only help those who have difficulties interpretating 2D drawings but also helped project members who had not yet seen the design to better understand it. Similarly, in an experimental study, Umair et al. (2022) observed that participants' task completion time was shorter in fully immersive VR compared to 2D drawings when identifying design issues. Studies have also investigated challenges to wider adoption of VR. Examples of these challenges are clients' lack of knowledge of how VR-based practices should be adopted (Zaker & Coloma, 2018) and the lack of real-life case studies that explore how decision-making that is typically done in later phases of the building process, could be made already in earlier design phases (e.g., concept design phase) (Nikolić & Whyte, 2021).

From an architect perspective, VR is seen as one of many available information and visualization mediums (Kim et al., 2016). Whilst drawing has been the traditional communication tool of architects (Scheer, 2014), recent years have seen a continuous increase in use of a 3D model-based approach when building information modelling (BIM) is used in project, whether it is throughout the entire construction process (Disney et al., 2022) or only limited to the design process (Smith, 2016). In this context of using 3D models in the design process, VR models have been used when extracting them from the BIM model (Johansson, 2016), resulting in architects able to showcase the building design in VR. Still, the literature shows that architects maintain control over decision-making in the design process when using VR as they have when 2D drawings are used (Scheer, 2014). An example is the use of pre-defined viewpoints in the VR model during architectural walkthroughs of the building design. The argument for using pre-defined viewpoints is that it prevents end-users from being overwhelmed with too much detail in the virtual environment, which ensures that end-users maintain focus on resolving intended issues during design review (Castronovo et al., 2013). Additionally, previous work highlights how VR challenges the hierarchical position of architects, who are used to predictable and controlled working methods, such as when 2D drawings are used (Cruickshank et al., 2013; Scheer, 2014).

Beyond these challenges relating to both client and architects, there is a lack of studies on how use of VR can affect stakeholders' acceptance of VR over time and how the interactions between architects and clients may be affected. While many research efforts have explored the use of VR-based design review in real-life cases, most of these have primarily concentrated on using VR in one-time sessions or semi-immersive use (e.g., power wall) rather than fully-immersive (e.g., HMD) VR-systems (Liu et al., 2020). Few have explored how the use of VR over several design review sessions, with the same stakeholders, influences their receptiveness or reluctance to use the VR-system. However, these studies do not delve into the impact of the shifting conventional roles between architects as "experts" and clients as "non-experts" on the design when using a VR system that supports both fully -immersive experiences (e.g., HMD) and non-immersive experiences (e.g., projector screen), combined with hand sketching.

2. STUDY DESIGN

In order to better understand how client representatives and architects interpret the impact of fully immersive VR and how it influences them towards becoming more receptive or reluctant towards using it, two (2) real-world projects were evaluated. The study follows a qualitative approach with data collected by means of observations, video recordings and semi-structured interviews.

2.1 Case study

The case study was based on the design of a new elementary school in the municipality of Gothenburg, Sweden, which was ongoing in different phases of the design process (e.g., spatial coordination phase, technical design) (Ostime, 2022). The project primarily used 2D drawings and incentive to use VR came from the clients when it was recognized that 2D drawings and illustrated rendered still images used by the architect could not provide a sufficient level of spatial understanding in the client group. Background information regarding the case study have been analyzed based on the following criteria: 1) purpose of using VR for design review, 2) participants' expectations prior and after each workshop as well as 3) outcome from having used VR in each of the workshops and how this influenced clients' and architects' stance on using VR. The case consisted of three workshop sessions in the following phases of the design process: preparation and brief, conceptual design stage and spatial coordination phase (Ostime, 2022).

2.2 Participants

To achieve sample representativeness, interviewees were selected based on the following criteria: 1) role in the design process, 2) prior experience of design reviews with traditional visual and information medias (e.g., 2D drawings, 3D models, physical mock-up rooms), and 3) involvement in ongoing projects for design of schools.

Whilst the focus of this study was on the same 2 client representatives and 2 architects who participated in all three VR workshops, a total of 7 other participants were also interviewed. These were the interior architect connected to the case study as well as 6 exterior architects who all had participated in separate school projects together with the client representatives interviewed in this study. The projects in which these 6 exterior architects had been involved in, involved using HMD VR for both informative- (i.e., feedback from client not incorporated into the design) and design review purposes.

It is also important to note that all participants in the studied case had prior experience of design review with 2D drawings. Moreover, all the client representatives in the studied case had experience of design review with 3D models whilst the architects had limited experience of design review with 3D models. Lastly, architects (exterior and interior) who had experience with VR had only used it for informative purposes (e.g., presenting the design to clients without incorporating any feedback).

2.3 VR-system

The Virtual Collaborative Design Environment (ViCoDE), a VR-system with support for fully- and non-immersive user-interfaces was used. It consists of several VR-headsets (e.g., Oculus Rift S kits), a multitouch table that facilitates collaborative design work with immediate, real-time feedback (i.e., object manipulation) (see fig 3) as well as a projector screen that mirrors the HMD users' view inside the virtual environment. The multitouch table uses a top view to visualize the facility. Users can pan and zoom in this view using the same standard multitouch interaction features found in most smartphones.

BIM-based components (e.g., loose and fixed furniture) are available via an asset library that is accessible on user-interface on the multitouch table, which can be added to the scene by drag-and-drop. Once added, a component can be repositioned, rotated, or removed, using the multitouch interface. The changes made on the multitouch table are then instantly updated in all the other connected user-interfaces (e.g., projector screen, HMD VR).

Fig. 3: ViCoDE set up with multitouch table and projector screen (left). Client representatives and architects design review via ViCoDE during the first workshop for project B (right).

Moreover, the HMD VR user-interface allows users access to interactive features such as measurement and dimensioning with snapping, filtering and color-coding, 3D-markups, object information (BIM-properties) and 3D-labels, section planes, miniature model (1:40 scale of the building design), multi-user and associated functionality (e.g., gather, goto), and BCF snapshots. During the three workshops, at least one person from the research team was available for supervision and providing help such as showing how to navigate with the HMD VR user-interface and how to use the various available interactive features.

2.4 Data collection and analysis

2.4.1 Interviews

The 2 client representatives and 2 exterior architects who attended all three VR workshops were interviewed as well as the interior architect of the project who participated in only the first workshop session. The focus of the interview questions were based on assessing the interior and exterior architects' and client representatives' views on 1) expectations before each respective workshop, 2) how VR influenced the dialogue of design review and how different interactive features were used to resolve design issues and 3) reflection after each workshop session.

Beyond the five interviews conducted with the 2 exterior architects, 1 interior architect and 2 client representatives involved in the project, an additional eight semi-structured interviews were also conducted with architects and client representatives who were not part of the case study but had collaborated with the same client representatives of the case study, on different projects. The purpose of these additional interviews was to gain a broader perspective on the client representatives' preferences and working dynamics between architects and client representatives when HMD VR is used for design review purposes. The assumption was that insights from individuals who had collaborated with the same client representatives on different projects could offer valuable comparative insights into preferences for information and visualization medium as well as decision-making processes when VR is used for design review.

These additional interviewees consisted of 6 exterior architects and 2 client representatives. The architects' experience of using HMD VR were mostly limited to informative purposes (i.e., presenting the building design without incorporating any feedback) and using HMD VR for design review purposes only during single VR workshop sessions. These architects were asked about 1) their expectation before and after the single VR-workshop session and 2) what challenges they consider as necessary to address in order to increase the use of VR for design review purposes. The 2 client representatives had used HMD VR for both informative and design review purposes were also interviewed and were asked about 1) their expectation before and after the single VR-workshop session and 2) how use of HMD VR helped them assess design issues and provide feedback to architects during design review.

2.4.2 Video recordings

The case with its three workshops were video recorded, with a GoPro 360 camera for a total of 3h, with 45 minutes from each workshop being selected. The two stationary GoPro 360 cameras were placed in elevated positions to capture the participants' collaboration, movement, and use of the different user-interfaces (e.g., multitouch-table, HMD VR) in the workshop room. The collected corpus of video data was transcribed for further analysis and later compared with the field notes and interview data.

The video data were analyzed by looking at the interactions between client representatives and the architects when resolving design issues as well as how both client representatives and architects each respectively interacted with the fully- (HMD VR) and non-immersive (i.e., projector screen and multitouch table) user-interfaces of ViCoDE. The verbal interaction between the participants was transcribed by one of the researchers. Segments of recording were selected based on when the greatest number of interactions took place between participants and the different user-interfaces of the VR-system in order to achieve sample representatives of captured data.

2.4.3 Analysis of interaction pattern

From the selected 45 min of video recordings of each workshop, 15 min were selected to analyze the interaction patterns between architects and client representatives and how both these type of stakeholders interacted with the fully- and non-immersive user-interfaces of ViCoDE. The selected time period for analysis of interaction patterns was based on 1) identifying parts of the selected video recordings where the architects and client representatives interacted the most with each other to resolve design issues, 2) interacted the most with the different user-interfaces, 3) specific moments where key design decisions were made (e.g., reaching consensus on design issues based on the design review agenda) and 4) number of user-interfaces that were used to resolve specific design issues (e.g., revising different room layouts on the multitouch table and validating these via HMD VR and projector screen).

These interactions are divided into three different groups:

- Group: statements, callouts and interactions not directed to a specific individual, but more to the whole group.
- Incoming: interactions directed to the person in question, such as a direct question and a request on the design
- Initiated: interaction initiated by the person in question. This includes questions directed to other person initiated by this particular person.

From the 15 min of each workshop that was video recorded, analysis was performed to count how many times the available user-interfaces – HMD, multitouch table, projector screen – were used by the different participants. These transcribed interactions were used to generate interaction graphs per workshop session with the different types of interaction documented in Microsoft Excel. The transcribed interactions were then imported to create a social network matrix using Gephi 0.10.1 to visualize these patterns emerging between users and the user-interface that they used (Bastian et al., 2009). The network comprises of nodes, representing participants in the different workshop as well as the available user-interface. The edges connecting the nodes are interactions between participants or participants and user-interfaces. Moreover, these edges are weighted by the amount of interaction occurring between the nodes, with distance and a bolder type of line indicating a stronger connection. Strong interconnection between participants/user-interfaces can be viewed in a cluster of nodes close to each other in the network as well. Lastly, the graphical layout algorithm selected for the social network is Fruchterman & Reingold layout algorithm (Fruchterman & Reingold, 1991), due to how it presents a good visualization of the interaction distribution.

3. RESULT

Based on the data analysis, six different visual interaction network graphs are presented, with two from each workshop showing the interaction between participants as well as the interaction participants had with the different user-interfaces of the VR-system. These graphs are presented together with the data captured in the semi-structured interviews as well as the video recordings. This was done to better understand how the use of the different user-interfaces of the ViCoDE system, used by the architects and client representatives, changed over the three VR workshop sessions.

3.1 Case study

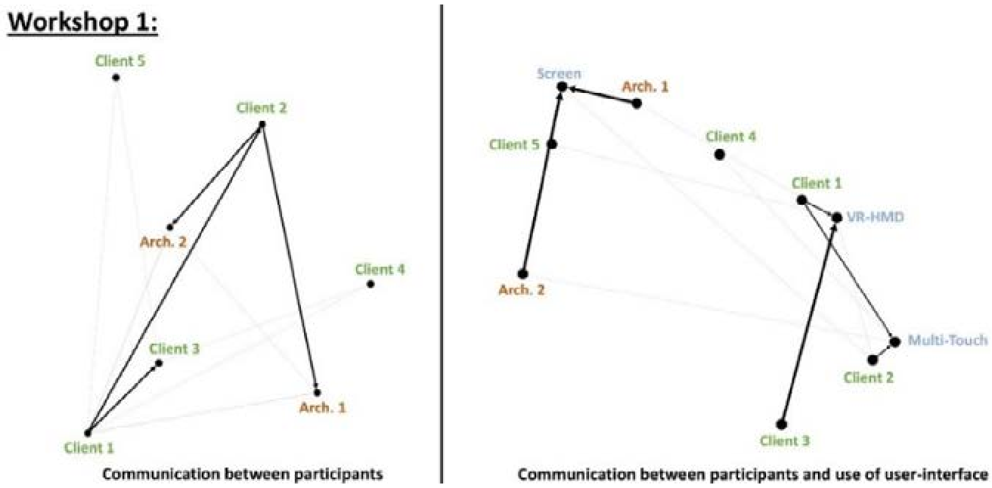

Fig. 4: Architects were noticeably receiving questions about the design from client representatives. Conversely, client representatives coordinated decision-making among themselves and used the HMD and multitouch table.

As illustrated by the edges of the nodes above the architects only used HMD VR once and instead used the non-immersive projector screen when viewing the virtual environment. Still, interesting to note is that when wearing HMD VR, design issues identified by client representatives were reviewed by architect 1 using the mark-up feature to assess the questions client 1 and 2 were asking. Rather than using HMD VR, both architects opted to view the projector screen, which displayed the perspective of HMD VR users, i.e., the virtual environment. Additionally, for a few minutes they used the multitouch table for discussing ideas and thoughts about the design. By seeing client representatives' view from inside the virtual environment, architects directed the client representatives to different points in the building design. The architects' non-immersive experience of the virtual environment via the projector screen was similarly observed in workshop 2 as well, with their fully-immersive (i.e., use of HMD VR) experience being limited to a few minutes during workshop 1.

From the client representative perspective, the multitouch table was the main user-interface used during the first workshop. This was done to resolve design issues in spaces such as classrooms to identify design issues related to hidden sightlines and furnishment. Specifically, by using interactive features such as object manipulation on the multitouch table and multi-scale in the HMD, client representatives used these different user-interfaces of the ViCoDE system to implement a scenario-based approach during design review. For instance, when changing the furnishment layout and placement of walls and windows on the multitouch table, client 1 and 2 viewed in real-time via the HMDs that there were insufficient space which would prevent teachers from performing their daily work tasks (see fig 5).

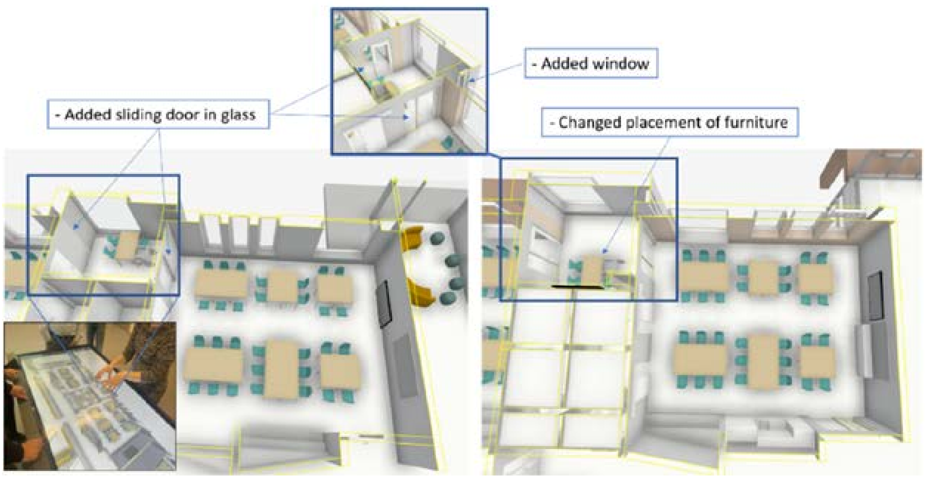

Fig. 5: Design issues identified and resolved in the first workshop via the multitouch table and HMD user-interface (left), which then were incorporated into the second workshop (right).

In the context of identifying design issues such as a lack of sufficient space, client representatives 1 and 2 who had experience interpretating 2D drawings, highlighted the difficulties with correctly assessing the design via 2D drawings. Explaining in the interview after the third workshop how "*regardless of our experience, there is a tendency for us to miss design issues when using 2D drawings [Client representative 1]"* but also *"difficulties with understanding the volume of object, such as loose furnishment, the room space itself or window elevation [Client representative 2]"*. This statement by the client representatives, however, contrasts those of the architects who shared in the interviews that they believed that *"client representatives experienced with interpretation of 2D drawings have sufficient understanding for assessing the building design correctly [Architect 1]"*. This belief among the architects could be explained by their previous experience of having worked with the same client representative when 2D drawings were used.

From the architects' perspective, the multitouch table was increasingly used in all three workshops. Even though HMD VR was not worn for more than a few minutes by either architect, with one of them explaining the reason being that *"that we already know how to visualize the virtual environment in our heads by spatial reasoning, as we have been trained by practice… [architect 1]"*, the multitouch table was the user-interface the architects interacted the most with. For example, whilst client representatives used all the different ViCoDE user-interfaces to identify and resolve design issues in the first workshop, the architects instead viewed the projector screen to discuss design issues with the client representatives. Then in the second workshop, both architects started to use the multitouch table more, as a result of helping client representatives who were unable to resolve design issues by themselves. Lastly, during the third workshop, they took the initiative to use the multitouch table and actively started to lead the discussions and in particular design issues related to building code requirements (see fig 6).

Fig. 6: Workshop 1-3. Architects directing client representatives (left) and discussing ideas with them whilst sketching (center), to directly using and reviewing the design via the multitouch table (right).

With none of the architects having used VR for design review purposes and only for informative purposes, the progressive interaction with the multitouch table indicated a certain acceptance among the architects. They used it for task-based scenarios, which could be shown and explored in VR (see fig 5 and 6).

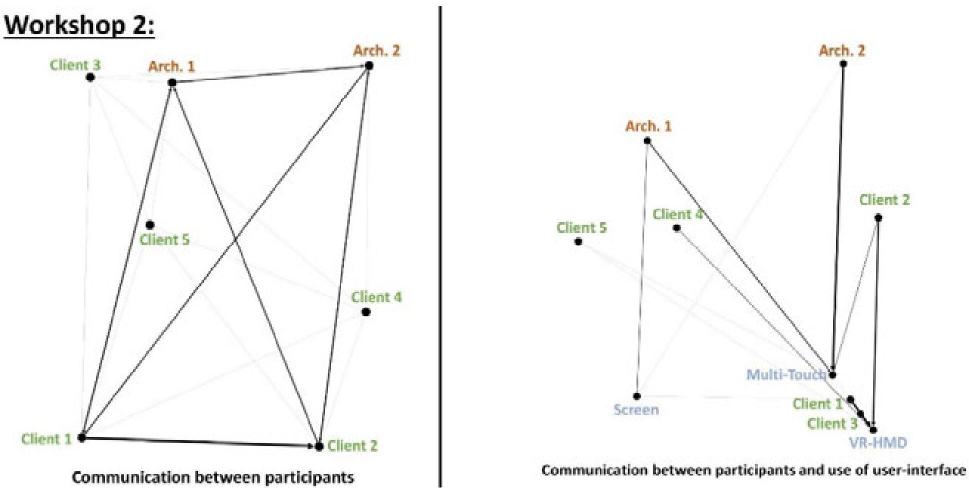

Fig. 7: Client representative 1 and 2 who participated in all three workshops had frequent interaction with each other (left). Both architects also became more involved via their use of the multitouch table (right).

As shown by the node cluster in Fig. 7 (right), client representatives continued using the multitouch table in combination with the HMD VR to rapidly review design revisions via task-based scenarios. Moreover, as indicated by Fig. 7 (left), both architects started to interact more with the rest of the participants as well as starting to primarily use the multitouch table instead of observing the virtual environment via the projector screen. In this context, video recordings show how both architects first sketched ideas on how certain room design layouts for different classrooms could be arranged (see fig 5 and 6). Following this sketching procedure, the object manipulation feature of the multitouch table would be used to validate the feasibility of the design based on these sketches. Lastly, after having decided upon different layouts, the architects would view the projector screen in combination with client representatives using HMD VR to discuss thoughts and ideas about the design together with the client representatives.

In workshop 2, the architects began using multitouch table and became more engaged in the design review process. Similarly to workshop 1, client representatives worked independently during design reviews, separate from the architects. In the context of resolved design issues, video recordings show how the first and second workshop focused on spatial zone relationships, hidden sightlines and furnishment of classrooms and different spaces. Once these design issues had been identified and resolved, 2D drawings were used alongside the multitouch table by both client representatives and architects. With the use of 2D drawings, the architects took a more active role during the design review and specifically the decision-making related to review of building code requirements.

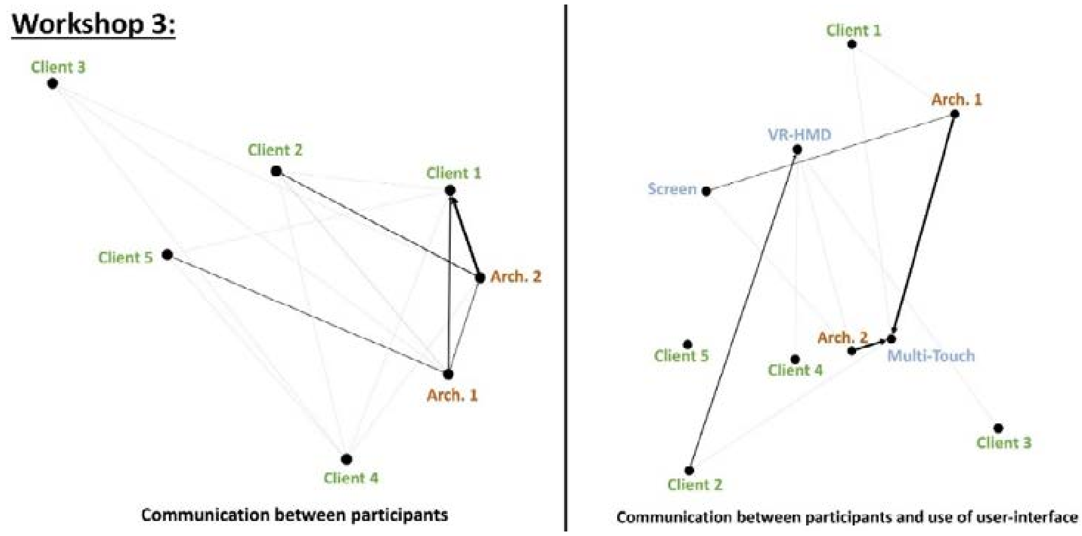

Fig. 8: Contrasting the first workshop, architects initiated more interactions with client representatives (left) as well as interacted more with the multitouch table (right). Clients had similar trend in their interactions as before.

As illustrated by Fig. 8, workshop 3 resulted in a shift in interactions from workshop 1. Specifically, during workshop 1, client representatives led the decision-making regarding the design and during this process used both the non-immersive (i.e., projector screen) and fully-immersive (i.e., HMD VR) user-interfaces of the ViCoDE system. This lead of the decision-making process by the client representatives differed from the 3rd workshop. Instead of being on the receiving end of decision-making, architects now initiated interactions with the different client representatives.

One explanation for the shift in decision-making could be based on the architects being unfamiliar with how to use VR-systems such as ViCoDE for design review, but slowly during three workshops grew more accustomed to the different user-interfaces. Another explanation is that after addressing design issues concerning spatial understanding of the building design, the architects took the lead in interactions and decision-making when reviewing the building code requirements, similar to a traditional design process involving 2D drawings. Connected to the last explanation, another possibility for the shift in decision-making could be that initially when client representatives were using the different user-interfaces of the VR-system, the architects were unsure on their "role" during design review with a VR-system such as ViCoDE. Specifically, whilst the video recordings show how the architects initiated interaction and discussions during the last workshop, the design review were mainly facilitated by the client representatives themselves. With client representatives doing design review mostly independent from the architect in the first two workshops, the role of the architects in these sessions was questioned, as evident by the incoming interactions shown in Fig. 4 but also as the video recordings show when the client representatives questioned design issues they previously were unable to identify during design review with 2D drawings. Moreover, this challenge of the architects' role in the design process was also pointed out in the interview with the interior architect involved in the project:

"When using VR for design review purposes, I sense that end-users such as client representatives identify design issues before we (architects) do and following this, ask questions about the design that we usually are the first to ask whenever 2D drawings and 3D models are used. [interior architect]"

Whilst the architects' lack of experience in using VR for design review purposes explains this statement, it could also explain client representatives' receptiveness towards using the VR-system from the very first workshop. For example, whilst the architects were initially reluctant to interact with the multitouch table, client representatives actively and continuously used all user-interfaces of the VR-system and in particular, the different interactive features of both the multitouch and HMD VR.

In general, results for all the three workshops showed client representatives and architects being receptive towards using many of the same user-interfaces of the VR-system. Whilst similarities in interaction towards using the multitouch table were apparent, equally apparent was the contrast in reluctance and receptiveness in using the HMD VR. From the architects perspective, they became more receptive towards use of interactive features such as object manipulation throughout the three workshop sessions. Specifically, by first sketching with pen and paper and then testing these different layouts on the screen showed how the architect initially started with directing client representatives via the projector screen to later in the second and third workshop actively being part of the discussions that took place. From the client representative perspective, receptiveness to both the non-immersive user-interfaces (i.e., multitouch table and projector screen) and the fully-immersive one (i.e., HMD VR) led to a decision-making process mostly independent of the architect. Moreover, this independence shifted in the second and in particular the third session when design issues related to building code requirements (e.g., daylight, distance between spatial zones) were reviewed. When reviewing these requirements, the architect was more receptive than the client representatives in using the multitouch table and with both type of participants showing reluctance towards using the HMD VR when reviewing building code requirements.

4. DISCUSSION

4.1 Participants' interaction with user-interfaces of a VR-system

Findings show that the different user-interfaces of the ViCoDE VR-system were used to varying degrees during the three workshops. On the one hand, client representatives from the first workshop all through the third session, interacted mainly with the HMD VR and multitouch table as well as the projector screen. On the other hand, the architects' reluctance to use HMD VR for design review persisted throughout all three sessions. Yet, both client representatives and architects frequently used the multitouch table.

From the client representatives' perspective, different interpretations can be made as to why their interactions with the different user-interfaces were consistent. Firstly, with mainly HMD VR increasing their spatial understanding compared to 2D drawings (Chowdhury & Schnabel, 2020) client representatives were able from the first workshop to identify and resolve design issues that they previously unaware of. This unawareness of design issues, regardless of previous experience with interpretation of 2D drawings, could also be interpreted as the client representatives being more receptive towards using the different user-interfaces of the ViCoDE system and in particular HMD VR. This could be due to HMD being perceived as a more engaging information and visualization medium than 2D drawings (Johansson, 2016) with the ego-centric frame of reference client representatives had via HMD VR (Paes et al., 2023), helped them better assess different furnished layouts in workshop 1 and 2. Moreover, the design changes made in the 1st workshop with HMD VR and multitouch table and later incorporated in the 2nd workshop, can be interpreted as client representatives being provided with clearer visual cues (e.g., size of room, placement of windows) (Hermund et al., 2017) when perceiving volumetric qualities of the building design better in fully-immersed virtual environment (Chowdhury & Schnabel, 2020). Secondly, it could be argued that by identifying design issues such as hidden sightlines, furnishment and design of different spaces (i.e., workshop 1 and 2) via HMD VR, client representatives grew more receptive towards continued interaction with HMD VR but also the multitouch table. Thirdly, by adopting task-based scenarios during design review (i.e., workshop 1 and 2), it can be argued that collaborative practices such as Co-design further helped facilitate their interaction with HMD VR and the ViCoDE system at large (Roupé et al., 2020). Also, as observed during workshop 1 and 2, client representatives made design changes such as furnishment and revision to layout of different spaces independently from the architects. This independence is further acknowledged by the project's interior architect when she explains how clients tend to identify and ask questions about the design in HMD VR before the architects do. This suggests that Co-design is more likely to emerge when VR-systems with support for both HMD VR and object manipulation are used during design review, as client representatives become part of the design team (Caixeta et al., 2019).

From the architects' perspective, it is interesting to notice, due to how VR being described primarily as a presentation tool used by architects (Achten, 2021; Scheer, 2014), that interaction with different user-interfaces in the different workshops, was mostly limited to the non-immersive experience, offered by the projector screen and the multitouch table. By viewing client representatives' HMD VR view of the virtual environment and using the projector screen to direct them in the building design, the architects' experience of the virtual environment was limited to a non-immersive one. In this context, when using sketching with pen and paper prior to testing the idea on the multitouch table, we saw that the architects are more receptive towards interacting with user-interfaces they perceive as familiar with their own traditional design tools (e.g., multitouch touch table with top-view similar to 2D drawings) (Scheer, 2014), rather than user-interfaces they do not have experience in using for design review purposes (i.e., HMD VR). This familiarity could be argued to be based on the top view perspective they are used to work with (e.g., 2D drawings) but also for how the use of interactive features such as object manipulation allowed them to seamlessly test and validate design proposals when swapping between sketching and multitouch table. This idea of familiarity could also explain why architect 1 in the first workshop, on their own accord, used the mark-up tool to better understand the client representatives' question on the design. To this point, it can be interesting for future studies to investigate whether architects design review in multi-user HMD VR, together with client representatives, would affect their resistance towards engagement with HMD VR. For instance, what interactive features would be needed in HMD VR to result in a shift for architects viewing HMD VR primarily as a presentation tool (Scheer, 2014), to one of their primarily chosen mediums used for design review?

4.2 Communication between participants when using VR-systems

Results from the three workshops suggest that VR-systems with support for multiple user-interfaces and available interactive features enable client representatives to have a Co-design approach to design review. With the architects being questioned on their decisions made earlier with 2D drawings (workshop 1 and 2), we could see that in conjunction with client representatives doing design review independently, that their role in the design review context came into question. With the third workshop instead consisting of architects initiating interactions with the client representatives as well as leading the design review when reviewing compliance with building code requirements via 2D drawings, the questioning of architects' hierarchical position is supported (Cruickshank et al., 2013; Scheer, 2014). Also, with the explanation provided by the interior architect on how design issues and questions on the design are now instead initiated by client representatives rather than the architect, it can be argued that the role of architects during design review with VR, needs to be further explored to address their resistance toward engaging with HMD VR.

Consequently, providing client representatives with the conditions to express their needs about the design (e.g., use of interactive features to enable design review via task-based scenarios) results in increased sense of ownership of decision-making. Nevertheless, with architects experiencing a loss of decision-making power (i.e., workshop 1 and 2) (Maftei et al., 2018), we saw that VR used for design review purposes would be useful in collaborative practices such as Co-design. In this context of Co-design, it is noteworthy how the architects in all three workshops started developing solutions to different design issues firstly via non-immersive design tools, i.e., sketching by hand, and then shifted over to the non-immersive user-interfaces of ViCoDE, i.e., multitouch table and projector screen. Whilst this hybrid design environment with both non-immersive and immersive user-interfaces can help involved participants to immediately validate their design decisions (Okeil, 2010), it could be argued that the design creation/feedback/revision cycle between architects and client representatives would be more efficient if alternation between non-immersive (i.e., projector screen and multitouch table) and fully-immersive (i.e., HMD VR) environments was not required. With architects developing and revising their design ideas in a fully-immersive environment, they would also likely face a loss of predictability in their working methods (Cruickshank et al., 2013) and decision-making on the design (Scheer, 2014). As such, the "loss" of predictability in working methods and decision-making power could make architects in the fully-immersive virtual environment susceptible to being wrong about certain design ideas, i.e., how the needs and wants of the building occupants are considered in the design.

Therefore, by immediately facing the consequences of their design ideas via use of task-based scenarios (Nikolić & Whyte, 2021; Roupé et al., 2020), it is more likely that the typical hierarchical position of the architect (Scheer, 2014) is questioned, due to client representatives identifying and resolving design issues independently from the architect, as evident by 1st and 2nd workshop. Although the setting of the workshops involved participants using both a non- and fully-immersive approach to design review, it could be argued that the questioning of the architects decisions of the design would be further reinforced when the design review with involved participants is mainly done in a fully-immersive environment. As a result, it is important to explore the conditions architects need, to design review in fully-immersive VR. For instance, how would availability of object manipulation in HMD VR influence collaboration between architects and client representatives? Would collaborative practices such as Co-design more likely be facilitated with everyone doing design review in the virtual environment? Connected to the last point and as evident by the video recordings from workshop 1 and 2, the VR-system tested in this study, i.e., ViCoDE, meant that 2 out of 3 design review sessions were observed to be an isolating experience for the architects. This isolating experience meant that the architect's typical role of a facilitator (Scheer, 2014), were not as apparent as in design processes involving traditional design medias (e.g., 2D drawings and 3D models). It would be of interest to further study what type of role, whether similar or a new one, architects need to take on when doing design review with fully-immersive VR (Maftei et al., 2018). Thus, these are just some of the questions worth exploring in future studies, to better understand the resistance to engagement with VR-systems.

COLLABORATIVE SITE LAYOUT PLANNING USING MULTI-TOUCH TABLE AND IMMERSIVE VR

Mikael Johansson, Mattias Roupé & Mikael Viklund Tallgren
Chalmers University of Technology, Sweden

ABSTRACT: *Building Information Modeling (BIM) is changing the way architects and engineers produce and deliver design results, and object-oriented 3D models are now starting to replace traditional 2D drawings during the construction phase. This allows for a number of applications to increase efficiency, such as quantity take-off, cost-estimation, and planning, but it also supports better communication and increased understanding at the construction site by means of detailed 3D models together with various visualization techniques. However, even in projects with a fully BIM-based design, there is one remaining part that is still done primarily using 2D drawings and sketches – the construction site layout plan. In addition to not take advantage of the benefits offered by 3D, it also makes it difficult to integrate site layout planning within the openBIM ecosystem. In this paper we present the design and evaluation of a user-friendly, IFC-compatible software system that supports collaborative, multi-user creation of construction site layout plans using both multi-touch table and immersive VR. By allowing temporary structures, machines, and other components to be easily added and updated it is possible to continuously produce and communicate 3D site layout plans that are aligned with the schedule and supports integration with other BIM-tools.*

KEYWORDS: *BIM, VIRTUAL REALITY, VR, OPENBIM, IFC.*

1. INTRODUCTION AND BACKGROUND

With increased focus on digitalization and efficiency within the Architecture, Engineering, and Construction (AEC) industries, detailed Building Information Models (BIM) from the design are now often available for use by the contractor. This can facilitate the tendering process and make cost estimation and planning more efficient, but above all it supports enhanced communication and understanding during the production phase in the form of detailed 3D models with corresponding metadata. Furthermore, already today there are examples of so-called *"drawingless"* projects such as Röforsbron, Slussen, and Celsius, which clearly shows that the industry is moving more and more towards a situation where traditional 2D drawings are given less space (Cousins, 2017; Johansson & Roupé, 2019). In fact, in Scandinavia, Total BIM has emerged as a concept where the BIM is the legally binding construction document and no traditional 2D drawings are delivered to the construction site (Disney et al 2022). However, there is still one document that the contractors themselves have to create and keep up to date – *the construction site layout plan*.

Currently, the site layout plan is often drawn up in 2D by default – often using Bluebeam – and although the work differs between projects, there are several recurring problems connected to it (Andersson et al., 2019). Gros (2019) investigated the work with site layout plans at one of Scandinavia's largest contractor and found that:

- Even if all of the design is done using BIM, the site plan is still usually in 2D
- Typically just one person working with the site plan
- The site plan is rarely updated and often differs from reality
- The work with the site plan is often linked to lack of time and stress
- Often poor communication and respect for the site plan (difficult to interpret plans)

However, there are also several good examples in practice which have shown the possibilities of working with site layout plans in 3D, often created and maintained in SketchUp (Jongeling, 2013). 3D offers many benefits regarding elevations and general workplace organization in the vertical dimension, at the same time as it is easier communicate and present ideas around it. Still, this approach typically requires a modeling expert responsible for updating the plan, and in the end these plans tend to be exported as static 2D images instead of being integrated with other BIM datasets (Gros, 2019).

Going beyond site layout planning in real-world projects, much research has focused on turning site layout planning into an optimization problem that can be automated, which – in many ways – is similar to using probabilistic and generative methods for automated creation of production plans and schedules (Taghaddos et al., 2021; Abune'Meh et al., 2016; Kumar and Cheng, 2015; Isaac and Shimanovich, 2021; Fischer et al., 2018). the same time, there is also research that emphasizes the benefits of collaboration, teambuilding, and commitment, and instead advocate more focus on user-friendly software tools and various visualization techniques, for instance Virtual Reality (VR), to support the collaborative planning work (Tallgren et al., 2021, Tallgren et al., 2020). VR, in particular, can clarify aspects of the design that are difficult to comprehend from traditional 2D documents, and can better resemble real work environments – features that are useful when evaluating planning scenarios and reviewing constructability (Zaker and Coloma, 2018; Wolfartsberger, 2019). Given these properties, it is therefore logical that the use of VR has been tested also for site layout planning (Xu et al., 2020; Muhammad et al., 2019). In this context, and when compared to traditional 2D methods, VR has been shown to make the plan more effective to comprehend and to enhance the ability to detect clashes (Muhammad et al., 2019). Nevertheless, certain aspects of the layout planning are still considered to be more efficient in 2D, which tells us that instead of trying to choose between either one of these interfaces it would perhaps make more sense to try and combine them, which has been a successful approach for both urban planning and collaborative healthcare design (Faliu et al., 2019; Roupé et al., 2020). In this paper we take inspiration from these ideas and present the design and evaluation of a multi-user, multimodal system for collaborative creation of site layout plans. The system combines multi-touch table and immersive VR, but contrary to similar approaches within urban planning and healthcare design much more focus has been put on integration within the openBIM ecosystem.

2. THE COLLABORATIVE SITE LAYOUT PLANNING ENVIRONMENT

To support a multi-user, multimodal planning environment we have used BIMXplorer and further customized it. BIMXplorer is a real-time desktop- and VR-viewer that directly supports the IFC file format and creation of federated building models (Johansson, 2016; BIMXplorer, 2023). IFC import is implemented using the xBIM framework (Lockley et al., 2017), and by taking advantage of efficient occlusion culling, BIMXplorer allows large and complex BIMs to be visualized in immersive VR without the need to simplify or decimate the input dataset. The VR user interface – explained in detail in (Johansson and Roupé, 2022) – consists of a tools palette with support for sectioning, measurement, filtering, markups, BCFs, and multi-user sessions (Fig 1). In the following subsections we further describe the multi-touch as well as VR interface that were developed to support user-friendly, collaborative creation of site layout plans. Fig 2 presents an overview of the new system using a sample configuration with both co-located and remote clients.

Fig. 1: Examples of different tools and models in BIMXplorer.

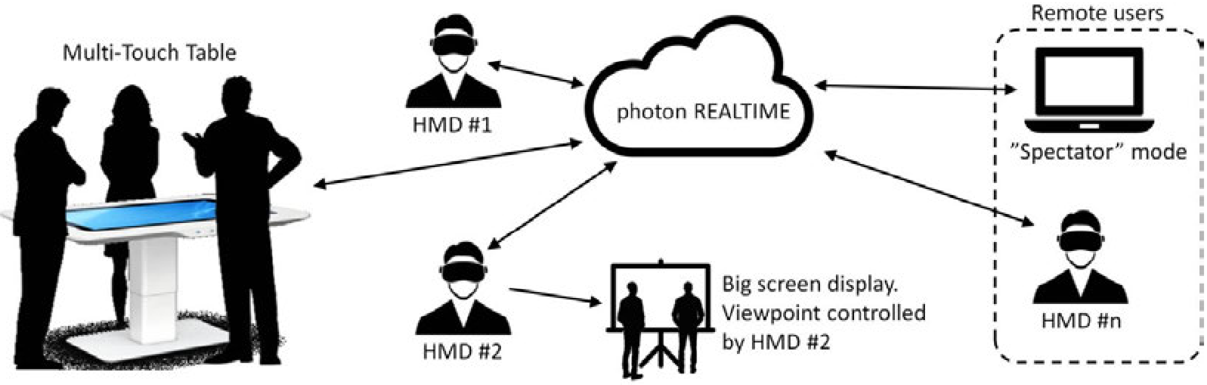

Fig. 2: System overview using a sample configuration.

2.1 Prefab database creation

Site layout planning in 3D mainly consists of placing 3D-objects that represents temporary structures, machines, and temporary placements for materials as instances in a 3D-environment. We refer to these objects as prefabs, and the motivation around the creation and organization steps was to allow easy creation from already present 3D-models or BIMs. We therefore implemented support for also importing .skp- and .fbx-files using their respective APIs, and then simply implemented a tool in BIMXplorer to select and save a single or multiple objects as a prefab, with the current view as the preview images (Fig 3, middle). Depending on the type of component it also makes sense to be able to select the center of rotation (i.e. during planning), which is why we optionally support placement of a pivot point using a standard translation gizmo. Finally, with a number of prefabs created, a user can then organize and group the prefabs in different folders and subfolder (Fig 3, right) before selecting a root-folder, which will then import and create a prefab database file (.pfd-file), which will have the same organizing structure. Assuming a very large number of prefabs are originally created, this makes it possible to select a subset for a certain planning workshop, like a template. The whole procedure is illustrated in Fig 3, where a SketchUp scene is first imported (left), followed by selection and isolation of a skip container that is save as a prefab (middle), and finally the folder structure where it is saved (right). Note however that this only has to be done once, to create a pfd-file, which can then be re-used as a template in several planning workshops.

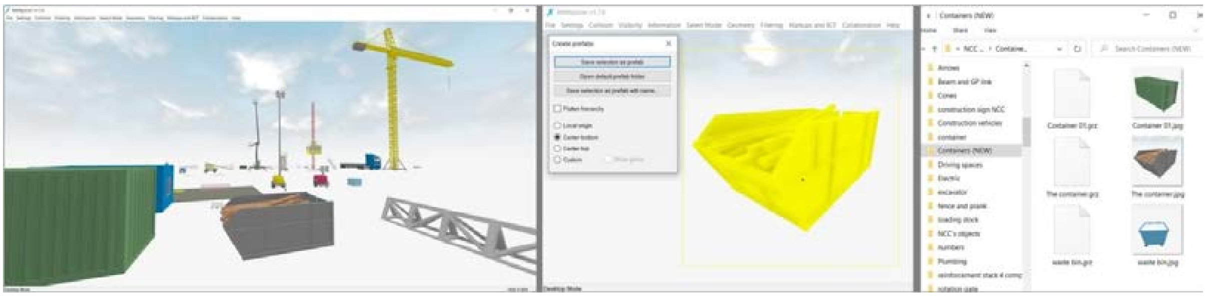

Fig. 3: The prefab creation process in BIMXplorer and file structure.

2.2 Desktop UI and touch interface

The desktop, multi-touch interface is inspired by our previous work for healthcare environment design (Roupé et al., 2020), but implemented on top of BIMXplorer and much more adopted for use in a openBIM ecosystem. The touch interaction is a custom implementation using "raw" touch events in Windows, i.e. listening to WM_TOUCH events. The actual interface follows that of StreamBIM, with two-finger pan-and-zoom, one-finger for look-around in 3D as well as scrolling in menus, and one-finger tap for selection and button pressing. No inertia is used. The UI is implemented with Dear IMGUI and has a collapsible toolbar with functionality for adding objects, sectioning, visibility and filtering, settings, and file I/O. As seen in Fig 4, sectioning is done by selecting a level/floor from IFC-data and can then be adjusted up or down. With BIMXplorer already using Dear IMGUI for the tools palette in VR, it was possible to directly re-use certain UI-element, such as for filtering and sub-model visibility. In this context, the filtering capabilities are particularly interesting as it allows for controlling visibility and colors of objects based on their properties. This makes it possible to filter out certain scenarios if the data is available in the IFC-file(s), such as subcontractor or scheduling information. For instance, if scheduling information is present, it's possible to filter out only those objects that will be constructed at a certain point in time, making site layout and logistics planning adhere to the real construction schedule.

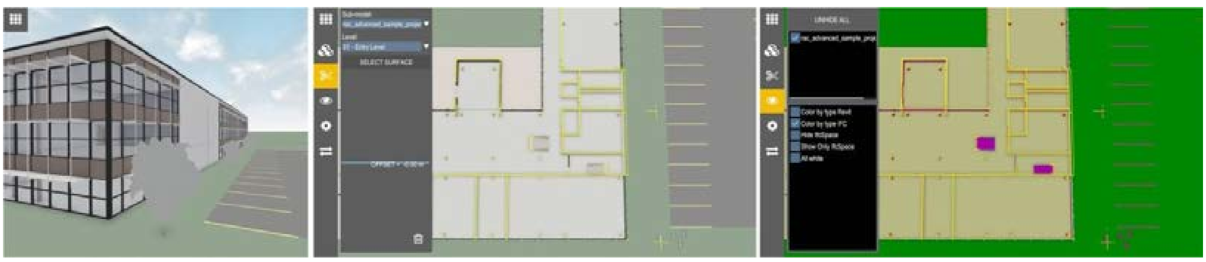

Fig. 4: The multi-touch table interface, including sectioning-by-floor, and filtering in the top-down view.

All the imported prefabs (i.e. the prefab database) are accessible in a folder structure and are added using drag-and-drop as illustrated in Fig 5. Selecting an object by tapping brings up the context menu making it possible to hide or delete the object. A selected object – or multiple selected objects – can directly be moved horizontally by dragging or rotated using the "gizmo". By toggling one of the context menu buttons, vertical movement is activated instead.

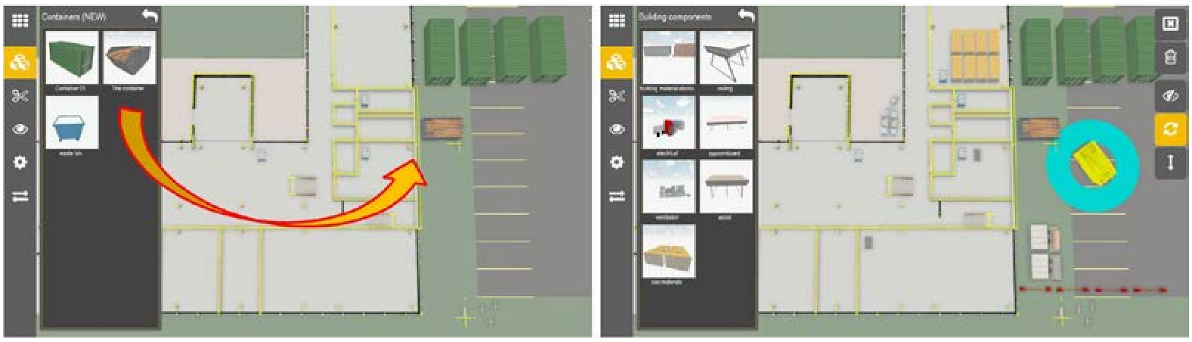

Fig. 5: Adding prefabs using drag-and-drop (left), and context menu and rotation gizmo (right)

2.3 VR interface

A similar interface for adding objects is implemented in VR as well by dragging and dropping prefabs from the tools palette, as seen in Fig 6, left. In fact, as this is done using Dear IMGUI the actual code is almost identical, which is one of the main benefits of using the same UI toolkit for both 2D desktop and immersive VR. Moving, re-placing, and rotating objects is also similar, but with gizmos more adapted for use in a pure 3D environment (as opposed to a 2D desktop interface).

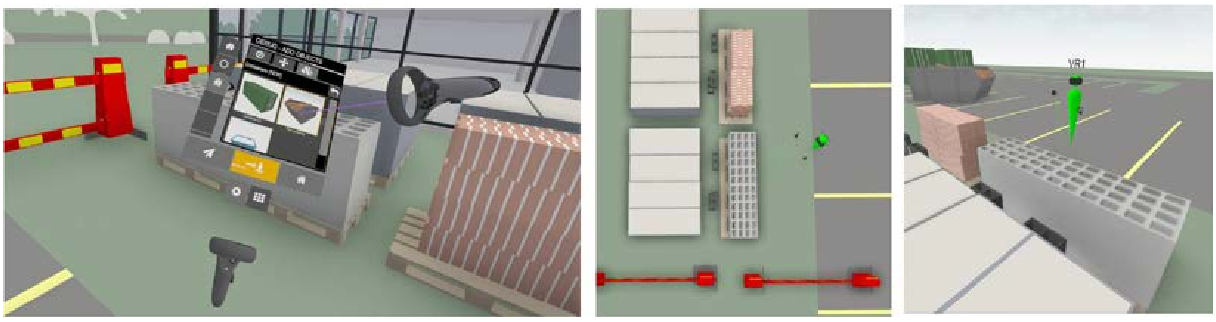

Fig. 6: Adding prefabs using drag-and-drop in VR (left), view of VR avatar in other clients (right)

2.4 Multi-user and collaborative planning

The multi-user functionality already present in BIMXplorer was extended to also support collaborative planning and adding, translation, and removal of instanced prefabs. The implementation is based on the Photon Realtime SDK and uses no other server infrastructure. All clients load the same model (.bmx-file) and prefab database (.pfd), and then call *"JoinOrCreateRoom"* (Photon API) with a previously agreed upon meeting ID. The first client that calls this function performs the actual creation of the Photon "room", and all other clients will then join it. Every modification to the shared environment, such as adding or translating objects, creating 3D-markups, or hiding/showing objects is transferred to all clients with the use of Photon events. These events use the *"SendReliable"* and *"Cached Event"* functionality in Photon to make sure that even if a client is connecting much later than the other, that client will still receive all the modification events that have already happened when joining. Position and orientation of all the clients (i.e. the avatars), on the other hand, is using *"SendUnreliable"* because it is regularly updated anyway. However, in either case, no 3D-data is ever sent over the network, just IDs and transformation matrices. The only exception is 3D markups which are represented as a polyline with 3D coordinates. Still, all clients must be able to uniquely identify objects and prefab instances even if created locally on a single client. The solution was to simply let each client generate and assign a GUID when adding or creating a new object (using *CoCreateGuid*).

2.5 IFC export and openBIM

As previously stated, one of the main challenges when considering site layout planning in a modern BIM context is the need to integrate and align different data sources, from design as well as from production. In essence, this means that we can no longer only produce images and 2D-data, but instead also needs to provide 3D-data. As the solution to consume BIM-data is through the IFC file format it thus makes sense to also use that for producing data. Fortunately, the xBIM framework that is used in BIMXplorer to import IFC-files also has functionality to create IFC-files. With the underlying geometry representation in BIMXplorer being indexed triangular meshes we have chosen to use IFC4 which has support for *"IfcTriangulatedFaceSet"*. The possible options exposed for IFC-export are everything, selected, or visible, which means that it is also possible to only export a subset of the planned components as an IFC-file. This makes it possible to separate the exported IFC-files both temporally and spatially. Furthermore, by using the BCF functionality it is possible to transfer additional information, either back to the design organization or as viewpoints or "points-of-interest" for on-site mobile communication platforms, such as Dalux or StreamBIM. Example of both IFC- and BCF-export is seen in Fig 7, where the sample layout shown in Fig 5 is exported as an IFC4 file and imported into Solibri together with two BCF viewpoints. In Fig 8 the openBIM-supported model- and dataflow is illustrated.

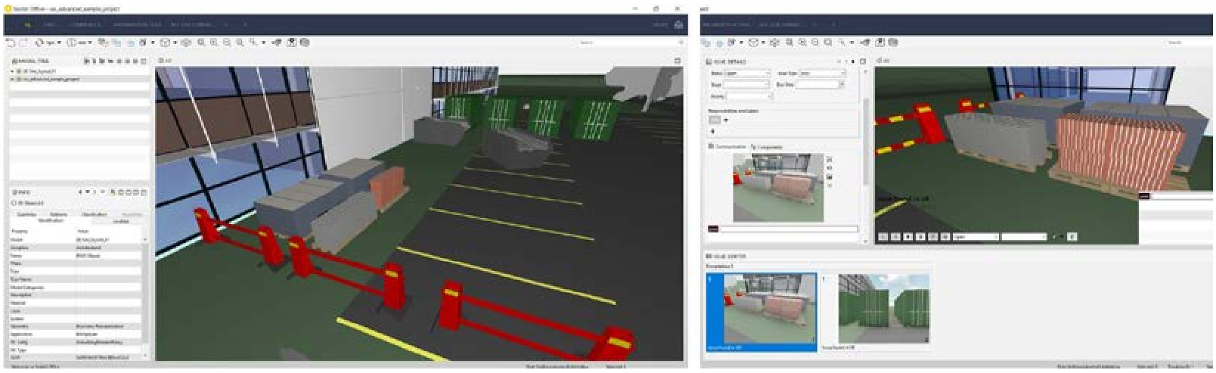

Fig. 7: The "Site component IFC" (left) and BCF (right) exported from BIMXplorer opened in Solibri.

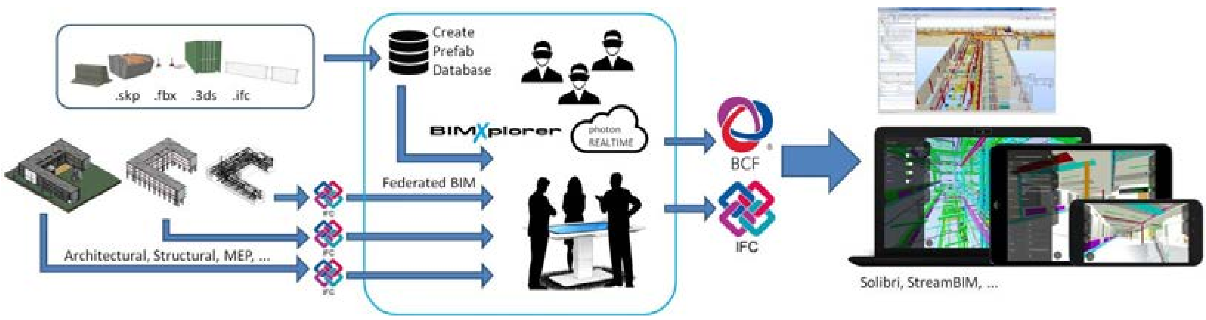

Fig. 8: Schematic illustration of the openBIM-supported 3D model- and dataflow.

3. EVALUATION

The developed system has been evaluated during a workshop session with representatives from the construction industry. The primary focus during the workshop was around safety and specifically to see if immersive VR could provide benefits in detecting hazardous situations compared to only using traditional 2D drawings. As part of that investigation the site layout planning functionality was tested and evaluated with respect to placing guardrails and temporary covers. The complete setup during the workshop can be seen in Fig 9. A single, large touch screen was used together with two VR headsets, one of them also connected to a projector. Seven (7) participants, both from design and production, took part in the exercise which lasted around three hours. The test case was the 6th floor of the Kineum project, a 27 story tall building recently constructed in Gothenburg, Sweden (Fig 10). This project was chosen due to the sheer size and complexity, but also because design documents included both BIMs and traditional 2D drawings. In the first part of the exercise the participants where ask to identify areas that can be hazardous during construction using only 2D drawings. In the second part the same was done, but this time in VR using multi-user. In the third part, safety equipment, such as guardrails and covers, was placed and updated using the site layout planning tools. However, note that the possibility of adding and moving objects in the immersive VR interface was not implemented at the time of the workshop. Still, all modifications done on the multi-touch table (add, move, delete, etc.) was updated in the VR interface. As an additional and final step, the evaluation was completed with a post-workshop interoperability test.

Fig. 9: The setup during the workshop.

4. RESULTS AND DISCUSSION

4.1 2D vs. VR and multi-touch table for safety review

Except for the outer perimeter, there were mainly four areas that required safety precautions; three large openings and the area around the elevator shafts. From the 2D exercise only two participants managed to identify all of them. Among the other participants there were various differences, but they all missed the triangular shaped opening, which is actually quite difficult to spot in 2D due to its somewhat uncommon shape. However, when moving on to the second part in the exercise, using VR, all areas requiring safety precautions were easily identified by all participants. On the one hand, this could be seen as an unfair comparison, considering that there were elements of collaboration with the multi-user setup. On the other hand, this was the first time using VR for four of the participants which introduce an extra layer of mental workload before navigation and interaction with the different tools are fully understood. Regardless, it was clear from the participants' response and comments that VR provided a much more immersive and true-to-scale experience that allowed all of them to easily detect all floor openings, including the one that most missed in the first part of the exercise. Still, already by inspecting the model top-down view at the touch table, openings were much easier to detect than in the 2D drawing alternative due to the 3D perspective and shading. However, VR was considered particularly valuable in complex situations that are difficult to assess through traditional methods. Furthermore, with the general understanding that every action in construction carries some level of risk to workers' safety, all participants acknowledge the unique properties of VR to understand and comprehend complex design choices from a safety and constructability perspective, thereby improving safety planning and design. Finally, in addition to simple identify the hazardous areas, the participants were also asked to use the markup tool to illustrate suitable safety measures, as seen in Fig 11.

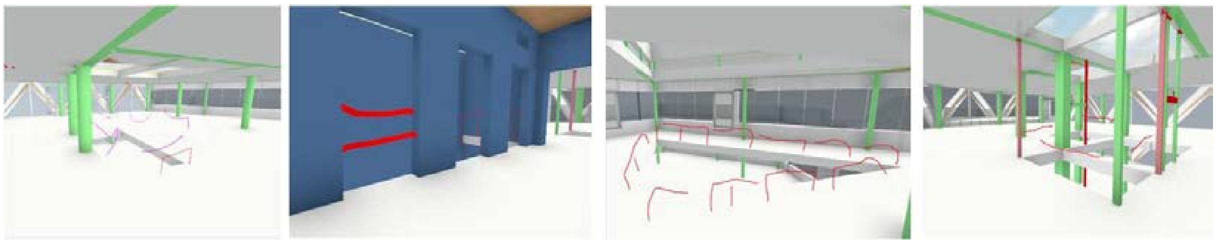

Fig. 11: Participants used the markup tool in VR to illustrate where safety measures were needed.

4.2 Planning and collaboration

In the third part, the top-down interface on the multi-touch table was used to place safety measures around the identified hazards, the results of which can be seen in Fig 12. One participant had experience from similar planning settings and specifically around the difficulties in getting people to interact with BIMs and 3D models on touch- and smartboards using desktop BIM-viewer applications and was surprised to see how easy and intuitive it was to add new components to a highly complex BIM using the multi-touch interface:

“We have always had problems in the past of getting non-experts and 'normal' people to be able to interact with these large and complex BIMs”

The main activity was around the touch-table and in that respect some participants indicated that they felt a bit isolated when immersed in VR, even if this was a multi-user session. Similar observations have been noted in previous research as well (Roupé et al., 2020; Truong et al., 2021). However, this might have been different if the functionality of adding and moving objects also in VR had been available during the workshop. Other than making markups, the VR users could only tell the other participants what to do and therefore became more of observers and reviewers, than that of creators. Still, participants around the touch-table liked that they always could see where VR viewers were. On the other hand, it was clear that immersive VR and the 1:1 scale was superior in order to understand narrow or wide space and to identify safety and constructability issues. For instance, the initially placed safety precautions for the elevator shaft section were later identified as too "light", which was not as easy to spot in the top-down desktop interface, but very obvious when seen in a first person, true-to-scale perspective. This actual combination and collaboration using multiple interaction and visualization interfaces was also identified as an efficient setting in order to increase understanding and share and exchange knowledge across professional disciplines. In particular, it was stated that the collaborative walkthrough between design and construction safety team can increase designers’ awareness and foster designer contribution for safety planning.

In addition to the request for also adding and moving components in the VR interface, there were several suggestions for improvements and also some identified issues. One suggestion that came very early during the workshop was to implement more of a polyline-drawing-tool for the guardrails, as it was found a bit inefficient and time-consuming to drag and drop all the individual sections and then place and rotate them correctly around the openings. To some degree this was also made extra cumbersome because the ray-intersection routine (i.e. hit-testing) does not use a dedicated collision shape but instead uses the actual geometry, which in the case of the guardrails consists of thin bars that are difficult to hit. The concept of a polyline drawingmode was also suggested for an area-drawing tool (i.e. surfaces). Even if 3D components are preferred as representations several participants highlighted the need to be able to also illustrate areas. Further suggestions included the possibility to group objects together to form composites and to be able to copy-paste objects (both individual and composite groups).

Fig. 12: Guardrails, temporary covers, and fences placed using the top-down interface on the multi-touch table.

4.3 Interoperability

All the safety equipment that was added to the project during the workshop was exported as a single IFC-file and then imported into both Solibri and StreamBIM together with other disciplines in the project (e.g. architectural, structural, MEP, etc.), which can be seen in Fig 13. In effect, this introduces a new discipline to the federated BIM – *Temporary Safety Components*. Although the IFC-export wasn't actually used during the workshop (i.e. it was imported into StreamBIM and Solibri at a later time), the functionality was discussed and the prospect of having an IFC-file with temporary structures and site objects as output sparked many ideas from the participants. For instance, it meant that all other tools that are part of the BIM palette, such as automatic quantity takeoffs and clash detection, could now also be used for temporary structures and components. However, regardless of future applications, the interoperability test successfully completed our initial evaluation which shows that, not only can non-designers collaboratively create construction site layout plans in 3D, but also directly integrate and use this 3D data together with all the other BIM sources received from the design organization.

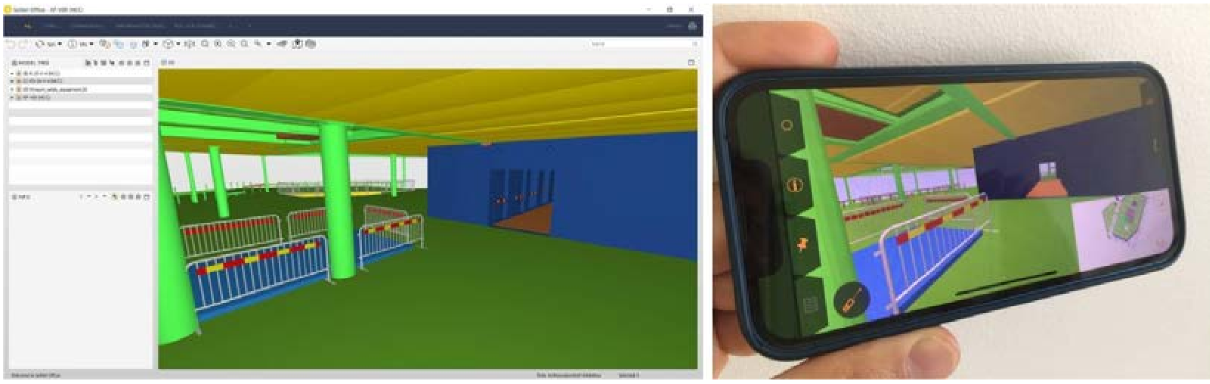

Fig. 13: The "temporary safety components" IFC-file imported into Solibri and StreamBIM.

5. CONCLUSIONS

In this paper we have present the design and technical details of a user-friendly, IFC-compatible software system that supports collaborative, multi-user creation of construction site layout plans using both multi-touch table and immersive VR. In addition we have presented an initial evaluation of this system with respect to safety review and planning and layout of temporary safety components. For the specific task of identifying hazardous situations, the presented system was found to be more efficient compared to only using traditional 2D drawings. The multiple interaction and visualization interfaces were found to complement each other and to provide an efficient environment for collaboration and knowledge sharing across different professional disciplines. In this context, the immersive VR interface was found to be superior in order for users to understand space, dimensions, and complex designs, whereas the multi-touch interface was considered very intuitive and easy to use with suitable tools for adding and modifying 3D components. With the ability to also export the planned environment as an IFC-file the system has been shown to support creation and continuous update of 3D site layout plans that can be fully integrated with a projects other BIM sources and tools.

For future work it would be interesting to implement some of the request and suggestions that were proposed during the evaluation, such as a polyline drawing tool for guardrails and grouping of components. Furthermore, it would be interesting to explore and evaluate the system with a more dedicated focus on all aspects of construction site layout planning, not only safety.

APPLICATION OF SMART TECHNOLOGIES FOR ASSESSING USERS' WELL-BEING FOR IMMERSIVE DESIGN STRATEGIES: A STATE-OF-THE-ART REVIEW

Eleonora D'Ascenzi, Vito Getuli & Irene Fiesoli
University of Florence, Florence

ABSTRACT: *As never before, during the COVID-19 pandemic, the effectiveness of the digital design strategies on the user's well-being has been questioned. However, a research branch astride digital design and neuroscience able to overcome net discipline borders to analyse users' well-being seems to be lacking. Today mainly qualitative data are used in the design field for the investigation of users' quality experience. Although fundamental, they also have great disadvantages such as unanswered questions, unconscientious responses, and respondents' biases. As such, a systematic state of art review is presented to find methodologies and tools currently used in medicine to identify the impact of digital design strategies (XR) on users' well-being through quantitative and objective data. The main technologies used for this purpose have been synthesized in a schematic chart by reporting the principal related biometric data (skin conductivity, heart rate metrics and breathing rates), as well as other technologies such as video/images/audio analysis based on sensors and machine learning to reach out mass numbers. In conclusion, gaps and future applications of this innovative approach within the virtual environment have been identified by the authors.*

KEYWORDS: *extended reality, virtual reality, neuro-design, digital design, immersive experience, user experience, well-being assessment*

1. INTRODUCTION

In these current times and especially within the COVID-19 frame, we are witnessing design calling itself under question by focusing on the redefinition of the relationship between users and spaces. Although the importance of quality space has been considered a central point in design planning, the current pandemic is indeed pointing out a global dissatisfaction in this regard (Melone & Borgo, 2020) (Amerio et al., 2020) (Alraouf, 2021). Concurrently, in this perspective, the advanced technologies - such as eXtended Reality (XR)- are increasingly used to early acknowledge people responses in terms of spaces' satisfaction. However, in this regard, is it possible to take a step back and understand the impact that such immersive technologies have on users' conscious and unconscious responses? We're witnessing an increasing digitization both in our daily lives and in the working environment to such an extent that the virtualisation of the spaces -for knowing the customer satisfaction in advance as well as for creating an alternative world- is becoming an increasingly debated issue. For this reason, it becomes critical and extremely relevant to understand what impacts immersive spaces have on people's well-being. Although the importance of user experience in terms of well-being has been traditionally recognised, few studies have been conducted in the evaluation through scientific wellbeing detection in virtual spaces. Furthermore, despite the medical concurrent and ongoing findings for stress investigation, the implications of these results appear to struggle to be applied in digital design and in design in general. In this sense, medicine is today perfecting an ongoing and relevant theme of stress detection analysis since increasingly stress is becoming a serious problem for users' productivity and efficiency in modern society (Feng et al., 2021) (Attallah, 2020). Although stress is one of the major contemporary problems, it is difficult for people to perceive even if they are subject to high stress levels or not (Sağbaş et al., 2020) and for this reason the research field is working on a method that is able to return real-time stress detection. The role of neurodesign should be able to spotlight and investigate not only the effects of environmental factors on people's behaviour but also study user's biometric parameters, to inform contemporary digital design. However, even if today there is an increasing and updated interest on the influence of the digital design on public health, there is at the same time a significant lack of research (Burton et al., 2011). The research methodology has been conducted through a systematic state of the art tools for well-being and stress detection in order to define the main technologies to use for future applications within the immersive digital design.
The methodological review begins with an extensive literature search to attain the desired research items, namely the well-being detection techniques and tools and it ends, through its synthesis, with the interpretation of the most relevant articles. To obtain pertinent articles on the topic, "Scopus", "Web of Science" and "Pubmed" were used as the primary scientific search engines. In order to collect the most used techniques for people well-being by overcrossing net disciplines boundaries through a interdisciplinary approach, the choice fell to these three databases due to their huge coverage of peer-reviewed journals and conference proceedings in environmental psychology, medicine, construction, architecture and design. The time span for publication was not restricted to

Eleonora D'Ascenzi, Vito Getuli, Irene Fiesoli, *Application of Smart Technologies for Assessing Users' Well-Being for Immersive Design Strategies: A State-of-the-Art Review,* pp. 91-99, DOI 10.36253/979-12-215-0289-3.09

recent times due to the willingness to maximise the inclusiveness of the searched items and obtain a wider possible framework. The first step of the literature research has been identified with the definition of the research scope and identification of keywords.
After that, a short listing of the most relevant articles on the theme have been pursued by accurately analysing them for the research purposes, in order to identify the most significative and representative studies. To provide a comprehensive review of the existing literature, this research led to an in-depth study and qualitative analysis of the contents, to present the main analysis carried out on the subject theme. As such, after a first reading of the articles, a deepening phase with the gathering of the main used techniques for well-being detection for evaluating immersive experience was collected. Thus, stress detection tools currently used in medicine have been investigated to understand if could be possible to apply these for well-being evaluation in the frame of immersive digital environment.

2. LITERATURE REVIEW FINDINGS

This section aims at providing an in-depth discussion of the important findings of the reviewed literature with the aim to underline the well-being measurement techniques to be exploited in construction.
The organisation of this section is twofold: first, it presents a collection of stress detection parameters; then, it provides insights regarding the tools to detect stress. Despite the extensive acknowledgment of the impact of the built environment on users' well-being and the recent advancement of smart technologies, just a limited attention has been dedicated to digital design studies of the consequences of immersive environments on the health of occupants. Furthermore, to validate virtual spaces, even a more restricted consideration has been dedicated to the application of smart technologies derived from different research areas. Thus, a focus on the implementation of operating procedures for assessing health and well-being were analysed and reported in the present paragraph by especially referring to psychological and medical research sphere that could be employed in construction and occupancy evaluation. However, not all the initially founded methods have been reported due to the inconsistency between the encountered medical techniques and the application in the digital immersive design field. The below-listed stress detection parameters and tools have been investigated due to their possible use for design research purposes.

2.1 Identification of the main stress detection parameters for stress detection to be implemented for evaluating immersive experience

The following sub-paragraph outlines the output of the research investigation through a brief synthesis of the main techniques adopted for stress detection. As follows, 10 kinds of stress detection adopted data have been identified as well as 6 main techniques to collect them. The following list represents the techniques most used in medicine and psychology for which exist technology and techniques that could be used also in immersive environments for planning process, management and control of virtual reality setting, as well as the detection of quality experience (Fig.1)

(1) Electrodermal activity (EDA)

Electrodermal activity (EDA) also known as Galvanic Skin Response (GSR) or Skin Conductance (SC) is an objective tool of stress indication. EDA measures the changes in conductance at the skin surface due to sweat production that is representative of the intensity of our emotional arousal. It could be considered as a non-intrusive control tool, and for this reason it has been used in many studies thanks to the use of wearable devices (Acerbi et al., 2017; Anusha et al., 2020; Debard et al., 2020; Delmastro et al., 2020; Kalimeri & Saitis, 2016; Minguillon et al., 2018; Mozos et al., 2017) or embedded sensors (Affanni et al., 2018; Sriramprakash et al., 2017a; Zalabarria et al., 2017) able to detect it.

(2) Heart Rate Variability (HRV)

While Heart Rate is the average number of beats in a minute, Heart Rate Variability (HRV) is defined as the standard variation of inter-beat intervals (Elzeiny & Qaraqe, 2018). HRV could be considered a biometric parameter upon which to determine people's stress conditions. Thanks to the use of a tool able to detect heart signals, HRV could be easily collected through wearable devices (Acerbi et al., 2017; Debard et al., 2020; Rani et al., 2002) or other monitoring tools with specific sensors (Mozos et al., 2017; Reanaree et al., 2016; Sriramprakash et al., 2017b; Zalabarria et al., 2017)(Mozos et al., 2017) or a traditional ECG. HRV could be also combined with social media microblogs (Feng et al., 2021).

(3) Electroencephalogram (EEG)

Electroencephalogram (EEG) is a tool to detect real-time stress in daily life by means of the use of specific headsets and its signals. Many studies analyse stress levels thanks to the use of brain electrodes in this technique (Attallah, 2020; Elzeiny & Qaraqe, 2018; Kalas & Momin, 2016; Reanaree et al., 2016) and helmet(Kalimeri & Saitis, 2016). Although from a medical point of view it could be a non-invasive method thanks to the use of scalp surface, from a perspective of stress monitoring, on the contrary, it is quite intrusive since it requires the use of electrodes.

(4) Electromyogram (EMG)

Electromyography (EMG) could be considered as another stress alarm system. EMG measures muscle response for evaluating electrical activity. It is not easy to apply this method for stress detection in a built environment. Several studies use this method for real-time detection of stress levels (Elzeiny & Qaraqe, 2018; Ghaderi et al., 2015; Minguillon et al., 2018).

(5) Cortisol

Cortisol is a hormone made by the adrenal glands that control mood and fear, and it is one of the most used biomarkers for stress levels. Salivary cortisol increases the brain's use of glucose and is one of the most indicative factors which can analyse stress level. It could be measured by means of pipettors although it is not the most suitable for the built environment even if it is one of the most used in medicine as demonstrated through the huge usage (Pascoe et al., 2017; Qiao et al., 2017; Wells et al., 2014).

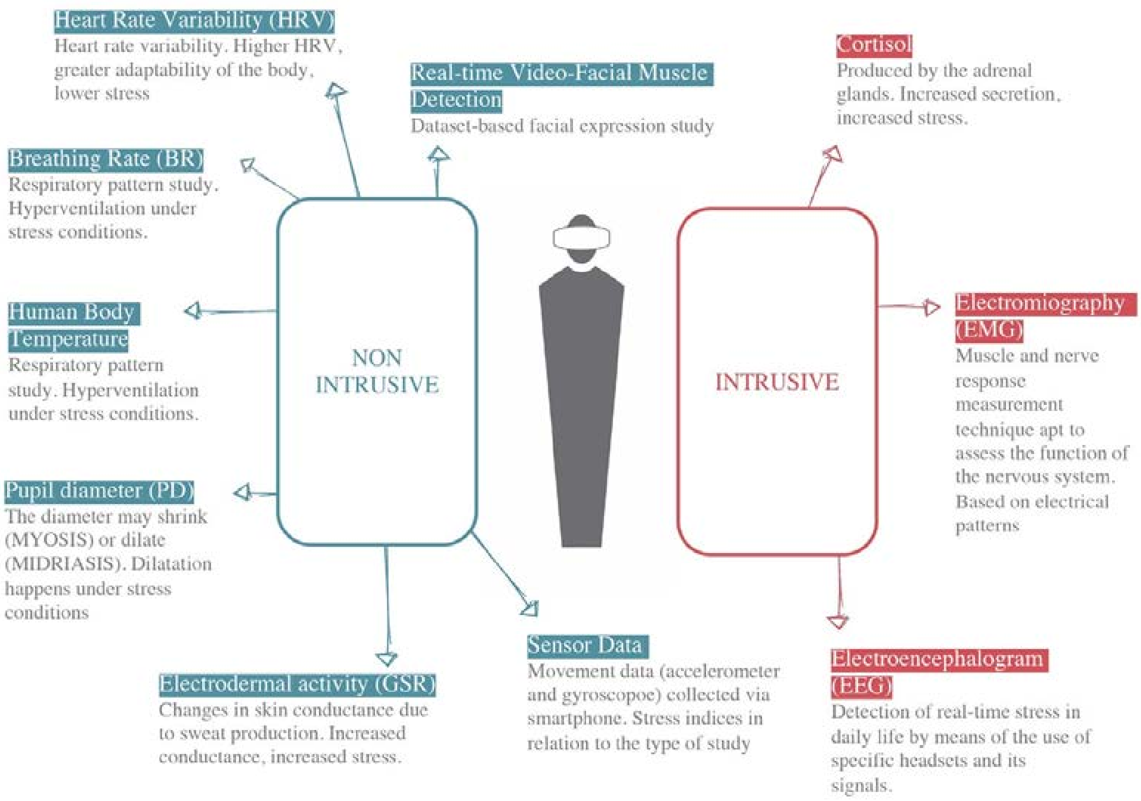

Fig. 1: Non-intrusive and intrusive parameters for evaluating immersive experience

(6) Human Body Temperature

The temperature of the human body could be one of the main data factors upon which it is possible to study stress. According to Rachakonda et al. (2019), in fact variation in body temperature is indicative of the physical and mental condition of people within a specific value range to identify high, medium and low stress. Many studies detect stress through this method by means of contact sensors ((Bin et al., 2015; Rachakonda et al., 2019) or non-contact sensors ((Elzeiny & Qaraqe, 2018).

(7) Pupil Diameter

Pupillometry is a primary index to investigate psychological phenomena. The diameter of the pupil reflects the correlation between its dimension and a human's well-being. The pupil can expand (this phenomenon is called mydriasis) or shrink (in this case it is defined as miosis). When the human body is under stress it induces mydriasis and hence pupil dilatation that can be measured through accurate tools that have also been used in the analysis of stress detection (Al Abdi et al., 2018; Gunawardhane et al., 2013).

(8) Breathing Rate

Another stress biomarker response is given by Breathing Rate. The respiratory pattern can be altered by stress and it can easily be measured with wearable devices(Can et al., 2019; Mozos et al., 2017) or specific tools (Al Abdi et al., 2018). If hyperventilation occurs (around 25/40 breathes per minute) the subject can be considered to be under stress.

(9) Sensor data (accelerometer and gyroscope)

Another index of stress can be indicated through data obtained by accelerometers and gyroscopes. The accelerometer sensor gives real-time information about motion and the related stress interpretation of data as shown in some research projects (Debard et al., 2020; Sağbaş et al., 2020).

(10) Real-time Video-Facial Muscle Detection

Video-Facial Muscle Detection demonstrates how a bespoke machine learning support vector machine (SVM) can be utilized to provide quick and reliable classification. Facial Muscle Detection Algorithm, machine learning and deep learning are today increasingly used for detecting stress (Healy et al., 2018; Zhang et al., 2020a).

(11) Others

Moreover, other studies focus on hand movements (Reanaree et al., 2016), tweeting content (Zhao et al., 2016) keyboard typing (Sağbaş et al., 2020; Vizer et al., 2009) and audio detection (Abburi et al., 2016).

2.2 Identification of the main adopted techniques for stress detection to be implemented for evaluating immersive experience

In this section the main techniques used for collecting stress detection's parameters have been outlined and synthesised as schematically reported. As mentioned in the previous paragraph, several parameters could be analysed for stress detection purposes and along this line, the main adopted techniques to detect (sometimes even simultaneously) well-being variables have been analysed (Fig.2).
Among others, it is worth mentioning:

(1) Wearable devices

Wearable devices are the tools most used to detect stress due to their versatility as well as their non-intrusiveness. Moreover, these kinds of instruments are accessible to all and for this reason they can be easily chosen for daily stress detection studies (Anusha et al., 2020; Debard et al., 2020; Delmastro et al., 2020; Mozos et al., 2017). In regard to physiological data collected, the majority presented on the market are able to detect HRV, EDA, BR, hand movement. Moreover, some smart wearable systems can collect ECG measurement such as Biopacs MP150, MP35 and Shimmer Sensing 3 (Can et al., 2019). Due to their non-invasiveness, they are sometimes employed without the user being aware of it.

(2) Smartphones

Among the unobtrusive devices for ten collections of physiological data, the common smartphone should be mentioned. Multiple features can be extracted from smartphones such as: accelerometer, audio classification, the time and duration of calls, light sensor data, gps information, screen mode changing frequency, videos, wi-fi conversations and so on (Gjoreski et al., 2015). The correlation between stress and collected smartphone data produces significant results. However, according to Can et al. (2019) the low classification of accuracy highlighted by Gjoreski, suggested the importance of adopting an integrated method with the support of the use of wearables and to not rely just on smartphones.

(3) Machine learning

Wearable devices as well as smartphones generate a massive amount of data to be processed, which sometimes necessarily requests the support of machine learning techniques, a branch of artificial intelligence. The issues of the big data generated, as well as their continuous flow demand algorithmic calculation for combining usage behaviours and collected data (Delmastro et al., 2020; Sağbaş et al., 2020). To provide a reliable categorisation, bio-parameters such as Breathing Rate, Galvanic Skin Response and Heart Rate are usually collected and analysed by machine learning systems via the main common classifiers such as K-nearest neighbour (KNN) and support vector machine (SVN) (Ghaderi et al., 2015). Moreover, in the scientific literature, new models for machine learning have been created specifically for detecting emotions through human face recognition (Healy et al., 2018).

(4) Neurosky headset
Stress detection can also be analysed through an intrusive wearable device, namely the EEG Neurosky headset which is a tool to monitor and record the electrical activity of the brain via electrodes placed in the headset. According to Reanaree et al. (2016) the Neurosky Headset could also be complemented by an intelligent watch made by Arduino that has been used in his project (Reanaree et al., 2016).

(5) Applied sensors
A number of applied sensors for Galvanic Skin Response (GSK), Electrocardiogram (ECG), Electroencephalogram (ECC) are available on the market. Differently from wearable and smartphones, these applied sensors are invasive, and the user is conscious of being under observation without specifically knowing the reason why. Although these kinds of applied sensors are different from each other, they can collect multiple signals or one single bio-parameter. At the same time, they can be both easily be portable and/or not movable (Attallah, 2020; Kalimeri & Saitis, 2016; Minguillon et al., 2018; Pandey et al., 2016).

(6) Images/video/ audio capturing tools
Other fundamental tools to be considered other than smartphones are video, audio and image-capturing devices. Among them, especially used for reaching out to a large number of people rather than to an individual person, are video cameras and contact-free camera sensors. By guaranteeing a cost-effective system, these are the most frequently used tools to detect users' facial expressions (Abburi et al., 2016; Zhang et al., 2020b).

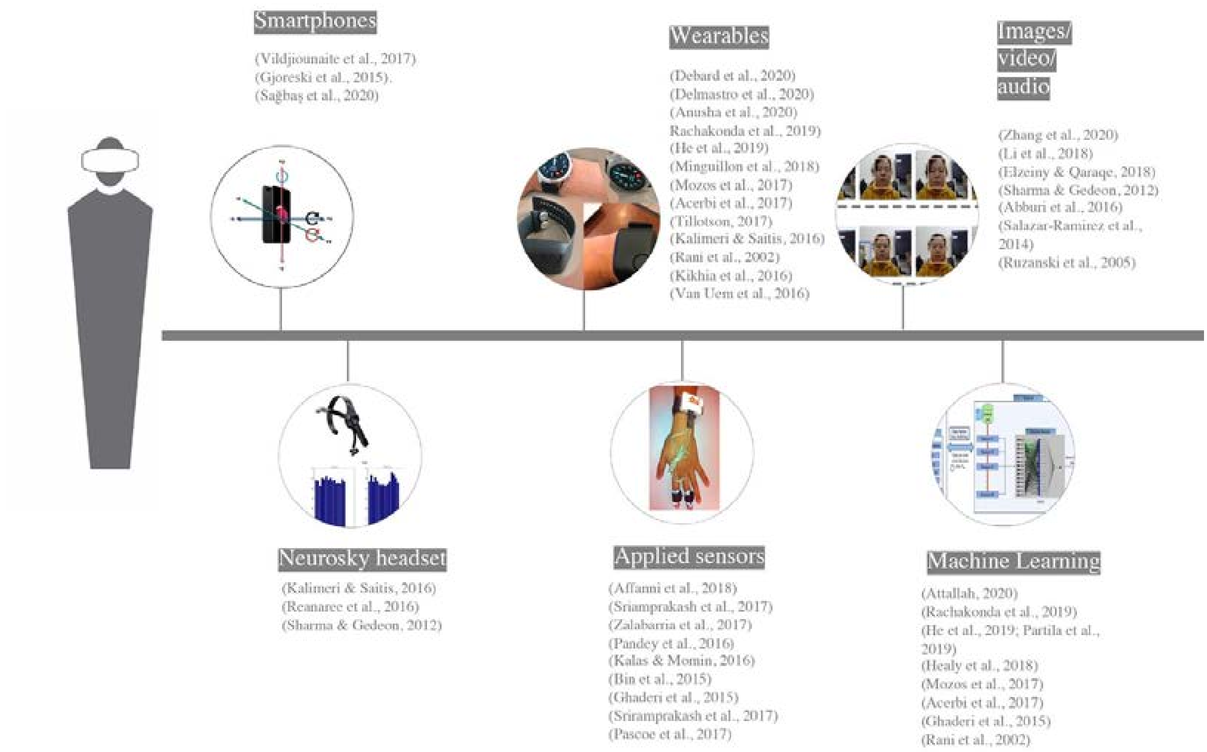

Fig. 2 Non-intrusive and intrusive techniques for evaluating immersive experience

3. DISCUSSION
In order to use them for future applications within the analysis of wellbeing in the digital immersive field, the present review summarizes the main technologies used in medicine. This investigation aims to disseminate tools and methodologies to make designers conscious of the actual impact of the digital environment in daily life and to

encourage planners to better design spaces by bearing in mind the impact of immersive environment on the users' well-being. To address this, a holistic approach is required since the comprehension of the high potential of a interdisciplinary concept that moves from the medical field to design is crucial. Based on the lessons learned from the COVID-19 pandemic, the role of this integrated approach is to provide an informational method that could reduce the gap between architects, engineers, and designers in regard to the expressed or unexpressed responses of users in terms of digital impact of immersive environments. As such, this review investigates the stress bio-parameters to be adopted in immersive digital design to outline possible indicators of high-quality satisfaction for new digital environments, by using not only qualitative data such as interviews and self-reported evaluation, but also quantitative data given by body feedbacks that inform through their unconscious responses. In this paper, the authors have reported two macro areas, namely stress bio-parameters and the related tools, to be applied in design as possible well-being indicators. The most recurring stress parameters as well as the main tools embraced in other fields, have been reported to give a complete overview of the current usage from which digital immersive design could extrapolate the non-invasive techniques with which to ascertain the impact of design strategies on the user's satisfaction. Our body is affected by the choice and design strategies adopted by virtual reality architect, engineers, and designers. There must be a scientifically recognised method to evaluate their implications for users' well-being that goes beyond the traditional qualitative data susceptible to respondents' bias. Choosing the most appropriate tool depends on the availability of resources, targets, and specific research purposes. Some advanced techniques such as video and picture analysis through machine learning, if properly used, could be beneficial for reaching out to the well-being analysis of a mass numbers of users. Therefore, the measurement of eye-pupil diameter and facial muscle movements are required for this type of analysis. It is different in the case of the analysis of a small number of users where artificial intelligence is not required. In this case, the analysis of Heart Rate Variability, Electrodermal Activity and Breathing Rate could be considered as the most informative techniques since, even an ordinary wearable can easily acquaint stress levels. However, adopting a transdisciplinary approach in which these technologies could be supplied to more deeply, investigation of the relationship between users and the built environment is advisable. Although it is widely recognized that human beings respond cognitively, emotionally and physiologically to the built environment, on the other hand, interdisciplinary studies of the physiological well-being connected to immersive environments seem to be lacking, underlining a gap that if investigated could be promising for construction. In this regard, an arising field called "neuroarchitecture/neuro design" is raising the question of how architecture can benefit from its intersection with neuroscience. However, so far, few scientific practical studies have been pursued. For this reason, this conceptual model based on the adoption of practical methodologies represents a central challenge of the present time and is expected to help the digital design researchers to integrate well-being medical analysis into the design evaluation process. Therefore, the authors attempt to improve this conceptual model in future case studies.

4. CONCLUSION AND FUTURE DEVELOPMENTS

The ongoing debate about the increasing digitisazion has raised people's awareness of the impact of the new immersive technologies. Although there is ample evidence in the scientific literature on how the living and working environment impact the psychophysiological states of the users, and despite a recent and ever-growing awareness, only limited attention has been paid to systematic research to find a quantitative tool for the detection of the effect of the virtual space characteristics on the psycho-physiology and perception of the users. The lack of a quantitative approach to evaluate users' impact should be filled by the ability to adapt medical technologies to compelling digital design requirements. Despite growing interest in research into crossing findings from different investigation fields, the application of medical results in digital environment field seems to be defective as demonstrated in the present literature. However, focusing on the trending results could help to explore promising eXtended Reality areas. Thus, by moving forward to the concept of virtual environment design, the questioning of digital spaces should be fundamental to tackle real human well-being intended as mental and emotional health, especially in these current times where the world "metaverse" is increasing advancing. Until today the use of new technologies has been focused on physical built environment rather than on eXtended Reality spaces.

Advanced research and interventions are necessary to deeply investigate the relationship between users and immersive environments. Currently, as far as we know at the time of writing, the use of bio-parameters in digital design is limited to few experimental trials mainly related to marketing field and not yet validated and introduced in the design practice as a validation method for immersive quality analysis. Therefore, if these technologies could be implemented and correctly integrated in digital design, the role of neuro-design would be enhanced. Medicine has a huge potential to inform design, and the impact of medical findings could be applied in digital design. A holistic and interdisciplinary approach could be largely adopted by opening the door to the fruitful pollination of different research fields with a clear goal: to design high quality digital environment place for wellbeing and the high-quality experience of the users. Following this, the authors have identified the applications within eXtended

Reality where the well-being analysis by using stress detection can make the best impact: real-time responsive design based on a human-centric approach; users' well-being monitoring in immersive environments; eXtended Reality "certification" based on human perception; education tools for designers and users to sensitize them to the impact of digital design on users' wellbeing; critical evaluation of extended reality design; real-time interpretation systems which arrange immersive experience variables such as illumination, length of experience, quality of design and so on. This conceptual framework aims to help, during the design process to ensure the proper attention to users' well-being. In short, there is a long road to travel, and much work needs to be done. This review is expected to help designers to rethink the impact of the digital environment in the light of the tangibility of objective and measurable data based on the well-being of users. The COVID-19 pandemic forces us to be aware of digital design implications. For an optimal design experience, our article directs a spotlight on the need for the adoption of medical techniques to evaluate the physical and mental users' well-being of the growing and ever evolving use of eXtended Reality.

INVESTIGATING THE ABILITY OF IMMERSIVE VIRTUAL ENVIRONMENTS TO FACILITATE OCCUPANT THERMAL STATE DATA COLLECTION INVOLVING FACE MASKS

Girish Srivatsa Rentala & Yimin Zhu
Department of Construction Management, Louisiana State University, Baton Rouge, LA 70803, USA

ABSTRACT: *This study examines the capability of an immersive virtual environment (IVE–based) experimental protocol to support occupant thermal state (sensation, acceptability, and comfort) data collection when participants wear face masks. Specifically, the goal is to see if there is a change in local thermal states due to face covering and would such a change affect overall thermal states. A between-subject experiment was conducted with fifty-four participants (27 masked; 27 unmasked) who were exposed to three-step temperatures (18.3ºC, 23.8ºC, and 29.4ºC) in a climate chamber under both cooling and heating sequences. In masked IVE experiments, participants donned a face mask and viewed the chamber's virtual model on a head-mounted display. In contrast, in unmasked IVE experiments, participants didn't use a face mask. Skin temperatures and overall/local thermal state responses were collected during the experiments. They were then statistically compared between masked IVE and unmasked IVE experiments. The results suggest that forehead temperature was significantly different under all step temperatures in the cooling sequence, with mean forehead temperature being larger in masked IVE than in unmasked IVE experiments. Furthermore, in masked IVE experiments, thermal sensation in the forehead, neck, and upper-back increased while the thermal acceptability in those same skin sites decreased, but this difference was not statistically significant. Also, in masked IVE experiments, the overall thermal sensation increased, whereas both the overall thermal acceptability and comfort decreased when compared with unmasked IVE experiments. Nonetheless, this difference was not statistically significant. To summarize, wearing a face mask didn't affect the participant's overall and local thermal states in IVEs, although few statistical differences were observed in skin temperatures.*

KEYWORDS: *Immersive virtual environment, thermal sensation, thermal comfort, thermal acceptability, face masks.*

1. INTRODUCTION

Immersive virtual environments (IVEs) are a technology that combines software and hardware systems to produce a virtual or simulated environment that arranges sensory input in a way that makes the user feel as though they are inside the virtual environment. With the help of this sensory input, the user becomes cognitively engaged and interacts with the elements of the virtual environment (Radianti et al., 2020). Head-mounted displays (HMD) are the most popular method to deliver IVEs because they are easy to set up and provide a wide field of stereoscopic vision. In a true 1:1 scaled setting, IVEs generally provide a favorable environment for sophisticated data collection methods, allowing researchers to effectively modify desired variables and test hypotheses at lower costs and shorter experimental times (Alamirah et al., 2022). As a result, IVEs are more frequently employed to research how occupant perception and satisfaction with the tested conditions are affected by changes in ambient conditions (such as lighting settings) (Heydarian et al., 2016). Specifically, IVEs are used to study the occupant's thermal states (thermal sensation, acceptability, and comfort) by incorporating thermal conditions through the use of closed environments like climate chambers (Rentala et al., 2021). Studies have also examined how well IVEs can simulate actual physical settings when evaluating users' comfort (Yeom et al., 2019). Other researchers used IVE to look at how people's perceptions of their indoor environment are influenced by psychological, physiological, and environmental factors (Chinazzo et al., 2020).

The general IVE experimental protocol for studying occupant thermal states usually consists of subjecting the participants to a building design in IVE while simultaneously manipulating environmental conditions such as operative temperatures, humidity, etc., in a test environment (e.g., climate chamber) and collecting their physiological (e.g., skin temperature, heart rate, etc.) and thermal perception responses (e.g., thermal sensation, acceptability, and comfort) (Alamirah et al., 2022). Normally, during these experiments, the participants do not wear any face coverings or face masks. However, there are certain situations where the IVE experiments must be performed with the participants wearing a face covering or a mask for health and safety purposes, such as during the COVID-19 pandemic. This mask-wearing presents new challenges for occupant thermal state experiments using IVEs. Face mask usage affects the respiratory system. It specifically interferes with breathing normally,

Girish Srivatsa Rentala, Yimin Zhu, *Investigating the Ability of Immersive Virtual Environments to Facilitate Occupant Thermal State Data Collection Involving Face Masks,* pp. 100-108, DOI 10.36253/979-12-215-0289-3.10

causing some carbon dioxide to be expelled and some inhaled throughout each breathing cycle (Lazzarino et al., 2020). Moreover, wearing a mask will directly lower the amount of oxygen inhaled by the body and prevent heat transmission between the facial region and the environment (Hu et al., 2022). Also, when wearing an HMD, the participant's face is already covered, which can trap heat and cause discomfort (Mehrfard et al., 2019). Adding a face mask on top of this can exacerbate the heat buildup, affecting a person's overall thermal state. As a result, it is reasonable to assume that using a face mask during IVE experiments may significantly impact how participants' thermal sensation, acceptability, and comfort are evaluated, thereby impacting the validity of IVE experiments. Therefore, it is necessary to investigate the effect of using face masks on participants' thermal states in IVE experiments. In this study, human subject experiments were performed in IVE under three-step temperatures in a climate chamber with participants who wore face masks (referred to as masked IVE experiments) and participants who did not wear face masks (referred as unmasked IVE experiments). Local skin temperatures and both the overall and local thermal state responses were collected. We hypothesize that the local skin temperatures, local thermal states and overall thermal states between the masked IVE and unmasked IVE experiments will differ significantly. The results of this analysis would provide new insights into developing IVE experimental protocols for occupant thermal state research particularly regarding the mask use. That is, whether to modify the experimental protocol to account for mask wearing or continue using the existing one when face masks needed to be used during the experiments.

2. METHODOLOGY

2.1 Participants

This study was approved by the university's Institutional Review Board. A total of fifty-four participants were enlisted for this study. Half of the participants did the masked IVE experiments, and the other half did the unmasked IVE experiments. Participants in both experimental groups are divided roughly equally by gender and age, with 15 men and 12 women participating in masked IVE experiments with a mean age of 21.9 years and 14 men and 13 women participating in unmasked IVE experiments with a mean age of 22.3 years, respectively. This was done to ensure that gender and age would not affect the results when statistically comparing the two groups.

2.2 Immersive Virtual Environment

Both masked and unmasked IVE experiments were carried out inside a climate chamber that was located on the university's campus. An immersive virtual environment of the climate chamber was delivered via an HTC Vive head-mounted display device. The chamber's 3D model was produced with Autodesk 3ds Max. The model, together with the material textures and lightmaps, was loaded into Unreal Engine 4, as shown in Figure 1. The climate chamber offers space heating and cooling in an IVE experiment for measuring occupant thermal states. At the same time, the users observe the virtual world of the chamber interior via a head-mounted display (HMD).

Fig. 1: Climate chamber's virtual environment

2.3 Experiment Procedure

Between-subject experiments were conducted using the procedure outlined in Figure 2. After the participants signed the consent forms, they were given a demographics survey and were asked to arrive at the chamber in a specific set of clothing (clo of 0.5-0.6), which included trousers and a T-shirt or a long-sleeve shirt. After coming to the chamber, the participants were tested for cigarette or alcohol use using the pre-experiment screening survey in the chamber's resting area, where the temperature and relative humidity were set to 75ºF/23.8ºC and 50% RH, respectively. Participants were excluded from the study if they were found to have used cigarettes or alcohol. The screening took about 10 minutes to complete and allowed the participants to adjust to the chamber's temperature and lessen the impact of their previous thermal state. Then, the participants were asked to enter the chamber's testing area and have the skin temperature sensors (Vernier surface temperature sensors; accuracy: ± 0.5 °C, resolution: 0.1 °C) attached to their bodies at eight locations, i.e., forehead, neck, chest, upper back, forearm, hand, calf and foot.

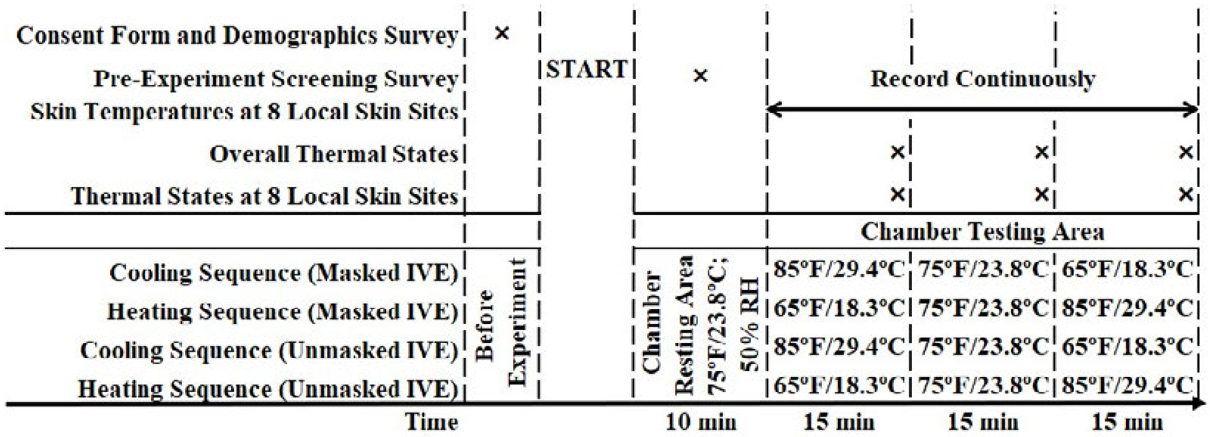

Fig. 2: Experiment procedure

Twenty-seven participants participated in masked IVE experiments, and another twenty-seven participants participated in unmasked IVE experiments. In masked IVE experiments, the participants wore a face mask that entirely covered the mouth and nose area and viewed the chamber's virtual model through the HTC Vive device, as shown in Fig. 3 (left). Whereas in unmasked IVE experiments, the participants only viewed the chamber's virtual model without wearing a face mask (Fig. 3 (right)). Also, both masked and unmasked IVE experiments consisted of cooling and heating sequences that were conducted at least two weeks apart. The cooling sequence had a decrease of three-step temperatures, i.e., 85ºF/29.4ºC –> 75ºF/23.8ºC –> 65ºF/18.3ºC and heating sequence had an increase of three-step temperatures, i.e., 65ºF/18.3ºC –> 75ºF/23.8ºC –> 85ºF/29.4ºC. So, overall there were four experimental sessions, i.e., (1) masked IVE in the cooling sequence, (2) masked IVE in the heating sequence, (3) unmasked IVE in the cooling sequence, (4) unmasked IVE in the heating sequence. The order of the four experimental sessions was random to reduce the order effect and was conducted with a set humidity of 55% RH and a CO_2 limit of 1,000 ppm. From the start of each trial until the end, the indoor control temperature around the participants (sensor placed at the height of 24 inches from the floor (ASHRAE, 2013)) and their skin temperatures were continuously recorded at one-second intervals. Following the stabilization of the indoor control temperature at each step temperature, the participants were subjected to that stabilized temperature for about 5 minutes, and then their overall and local thermal state votes were recorded. The thermal states included responses for thermal sensation, thermal acceptability, and thermal comfort. For local thermal states, only thermal sensation and thermal acceptability were recorded at the exact eight locations where the skin temperatures were sampled from. The ASHRAE Standard 55 Thermal Comfort seven-point scale was used to record overall and local thermal sensation (ASHRAE, 2013). In contrast, six-point scales were used to record the overall thermal comfort and overall/local thermal acceptability (Rentala et al., 2021).

Fig. 3: An experimental session with mask (left) vs. without mask (right).

2.4 Data Processing

After completing the experiments, the mean of the skin temperatures at eight sites and the indoor control temperature for each participant was calculated using the last five-minute data (i.e., data from when the control temperature stabilized to the end of the end thermal state surveys). This 5-minute averaged data was used for all statistical analyses. Furthermore, the mean indoor control temperature was statistically compared between masked IVE and unmasked IVE experiments under all step temperatures in both cooling and heating sequences to ensure that the indoor temperature was properly controlled and remained the same in both sets of experiments. A two-tailed independent sample T-test was used for comparisons. The tests revealed that the p-values in all the cases were not statistically significant ($p > 0.05$), indicating that the control temperature in the masked IVE experiments was comparable with unmasked IVE experiments.

3. RESULTS

Several statistical tests were performed to test the hypothesis that the local skin temperatures, local thermal states, and overall thermal states were significantly different between masked IVE and unmasked IVE experiments under all the step temperatures in both cooling and heating sequences. Independent sample T-tests were used to compare the skin temperatures collected at eight local sites. Wilcoxon Rank Sum tests were used to compare the local and overall thermal state responses. All statistical tests were performed at the significance threshold of 0.05.

3.1 Skin Temperature

Table 1 shows the results where the mean forehead temperature significantly differed ($p < 0.05$) between masked and unmasked IVE experiments under all step temperatures in the cooling sequence. Also, in the cooling sequence, the forehead temperature was higher in masked IVE than in unmasked IVE by an average of 0.5°C under all step temperatures. However, no significant differences in the forehead temperature were observed in the heating sequence under all the step temperatures, even though the forehead temperature under all step temperatures was higher in masked IVE than in unmasked IVE by an average of 1.06°C in the heating sequence. In addition, no significant differences were observed in skin temperatures at other sites (i.e., neck, chest, upper back, forearm, hand, calf, foot) between masked and unmasked IVE experiments under all step temperatures in both cooling and heating sequences. However, like forehead temperature, the neck, chest, upper back, forearm, hand, calf, and foot temperatures were higher in masked IVE than in unmasked IVE experiments by an average of 0.55°C, 0.57°C, 0.49°C, 0.66°C, 0.52°C, 0.48°C, 0.69°C under all step temperatures in both sequences.

Table 1: Independent sample T-test results of skin temperatures

Experiment sequences	Step Temperature	Skin Sites	Masked IVE		Unmasked IVE		p
			Mean (ºC)	SD	Mean (ºC)	SD	
Cooling	65 ºF/18.3 ºC	Forehead	36.75	0.43	36.13	0.71	0.001
	75 ºF/23.8 ºC	Forehead	36.7	0.45	36.17	0.58	0.001
	85 ºF/29.4 ºC	Forehead	36.49	0.41	35.99	0.49	0.001

3.2 Overall Thermal States

The mean overall thermal sensation votes were higher in masked IVE experiments than in unmasked IVE experiments by 0.44, 0.36, 0.4, 0.46, 0.27, and 0.38 (with an average of 0.38) in all step temperatures under both cooling and heating sequences (Fig. 4). This indicates that wearing a mask increases the overall sensation. Still, this increase was not statistically significant ($p > 0.05$) in all conditions. This result is corroborated by an earlier study in a climate chamber that did not use IVE (Yoshihara et al., 2021). On the other hand, in masked IVE experiments compared to unmasked IVE experiments, the mean overall thermal acceptability votes were lower by 0.28, 0.96, 0.72, 0.26, 0.58, and 0.04 (with an average of 0.47) across all step temperatures during both cooling and heating sequences (Fig. 5). Similarly, the mean overall thermal comfort votes were lower by 0.08, 1, 0.44, 0, 0.75, and 0.87 (with an average of 0.52) in masked IVE experiments when compared with unmasked IVE experiments across all step temperatures during both cooling and heating sequences (Fig. 6). These findings indicate that wearing a mask reduces the overall thermal acceptability and overall thermal comfort. However, similar to the results observed for overall thermal sensation, the decrease in overall thermal acceptability and thermal comfort was not statistically significant in all conditions. These results are consistent with an earlier study conducted in a non-IVE climate chamber (Zhang et al., 2021).

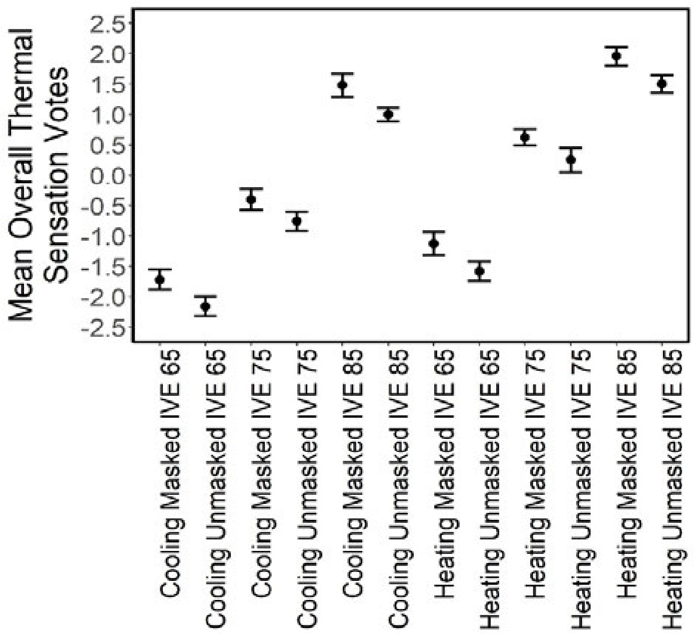

Fig. 4: Mean overall thermal sensation votes.

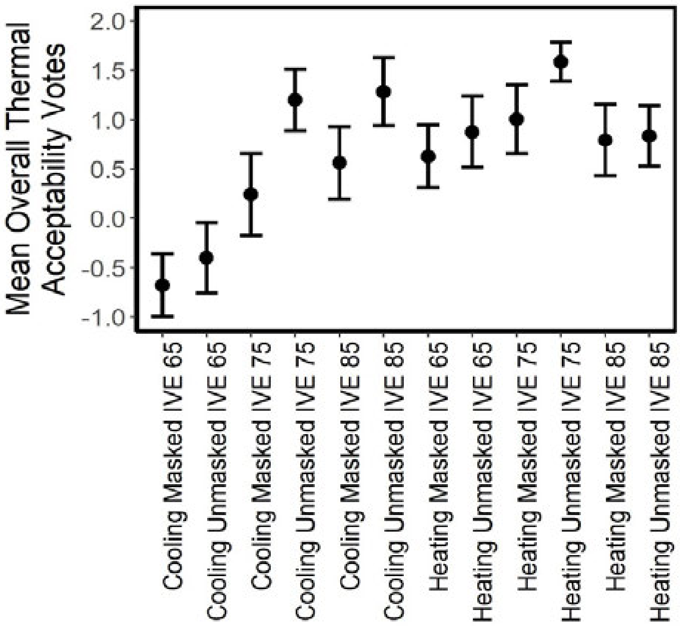

Fig. 5: Mean overall thermal acceptability votes.

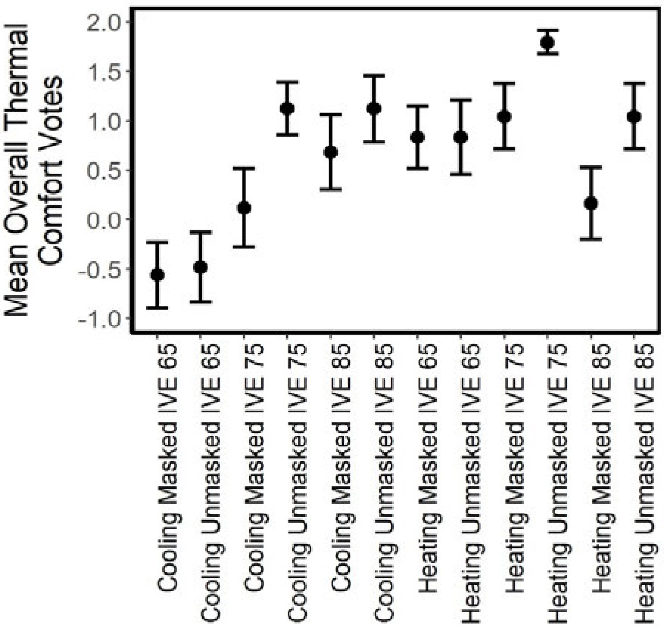

Fig. 6: Mean overall thermal comfort votes.

3.3 Local Thermal States

The thermal sensation and thermal acceptability at the eight local skin sites were also analyzed. The mean thermal sensation on the upper body, specifically at the forehead, neck, and upper back, increased by an average of 0.5, 0.18, and 0.24, respectively, in masked IVE when compared with unmasked IVE under all step temperatures in both cooling and heating sequences (Fig. 7). This finding is partially supported by a prior non-IVE study where they reported higher mean thermal sensations at only forehead and upper back (Tang et al., 2022). Also, the reason for the thermal sensation increase is that mask use can affect the frequency of breathing, leading to heat buildup around the face and neck area, causing the participants to feel warmer (Zhang et al., 2021). On the contrary, the thermal acceptability at those same three skin sites decreased by an average of 0.62, 0.23, and 0.16, respectively, in masked IVE when compared with unmasked IVE, under all step temperatures in both cooling and heating sequences (Fig. 8). However, the increase in thermal sensation and decrease in thermal acceptability at those three skin sites were not statistically significant ($p > 0.05$) in all step temperatures under both cooling and heating sequence even though the forehead temperature was statistically significant in the cooling sequence (Table 1). Similarly, thermal sensation and thermal acceptability at other skin sites (chest, forearm, hand, calf, and foot) were also not statistically significant ($p > 0.05$) between masked IVE and unmasked IVE experiments.

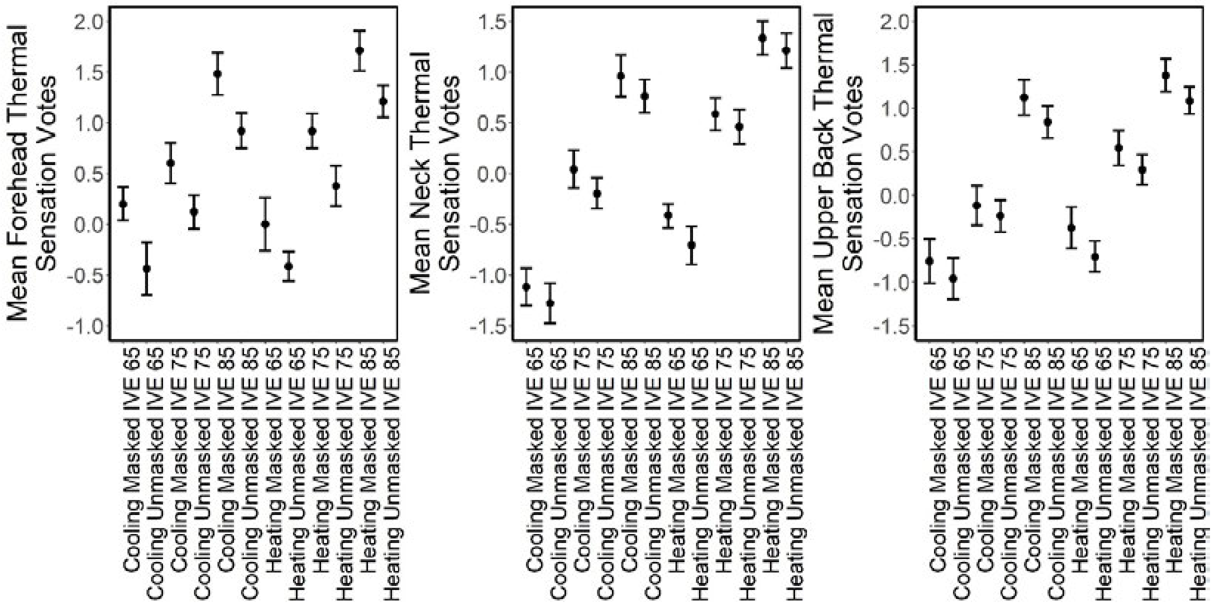

Fig. 7: (Left to right) Mean forehead, neck and upper back thermal sensation votes.

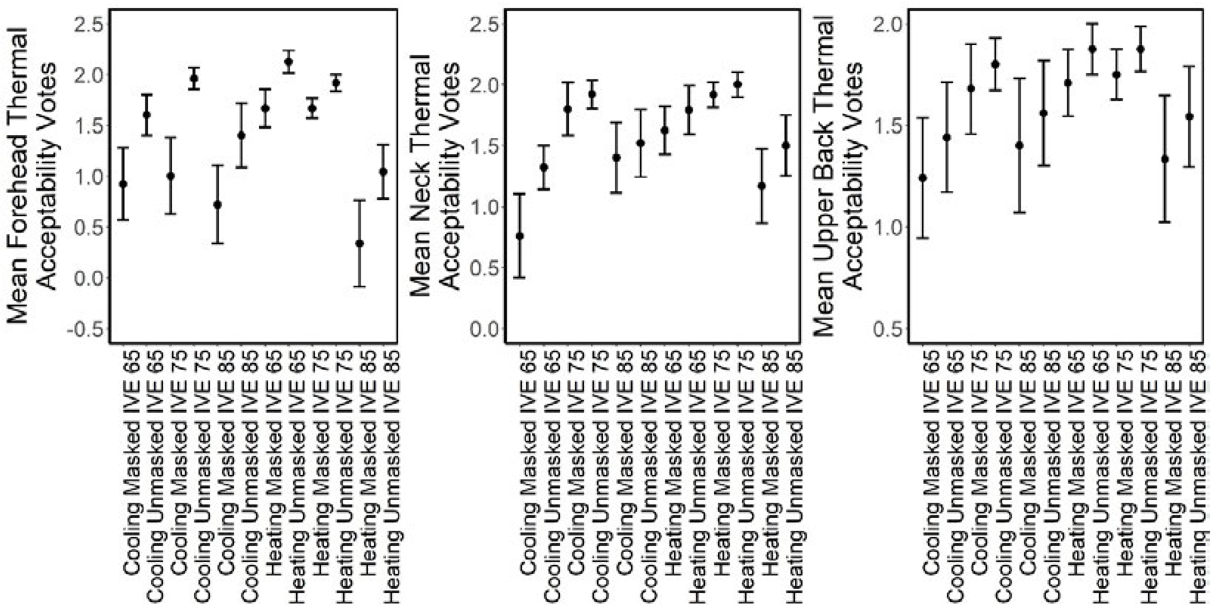

Fig. 8: (Left to right) Mean forehead, neck and upper back thermal acceptability votes.

4. CONCLUSIONS AND FUTURE STUDIES

The study shows that wearing a face covering or mask while performing IVE experiments did not significantly affect the participants' overall thermal states as well as their local thermal sensation and acceptability at the eight skin sites. In other words, an appropriately designed experimental approach can support IVE experiments involving face masks. This approach should include precisely regulating the indoor test environment (e.g., temperature and humidity), offering an adequately designed virtual environment that induces high immersion with minimal motion sickness, and closely monitoring the participants throughout the experiment to make sure the masks are fitted correctly and do not interfere with the experimental apparatus (e.g., sensors). Even though the results were not statistically significant, small differences were observed in the mean votes, such as higher overall thermal sensation and lower overall thermal acceptability and comfort in masked IVE compared to unmasked IVE experiments. Higher thermal sensation and lower thermal acceptability were observed at the forehead, neck, and upper back in masked IVE compared to unmasked IVE experiments. Furthermore, higher temperatures were observed at all eight skin sites in masked IVE than in unmasked IVE under all step temperatures in both sequences. But these results were not statistically significant except at the forehead in the cooling sequence. Also, the increase in forehead temperature did not affect the forehead sensation, acceptability, or overall thermal states. While the results are noteworthy, they may be affected by some limitations. Firstly, the sample size within both the masked and unmasked groups was relatively small (n = 27). Therefore, the lack of statistical significance in the results could be attributed to the small sample size. Future investigations should aim to explore the impact of face masks on the validity of the IVE experimental protocol using a larger sample size. Secondly, this study only accounted for indoor air temperature and skin temperature, and future research may extend its scope to incorporate other environmental and physiological factors, such as the impact of relative humidity, air velocity, skin electrodermal activity, and heart rates. Finally, future studies may test the validity of the IVE experimental protocol involving mask use in different outdoor temperature conditions or seasons.

SEAMLESS INDOOR/OUTDOOR MARKER-LESS AUGMENTED REALITY REGISTRATION SUPPORTING FACILITY MANAGEMENT OPERATIONS

Leonardo Messi, Francesco Spegni, Massimo Vaccarini, Alessandra Corneli & Leonardo Binni
Università Politecnica delle Marche (UNIVPM), Faculty of Engineering, DICEA Department, Ancona, Italy

ABSTRACT: *Augmented reality (AR) still struggles to be widely used in real processes in the construction industry despite its great potential. This is partly due to the difficulties that exist in aligning holograms and maintaining their stability, especially for outdoor applications. In addition, being indoor-outdoor interactions crucial for built environment management, it would be important that AR apps can work seamlessly. Alignment in indoor environments cannot make use of methods such as GNSS, nor can all environments be assumed to have been previously initialized with AR tools. Thus, marker-less AR registration is crucial for indoor applications. This paper presents an approach for marker-less AR registration seamlessly in both outdoor and indoor environments. Real-time kinematic positioning (RTK) and Inertial Measurement Units (IMU) technologies have been chosen for outdoor registration, while image comparison based on convolutional neural networks (CNN) for indoor registration. In this research, the application of these two technologies and their integration have been studied and tested on site on a real Facility Management use case related to a university campus. The proposed approach has shown very promising results in displaying BIM elements of the electrical system seamlessly superimposed through AR to their physical counterparts in mixed indoor-outdoor environments.*

KEYWORDS: *Augmented Reality, Seamless Registration, Feature Matching, Pose Estimation, Real-Time Kinematic, Facility Management.*

1. INTRODUCTION

The AECO industry, although commonly recognized as one of the least digitized industries, is increasingly moving towards embracing more and more computer-based technologies to provide better performance in various stages of buildings lifecycle (Albahbah et al., 2021). The Operation and Maintenance (O&M) phase of Facility Management (FM) accounts for the largest proportion of the whole life costs of the building process (Salman & Ahmad, 2023). The costs of the O&M phase represent 50–70% of the total annual facility operating costs and 85% of the entire lifecycle cost of a building. Ever since the facilities started to become more complex, the day-to-day tasks have also become more difficult. In fact, the increased need of the construction industry for visualization technologies arises from the complex nature of the industry and its high demand for information access for assessment, communication, and collaboration. Lack of coordination between facility managers and field workers results in delays and cost overruns which could easily be avoided with better coordination and visualization tools. In this domain, Augmented Reality (AR) technologies can be used as visualization tools for facilities' O&M tasks and can provide significant advantages. AR impacts the mobile computing industry by radically changing the type of interaction between humans and computers. In fact, such technology creates direct, automatic, and practicable connections between the physical world and digital information by providing a simple and immediate user interface to a digitally enhanced physical world. Since AR allows virtual objects to be simultaneously superimposed on the real world, it helps to locate and view the occluded facilities and equipment and provides maintenance guiding instruction for the field workers (Salman & Ahmad, 2023). Through a hand-held device (HHD) or head mount device (HMD), it augments the real world by making implicit information apparent to the user when required. Many journal publications demonstrate that AR technology can be applied to various domains in AECO industry, especially in the O&M phase of the project lifecycle (Baek et al., 2019; Jurado et al., 2021; Naticchia et al., 2021; Vaccarini et al., 2022). For example, current maintenance practices are characterized by scattered and disoriented facility information that the maintenance staff must fetch through specifications, maintenance reports, and checklists. In fact, 50% of the on-site maintenance time is still spent on localizing and navigating targets inside a facility (Salman & Ahmad, 2023). Even after locating the target, maintenance staff must put additional effort into seeing the target as it could be concealed in the case of piping, overhead ducts or behind a wall.

AR poses a number of demanding technological requirements for its implementation (Costanza et al., 2009). One challenge is related to display technology, which has registered remarkable breakthroughs in the last decades. Precise position tracking constitutes another significant challenge. In order to give the illusion that virtual objects

are located at fixed physical positions or attached to physical items, the system must know the position of relevant physical objects relative to the display system. Since the earliest days, spatial registration has been considered as one of the most important technical aspects of an AR systems and is considered a core part of AR functionality (Albahbah et al., 2021; Salman & Ahmad, 2023). Spatial registration can combine virtual objects and the real environment with the correct spatial perspective relationship by calculating the corresponding relation of both the virtual world and the real-world coordinate systems (Cheng et al., 2020). More in detail, spatial registration is responsible for calculating the user's correct spatial position and orientation in accordance with the real-world coordinate systems (Albahbah et al., 2021).

The spatial registration methods are generally classified into two categories: “marker-based” and “marker-less” methods. The first one is considered the most widely used spatial registration method. Markers can be 2D images with visual features or natural 3D objects in the real environment (Cheng et al., 2020). The high use of this method may be returned to the simplicity, efficiency, and convenience of image recognition for superimposing virtual objects to the real world. Image recognition methods rely on extracting features from images instead of using complicated algorithms for calculating the relationship of relative positions. A similar approach can be applied with invisible markers, such as infrared and RFID ones (El Barhoumi et al., 2022). With marker-less approaches, instead of tracking features of markers, localization technologies are used to control the relative position between the real environment and virtual objects. GNSS is the most popular marker-less localization technology due to its suitability for use in a large open area such as a construction site and the ease of its signal receiving by common mobile devices (Cheng et al., 2020). According to the official US Government information on GNSS, the user range error (URE) for civil commitments cannot reach lower than 0.8 m (Cheng et al., 2020). The localization accuracy of GNSS is much worse in indoor environments, given that the buildings block the GNSS signal. The low accuracy of GNSS is not suitable for activities that require high accuracy or that mainly occur indoors. Compared with GNSS, some other marker-less localization technologies, such as Wi-Fi, Ultra-wideband (UWB), Inertial Measurement Unit (IMU), and Simultaneous Localization and Mapping (SLAM) can provide higher accuracy and can be applied to indoor activities. Another marker-less category is represented by vision-based methods using natural features for registration purposes (El Barhoumi et al., 2022). Each of these methods for spatial registration has its limitations in either accuracy or practicality. To promote the application of AR in the FM, which typically involves both indoor and outdoor environments, an advanced localization method that can provide an accurate and seamless registration in heterogeneous scenarios is needed. In order to cover this gap, a marker-less localization system for seamless indoor/outdoor AR registration has been developed by defining a cloud platform that hosts an indoor registration engine, an outdoor registration engine, plus a switch engine that manages the priority between the two. The developed system, tested on site on a real FM use case related to a university campus, has shown very promising results. The remainder of this paper is structured as follows. In Section 2, a literature review is presented. Section 3 reports the methodology adopted for the development of the proposed system. In Section 4, experiments design and execution on a FM use case are presented. Finally, Section 5 is devoted to results discussion and conclusions.

2. LITERATURE REVIEW

In this section, a literature review concerning existing AR registration methodologies applied to both indoor (Section 2.1) and outdoor (Section 2.2) environments is reported. Understanding strength and eventual gaps of approaches proposed by past studies and commercially available solutions paved the way to the definition of the indoor/outdoor seamless registration system proposed by this study.

2.1 Indoor AR registration

In the AECO industry, several AR registration methodologies for indoor applications have been developed and tested so far. Past studies have exhaustively tested marker-based approaches using visual markers distinctive in the scene (Lee & Akin, 2011; Park et al., 2013). Even though artificial markers are advantageous in terms of robustness in detection, they should be installed all over the facility before on-site activities, such as the actual FM, occur. In addition, visual markers can trigger aesthetic issues because of their distinctive appearance. Alternative solutions are represented by invisible markers, such as infrared (Kuo et al., 2013) and RFID (Carbonari et al., 2022; Naticchia et al., 2021), and natural markers (Koch et al., 2014) that do not aesthetically change the scene. However, even though invisible markers do not have aesthetic issues, they should be pre-installed. Natural markers, instead, have the limitation of depending on signs, including exit signs, fire extinguisher signs, and textual information signs. If the scene does not have such designated signs, the localization can be restricted (Baek et al., 2019). Commercial AR libraries, such as Vuforia (PTC Products, 2023), ARcore (Google LLC, 2023), and World Locking

Tools (WLTs) (Microsoft, 2023) have been tested in indoor environments (Ashour et al., 2022; El Barhoumi et al., 2022). Comparative tests in indoor environments of Vuforia Image Target and WLTs showed better results of the second ones (Teruggi & Fassi, 2022).

Among marker-less methods, GNSS-based AR systems have been largely studied (Kim et al., 2013). However, they are considered inappropriate for indoor applications because of their low accuracy (Chen et al., 2019). Therefore, many studies have employed the Wi-Fi fingerprinting technology for indoor localization purposes (Ahmad et al., 2020; Chen et al., 2019). This approach loses accuracy in the case of multiple mobile devices. In fact, the localization accuracy of the order of 1 m, ensured by Wi-Fi-based collaborative systems (Chen et al., 2019), can be still improved. Another marker-less methodology for indoor localization is based on image comparison. Image-based localization is classically tackled by estimating a camera pose from correspondences established between sparse local features (Ethan Rublee et al., 2011) and a 3D Structure-from-Motion (SfM) (Schönberger & Frahm, 2016) map of the scene (Li et al., 2012). Image comparison methodologies are classified into direct-matching and image-retrieval methodologies (Baek et al., 2019). Direct-matching methodologies do not render images for dataset, but directly find correspondences between 3D structure and the queried image (Humenberger et al., 2020). This pipeline scales to large scenes using image retrieval (Cao et al., 2020). Image-retrieval methodologies attempt to find the closest image to the queried image among the preliminarily prepared dataset. The dataset images can be preliminarily collected by photographs or rendered from three-dimensional structure estimation. Recently, many of these steps or even the end-to-end pipeline have been successfully learned with neural networks (DeTone et al., 2017; Lindenberger et al., 2023; Sarlin, Cadena, et al., 2018). This approach, although may lose accuracy whenever there is lack of context or repetitive elements, has shown great potential to develop indoor AR registration apps with applicability for non-expert users (Baek et al., 2019).

2.2 Outdoor AR registration

AR registration in outdoor environments presents distinct challenges compared to those encountered in indoor environments. Tracking and alignment approaches such as SLAM enable the placement of virtual objects relative to a local reference frame. However, the reliability of such tracking approaches in open environments is compromised due to (i) expanded spatial dimensions, (ii) the absence of readily available reference points, (iii) computational costs in large environments, and (iv) the dynamic nature of external spaces that undergoes frequent changes. Therefore, the AR registration approach in outdoor environments cannot solely rely on local reference systems but must necessarily be based on an absolute reference system, enabling the determination of the geographic pose of both the user and virtual objects (Cyrus et al., 2019; Ling et al., 2019; Marchand et al., 2016). To this end, hybrid AR registration approaches, based on the combined use of IMU and high-precision Global Navigation Satellite System (GNSS) such as the Real-Time Kinematics (RTK), have been pursued for the visualization of underground pipelines and subsurface data (Hansen et al., 2021; He et al., 2006; Roberts et al., 2002), for urban navigation (Guarese & Maciel, 2019; Zhao et al., 2016), for agricultural vehicle navigation (Kaizu & Choi, 2012), and for the alignment of multiple smaller maps from an existing SLAM tracking system (Ling et al., 2019). Even from a commercial standpoint, there are currently not many solutions available that ensure the use of AR apps in outdoor environments either without relying on some kind of additional infrastructures (e.g., markers, QRcode, RFID, beacons, etc.) or without the need of manual/semi-manual alignment procedures, with some exceptions. For instance, Trimble Site Vision (Trimble Inc., 2023) makes use of the built-in GNSS receiver to achieve 1 centimeter of horizontal accuracy under RTK coverage. Similarly, Engineering-grade AR for AEC (vGIS Inc., 2023) developed by vGIS achieves the same centimeter-level accuracy under RTK coverage. In this case the RTK antenna is not directly integrated into the system but needs to be obtained from third-party vendors. However, relying on GNSS technology only means that the system cannot cope with urban-canyon scenarios and indoor environment. Due to these limitations and the persistently high costs, these solutions have not yet experienced widespread adoption in the construction industry. Delving deeper into this last notion, it is noteworthy that the individual components of RTK receivers are economically affordable, thereby fostering the proliferation of applications of this technology (Hansen et al., 2021).

2.3 Research questions

As demonstrated by the literature review reported in Sections 2.1 and 2.2, several AR registration methodologies exist. Limitations of existing indoor AR registration approaches must be considered. Marker-based approaches share the limitation of requiring a preliminary survey to install markers or the existence of signs to be used as natural markers (Baek et al., 2019). Among marker-less approaches, GNSS-based solutions are inappropriate for indoor applications because of the weakness of GNSS signals (Chen et al., 2019), whereas Wi-Fi-based approaches lose localization accuracy in case of multiple mobile devices (Salman & Ahmad, 2023). On the other hand, image-based systems, although may lose accuracy whenever there is lack of context or repetitive elements, show great potential to develop indoor AR registration applications with applicability for non-expert users (Baek et al., 2019). With reference to outdoor AR registration approaches, limitations of marker-less GNSS-based approaches must be considered. First of all, the reduced reliability of GNSS in urban-canyon scenarios (e.g., proximity to urban elements, such as buildings, roofs, trees, and so on) limits possibilities of applications (Cheng et al., 2020; Ling et al., 2019). In addition, GNSS-based solutions are currently expensive (especially for high-precision RTK GNSS systems). Despite this, since single RTK receivers' components are becoming available at affordable prices, the development of in-house devices is showing promising growth (Hansen et al., 2021). Finally, outdoor AR registration approaches are affected by the lack of integration to indoor scenarios, except through the use of additional supporting infrastructure (such as beacons) that constrain the deployment area (Cheng et al., 2020). Considering that indoor-outdoor interactions are crucial for managing the built environment, it would be important that AR applications can work seamlessly even during changes in environment. In addition, in order to ensure a wider applicability of AR, preliminary set up procedures for registration should be as simple as possible. In order to cover these gaps, this study aims to answer the following research questions:

RQ1 What system architecture would ensure a seamless AR indoor/outdoor registration?
RQ2 What technical solutions would make AR registration "plug-and-play" for wider applicability even among non-expert users?

3. METHODOLOGY

3.1 System architecture

In order to answer the research questions (Section 2.3), the system architecture, reported in Fig. 1, has been defined. The proposed architecture is built on top of a BIM Cloud Platform which hosts the following four elements, each playing a crucial role in the overall functionality: (i) the Common Data Environment (CDE), (ii) the Outdoor AR Registration Engine, (iii) the Indoor AR Registration Engine, and (iv) the Switch Engine (Fig. 1). The BIM Cloud Platform serves as a centralized resource and processes hub that facilitates data processing, storage, and distribution. An important characteristic of the platform is its ability to host, localize, and align BIM models, images, and point clouds within a geospatial context. This geolocation feature enables the precise mapping of virtual assets and features to their corresponding real-world locations, facilitating the integration between the virtual and physical realms. One of the key responsibilities of the BIM Cloud Platform is therefore to manage the alignment processes. Particularly, the positioning of images within the platform is achieved by referencing the absolute world coordinates of the acquisition point, along with the accurate rotations. This process ensures that images (and point clouds) are precisely georeferenced and aligned to their real-world locations. This approach lays the foundation for understanding the subsequent paragraphs, which delve into the concept of "images in the vicinity of the user's position".

The CDE is responsible for structured (e.g., .ifc files) and unstructured (e.g., images) data storage. It facilitates accessibility to AR applications through dedicated clients. In this work, the CDE of the DICEA Department of the Università Politecnica delle Marche has been used. At its core, a graph database provides a resilient backbone, offering efficient storage, retrieval, and traversal of interconnected data elements. The next integral components are the two distinct registration engines, specialized for outdoor and indoor environments, respectively. The Outdoor AR Registration Engine, which relies on the combination of RTK GNSS and IMU systems, is tailored to tackle the unique challenges presented in open spaces, such as dealing with the absence of reliable reference points and coping with large and dynamic environments. On the other hand, the Indoor AR Registration Engine is designed to excel in environments characterized by restricted access to GNSS signals, leveraging features like point clouds and aligned images to achieve accurate positioning. To this purpose, convolutional neural networks (CNN) (Sarlin, Cadena, et al., 2018; Sarlin, Debraine, et al., 2018) that simultaneously predict local features and global descriptors have been applied for accurate 6-DoF localization. Finally, the pivotal feature of this system lies in the Switch Engine, which effectively serves as an integrator between the outdoor and indoor registration engines. It is a rule-based engine that assesses the availability of either GNSS signals, or features, or both, and dynamically switches between the two registration approaches to maintain a consistent and uninterrupted AR experience. By synergistically combining the aforementioned four elements within the BIM Cloud Platform, the system architecture (Fig. 1) delivers a robust and marker-less AR system that can seamlessly adapt to both indoor and outdoor scenarios (i.e., answer to RQ1). Although the approach and methodology proposed in this paper are applicable to both head-mounted and hand-held AR devices, the focus from this point forward will be specifically on the usage of Microsoft's AR tool, HoloLens2. To this end, a novel addition to the tool is introduced, developed, and physically realized, enabling a robust connection between the HoloLens2 device and the RTK receiver for precise calibration between the systems. The presented system architecture has been implemented in an AR application for HoloLens2 developed using the C# programming language and the serious game engine Unity3D.

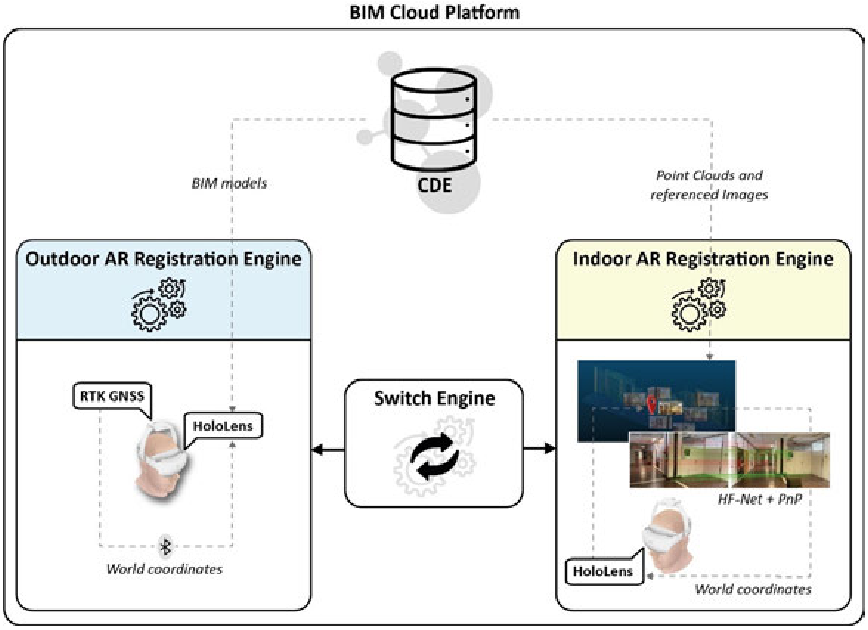

Fig. 1: Architecture of the proposed system for seamless outdoor and indoor AR registration.

3.1.1 Outdoor AR Registration Engine

Following the works made by Hansen et al. (2021) and Ling et al. (2019), the Outdoor AR Registration Engine proposed in this paper relies on the combination of a RTK GNSS tracking system and the HoloLens2' built-in inertial tracking system. By aligning the local frame reference of the HoloLens2 device to global coordinates exploiting the RTK measurements and using the HoloLens2 capability to localize itself in the environment through a real time mapping service, a geographical SLAM algorithm can be developed in order to have an absolute 6-DoF localization of the AR device and therefore aligned virtual objects. Some considerations must be made:

- a general 3D object in the BIM Cloud Platform has its own reference frame located in the world that is fully specified by its geographical coordinates and its orientation with respect to the North: Latitude (°), Longitude (°), Altitude (m), and Azimuth (°). Object's coordinates refer to the WGS-84 standard;
- the coordinates retrieved from the RTK system are based on the WGS-84 standard;
- the RTK receiver has been developed in-house with contained costs in the perspective of widespread adoption;
- the RTK receiver and the HoloLens2 must be solidly connected to each other;
- the RTK system is reliable as long as the receiver is within 10 km of the RTK base station antenna;
- the HoloLens2' local coordinate frame originates at the point where the AR application is turned on.

The problem of placing world-referenced 3D BIM objects into the HoloLens2 local frame can be achieved by fulfilling the following steps (Fig. 2): (i) aligning the local frame with the North direction, (ii) adjusting the object position, (iii) adjusting the object altitude, and (iv) placing objects based on the distance from the observer. The resulting Outdoor AR Registration Engine's process (Fig. 2) is automatically executed (i.e., answer to RQ2). Hence, the outdoor registration process, not requiring any particular action from the user, can find applicability even among non-expert users.

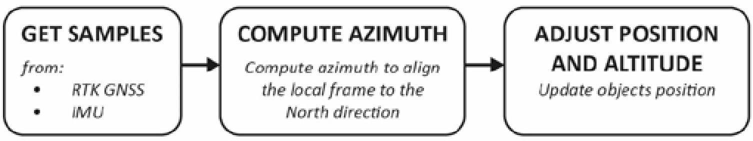

Fig. 2: A schematization of the outdoor AR registration engine's processes.

The first part of the outdoor engine involves the initialization phase of the HoloLens2 position. It includes acquiring initial samples from both the RTK and IMU systems. Once initialized, the RTK system provides absolute 3D coordinates of the body frame (Latitude φ_1, Longitude λ_1, and Altitude h_1), while the IMU provides for local 3D coordinates (x, y, z) and rotations of the body frame. The local equirectangular projection must have y axis directed toward the North. However, at the beginning, the HoloLens2' local frame has an arbitrary unknown orientation with respect to the North. To solve this, when moving between two positions, the performed segment has an orientation β' with respect to the y' axis but the same movement forms a bearing angle β with respect to North as shown in Fig. 3.

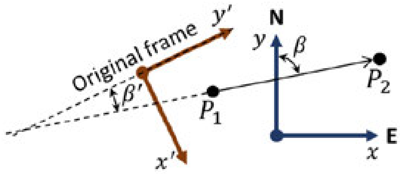

Fig. 3: Bearing angles with respect to North direction.

Given latitude and longitude of the start point (φ_1, λ_1) and latitude and longitude for the end point φ_2, λ_2 of a straight line along a great-circle area, the initial bearing (sometimes referred to as forward azimuth) can be computed as follow:

$$\beta = atan2\left(\frac{sin(\lambda_2-\lambda_1)cos(\varphi_2)}{cos(\varphi_1)sin(\varphi_2)-sin(\varphi_1)cos(\varphi_2)cos(\lambda_2-\lambda_1)}\right) \tag{1}$$

The geographical position of its reference frame (φ_0, λ_0) can be computed by inverting the reverse projection:

$$\lambda_0 = \lambda' - \frac{x}{Rcos\varphi_1} \tag{2}$$

$$\varphi_0 = \varphi' - \frac{y}{R} \tag{3}$$

assuming that $\varphi_0 = \varphi_1$ and where (φ', λ') are the GNSS coordinates and R is the radius of the globe. When the local frame position (φ_0, λ_0) and the object's geographic coordinates (φ'', λ'') are known, the corresponding local planar coordinates can be computed by the forward projection:

$$x = R(\lambda'' - \lambda_0)cos\varphi_1 \tag{4}$$

$$y = R(\varphi'' - \varphi_0) \tag{5}$$

When the observer moves too far from the origin, the local reference should be translated in the new position and the 3D objects must be positioned with respect to the new reference system by re-applying the previous equations. To track the true value of the observer altitude, each time a GNSS measure is acquired for the observer's altitude h', its height in the local coordinate system can be stored for later use as height of the origin of the local frame. Consequently, given the altitude of the local frame (h_0), its height in local coordinates z_0 and the altitude of an object (h''), the corresponding vertical coordinate z of an object can be computed by:

$$z = h'' - h_0 + z_0 \tag{6}$$

If the observer vertically moves the objects at z' to match their true height from the ground, the resulting true altitude is computed and stored. When the observer moves too far from the origin, the local reference should be vertically translated in the new altitude and the 3D objects must be positioned with respect to the new reference system by re-applying the previous equations.

3.1.2 Indoor AR Registration Engine

The AR registration in indoor environments, which contrarily to the outdoor ones are affected by restricted GNSS signals, required a dedicated solution different from the one presented in Section 3.1.1. For this reason, an Indoor AR Registration Engine, based on image comparison with survey data of the analyzed environment, has been developed (Fig. 4). A preliminary on-site survey with a camera and LiDAR scanner (e.g., GeoSLAM ZEB Horizon) must be carried out in order to collect point cloud and aligned photos of the analyzed environment. Alternatively, point clouds can be generated from a photos collection using the incremental Structure-from-Motion methodology implemented by the COLMAP library (Schönberger & Frahm, 2016). The basic idea is 6-DoF localizing the HoloLens2 by comparing a frame from its current view (i.e., query image) with images referenced to the point cloud of the analyzed environment (i.e., reference images). Both reference images and the point cloud are stored in the BIM Cloud Platform. In this study, the Hierarchical Feature Network (HF-Net) technology has been implemented for image comparison (Sarlin, Cadena, et al., 2018; Sarlin, Debraine, et al., 2018). HF-Net consists of a CNN able to simultaneously detect feature keypoints and compute local and global descriptors for accurate 6-DoF localization. The "hierarchical" attribute refers to the HF-Net feature close to the humans' attitude of naturally localizing, in a previously visited environment, with a "from coarse to fine" approach. In other words, humans first localize themselves by looking at the global scene appearance and subsequently inferring an accurate location from a set of likely places using local visual clues. This means that for each HoloLens2 registration call, a coarse search, consisting in a global-descriptors matching between the query image and the reference images, is performed. Afterwards, a finer search based on a local-descriptors matching between the query image's 2D keypoints and the point cloud's 3D points covisibile in reference images is executed. Finally, a 6 DoF pose estimation of the query image is carried out by solving the Perspective-n-Point (PnP) problem (Kneip et al., 2011). The estimated pose is thus the rotation and the translation vectors that allow transforming 3D points expressed in the world coordinate system into the camera coordinate system. These parameters enable the indoor AR registration of HoloLens2's gaze.

The presented Indoor AR Registration Engine's process (Fig. 4), once the survey of the interested area is completed, can be automatically executed (i.e., answer to RQ2). Hence, the indoor registration process, not requiring the user to do any particular actions, can find applicability even among non-expert users.

Fig. 4: A schematization of the Indoor AR Registration Engine's processes.

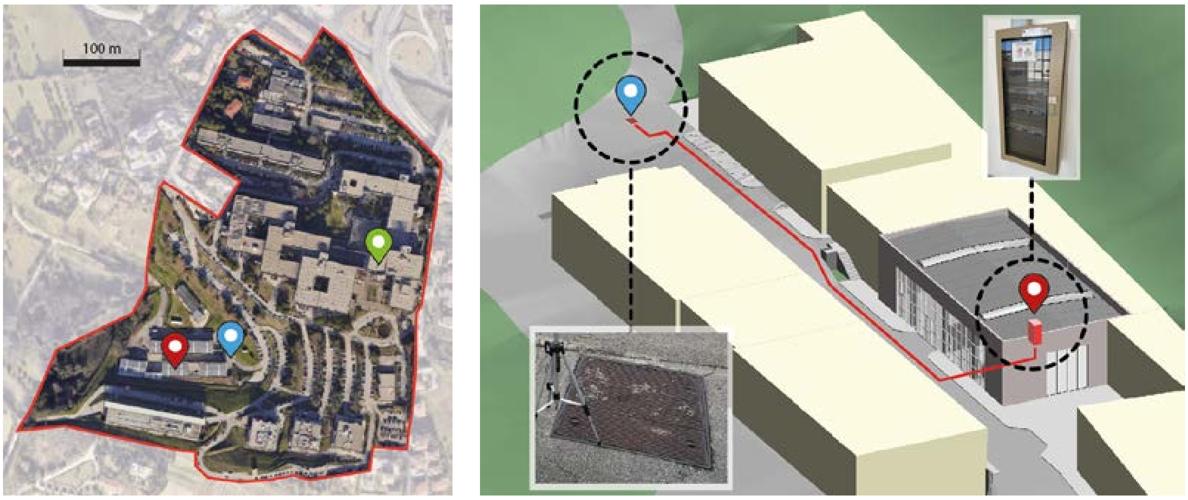
3.1.3 The Switch Engine

As illustrated in Fig. 1, the Switch Engine serves as a seamless integrator between the two types of registration, contributing to answer both RQ1 and RQ2. This component is a rule-based engine that enables seamless indoor/autdoor AR registration. The Switch Engine acts differently according to 3 possible scenarios: (i) RTK only (outdoor), (ii) RTK plus images/point clouds (outdoor), and (iii) images/point clouds only (indoor). In the first scenario, the Switch Engine identifies the availability of a stable and reliable RTK connection in outdoor scenarios. Consequently, the Switch Engine triggers the outdoor AR Registration Engine. The second scenario occurs when, in outdoor environments, images and point clouds are available simultaneously with RTK connection. The third scenario, instead, refers to indoor scenarios in which only images and point clouds are available. In both the second and third scenarios, as the Switch Engine identifies the presence of images and point clouds in the vicinity of the user's real-world position (e.g., when approaching a previously surveyed building or asset), the system triggers the Indoor AR Registration Engine. At that point, the system entirely relies on images and point clouds for AR registration.

4. EXPERIMENTS

4.1 FM use case

The methodology proposed in this study has been tested on a FM use case based on a university campus, assumed as case study. Specifically, the study focused on the FM of the Digital Construction Capability Centre (DC3) Lab at the Università Politecnica delle Marche (Fig. 5 (a)). The DC3 Lab, which covers an area as large as 240 m^2, is composed of a main open space, a changing room, an office, and the restroom. Within this context, the management of the electrical system, and in particular of the internal electrical panel of the DC3 Lab, has been considered. During this activity, the technician in charge of FM operations spends time first locating the electrical panel. Then, in order to find the root cause of the problem, the technician may be asked to locate the panel's associated cabling, which extends externally to the building. These cables can be accessed through manholes located on the road in front of the building (Fig. 5 (a)). Once located all the elements interested by FM operations, the technician may need technical information about the electrical system. To this purpose, he/she needs to access the as-built BIM model (Fig. 5 (b)). The implementation of the proposed methodology (Section 3) enables the seamless AR registration in heterogeneous indoor/outdoor scenarios. Testing the proposed system to the presented use case, its applicability in real-life situations will be assessed. As described more in detail in Section 4.2, the experimentation primarily revolves around the utilization of an AR application implemented on the HoloLens2 device.



(a) (b)

Fig. 5: (a) Aerial view of the university campus, assumed as case study, identifying the positions of the DC3 Lab (i.e., red placemark), the manhole cover (i.e., blue placemark), and the RTK base antenna (i.e., green placemark); (b) view of the BIM model of the DC3 Lab identifying the positions of the indoor electrical panel (i.e., red placemark) and the outdoor manhole cover (i.e., blue placemark).

4.2 Experiments design and execution

The developed system has been tested on the selected use case (Section 4.1) following the steps summarized in this section. First of all, a preliminary set-up phase consisting in collecting and initializing input data has been executed. This phase must be executed only once since related input and settings are maintained. It includes:

1. collecting point clouds and aligned photos by carrying out a survey of the DC3 Lab. In this study, the survey has been carried out by using GeoSLAM Backpack Vision (Fig. 6 (a)), which collects simultaneously both point clouds and aligned photos with a single scanning (Fig. 6 (b)). Alternatively, the survey can be carried out by collecting photos (e.g., with a smartphone) and then generating a point cloud through the Structure-from-Motion methodology implemented by the COLMAP library (Schönberger & Frahm, 2016);
2. collecting the BIM model of the DC3 Lab (Fig. 5 (b));
3. uploading the BIM model, point cloud, and images, related to the selected use case, on the BIM cloud platform. It must be noted that point cloud and images result aligned directly from the survey. The BIM model must be aligned to the previous dataset by selected reference points; it must be noted that this alignment is executed only once since it is maintained.

Once the previous preliminary steps are completed, the AR-based inspection of the electrical system related to the selected use case can start. In this study, the head-mounted AR device Microsoft HoloLens2 has been used (Fig. 6 (c)). The AR application, based on the system architecture reported in Fig. 1, has been developed to support the technician inspecting the electrical system distributed in a heterogeneous indoor/outdoor scenario. The main contribution of the proposed system is the marker-less AR registration for displaying BIM models seamlessly superimposed to the whole inspected environment. The following steps have been executed on-site:

4. having on the HoloLens2 with installed RTK receiver (Fig. 6 (c)) and launching the AR application;
5. moving around the campus of the Faculty of Engineering at Università Politecnica delle Marche. During this preliminary step outside the DC3 Lab, the Outdoor AR Registration Engine is triggered in order to localize the user and drive him/her to the DC3 Lab;
6. heading to the internal electrical infrastructure to inspect the electrical panel located inside the DC3 Lab (Fig. 5 (a)). As the user moves from the outdoor to the indoor, the GNSS coverage decreases and the collected dataset (i.e., point clouds and aligned images) is found in the surrounding of the user position. Hence, the system seamlessly switches to the Indoor AR Registration Engine. This transition occurs without interruption as the system switches between registration modes through the Switch Engine's algorithm;
7. inspecting the internal electrical infrastructure, specifically focusing on the indoor electrical panel. During the

indoor phase, the AR application relies on the Indoor AR Registration Engine. It superimposes the digital model of the electrical panel on the real asset to let the facility managers have all the required information from the BIM model for the inspection (Fig. 7 (a));

8. heading to the external electrical infrastructure to inspect the cablings associated to the internal electrical panel. As the user moves from the indoor to the outdoor, the GNSS coverage rises again and the system seamlessly switches to the Outdoor AR Registration Engine. This transition occurs without interruption as the system switches between registration modes through the Switch Engine's algorithm;
9. inspecting the external electrical infrastructure, specifically focusing on the manhole covers located on the street facing the building (Fig. 5 (b)). During the outdoor phase, the AR application relies on the Outdoor AR Registration Engine, leveraging geospatial data retrieved from the RTK receiver to overlay BIM data on the real asset (Fig. 7 (b)).

5. DISCUSSION AND CONCLUSIONS

This paper addresses the open issue of AR registration in mixed scenarios considering that indoor-outdoor interactions are crucial for built environment management. An extended literature review has found limitations of existing indoor and outdoor AR registration approaches, drawing the conclusion that an all-in-one solution conceived for heterogeneous scenarios do not exist yet. Hence, this work focuses on defining and implementing a system architecture for seamless AR registration even during changes in environment (i.e., RQ1). In doing this, technical solutions that would make AR registration applicable even among non-expert users have been considered (i.e., RQ2). In order to answer RQ1, a system architecture (Section 3.1), which delivers a robust and marker-less AR registration system for both indoor and outdoor scenarios, has been defined and implemented. The resulting system has been tested on-site on a FM use case (Section 4.1). The proposed marker-less localization system has been put in place considering the FM of a university laboratory's electrical system. It has been selected because in-charge technicians and facility managers are continuously asked to locate, inspect, and repair interrelated system elements distributed in a heterogenous indoor/outdoor environment. Efficiency of such activities is expected to be considerably improved by accessing BIM models directly superimposed to their physical counterparts. In this study, the head-mounted AR device Microsoft HoloLens2 has been used for 6DoF localization and seamless gaze registration in heterogeneous environments. Indoor inspections of the electrical system have specifically focused on the laboratory electrical panel, whereas the outdoor ones on the related cablings that can be inspected through a dedicated manhole cover. The proposed system has shown promising results in registering the BIM model on-site. In fact, the holograms of the electrical panel and the manhole cover resulted superimposed to their physical counterpart even if they are located respectively in indoor and outdoor environments. This has confirmed one of the main contributions of the proposed system, that is a marker-less AR registration for displaying BIM models seamlessly superimposed to the whole inspected environment. In order to ensure a user-friendly AR registration process in mixed environments, hence providing an answer to RQ2, the proposed system requires only a preliminary set-up phase (i.e., steps 1-3 in Section 4.2) whose settings are then maintained. In fact, as confirmed by experiments, the AR experience is supported by the Switch Engine that manages priorities of the indoor and outdoor AR registration engines. In areas with GNSS coverage (i.e., generally outdoor environment), the Switch Engine delegates holograms superimpositions to the Outdoor AR Registration Engine. This is the logic that regulates the superimposition of the external manhole cover hologram to its physical counterpart. As the GNSS coverage is lost and collected datasets (i.e., point clouds and aligned images) are found in the surrounding of the user position (i.e., generally indoor environments), the Switch Engine delegates holograms superimpositions to the Indoor AR Registration Engine. This is the logic behind the superimposition of the internal electrical panel. As a result, since AR registration is automatically fulfilled in heterogeneous environments, the proposed solution can find applicability even among non-expert users.

Current limitations of the proposed methodology can be traced back to technologies adopted by system's engines. Accuracy loss may affect image comparison, adopted by the Indoor AR Registration Engine, in case of reference and/or query images with lack of context or repetitive elements. Follow-up studies may quantify such limitation. On the other hand, the Outdoor AR Registration Engine strongly relies on the availability of RTK coverage. Despite such technology is currently economically expensive, it is noteworthy that since the individual components of RTK systems are economically affordable, the proliferation of applications of this technology is highly expected. Further studies will be carried out in order to assess registration accuracy of both the Indoor and Outdoor AR Registration Engine. More tests must be carried out in order to optimize switching thresholds based on GNSS coverage and datasets (i.e., point clouds and aligned images) availability in the surrounding of the user position. Future developments will focus also on the definition of a graphical user interface for better managing the entire AR registration workflow. Finally, the proposed system will be provided to non-expert users in order to quantify its contribution in terms of saved time for completing a task.

ABSTRACT: Due to challenges in filling vacant positions and the heightened demands posed on existing staff, employers and project managers are progressively considering the recruitment of inexperienced individuals and seeking strategies to swiftly provide them with essential job-specific knowledge. The potential of industrial AR has been widely researched to support workers in overcoming skill-related knowledge and enhancing industrial processes. However, most studies focus on demonstrating technology usability across different processes and overcoming engineering hurdles on a case-by-case basis. There is no direct benefit analysis on how AR assists construction tasks at human motion level, and how to eliminate the ineffective motions and reduce the duration of effective motions. To fill this gap, this paper first establishes an AR-based near real-time object detection system of small tools and components involved in task processes for egocentric perception of workers in the construction industry. Later, the Standard Operating Procedure (SOP) for scaffolding assembly activities is deconstructed from a manual process into Therbligs-based elemental motions. Finally, this research conducted a comparative study of two prototypes across four dimensions of evaluation. As a step forward in this direction, this paper renews the connotations of Therbligs theory under industry 5.0 era, rethinks the AR-assisted construction task processes, and applies appropriate technologies enhancing the adaptability of AR technology for construction workers' needs.

KEYWORDS: *Augmented Reality (AR); Microsoft HoloLens 2; Object Detection; Task Assistance; Therbligs*

1. INTRODUCTION

The construction industry, characterized as one of the least digitized and toughest labor challenges, urgently seeks solutions for industry transformation (Liao, Iseley, & Behbahani, 2022). In Canada, nearly half of the construction employers are facing the obstacle of recruiting skilled employees over the next three months (Government of Canada, 2022). Meanwhile, increased project complexity implies a high degree of technical, organizational and environmental variability and uncertainty, which leads to greater risk and poorer performance by construction personnel (Peñaloza, Saurin, & Formoso, 2020). In terms of technical requirements alone, project contributors must possess a more reliable and advanced technical qualification (Trinh & Feng, 2020). From the organizational and demographic characteristics, most construction workers rather rely heavily on previous work experience or oral interpretation from peers than follow the correct mechanical operation steps or standardized operation procedure (Ke, 2018). Oyekan et al., propose one of the mental challenges faced by workers, highlighting that as task operations become more complex, the cognitive load on operators also intensifies. This heightened cognitive load can be reflected in various human mental reactions of "Search," "Find," "Select," and other Therbligs. Consequently, due to the greater difficulty in filling vacant positions and the increased demands placed on employed personnel by the complexity of construction projects, employers and project managers are gradually hiring inexperienced newcomers and are eager to find countermeasures to equip them with the necessary job-related knowledge in a short time (Büttner, Prilla, & Röcker, 2020).

Industrial AR, deploying Augmented Reality (AR) technology into dynamic industrial environments targeting inhomogeneous user groups, is seen as potential solution to above dilemma and gains more momentum in both academic and industry (Grubert et al., 2010). The potential of Industrial AR has been widely researched to support workers in industrial scenarios in overcoming skill-related knowledge and enhancing industrial processes (de Souza Cardoso, Mariano, & Zorzal, 2020). In the context of industrial AR, one of the more fruitful and practical projects is the AR-Driven Task Assistance system, which supports workers by providing real-time sequence of assembly operations, tools to be used and collision free assembly paths at the workplace (Eswaran & Bahubalendruni, 2022). Previous research and the authors of this paper have also contributed to the development

Referee List (DOI: 10.36253/fup_referee_list)
FUP Best Practice in Scholarly Publishing (DOI 10.36253/fup_best_practice)
Xiang Yuan, Qipei Mei, Xinming Li, *Integrating Real-Time Object Detection into an AR-Driven Task Assistance Prototype: An Approach Towards Reducing Specific Motions in Therbligs Theory,* pp. 121-132, DOI 10.36253/979-12-215-0289-3.12

of a similar task-assisted AR prototype, which in this paper is expected to focus on the second function for highlighting recommended tools in the user's view while performing a task. Oyekan et al. addressed the mentioned challenge by using Therbligs to embed intelligence in workpieces and make them interactable and communicable. They developed smart workpieces to actively participate in assembly operations by providing their location and operational sequence to an operator (Oyekan et al., 2020). However, their solution may encounter various practical issues, such as overloaded servers when many workpieces update their status simultaneously, mispositioning of sensors and LEDs leading to electronic faults, and greater weight and more challenging manipulation of workpieces due to the addition of extra components.

It is obvious that CV and AR are theoretically linked and mutual fulfillment of each other, as OD could quickly identify and localize specific objects and draw bounding boxes around instances, and AR greatly extends users' capability and experiences by directly presenting detected objects and their digital data in an immersive, interactive way (Z. Wu, Zhao, & Nguyen, 2020). Thus, this paper proposes another computer vision-based solution to the same challenge by integrating OD into an AR-driven task assistance prototype. The choice of deployed technologies is highly related to their ability and referred to prior successful cases. While researchers have established the effectiveness of Industrial AR and its widespread adoption in construction task assistance over the past two decades, most studies focus on demonstrating technology usability across different processes and overcoming engineering hurdles on a case-by-case basis (Kim, Olsen, & Renfroe, 2022; S. Wu, Hou, Zhang, & Chen, 2022). However, user-related assessment of AR assistance systems and worker-oriented effectiveness in industrial environments is not a major focus (Tao, Lai, Leu, Yin, & Qin, 2019). To be more specific, there is no direct benefit analysis of how AR assists construction tasks at the human motion level and how to eliminate ineffective motions and reduce the duration of effective motions.

To fill this gap, this research first reports the further exploration of embedded object detection into the existing AR-driven task assistance prototype developed by authors. The existing AR prototype is targeted at construction workers without any previous work experience to conduct tasks from the beginning. But it only provides fixed information designed in advance about the activities and corresponding contents step by step. More advanced, the prototype developed in this research realizes a real-time detection of multiple scaffolding components, superimposes holographic texts, and gives hints about the correct selections which helps new industry entrants make the right choices from a wide range of tools and components. Later, the Standard Operating Procedure (SOP) of scaffolding assembly activity is decomposed from a human manual process into Therbligs-based elemental motions. It serves as both a specific example to enhance the understanding of Therbligs-based task processes and the foundation of subsequent benefit analysis. To present a more intuitive and clear effect, this research finally adopted a comparative study of a traditional AR prototype and an advanced AR prototype with object detection function from four dimensions of evaluation. It will demonstrate the superiority of the proposed prototype in easing cognitive load, eliciting contextual awareness, and reducing particular motion costs on Search, Select, and Find.

The proposed pathway not only explores the possibility of fully exploiting the advantages of both Augmented Reality and Object Detection, but also allows novice workers to easily perform high requirements tasks with a satisfied completion accuracy. As a step forward in this direction, this paper renews the connotations of Therbligs theory under industry 5.0 era, rethinks the AR-assisted construction task processes, and applies appropriate technologies enhancing the adaptability of AR technology for construction workers' needs. It is expected this research could inspire substantial discussions, enhance the implementation of AR-driven task assistance, and provide a valuable reference for construction workforce preparation.

2. RELATED WORK

2.1 Therbligs overview

Therbligs, first invented by Frank Gilbreth during the early 20th century, is a collection of 18 elemental human mental and physical motions used to describe any task and analyze the motion economy in the workplace (Sung, Ritchie, Lim, & Medellin, 2009). The full collection of 18 Therbligs and their symbols used for depicting when performing work is shown in Table 1. It is useful to use Therbligs to analyze the impact of technology adoption on individual earnings (Wang et al., 2021). The overall efficiency and productivity of tasks will be significantly improved because less time wasted on non-value-added activities and more time spent on productive work. The selection of Therbligs to be analyzed and addressed in this paper is not random. Taking consideration of the capabilities of computer vision technology and extended understanding of Therbligs connotation in the context of the construction tasks, this research mainly focuses on elemental motions of "Search", "Select" and "Find", which is also complied with previous research of Oyekan et al. The description of chosen Therbligs and their connotation in the context of the construction industry could be found in Table 2, gathering previous research and examples mentioned in the conversation with experts in both the ergonomics field and construction industry (David, 2000). For the application scenarios in this research, object detection function will be deployed to reduce the efforts needed by construction workers to search and select the tools and components they need.

Table 1: 18 Therbligs with symbols (Ninjatacoshell, 2012)

Table 2: Description of chosen Therbligs and their connotation in the context of the construction industry

Therbligs	Symbol	Description (Niebel & Freivalds, 2013)	Examples in the construction activities
Search	S	Eyes or hands groping for object; begins as the eyes move in to locate an object.	A construction worker looks for the location of a hammer in a warehouse.
Select	SE	Choosing one item from several; usually follows Search.	A construction worker selects the appropriately sized steel beam from a range of options.
Find	F	Defines the momentary mental reaction at the end of the Search cycle.	A construction worker realizes that he had found the correct 5 mm drill.

2.2 AR for Worker Onboarding and Skill Development

Industrial AR related to worker onboarding and skill development typically falls into two categories based on the research purposes and system functions: Step-by-Step Assistance AR and Hands-on Training AR (Butaslac, Fujimoto, Sawabe, Kanbara, & Kato, 2022). Both systems essentially start from the premise of breaking down knowledge barriers for people who do not have the ability or experience to perform the task contents. The difference between them is Hands-on Training AR will emphasize more on the knowledge stock after using the system and the ability to work independently when users are not equipped with system (Büttner et al., 2020), while Step-by-Step Assistance AR will emphasize the prompts, flexibility, and adaptive to users' needs and facilitate quicker familiarization and more regulated execution of predetermined task procedures (Zhang, Xuan, Yadav, Omrani, & Fjeld, 2023). For the user groups and specific scenarios targeted in this paper, the system built can be categorized as a Step-by-Step Assistance AR system.

2.3 Object Detection for AR

Numerous papers have extensively explored the applications of AR and OD within the construction industry, individually. From data preparation for construction objects, the traditional object detection dataset in the construction context is a collection of various categories (e.g., materials, workers, and their behavior of wearing PPE or falling from height), messy site layout, and large objects (e.g., heavy equipment of crane, excavators, bulldozers, and backhoe diggers). Thus, this research establishes a near real-time object detection dataset for small tools and components involved in task processes for workers' egocentric perception in construction industry. Besides, there exists relatively limited progress in cross-studies of AR and OD in this industry, despite its potential for significant advancement and promising opportunities. Wu et al. measured the utility and effectiveness of AR warning system on onsite construction workers with object detection for tracking onsite workers' locations and dynamic hazard areas (S. Wu, Hou, & Chen, n.d.).

Meanwhile, several other industries, such as smart manufacturing, have conducted successful research on the integration of AR and OD, which can serve as valuable points of reference for further exploration in the context of construction industry. They highlighted possible computing pathways, which could be broadly categorized based on where the data are handled into server-side processing, running locally on the device, or both (Ghasemi, Jeong, Choi, Park, & Lee, 2022). Considering the trade-offs between computational requirement and device limitation, cost and latency tolerance, and network connectivity, this research will adopt Microsoft Azure Custom Vision library as it offers a complete high-level solution suiting for HoloLens computing capabilities and is more common for implementation (Łysakowski et al., 2023).

Several publications investigated the utilization of Microsoft HoloLens 2 along with Azure Custom Vision services for object detection for different purposes (PatrickFarley, 2023). George created a training dataset of 215 images for motherboard and RAM in computer assembly task and reached an 80% match score even in varying environments, but also reveals challenges in limited experimental sample of three participants and false positives in similar components (George, 2021). Fuglseth created a proof of concept program for specific objects recognition and text information visualization in users' view with an open-source Microsoft COCO dataset (Fuglseth, 2022). Although this research demonstrated the technical feasibility of general objects detection in daily life, it lacks a specific use-case context and highlights the limitations of single object detection at a time. Casano used 9 specific classes of the COCO dataset and successfully implemented Azure Custom Vision object detector in the HoloLens for assisting and supporting users for better life or easier work style (Casano, 2021). This paper introduced a more mature and customized system by integrating eye motions, gestures, and voice commands, but faced limitations of predictions efficiency and more rigorous evaluation. Their pipelines to realize the object detection function are similar with each other. HoloLens will take a picture based on users' commands and uploads the picture to the Azure Custom Vision API. After successfully identifying, a label or images will be placed in users' AR view for easier awareness. These studies underscore the growing significance and feasibility of object detection in AR applications, point out challenges associated with their specific applications, and also highlight the potential for further improvements. It includes realizing a real-time object detection, testing its usability in practical application scenarios of industrial tasks, and developing a more powerful AR system to support more reliable multi-objects detection results.

3. PROTOTYPE DESIGN AND DEVELOPMENT

3.1 Prototype Overview

The fundamental idea behind the envisioned prototype involves the utilization of HoloLens 2 as an aiding instrument for promptly identifying objects in near-real time. Its primary function is to aid workers in identifying the precise tools and components required for the ongoing task phase. The target users for this prototype comprises generic individuals who lack prior work experience but seek rapid acquaintanceship with task-related details to ensure adherence to standards. For example, a novice construction worker aims to efficiently select tools and components aligned with the day's designated task and make high-quality commitments to their work activities. The object detection function will be triggered by users' voice commands, touch buttons, or gestures. The objects will be identified according to the current task step and its mentioned tools or parts. Once related objects are successfully recognized, the list of expected results will be three main parts (Farasin, Peciarolo, Grangetto, Gianaria, & Garza, 2020). A bounding box is a rectangle area that represents the object and its region. The class is a tag of the most probable category that the object belongs to. The probability score is the confidence level of algorithms in the detection accuracy and serves as a critical criterion for accepting or rejecting results. All information included will be displayed in the AR view as a visualized cue to workers.

3.2 Hardware and Software

Trimble XR10 with HoloLens 2 - Full Brim Hardhat is an integrated device in which a construction hard hat ensures easier wireless use in safety-constrained environments and the HoloLens 2 is the most commonly used XR headset. Microsoft HoloLens 2 is an ideal platform with high-tech hardware features for computer vision research, and also provides scalability of cloud services and connection to Microsoft Azure AI platform (Ungureanu et al., 2020). It sets a suitable equipment base that could serve multiple roles in proposed research and subsequent research, such as the source for capturing data in the form of video and frames, a computer of executing detection functions, and the tool for visualizing processed data and related task information (Qin et al., 2023). The proposed prototype is developed in the Unity cross-platform graphics engine (version 2022.3.3f1 LTS) using C# as programming language and MRTK (Mixed Reality ToolKit) packages for assets and interactive UI creation. Currently, this research adopted Microsoft Azure Cognitive Services to deploy object detection function by using

REST APIs and client library SDKs.

3.3 Object Detection using Azure Custom Vision in HoloLens

Microsoft Azure Custom Vision services enable users to rapidly customize cloud-based computer vision models and simply manage it using REST API calls. The overall design of architecture is shown in Figure 1. This research created the computer vision project in Azure Custom Vision portal and labelled a total of 12 classes including 1,224 images and 2,008 objects. The training model and its performance is further illustrated in both Section 4.4 and Section 5. The AR application, developed in Unity, adopted MRTK for user interaction and established a connection to the Azure Custom Vision API through endpoints. The Azure platform authenticates the AR system using Azure credentials and provides external GPU computational capabilities to preprocess the images and send the response through Wi-Fi. Once HoloLens receives object detection results from Azure Custom Vision, display holograms or annotations in the user world to indicate the detected objects.

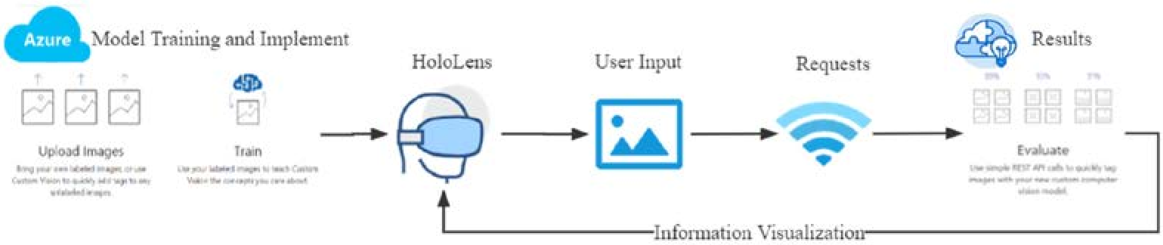

Figure 1 Pipeline design of using Azure Custom Vision and HoloLens 2

4. EXPERIMENT DESIGN FOR EVALUATION

The purpose of designing experiments is to provide a comprehensive insight into whether different forms of AR and varying technologies involved might impact user performance on the motion level. This study is designed with two independent variables: the complexity of construction tasks and the assisted tools used by participants to accomplish these tasks. Each variable is further subdivided, as task complexity has two levels (referred to as Task 1 and 2 hereafter), and using task-assisting tools comes in two types. Task 1 of the Miter Saw Stand assembly is the most complicated to build due to all the extra pieces and steps participants need to follow to make it work properly. Task 2 of the Scaffolding assembly is straightforward to understand what the task entails, but it's also easy to assemble it incorrectly and skip steps on some safety details. Detailed descriptions of these task specifications can be found in the subsequent section (section 4.3). The first type of assisted tools is a conventional AR prototype, which presents participants with guided text, images, and videos (referred to as Prototype 1 hereafter). On the other hand, the second type employs a more advanced AR prototype that includes object detection functionality to highlight crucial components for users (referred to as Prototype 2 hereafter).

4.1 Hypotheses

This research is formulated following hypotheses: **H1:** When using Prototype 2, participants were able to make fewer mistakes and complete the task with higher quality. **H2:** When using Prototype 2, participants were able to complete the task more efficiently, spending less time on "Search", "Select", and "Find" Therbligs. **H3:** When using Prototype 2, participants' cognitive demands were lower, and they can obtain better understandability for task contents and unfamiliar tools. **H4:** When using Prototype 2, participants think it is more intuitive, efficient, and enjoyable to use.

4.2 Bias Control

Potential bias and the effects of irrelevant factors, such as participants' familiarity with AR concepts and interaction, existing skills or learning curve, are more or less to interfere with the experiment results. The counterbalancing design principle and within-subject principle are throughout the entire experimental design and adopted controlling measures are stated as follows. Given that participants might have varying levels of proficiency with AR, some individuals are experienced users and developers, while others have a more superficial understanding [21]. Though researchers prepare an illustrative ppt for introducing experiments, explaining the meanings of prototype UI and panel, and briefly showing how to perform the sample tasks using different prototypes, researchers concern 2D-based explanation is less intuitive than real experience with device. Therefore, the prototype provides a comprehensive quick start guide to build perceptual awareness of AR capabilities and narrow knowledge gap among all participants. To mitigate the potential order effects and learning curve, there is also a clear definition of how to assign the participants into groups and decide their starting sequence. All participants will be randomly divided into two Group A and B. Both Group A and Group B will be exposed to two kinds of prototype and operate the same task, assembly Miter Saw Stand in the test phase 1 and assembly Scaffolding in the test phase 2, as shown in Figure 2. The difference between the two groups is Group A will start using Prototype 1 first, then they will shift to Prototype 2 in the test phase 2, while Group B will use two prototypes in reverse order.

4.3 Task Specification and Therbligs-based Information Presentation

As the basis of experiment design, this research selected the Metaltech Multipurpose 4-in-1 6 ft. Baker Scaffold as the specific user case for experiments, as the scaffolding is a typical and normal task in the construction site with higher hazards (Khan, Saleem, Lee, Park, & Park, 2021). Rigorously building up scaffolds is a vital safety management measure and prevents potential serious individual accidents. In terms of task content design, it can also be converted into another form of miter saw stand, which is a routine task for carpentry but different from those steps and used components in scaffolding assembly. Meanwhile, the difference in difficulty levels between the two tasks makes this choice more suitable for designing an experiment. After field assembly by three researchers, they agreed that the miter saw stand was the most complex and difficult to build, while the remaining three types were not as difficult to distinguish. As mentioned in previous section, the effect of decreased physical strength on experimental effectiveness, as well as increasing the difficulty differentiation between two tasks, two researchers worked together to simplify the task of scaffold assembly. Subjects would neither assemble the upper ladder to the lower part to prevent a total shelf height of about two meters, nor would they rotate the assembled shelf up and down. In the step of transitioning between the scaffold and the miter saw stand, they won't flip the entire platform due to its potentially harmful weight and surface area.

Figure 2 Selected Multipurpose 4-in-1 6 ft. Baker Scaffold for Experiment (The Home Depot, 2022)

Figure 3 shows the partial sequence of the assembly scaffold in the form of "Search", "Select", and "Find" Therbligs. The experiment workplace setup is shown in Figure 4, where all components are lying on the ground and a nearby shelf is for PPE equipment. "Search" Therbligs is reflected in locating the same type of tools from numerous building components in the package, such as searching ladders, braces, and locking pins. "Select" Therbligs happens less often than search, which is embodied in choosing the right one from a variety of similar things or alternatives, such as selecting a lower ladder from ladders where the upper ladder is a misleading option for participants (as shown in Figure 5). "Find" Therbligs is a momentary mental activity that is reflected in the participant starting to move on to the next activity, such as the participant grabbing the searched brace and locking it in place using the U-lock kit.

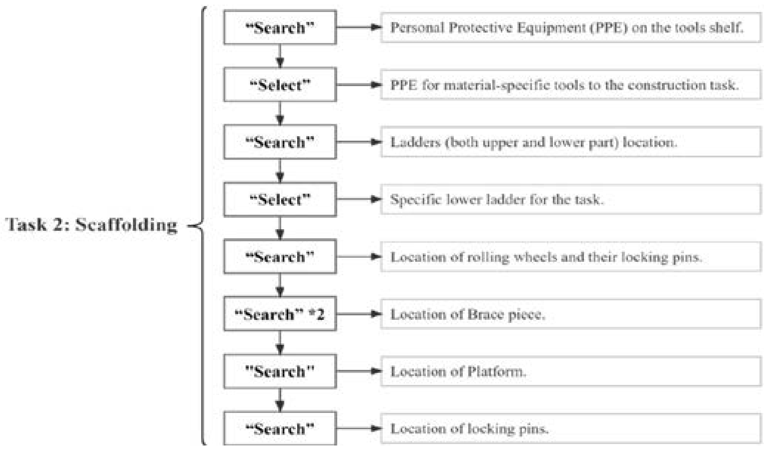

Figure 3 Partial sequence of assembly scaffold in the form of "Search", "Select", and "Find" Therbligs.

Figure 4 Experiment workplace setup.

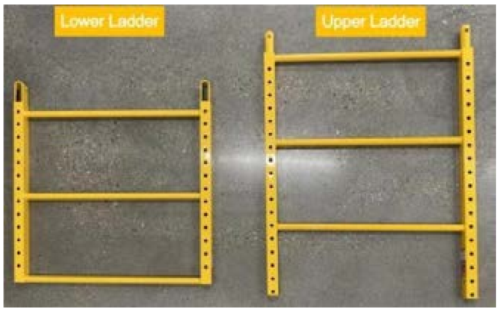

Figure 5 Experiment setting example for “select”.

4.4 Dataset Preparation

High-quality image data for target objects matters a lot to create a robust object-detection model (Lee, Jeon, & Shin, 2023). As shown in Table 3 and Table 4, this present study constructed a dataset to train and test the detection model, which took a total of 1,224 images, including 2,008 objects with 12 categories of classes. The dataset is compiled by two researchers using four devices of Hololens, iPhone, iPad, and Android Phone. This collection covers a diverse range of angles, lighting conditions, and backgrounds, drawing from the environments of two distinct research laboratories. In addition to sufficiently high-quality images of the objects in question, another important thing is the quality and quantity of annotation. The two researchers agreed on the labeling to ensure that the bounding box was strictly around each object. When one researcher’s annotation is complete, another researcher will cross-review each annotation result to ensure consistency. The quantity of each tag is roughly above 120 images, which makes the distribution even and not biased.

Table 3 List of scaffolding components for object detector training

No.	QTY. Used in EXP.	Class	No. Annotated Images
1	2	Lower ladder	137
2	1	Platform	144
3	4	Mounting bracket	194
4	2	Piece support	132
5	2	Brace	147
6	2	Shelf brace	169
7	1	Wire grid shelf (S)	216
8	5	Wire grid shelf (L)	217
9	4	5 in. caster	168
10	10	Locking pin	168
11	2	Anti-tip assembly	183
12	2	Tightening knob	128

4.5 Procedure and Evaluation Metrics

The overall experiment procedure is shown in Figure 6 an estimated duration of 20-25 minutes. Three GoPro cameras, each at an angle of 120 degrees to each other, were used to record the entire experiment to facilitate the subsequent analysis of the participants' Therbligs-based movements. Each participant will be through four steps: one preparation step, two test steps, and one after-testing step. After both Test Phase 1 and Test Phase 2, participants will be required to fill in a designed after-testing questionnaire immediately to express their direct subjective perception. At the end of the experiment, participants were allowed to volunteer for a short interview to express their opinions on improvements to the system prototype, their willingness to accept the technology, and other feelings not covered in the questionnaire. The data acquisition is based on a four dimensions evaluation: Quality, Efficiency, Mental Demand, and User Experience. The purpose of quality assessment is to detect the degree of precision in the work of the participants. This is done manually by experimental observers and is scored based on a complete error protocol. The error protocol describes errors in detail for two tasks, scores each of the two archetypes, and assigns three levels of scores according to the severity of the error (Wolf et al., 2021). The number of errors and the weighted total error score were finally statistically analyzed. Efficiency can be assessed in two ways. On a macro level, the overall time spent by each participant in completing the tasks using the two prototypes will be compared. On a micro level, experimental observers will use a timer to calculate the duration spent on the motion level of each Therbligs. This paper will explore to what degree user-centered process-oriented object detection has a significant effect on "Search", "Select", and "Find" Therbligs. Mental demand and user experience are mainly obtained through validated questionnaires and supplemented with optional semi-interviews.

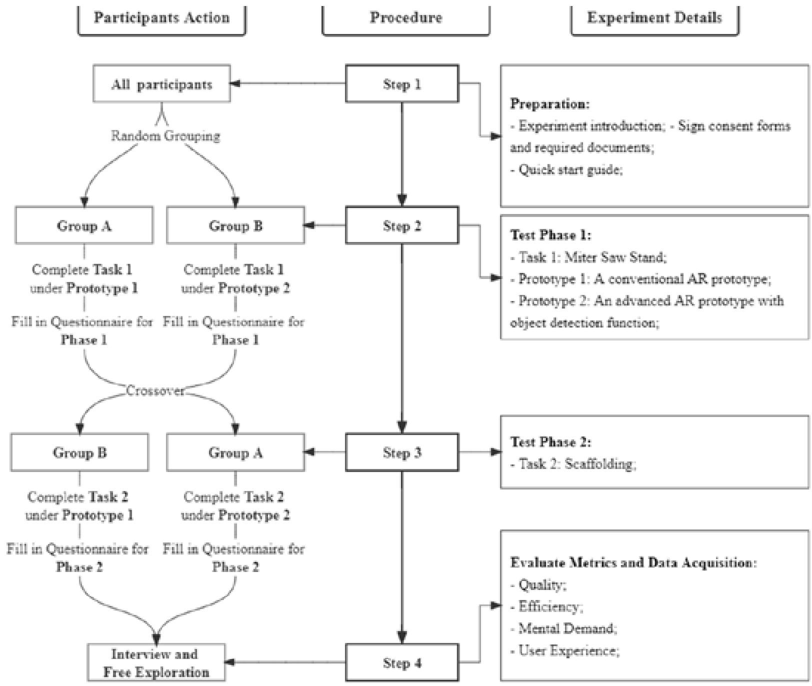

Figure 6 Experimental comparison between conventional AR and advanced AR with object detection

5. OBJECT DETECTION MODEL TRAINING RESULT

After training the model using 3 hours budget with General (compact) domain, the second-iteration training ended with 85.6% precision, 86.4 % recall, and 92% mAP. It is noted that when trying to train for more budget hours, the results remained the same which indicates that object detection model reaches its limitation by using current dataset. These metrics provide critical insights to evaluate the accuracy and effectiveness of object detection models. Precision is how many of the predicted instances are to be actually correct, recall gauges how well the model is capturing all the relevant correct instances, and mAP (mean Average Precision) represents the overall performance. This proposed model has a relatively higher performance in the mAP, which means that the model achieves a good balance between the precision and recall across different thresholds.

The excellent performance of this model is not only reflected in the data metrics, but also in the test images, as shown in . All objects, including very small Tightening Knob and Anti-tip Assembly objects, were successfully recognized one by one with a high success rate of more than 50%. However, there is still room for improvement in this model, as shown in Figure 8. As we mentioned above, we used the upper ladder as a misleading option, allowing participants to select the correct one from the two ladders for subsequent experiments. The trained model was unable to effectively distinguish between the two ladders when recognizing similar ones.

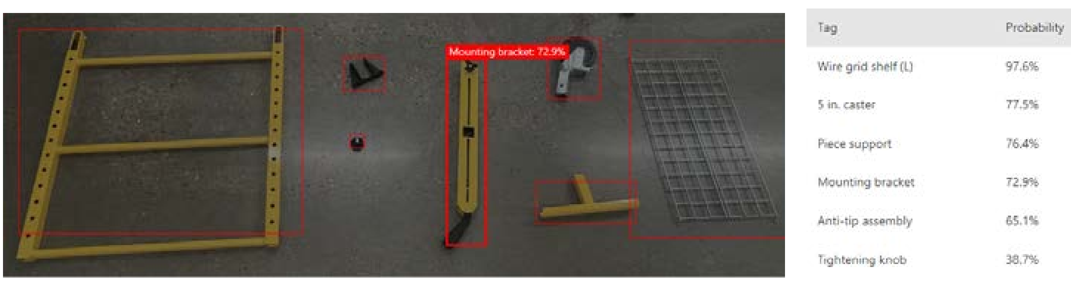

Figure 7 Examples of Object Detection Results from developed model

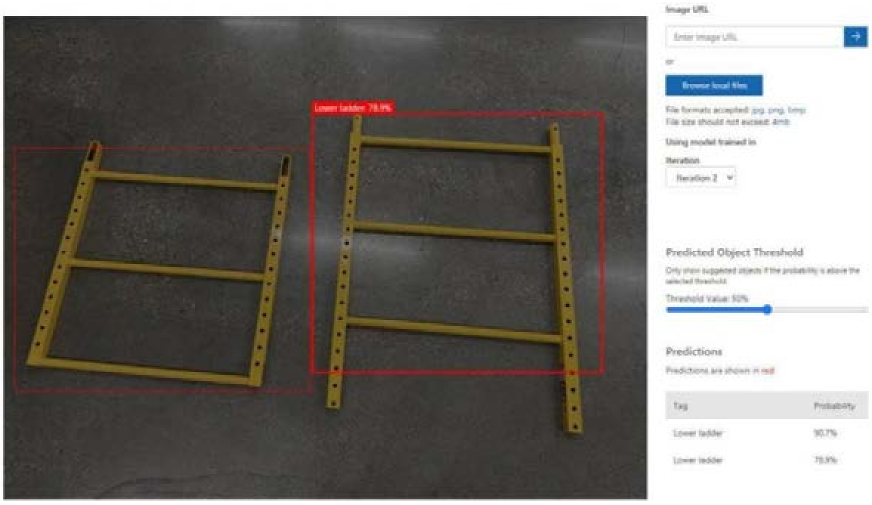

Figure 8 Improvements needed in the model.

6. CONCLUSION AND FUTURE WORK

This research further developed the AR-Driven Task Assistance prototype by integrating object detection function to reduce elemental motions of “Search”, “Select” and “Find” in the Therbligs theory, and designed experiments to verify its direct benefits for construction workers and ease cognitive demanding during performing tasks. By integrating real time object detection into an AR-driven task assistance prototype, it is expected to enhance construction workers’ perception and situational awareness with a wearable, hands-free AR headset, which won’t interfere with workers’ current activities and enable a relatively larger and flexible Field of Vision (FoV) than mobile phone or tablets (Łysakowski et al., 2023).

This research is limited to a single pipeline to realize proposed application scenario, which leaves a researchable question on “Is there an optimal solution for the same function”. Since existing methods do not discriminate well between similar things, it is worth further improving the algorithm or exploring other publicly known algorithms in this domain. Besides, though there are some publications realizing a similar function on HoloLens, it is still worth comparing the performance of different algorithms by using a dataset of the same quality, diversity, and complexity. What’s more, this research is proposed to deploy real-time object detection into an AR-driven task assistance prototype and also verified by scaffolding and miter saw assembly activity, which is aimed at solving practical problems faced by construction industry. However, despite construction industry, other industries might encounter similar issues and challenges awaiting to be further improved. This leaves future efforts to generalize this proposed pathway to other industries and slightly adjust to their specific challenges.

VISUALIZATION OF WEATHER-AWARE AMBIENT HEAT RISKS WITH GLOBAL ILLUMINATION IN GAME ENGINE

Naotaka Sumida, Taira Ozaki, Satoshi Kubota, Dan Hiroshige & Yoshihiro Yasumuro
Kansai University, Japan

ABSTRACT: *In recent years, the risk of heat stroke has been increasing due to global warming and other factors, and the Ministry of the Environment has been using the heat index to alert people in urban areas. Still, citizens need help knowing the detailed risk information for their neighborhoods. The heat index considers the human body's heat balance and is measured with specialized instruments, so comprehensive and high-density measurement is difficult. In this research, by using global illumination (GI) and primary weather data obtained from the Open Weather Map API for each area, we can realistically render the sunlight condition considering the weather and map and visualize the heat index per pixel based on shaded CG. Furthermore, by reconstructing urban 3D geometry from Google Maps, we have developed a system that visualizes the ever-changing heat index distribution for an arbitrary location in real time. The system has shown the possibility of reducing the number of heat stroke patients by using this system.*

KEYWORDS: *heat index, WBGT (wet bulb globe temperature), real-time global illumination, game engine*

1. INTRODUCTION

The number of heat stroke cases and deaths continues to increase in modern society due to the effects of severe climate change caused by global warming and the heat island effect (Ministry of Health, Labour and Welfare, 2013~2020).In particular, the proportion of heat stroke patients who suffer heat stroke when outside has reached approximately 60% of all cases (Ministry of Internal Affairs and Communications, 2022), and the possibility that heat stroke is not limited to certain times of the day is also increasing (Ministry of Health, Labour and Welfare, 2018-2022).In addition, the WBGT (Wet Bulb Globe Temperature), an indicator of heat stroke risk provided by the Ministry of the Environment, showed that the value in 2022 exceeded the average value of the previous ten years and that the upward trend is continuing (Ministry of the Environment, 2022). Daily life activities require outdoor maintenance and cleaning work, visits to neighborhood stores, etc., and from the viewpoint of health promotion, visits to parks have become habitual activities for a wide range of age groups (T. Ozaki et al., 2019). The Ministry of the Environment publishes WBGT values for each city on the Web to alert the public (Ministry of the Environment, 2023). However, as one WBGT value is assigned to a metropolitan area, the outdoor environment of each location, comprising different geographical features such as city blocks, parks, and construction sites, is not considered. Facility and site managers must accurately understand the environmental risks visitors and workers face. In addition, schools and other educational institutions are required to regularly measure WBGT before and during outdoor activities such as sports festivals and excursions to ascertain the level of risk so that classes and activities can be conducted more safely (Ministry of the Environment, Ministry of Education, Culture, Sports, Science and Technology, 2021). However, there are limitations to deploying a large number of WBGT measuring devices to collect information. Each individual needs to make decisions and respond based on their own experience. In this study, we propose a new method to visualize the distribution of heat index under sequential changes in the sunshine environment and provide it to general users by using regional meteorological data and 3DCG-based surface solar radiation estimation using global illumination (GI).

2. PREVIOUS WORK

2.1 Okada-Kusaka black-bulb temperature estimation formula

WBGT is an index focusing on the heat balance between the human body and the outside air and is calculated using equation (1), considering the surrounding thermal environment such as humidity, solar radiation, and air temperature. A black-bulb thermometer is required to measure radiant heat, but Okada et al. point out that it is difficult to measure the temperature stably and continuously. Therefore, Okada et al. estimated black-ball temperatures using total solar radiation, wind speed, and dry-ball temperature as explanatory variables (M. Okada et al., 2013). The estimation equation (2) enables the estimation of black-ball temperature from meteorological data on total solar radiation, wind speed, and dry-ball temperature, making it possible to calculate WBGT estimates not only for sunny days but also for a wide variety of weather conditions.

Naotaka Sumida, Taira Ozaki, Satoshi Kubota, Dan Hiroshige, Yoshihiro Yasumuro, *Visualization of Weather-Aware Ambient Heat Risks With Global Illumination in Game Engine,* pp. 133-141, DOI 10.36253/979-12-215-0289-3.13

$$WBGT = 0.7 \times Wet\ Bulb\ Temp. + 0.2 \times Black\ Bulb\ Temp. + 0.1 \times Dry\ Bulb\ Temp. \quad (1)$$

$$Black\ Bulb\ Temp. = \frac{Global\ Solar\ Radiation - 38.5}{0.0217 \times Global\ Solar\ Radiation + 4.35 \times Wind\ Speed + 23.5} + Dry\ Bulb\ Temp. \quad (2)$$

2.2 3DCG-Based Estimation Method of WBGT and Its Application

Yasumuro et al. proposed a method to estimate WBGT by optical calculation using GI for 3DCG rendering to visualize the effect of green shade against heat, as shown in Fig. 1(Y. Yasumuro et al., 2018). First, standard reflectors placed under various shades of green were photographed with a single-lens reflex camera at fixed exposures, and the pixel values were converted to absolute luminance values. On the other hand, the total solar irradiance at the position in the reflector corresponding to each pixel is also measured, and a linear regression analysis is used to determine the correlation between the absolute luminance and the total solar irradiance. WBGT can be estimated from Equation (1) by obtaining the black-bulb temperature using the estimation equation (2) of Okada et al. based on the total solar irradiance calculated using this correlation equation and primary meteorological data such as dry-bulb temperature, wet-bulb temperature, and wind speed, which indicate the conditions at the target location. Furthermore, Yasumuro et al. have made it possible to estimate WBGT without the need for on-site photography by realistically rendering shades using GI with CG that virtually sets the same reflectance characteristics as the standard reflector shown in Fig. 2. By preparing a 3D model of a landmark, it is possible to reproduce solar radiation conditions in 3DCG based on the latitude and longitude of the landmark and its position concerning the sun, making it possible to determine the heat-protection effect of green shade at any given time. In this research, the GI that reproduces photorealistic solar radiation conditions in CG requires a large amount of light path search, and the generation of CG takes time each time the conditions are changed.

(left: Current planting condition, right: Doubled planting condition)

2.3 Visualization of Environmental Heat Risks with Global Illumination in Game Engine

The authors proposed a method to visualize heat index distribution for ever-changing sunlight conditions regardless of location and stream it to general users on the Web by using a game engine utilizing real-time GI to speed up the generation of solar radiation CG by GI and developing a system to obtain basic weather information in real-time as shown in Fig. 3 and demonstrated the effectiveness of this function (N. Sumida et al., 2022). According to the estimated WBGT value, a function is implemented to visualize the risk of heat stroke as a multi-step heat map using CG by setting colors and interpolation processing using the UV coordinates of the texture based on the colors of the danger levels shown by the Ministry of the Environment in Fig. 4. Although the visualization results are provided universally to the user's terminal via a web browser, this method requires 3D data on the terrain covering the target area for generating CG, and there are many areas where 3D data are not publicly available, limiting the applicable target areas. In addition, the calculation of WBGT requires primary meteorological data for the area. Still, a system that can automatically collect and reference these by region and time needs to be solved. Systematization to solve these problems remains challenging to realize an information service that presents heat risks for any given location and time in response to user requests.

3. PROPOSED METHOD

In this study, we propose a system that collects and utilizes necessary data by employing weather data services and 3D information services available on the Internet for an application server with a WBGT estimation function, which the authors have already constructed. Fig. 5 shows the processing procedure of the system proposed in this study. In the real-time GI used by the application server, many image data (called light probes) mapping light source information in all directions are placed in the target space, and information on many light ray paths, including inter-reflection by static objects such as buildings, is pre-calculated as textures. By tracing light probe information, the cost of calculating the synergistic effects of light rays can be significantly reduced, and high-quality computer graphics that include effects such as indirect light can be rendered in real-time. (SILVENNOINEN, A et al., 2017) (K. Kurachi. 2007). Although the target scenes of this study include complex shapes such as trees and buildings, dynamically changing geographic objects are not required, making the system suitable for introducing real-time GI. The user specifies the date, time, and location from a Web browser on the terminal at hand and accesses the application server via the network to use this application. The application server uses the date, time, and location information specified by the user as a query, extracts the corresponding weather data and 3D data from the database, generates CG of the sunshine conditions, and estimates WBGT. The weather data collection server automatically obtains weather information using weather data services provided through public APIs and sensor networks of instruments installed in the region. It stores the relevant information in the weather information database. The 3D data collection server automatically collects 3D data and material information of publicly available geographic objects and stores this information in a 3D model database. For areas where 3D data is not publicly available, a database is created by reconstructing 3D models from map services that can be viewed in 3D on the Internet. By designing the database with the data items required for WBGT calculation in the application server as attributes, data collected from different information sources can be effectively utilized. The 3D data collection server automatically collects 3D data and material information of publicly available geographic features and stores this information in the 3D model database. For areas where 3D data is not publicly available, a database is created by reconstructing 3D models from map services that can be viewed in 3D on the Internet. This system configuration is expected to increase the affinity with the information provided by other services already widely used as information infrastructure and extend the range of applications of this method.

4. IMPLEMENTATION AND VERIFICATION

This study utilized Unreal Engine 4 (UE), a game development platform with real-time GI and sun placement functions based on geographic coordinates and functions equivalent to the exposure settings of a single-lens reflex camera, which can be used to generate realistic computer graphics. An input interface shown in Fig. 7 is implemented in the UE to allow users to select specific locations. After entering a place name, a button for selecting the corresponding place name is displayed. When the user clicks the button, the user is automatically redirected to a map showing 3D data of the corresponding area. When the user clicks on a button, the user is automatically redirected to a map displaying 3D data of the corresponding area. When the place name is searched by prefecture, all buttons for the corresponding city, town, or ward are listed and can be selected in a scrolling format. The method of setting the date and time and the output process of the heat map of WBGT distribution after setting the date and time are based on the authors' existing method.

The weather data collection server in the proposed system uses Open Weather Map API provided by Open Weather to obtain publicly available weather forecast data. Open Weather Map API is suitable for this study because it can provide basic weather information required for WBGT estimation, as well as information on specific locations and times required for CG generation using real-time GI. In addition, a DAVIS VantagePro2 sensor is used to collect real-time weather information at individual sites. The Open Weather Map API and the VantagePro2 are suitable for this study because they are commercially available and can be installed at individual sites. Considering that VantagePro2 sends data in Json format to the weather data collection server, as shown in Fig. 7, we implemented a parsing function in the application server UE to analyze the received Json data and sort them into attributes suitable for this system. This implementation makes it possible to comprehensively process the acquired information and convert it into a format suitable for the proposed system, even when the data sources differ.

Fig. 6: Pull-down menu interface for selecting location incorporated in the game engine

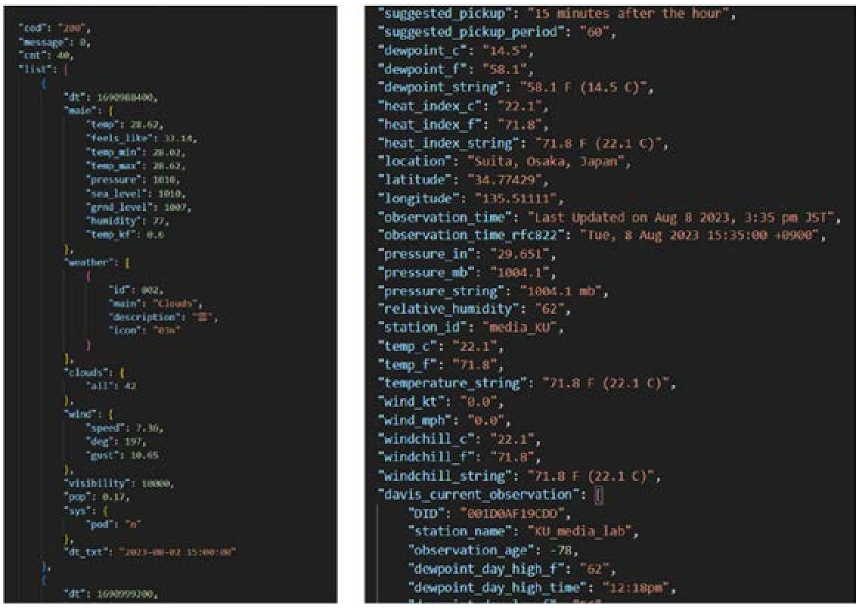

Fig. 7: Json data from Open Weather Map API (left)
and Json data from VantagePro2 (right)

The authors implemented a system that enables data acquired by a weather data collection server to be stored in a weather data database created in the relational database service (RDS) of AWS, a cloud service provided by Amazon, Inc. In addition to the basic meteorological information necessary for WBGT estimation, the database is designed to prevent data inconsistencies by setting latitude/longitude and place name information necessary for location identification as attributes. However, although wet-bulb temperature is required to calculate WBGT from Equation (1), some measurement equipment measures humidity instead of wet-bulb temperature. Open Weather Map API and VantagePro2 used in this paper do not measure wet-bulb temperature, so they calculate an approximation of wet-bulb temperature from humidity and dry-bulb temperature. If the equipment measures wet-bulb temperature, it is directly stored in the database, and if it cannot measure wet-bulb temperature, the system calculates an approximate value.

The 3D data collection server in the proposed system acquires extensive and detailed 3D city data publicly available, such as PLATEAU provided by the Ministry of Land, Infrastructure, Transport and Tourism in Japan. As a method of storing the acquired 3D data, we are considering a method for directly storing the data in a database or storing the 3D data in a cloud service such as Dropbox or Google Cloud Platform (GCP) and storing only a link to the destination in the database. In cases where open-source data is unavailable, we adopt a method of reconstructing 3D data from information sources such as 3D data from online map services such as Google Maps. The verification procedure is to set multiple waypoints in Google Maps, as shown in Fig. 8 (left), and create a KML file that contains geographic coordinate information to specify the route of the viewing viewpoint. By importing and executing the created KML file into Google Earth, it is possible to capture virtual aerial images that simulate UAV flight as shown in Fig. 8 (right), and through 3D reconstruction by SfM using photogrammetry, 3D data acquisition, as shown in Fig. 9, is realized. With the above implementation, obtaining the data necessary to generate a heat map is now possible using only the specific date, time, and location information entered by the user.

5. EXPERIMENTAL APPLICATIONS

5.1 Case Study in Shibuya and Shinjuku City, Tokyo

The following is an example of applying the proposed system to 3D data of Shibuya and Shinjuku city obtained from PLATEAU, a 3D data utilization service provided by the Ministry of Land, Infrastructure, Transport and Tourism (MLIT). Furthermore, we show that the system can visualize the detailed distribution of heat stroke risk during the day and night by combining the system with time-dependent weather data stored in the weather information database, as shown in Fig. 10 and Fig. 11. At the time of writing this paper, the weather information for August 2023 was not available, so the data for August 11, 2022, was used for CG generation.

5.2 Examples of heat stroke risk prediction validation

During the Golden Week (early-May holiday season in Japan) of 2023, temperatures exceeding the average of 18.8°C announced by the Japan Meteorological Agency were observed. The maximum temperature in Tokyo on May 6 reached 27.9°C, which potentially increased the risk of heat stroke for people outside the city. This result shows that the risk of heat stroke in front of Shinjuku Station was at a level where it is recommended to actively hydrate oneself (Fig. 12). This result suggests that even during periods when the risk of heat stroke is generally recognized as low, the risk may still exist, and this system is an effective means of verifying this.

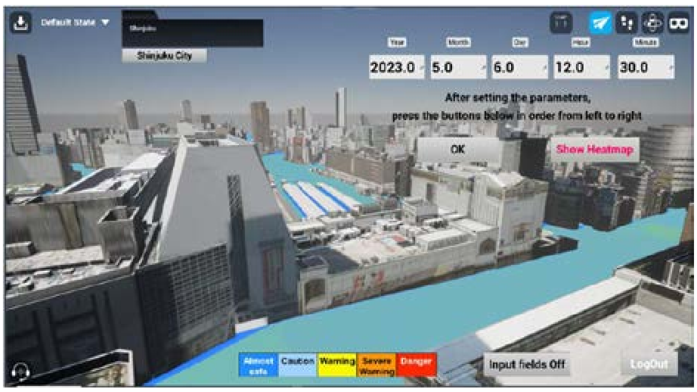

Fig. 12: Heat map of Shinjuku City during the day May 6, 2023, 12:30 p.m.

5.3 Case Study in Suita City, Osaka

For areas where open-source 3D data such as PLATEAU (see (1)) is not available, this method can be applied to 3D reconstruction using SfM from existing services such as Google Map's 3D view to generate a heat map as shown in Fig. 13. By importing kml files containing geographic coordinate information into Google Earth, it is possible to take aerial images that simulate UAV flights. We have shown that large-scale collection of 3D data is possible at low cost by using Google Earth to take comprehensive aerial photographs of surrounding areas.

(3D reconstruction based on SfM), August 2, 2021, 12:52 PM

6. CONCLUSION

In our research, we developed a system that utilizes public weather information and 3D data using a game engine, enabling WBGT estimation and real-time heat maps for various regions and times. In the future, we aim to create a new solar radiation correlation equation that enables WBGT estimation on cloudy days based on weather information such as clear and cloudy skies obtained from meteorological data. In addition, the physical characteristics of 3D models of geological objects have yet to be considered. We plan to analyze the impact on WBGT by the reflectance and transmittance of surrounding buildings' surface materials and vegetation, considering the findings of prior CFD (computational fluids dynamics) studies. Incorporating the results of these analyses into the model will allow for a more accurate and realistic assessment of the thermal environment.

IMPROVING SENSE-MAKING FOR CONSTRUCTION PLANNING TASKS USING VISUAL AND HAPTIC STIMULI IN VIRTUAL REALITY ENVIRONMENTS

Ivan Mutis, Marina Oberemok, & Nishanth Purushotham
Illinois Institute of Technology, Chicago, Illinois, United States of America

ABSTRACT: *Design documents, drawings, and specifications are visual representations that are fundamental and prevalent in today's construction engineering practice. Construction specialties (e.g., structural, mechanical) rely on these visual representations to express and draw meaning during collaborations. Construction engineering and management (CEM) students must acquire the knowledge, skills, and abilities — a key example of which is perceptual competence —for interpreting visual representations to facilitate efficient task execution, such as planning. Empowering learners with new technology using robust real-world immersion and interactive features is a significant step towards this target. The presented research explores new human-machine interactions to determine the best way for CEM students to learn through the combined senses of sight and touch. The approach merges visual and haptic interactions within an immersive environment to enhance perception and reasoning skills. The research demonstrates how CEM learners interact with and interpret the meanings of information within a planning task. It explores how VR and haptic technology augment the ability to recognize meanings — a new type of representational competency — for improved interpretation of information related to components with respect to engineering disciplines and sub-systems in a CEM, and investigates learners' problem-solving ability by using perception-rich enhanced virtual reality (VR) and haptic affordances.*

KEYWORDS: *haptic cues, human-computer-interaction, design interpretations*

1. INTRODUCTION

To satisfy the educational needs of STEM learners and foster essential 21st-century skills, such as critical thinking, reasoning, problem-solving, collaboration, and communication, educators must integrate innovative technology into the learning process (NSF, 2020). To address these requirements, human-computer interaction (HCI) offers viable solutions to augment human senses and enrich sensory input, including vision, hearing, smell, and touch (Manchanda et al., 2017).

The sense of touch or haptics is one of the most informative human senses. This sense includes both cutaneous and kinesthetic sensations. Embracing haptics opens up new possibilities to expand human capabilities, such as improving manual dexterity and enhancing sensory perception (Chryssa & Julie-Ann, 2020). This research takes advantage of the HCI affordances and explores the use of haptic technology in learning for Construction Engineering and Management (CEM) students.

Fundamentally, to explore the use of haptics in CEM learning, the presented approach draws on an individual's spatial-temporal cognitive ability (STCA) (Mutis, 2018a). Spatial-temporal ability allows learners to effectively manage and comprehend significant amounts of spatial (how design components are related to one another in the 3D space) and temporal (the logic in a process, such as the order, sequences, and hierarchies of the resources within a construction task) information (Mutis, 2018a). Limited or no ability to process spatial and temporal information (i.e., lack of spatial and temporal cognitive ability hinders the understanding of designs and management of the varying local conditions (e.g., unplanned conditions) (P. Antonenko & I. Mutis, 2017; P. D. Antonenko & I. Mutis, 2017; Mutis, 2014, 2015; Mutis, 2018b). The ability helps learners to conceptualize three-dimensional relationships between objects in space and mentally manipulate them as sequential transformations over time.

The STCA cognitive ability allows the CEM learners to recognize meanings and facilitates coupling observed representation to the given contexts – a new representational competency. The coupling abilities (spatial and temporal) significantly benefit the decision-making process. Individual spatial-temporal abilities are associated with high cognitive reasoning that defines the cognitive-processing chain — from basic visual attention to higher-level reasoning, such as an interaction between organizing, performing, and supervising the effectiveness of a plan (Mutis, 2018a). For instance, planning is a highly cognitively demanding task where STCA plays a pivotal role. Planning is critical as the learner couples observed representation in a given context to organize, perform, and supervise the effectiveness of a plan while interpreting information from engineering designs. Effective STCA training enables individuals to instantly identify concepts, events, and patterns for comprehension and projection,

Ivan Mutis, Marina Oberemok, Nishanth Purushotham, *Improving Sense-Making for Construction Planning Tasks Using Visual and Haptic Stimuli in Virtual Reality Environments,* pp. 142-154, DOI 10.36253/979-12-215-0289-3.14

streamlining actions, solutions, and implementations in planning.

The presented approach explores the uses of haptic technology to augment cognitive capabilities, in particular the STCA. The STCA augmentation effect is from the cognitive load reduction by using a new sensing channel (haptics) in the cognitive process by liberating mental resources for other cognitive tasks (Sweller, 1988; Sweller et al., 2019), potentially enhancing spatial and temporal processes that are fundamental in problem-solving tasks. The assumption is that learners can rely on their haptic sense to reduce efforts of converting cognitive processes into physical actions— alleviating the burden of effort for processing spatial (e.g., spatial configurations of design components in the 3D space) and temporal (e.g., the logical sequence of design components for their assembly) information. The use of new senses (haptics) is a form of increasing the impact of embodied intervention in the cognitive process by, for instance, facilitating tracking information and gaining object rotations to feel and comprehend spatial relations more accurately (Tran et al., 2017).

By using perception-rich enhanced virtual reality (VR) with haptic affordances, this study addresses the following questions:

1. What aspects of haptic stimulus impact the learners' development of representational competence for better interpretation of information related to designs in a CEM? The research outlines the importance of improving *spatial-temporal skills* to facilitate high-level reasoning in complex situations.
2. What *new HCI factors*, combining visual and haptic (VH) interactions with engineering designs, enrich the perception and reasoning skills of CEM learners, leading to more accurate and efficient task execution? The solution presents *a haptic language* that implies tactile cues enhancing spatial awareness for the given context.

2. BACKGROUND

Researchers in STEM education are exploring the ways in which haptic technology can enhance the learning process, including improving student engagement, conceptual understanding, and skill acquisition. Early studies focused on developing haptic devices for enhancing spatial awareness and visualization skills (Liu et al., 2003; Williams Ii et al., 2001). Later research underlined the benefits of haptic feedback in improving interactions and spatial guidance (Jong, 2014; Takahashi et al., 2009). As demonstrated in further publications, augmenting VR with haptics increases overall task performance and the users' perceived sense of presence (Cooper et al., 2018; Kreimeier et al., 2019).

Over the years, haptic interventions in architecture, engineering, and construction (AEC) have been applied to simulate assembly tasks (Medellín-Castillo et al., 2015) and develop vocational training for construction personnel such as carpenters, plumbers, and masons (Jose et al., 2016; Ranjith et al., 2014). Current research aims to cultivate more sophisticated haptic devices and techniques for human-machine interaction in AEC, including haptic feedback for mixed reality and teleoperation (Adami et al., 2022).

In general, haptics is extensively used in engineering learning, including training, physics and chemistry simulations, robotics, and automation (Prabhakaran et al., 2022; Sanfilippo et al., 2022). Engineering education utilizes haptic interfaces to provide students with hands-on experience with virtual simulations. Likewise, vocational training with haptics provides realistic practice in handling heavy machinery and tools. Lastly, by using haptic devices on remote-controlled construction robots, operators are able to discern the properties of various objects and materials during the manipulation (Alakhawand et al., 2022). Thus, haptic technology shows promise to transform traditional learning and training methods, offering advantages such as enhanced knowledge retention, engagement, skill acquisition, safety, and accessibility (Mastrolembo Ventura et al., 2022).

Several studies have been conducted on assembly techniques, but only a few have explored the incorporation of haptics due to their relative novelty as an assistive tool in STEM learning. However, the development of haptics shows potential for enabling innovative approaches to enhance cognitive and motor skills, particularly in tasks like modeling, assembling, and teleoperation. For virtual assemblies, Yuan et al. (2008) introduced an augmented reality (AR) approach, utilizing a virtual interactive tool called VirIP and a visual assembly tree structure (VATS). This system enables assembly operators to seamlessly follow a pre-defined assembly plan/sequence without requiring sensor schemes or markers on the assembly components. Hu and Zhang (2012) presented a method leveraging a 3D game engine and software component technique to rapidly construct a reusable component library to develop virtual assembly experiments. In recent work, Li et al. (2020) proposed a framework with advanced computations such as runtime degrees of freedom (DOF) determination, disassembly directionality computation, and assembly/disassembly sequence generation. These computations efficiently integrate assembly constraint information into a virtual assembly application with minimal effort required.

Haptic technology allows the transfer of touch-based information between humans and computer interfaces (OED, 2020). Haptics can enhance the learning experience and support an environment that cultivates student engagement, motivation, and interest in the subject matter (Tytler, 2020). Haptic interaction is crucial for a sense of presence and manipulating objects in remote or virtual environments with manual dexterity (Kortum, 2008, p. 25). For example, by providing users with tactile cues, haptics makes the digital environment more interactive and informative.

In the AEC discipline, there are proposed haptic interventions that aim to assist users in accomplishing an engineering task providing guidance for the decision-making process. Rahimian and Ibrahim (2011) proposed a haptic-based VR 3D sketching interface to improve novice designers' engagement with "problem-space" and "solution-space", leading to increased artifact maturity in collaborative conceptual architectural design. Following Christiand and Yoon (2011) work, haptic-path sequence guidance reduces the assembly time and the travel distance that enhances the working performance of virtual assembly tasks. Also, the availability of haptics in large immersive environments can contribute to future advances in virtual assembly planning and factory simulation (Pavlik et al., 2013). Yeh et al. (2013) suggested that multi-symbolic representations (text, digits, and colors) in haptics-enhanced virtual reality systems have the potential to help collaborative work effectively. James et al. (2019) proposed a bi-manual haptic interface for skill acquisition in surface mount device soldering. Coffey and Pierson (2022) demonstrated the effectiveness of the proposed haptic guidance system for co-navigation of non-holonomic vehicles through teleoperation. Williams et al. (2023) presented a framework for active haptic guidance in mixed reality using one or more robotic haptic proxies to influence user behavior and deliver a safer and more immersive virtual experience.

The primary focus of the mentioned studies was to improve the understanding of a process for training (e.g., the process of assembling building components). The studies have incorporated haptic guidance into the assembly processes, which helped users receive tactile feedback during the assembly tasks. However, the haptic guidance implementations fell short in providing spatial awareness and addressing high-order cognition in cognitively demanding tasks such as identification of the dependencies or hierarchy of building components for planning. While the haptic guidance aids in recognizing information about movements in training tasks through haptic feedback, the approaches do not offer a comprehensive understanding of the entire spatial context or interconnections between various building components. The presented study aims to overcome these limitations by exploring spatial-temporal cognitive abilities using visual and haptic stimuli.

Haptic feedback

Using electronic devices, we encounter multiple interactions, including sounds, flashes, and buzzing haptics (Müller, 2020). Such a combination of sensory stimuli allows the user to be fully engaged in the experience, which enriches the overall quality of the interaction. A crucial aspect of this set is haptic feedback, which draws from the psychological nature of interaction with the environment and other humans (e.g., social touch). Therefore, achieving precise replication of haptic signals in devices requires a deep comprehension of how humans perceive and attribute meaning to tactile interactions to portray their semantics accurately.

The human skin's discriminative ability arises from a dense network of cutaneous receptors allowing us to differentiate fine touch, pressure, texture, and temperature (Fulkerson, 2020). This adaptability of touch perception, known as adaptation rate, enables us to prioritize novel sensations while filtering out constant stimuli. Unlike some other senses perceived passively, haptic perception is inherently interactive and bidirectional – we actively explore and manipulate the environment to extract tactile details.

To recreate physical sensations, HCI incorporates various types of haptic technology, including force, vibrotactile, ultrasonic, thermal, and other forms of haptic feedback (Hatzfeld et al., 2015). Haptic interfaces allow users to experience tactile sensations while manipulating objects, discriminating textures, and applying forces in the virtual and physical environment.

According to the literature (Adilkhanov et al., 2022), haptics performs three primary functions such as simulation, teleoperation, and guidance. Through *simulations,* haptic feedback imitates physical interaction with the environment and its attributes to heighten the realism of learning scenarios. In *teleoperation,* the haptic interface provides a two-way communication channel between a robot and an operator, allowing the operator to perceive tactile feedback from the robotic tool (Luo et al., 2019). As part of the *guidance* process, haptics implement tactile patterns to derive directional cues to the user (Huang et al., 2019).

Guiding haptics becomes especially beneficial for facilitating the decision-making process and fostering problem-solving abilities by providing tactile cues to assist users in performing tasks or enhancing interactions in a physical and virtual environment (Bluteau et al., 2008; Feygin et al., 2002). This haptic function utilizes touch-based sensations to provide the users with real-time information, helping them make informed decisions and improving their overall performance and understanding of the context. Research suggests that using intuitive haptic guidance to assist the movement reduces errors (Mugge et al., 2016). Moreover, a partial-then-full haptic guidance strategy seems the most effective in improving learning outcomes (Teranishi et al., 2018). The most common applications of guiding haptics include vibrotactile feedback, often incorporated into commercial smartwatches for haptic notifications and alerts.

Haptic guidance can be achieved through a *haptic code* that utilizes touch-based symbols (e.g., haptic icons or "hapticons" (Enriquez & MacLean, 2003)) to instantly deliver information to the user via vibrations, pressure, or movement (Hatzfeld et al., 2015, p. 75). According to Enriquez et al. (2006), haptic code has to meet the following conditions in order to offer explicit meaning:

- *Differentiable*: All haptics must be distinct from one another when presented either alone or in any common haptic combinations.
- *Identifiable*: Once a meaning has been connected to a stimulus to form an icon, it must be simple to recall.
- *Learnable*: The associations between meanings and stimuli should be intuitive and easily remembered.

The elementary functions of the haptic code include providing notifications with neutral feedback and signals with either positive or negative meaning in response to the user's actions.

Haptic code can be applied even on a broader spectrum, e.g., for rendering abstract models or concepts as a new modality for communication. At the lowest level, haptic devices notify users of an event, their identity, or their current state or contents. A higher level of abstraction implies haptic associations that allow the users to identify interdependencies and determine a sequence of actions by assigning physical sensations to an object hierarchy. Accordingly, systematic, perceptually guided haptic design can support expressive and nuanced communication that qualifies as a new haptic language.

3. METHODOLOGY AND APPROACH

The study consists of two main phases: (1) the creation of the experimental training platform, designed to be interactive and informative; (2) experimentation, with active student participation for practical application and assessment of the learning outcomes. This comprehensive approach provides an effective and engaging program for students to develop their skills and comprehend complex building concepts in a virtual and immersive environment. The presented research is the first phase, including a case example to illustrate the approach.

Immersive virtual platform

The VR design consists of the development of a VR environment based on the detailed design of a building project (e.g., a small residential building). See Fig 1. The design was represented in a Building Information Model (BIM) with at least a Level of Detail 300. The BIM model contains rich data on engineering systems through represented objects or component assemblies, such as quantity, size, shape, location, and orientation. The design was exported as an Industry Foundation Class (IFC) file to preserve the semantic information of the building components. The exported model was then imported into Unity for two purposes. First, it acts as a reference point in the form of a translucent building, allowing the user to place building components accurately. Second, it is semantically broken down into corresponding building components to build game objects. The resulting structures were game objects created based on the standard categorization of the building into Sub-Structure and Superstructure and further classified into Structural, Architectural, and Mechanical components.

It is critical to note that the created game objects were set for true building scale, generating an immersion that represents dimensions for easy manipulation in the VR environment. Each game object had a representation that described data and text information in a structured format, involving attributes as game elements based on IFC structure. For example, each object game had data related to the activity (used for planning) in their element attributes (element descriptors). The element attributes held in addition to the planning activity information associated with unique haptic feedback, as discussed in the section below. For a logical representation in planning, game objects were nested based on a work breakdown structure (WBS)— a hierarchical tree structure subdividing the deliverables and work. The WBS disciplines will deliver the work specified in each work package—the lowest level in the WBS that represents a specific amount of work. The work package as product and deliverable has a VR object representation. The structure of these components is shown in Fig. 1.

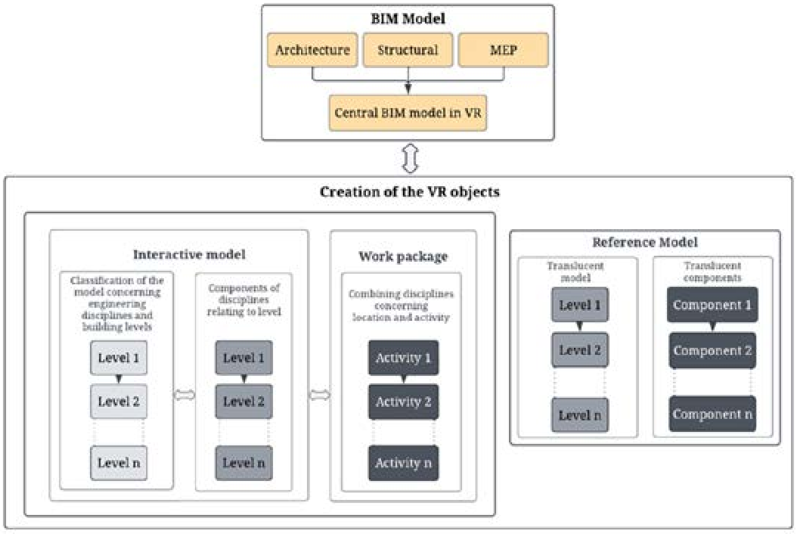

Fig. 1: Design structure of the VR platform.

Experimental Platform

Unity software integrated with a VR headset Oculus Pro and a full set of haptics devices (see 2) were used for the development. This state-of-the-art platform provides users with a fully immersive experience. An example of the visualizations is shown in Fig. 5a and Fig. 5b. They illustrate a dashboard and virtual design components where users learn virtual manipulation, featuring an informative activity pane to hold building components as activity tiles and servicing as a comprehensive reference model for planning activities to enhance the overall learning experience.

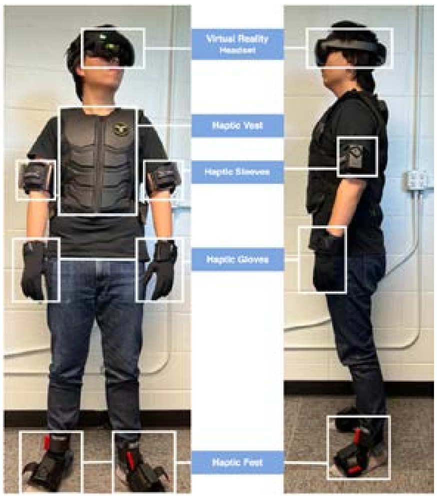

Fig. 2: Haptic devices for the VR platform.

Haptic (*vibrotactile*) code

The researchers systematically structured the haptic code as feedback for the simulation and experimentation in VR environment. The code contains the logical patterns that guide the user's manipulation of the building components through interaction augmented by haptic feedback. The code has signatures expressed as haptic icons, i.e., a haptic icon is a brief haptic stimulus associated with meanings. The haptic icons were designed to intuitively comprehend cues about a function of the object and interact (user-object effects) in the virtual environment. The code is a form of primary language wherein each icon is a constant pattern with associated semantics. The learners (users) are required to get familiarized with the code (akin to learning a primary language to operate a system) *a-priory*.

To associate semantics to the haptic code, four key perceiving haptic features play a crucial role in defining the tactile experience:

- *Intensity*. It governs the strength or magnitude of the tactile sensation delivered to the user. It determines how strong or weak the haptic feedback feels, allowing for the creation of subtle or intense tactile perceptions.
- *Sharpness*. It relates to the perceived abruptness or distinctness of the haptic sensation. It influences whether the sensation feels smooth or sudden.
- *Duration*. It refers to the length of time of the perception of haptic feedback. Short durations can convey quick events, while longer durations can simulate prolonged interactions or sustained sensations.
- *Granularity.* It is determined by the frequency of impulses and their spacing. The more granularity, the more rapid the impulses.

Manipulations with these haptic features enable prototyping and fine-tuning haptic experiences to match specific interactions and simulation scenarios, enhancing user engagement and immersion in virtual environments. The combinations of the haptic features assigned to a haptic device evolve into distinctive haptic patterns.

Haptic code (*vibrotactile*) types

The haptic code consists of two types of haptic feedback: operational and functional.

Operational

It refers to haptic feedback of the basic human-computer interaction (HCI) with the elements of the virtual environment, such as feedback on actions on the system components (to select, cancel, move, etc.). The approach includes three types of operational haptic feedback:

- *Positive* to reflect the correct actions of the user by giving soft impulses with low or medium intensity;
- *Negative* to associate the mistakes and has more even rigid impulses, medium or high intensity;
- *Neutral* to provide alerts to the user regarding updates or notifications (it is presented as a row of short impulses with gaps in between).

Functional

It refers to the feedback that gives semantics associated with activity planned in VR deployment.

Parameters of duration (D), granularity (G), intensity (I), and sharpness (S) define the functional haptic code. The combination of parameters defines features that indicate semantics. The combination can be represented in a two-dimensional matrix of *n* rows (where *n* is the number of combinations). See Fig. 3. Each row represents the distribution of values of parameters (D, G, I, S).

A VR object will have an associated haptic code combination (DGIS), representing a specific value and semantics.

Fig. 1 illustrates the approach conceptualization of the intersecting components (virtual environment, structure of VR objects, haptic (vibrotactile) code, semantics haptic feedback (as semantics), and the spatial temporal cognitive ability (while interacting with problem solving in CEM). The arrangement impacts the spatial-temporal cognitive abilities of learners, assisting them in accurately defining the sequence of activities through the integration of visual and tactile cues.

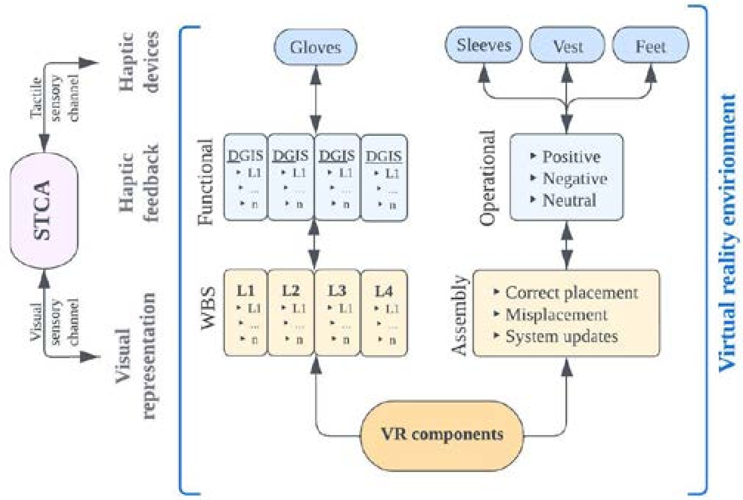

Fig. 1: Approach conceptualization.

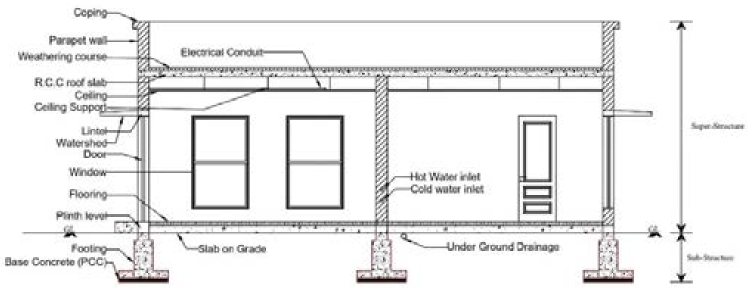
Case Example

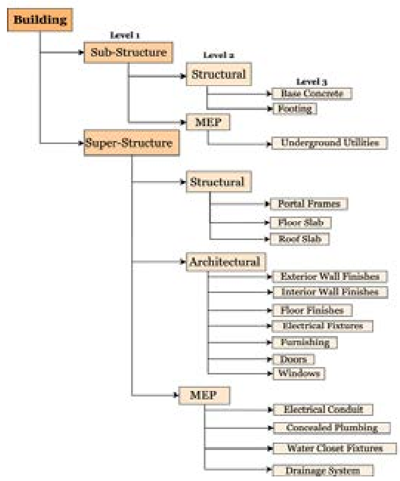
Learners are required to plan the construction of a small building design section in the VR environment (see Fig. 2). The user should build the plan by identifying construction work packets (associated components and activities). A work package (construction product deliverable) serves to establish a coherent and feasible subdivision of tasks within the construction project. Each packet has associations with physical areas (work zones) to cover all the components of the design.

A work breakdown structure (WBS) that incorporates the components and activities associated with the small building design (see Fig. 2a) is presented as a dashboard in the VR environment (see Fig. 5a). The WBS is used as a baseline for planning. The first milestone is set for substructure completion of the building design, and the second is set for the superstructure (see Fig. 2b). Each building component from the design is the deliverable of an activity.

The assembly sequence for each activity and packet (construction product deliverable) is based on the Finish-To-Start (FS) inference (logical relationship between two activities). A finish-to-start relationship implies that the predecessor activity needs to be finished before any subsequent actions can start.



(a) Building components



(b) A breakdown of the building components in a hierarchical structure

Fig. 2: Construction product deliverables from work breakdown structure (WBS).

After the user selects the packet from the dashboard in the virtual environment (see Fig. 5a), the next step is to select, drag, and drop the design component (deliverable) of the small building on a virtual layout by performing a virtual walkthrough (see Fig. 5b).

(a) A dashboard servicing as a reference model to visualize WBS packages for conceptual planning.

(b) Snapshot of the mapping between the work package and the reference model (virtual layout of the building).

Fig. 5: Interactive haptic activity for a planning task in the VR environment.

The order of activities corresponds to the deliverable sequence, and each deliverable has an associated location in the virtual layout. The assumption for the case example is that the presented activities depend on the completion of others before they can begin (FS precedence). Planning these activities takes the dependencies (precedents) into account by arranging activities in a logical sequence. The arrangement of all deliverables is the planning of the construction section of a small building design in the VR environment.

The users need to locate (by dragging and dropping) all the deliverables of the building section in the virtual layout space during the virtual walkthrough. By completing all the packets in the dashboard, the user can complete the planning of the building.

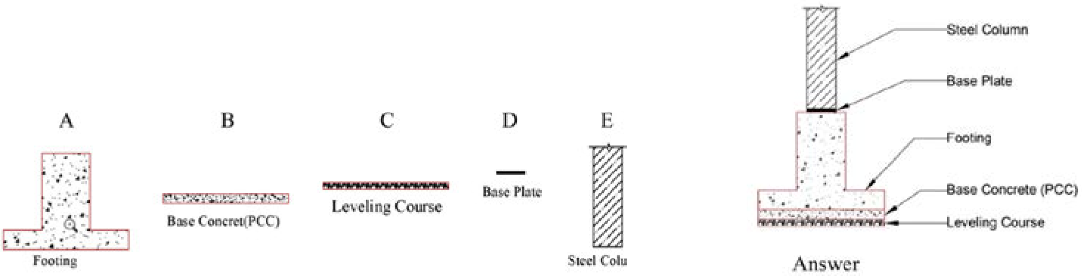
Haptic feedback is an interactive feature that responds to the actions of the users within the VR environment — i.e., certain actions generate a type of haptic feedback with associated code (meaning). When the user drags and drops a deliverable on its selected location, there are two potential haptic feedback: functional and operational. Thus, *operational* and *functional* haptics complement each other to assist with the understanding of the semantics and ensure proper placement of the system components. Operational haptic feedback is on basic human-technology interaction, while functional haptics are systematically organized and tailored to specific semantics that indicate hierarchical structures.

For example, if the deliverable is placed correctly, operational haptic feedback (*positive operational feedback* using soft impulses with low or medium intensity) would indicate a code that will inform the user that the correct location was correctly selected. However, if it is misplaced, operational feedback with the associated code (*negative operational feedback* using rigid impulses, medium and high intensity) is given to indicate to the user the error of displacement. Another example of operational feedback is *positive* when the user reaches a designated milestone while finalizing the packets from the WBS. Otherwise, *negative* feedback is given — indicating that more selections are required for planning. *Operational* haptic (vibrotactile) is produced by the haptic sleeves, which offer feedback for component manipulations like selection and canceling, as well as the haptic vest and feet, which are responsible for delivering notifications, success signals, and failure alerts. Code examples of operational feedback are shown in Table 1.

Table 1: Operational haptic feedback code

Events	Meaning	Haptic feedback	Intensity		Duration [ms]	
Select	A component is taken	Medium intensity, medium sharpness, and short duration, two short impulses with increasing intensity	low	0.2	short	150
			medium	0.5	short	200
Cancel	A component is thrown	Medium intensity, medium sharpness, and short duration, two short impulses with decreasing intensity	medium	0.4	short	100
			low	0.2	short	150
Notification	Generating another component	Medium intensity, medium sharpness, two short impulses	medium	0.4	short	50
Error	Implementation of a component meets the constraints	High intensity, sharp vibration, medium duration	high	1.0	middle	400
Success	The component is applied	Short burst of impulse, high intensity, medium sharpness	high	0.7	short	100
			high	0.7	short	150
Epic success	A milestone is accomplished	High intensity, medium sharpness	high	0.7	Short	100
Failure	A task is failed	Five short bursts of impulse with overlay, max intensity, high sharpness	high	1.0	short	200, 250, 300

Functional haptic feedback provides semantics related to reasoning in problem-solving, involving analytical tasks for planning. Of particular interest is the user's understanding of the relationships between design components in the physical space. An example of a relationship is the priority for construction, assembly, or installation of the design components in the physical space. Reasoning on the relationship demands spatial and temporal cognitive abilities (STCA). The aim of *functional* haptic feedback is to assist the user's reasoning (spatial and temporal reasoning) when required. An example is providing a better comprehension or awareness of the order for construction and assembly among two or more design components—by featuring STCA— as shown in Fig. 5a and 5b.



(a) Design components (as defined in the WBS)

(b) Spatial and temporal information on the design components: an instance of relationship among components

Fig. 6: Spatial and temporal reasoning on design components (using STCA).

Functional haptic feedback informs the user which elements possess the highest priority for their construction and assembly (i.e., some design elements have higher priority than others to make their construction feasible and efficient). ga, for instance, illustrates the building components— without any spatial and temporal information. Fig. b illustrates spatial and temporal information — the relationship among the objects in the physical space, by establishing the priority and order for their construction. Haptic code will help the learner to reason on spatial and temporal information using a combination of duration (D), granularity (G), intensity (I), and sharpness (S) features. For example, a combination of values from the parameters D, I, and S will inform the order distribution in a spectrum (e.g., from the lowest to the highest value or from the highest to the lowest value). Consequently, each component on the final level has its unique haptic code (DGIS) comprising values for each parameter.

The *functional haptic* (*vibrotactile*) *feedback* is related to information on the hierarchy of construction activity sequencing. Interaction with each component is assigned with unique feedback, which allows the user to easily discriminate the components one from another based on their semantics by selecting them from the WBS of the building (Fig. 2b). Due to the perceptive haptic nature of hands, functional haptics is assigned to the haptic gloves.

4. CONCLUSION

The presented study describes an exploration of new human-machine interactions to determine the effects of learning through the combined visual and haptic modalities in VR environments. The interactions with an immersive environment involve engineering design comprehension for planning activities— framed in a problem-solving task. The study presents the technology environment using VR and real-time haptic feedback for experiencing problem-solving tasks — by complementing semantics of visualizations (e.g., 3D designs) with haptic feedback (e.g., vibrations) for a CEM task.

The approach to building a VR environment with dual interactive mode (visual and haptic) facilitates the creation of new forms of understanding problems in planning, a highly cognitively demanding task where STCA plays a pivotal role. Learners map VR visual and haptic features to domain (CEM) problems and build solutions to the planning problem. They used VR technology (headset and controllers) to engage embodied perceptuomotor information by interacting with visual and haptic representations. For example, users navigate the 3D design in VR to approach locations of interest, allowing iterations between representations and reflection while problem-solving. In future work with a higher number of testing subjects, it is expected to demonstrate that haptic feedback (haptic code) effectively informs the learners of the semantics of the components for the planning task, enabling the learner to infer conditions in a virtual scene.

The technology's pedagogical features will make design information from multiple engineering specialties readily available for haptic and visual perception in a stepwise process to learn planning tasks. The technology will facilitate learning through observation and VR movements of design components. The approach uses work packets (construction product deliverables) that would enable scenarios of learning about understanding deliverables as chunks of workload for planning—the smallest unit that can be planned and managed for construction operations. By enabling learning with a work packet focus, the approach facilitates understanding of planning by framing control into a process (set of steps for delivery) of construction (assembly). The method provides opportunities for the learner to assimilate complex simulated realities of the physical space and develop spatial-temporal cognitive ability. Spatial-temporal ability allows learners to effectively manage and comprehend significant amounts of spatial (how design components are related to one another in the 3D space) and temporal (the logic in a process, such as the order, sequences, and hierarchies of the resources within a construction task) information.

The insights collected from this study underscore the significant potential of the VR and haptic cues to enhance the learners' perception of a problem's conditions that are not visible to the learner. Further exploration of technology experimentations will allow researchers to draw conclusions on the learners' perceptual competence and problem-solving capabilities, thereby contributing to the formation of project engineers with high levels of productivity in the construction industry.

ENHANCING THE REALISM OF VIRTUAL CONSTRUCTION SAFETY TRAINING: INTEGRATION OF REAL-TIME LOCATION SYSTEMS FOR REAL-WORLD HAZARD SIMULATIONS

Kilian Speiser, Kepeng Hong & Jochen Teizer
Department of Civil and Mechanical Engineering, Technical University of Denmark, Denmark

ABSTRACT: *In numerous studies, virtual training for construction safety has been proposed as a promising approach. However, creating realistic training scenarios requires significant resources, encompassing various elements such as sound, graphics, agent behavior, and realistic hazards. Digital Twins have revolutionized this process, and although so far, on a conceptual level only, significantly reducing the associated workload, it is still not exploiting its full potential. In this work, we propose a novel approach that leverages Real-time Location Systems (RTLS) data to simulate the real-world behavior of construction workers and equipment within Virtual Training Environments (VTEs). We aim to create training scenarios with dynamic real-world instead of hardcoded made-up hazardous events. To achieve this, we propose an extension to our Digital Twin for Construction Safety (DTCS) framework that now integrates (a) trajectory data streams of construction personnel and equipment and (b) technical specifications of the construction site work environment, including location and geometry of terrain and surface objects, to simulate real-world hazards in virtual safety training scenarios. Our further contribution is a case study application to explore the DTCS training capacity. Applying a logical filtering algorithm, we can process the RTLS data and ensure that the movements of the workers and equipment within the virtual environment are as realistic and representative as within the real world. This then enables the creation of realistic hazards that trainees can encounter in the training phase. Preliminary results with trainees suggest that the proposed work can have a high potential to enhance the realism of safety training, especially when they need to experience human-machine-related interactions safely. However, further work is required to create more responsive learning environments where the equipment follows real trajectories but also responds intelligently to the trainees' actions. By leveraging real-time data and advanced visualization technologies, we bridge the gap between the physical and virtual realms, enabling trainees to interact and navigate within a realistic virtual environment.*

1. INTRODUCTION

The numbers of occupational injuries and fatalities in the construction industry remain high despite significant investments in safety measures. Working on construction sites is one of the most fatal workplaces in the United States (BLS, 2022). The industry has introduced several approaches to increase safety. Generally, they can be separated into three categories: (1) Prevention through design and planning, (2) Right-time intervention, and (3) Prevention through training and education. Training in simulated environments has become more popular over the last few years. Among others, an advantage of virtual training is that the trainee can practice tasks in a safe environment without hazards where mistakes cannot lead to injuries. Several studies investigated virtual training for construction safety using Virtual Reality (VR) with head-mounted displays (Fang et al., 2014; Hilfert et al., 2016; Wolf et al., 2019; Jacobsen et al., 2022; Sacks et al., 2013; Jelonek et al., 2022), or desktop-based virtual training (Speiser & Teizer, 2023a). More recently, Bükrü et al. (2019) and Wolf et al. (2022) developed the concept of Augmented Virtuality (AV) in construction safety training. Noteworthy in their study is the use of real hand-powered tools to generate haptic control and feedback in a virtual learning environment made for construction trainees and not necessarily anymore for academic student participants. These studies highlight that it requires significant efforts to create such training environments independently of the used technology. To ease the creation of the training environment, Golovina et al. (2019a) use Building Information Modelling (BIM), and our previous research introduced a data model for a digital twin, indicating a significant decrease in resources for generating the training scenes (Speiser & Teizer, 2023b). Still, most studies developed hard-coded scenarios where hazards are artificial. Hence, there is potential for more realism with less effort by including additional data sources and realistic hazards.

Despite VR being adopted in various industries, the terminology remains ill-defined. VR is often associated with an immersive experience using head-mounted displays. Some studies consider desktop-based experiences as VR (Wang et al., 2018), while others speak of fully immersed systems that utilize a head-mounted display (Kim et al.,

Kilian Speiser, Kepeng Hong, Jochen Teizer, *Enhancing the Realism of Virtual Construction Safety Training: Integration of Real-Time Location Systems for Real-World Hazard Simulations,* pp. 155-166, DOI 10.36253/979-12-215-0289-3.15

2017). Milgram et al. (1994) first introduced a continuum describing the different mixtures of reality and virtuality. In this continuum, VR defines an environment where only virtual elements exist. At the same time, Augmented Reality (AR) describes systems where most elements are real and a few are virtual. This continuum intended to classify Mixed Reality (MR) experiences with visual displays. However, since 1994, several studies have developed other kinds of displays to include haptics (Azmandian et al., 2016), multidimensional sound (Savioja & Svensson, 2015), and scent (Yanagida, 2012). Integrating such displays creates a new level of immersion.

Based on the latest developments, Skarbez et al. (2021) revisited the continuum from Milgram et al. (1994) and proposed new indicators considering the latest developments in new technologies: (1) the *Extent of World Knowledge (EWK)*, (2) *IMmersion (IM)*, and (3) *COherence (CO)*. The system's immersion defines the level of immersive feedback to actions. Skarbez et al. (2021) conclude that a fully immersive system must realistically respond to all human senses. *EWK* describes what objects are part of the virtual experience and how they are represented. Nowadays, the Internet of Things (IoT) can provide advanced information and replicate real elements in virtuality more accurately. *CO* indicates how consistently the system reacts to the users' intentions. Game engines provide functionalities such as realistic lighting or gravity to make virtual environments coherent.

As mentioned before, creating virtual training in construction safety is time-consuming and requires realistic hazards. Much of the work is dedicated to developing realistic training scenarios where machines perform realistic tasks and move accordingly to represent realistic hazards. IoT can provide such real-world data, and game engines provide real-world physics to achieve coherent experiences. While previous studies have used game engines for creating virtual experiences, no previous work integrated real-world hazards from IoT devices. This study proposes a novel method for bridging this gap by streaming data from IoT devices into a Virtual Training Environment (VTE). The objective is to create more realistic training scenarios with hazards from real-world data. The method increases the *EWK* as well as the *CO* of these systems. The remainder of this paper describes the relevant research gap and introduces the framework integrating IoT devices. Second, a case study validates the proposed method using two training scenarios before summarizing the results and concluding with future work.

2. RELATED WORK AND IDENTIFIED RESEARCH GAP

While virtual training for construction safety has shown promise in improving workers' safety awareness (Adami et al., 2023), a significant research gap exists. The current state of virtual training for construction workers lacks the integration of real-world data from IoT devices, which hinders higher levels of realism in the training experiences. A literature review revealed that studies have explored the use of game engines for simulating real-world physics (Juang et al., 2011), BIM (Golovina & Teizer, 2022), and digital twins (Speiser & Teizer, 2023a; Teizer et al., 2024) to create virtual training scenarios for construction safety. These approaches have enabled the development of more interactive and immersive training environments, allowing trainees to practice tasks safely. However, to date, no previous work has integrated real-world data obtained through IoT into virtual safety training to expose the trainees to realistic hazards despite the potential benefits (Salinas et al., 2022; Zoleykani et al., 2023).

Several studies on Real-Time-Location-Systems (RTLS) exist in construction as they can monitor the precise location of objects. Park et al. (2017) detected hazard exposure in workers using Bluetooth Low Energy (BLE), a technology enabling low-power communication between devices. Chae & Yoshida (2010) introduced an approach to prevent collisions with heavy construction machinery using radio-frequency identification (RFID). Teizer et al. (2008) used Ultra Wideband (UWB) for tracking construction resources and later for visualizing worker and gantry crane trajectory data in a first-of-a-time real-time VR learning environment for ironworker trainees (Teizer et al., 2013). Narumi et al. (2018) stressed the applicability of Real-Time-Kinematic Global Navigation Satellite Systems (RTK-GNSS) for teleoperating construction equipment.

This research bridges the research gap and unlocks crucial advantages by incorporating real-world data from RTLS devices into the VTEs. First, the IoT data will significantly increase the realism of the training simulations as the trainees virtually experience accurate information about the construction site conditions, worker locations, and equipment status. Second, the IoT data will enable the realistic reproduction of hazardous events for the trainee and, therefore, make the performance assessment more meaningful. Third, processing the data with appropriate algorithms will enhance the coherence. Construction sites are dynamic environments with numerous interacting elements. Incorporating data from IoT devices will allow the VTE to respond dynamically to changes in real-world conditions, thereby creating more coherent and contextually relevant training experiences.

In summary, the identified research gap is the lack of integrating real-world data from IoT devices into VTEs for construction safety. The proposed research aims to address this gap by developing a novel method that leverages RTLS data to enhance the realism, coherence, and practicality of virtual training scenarios, ultimately contributing to improved safety measures and reduced occupational injuries and fatalities in the construction industry.

3. DIGITAL TWIN FRAMEWORK AND REAL-TIME DATA PROCESSING

Figure 1 illustrates the proposed framework enabling real-time training for construction safety that is based on the DTCS proposed by Teizer et al. (2024) but focuses on components related to virtual training.

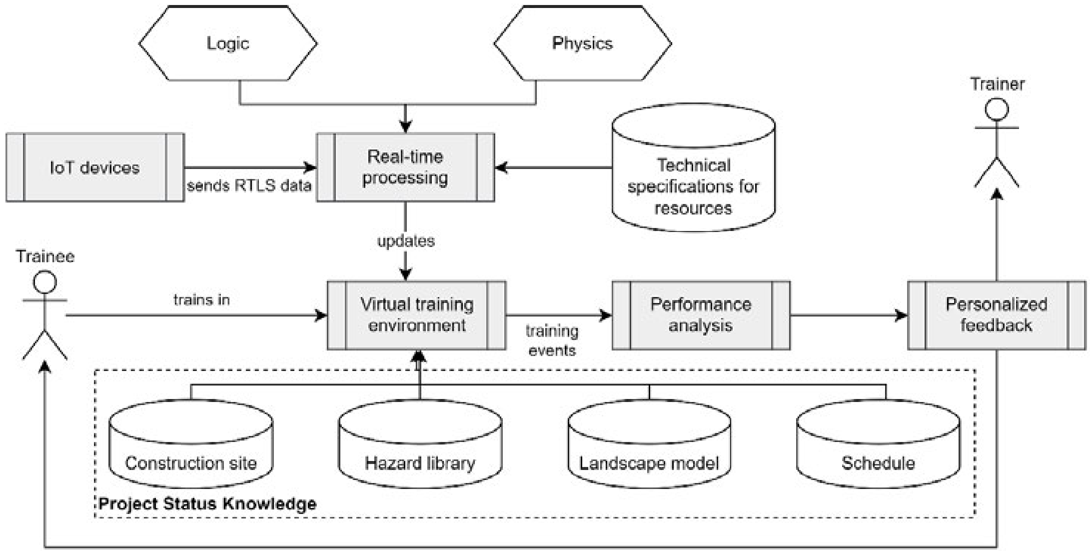

Fig. 1: Digital Twin framework integrating IoT data into virtual training environments.

3.1 Input data

The core of the framework is the VTE that utilizes the Project Status Knowledge (PSK) from the DTCS to virtually represent the construction site. The PSK contains the BIM model, a landscape model, the required resources, and a construction schedule. The PSK also encompasses a hazard library defining currently existing hazards such as restricted working areas, fall hazards, or moving machinery. These hazard zones geometrically describe areas where workers are in danger. Our previous work proposed a data model integrating hazards and safety regulations in a VTE (Speiser & Teizer, 2023b). The hazards can either be automatically detected by algorithms evaluating the PSK using safety regulations or can be modeled manually. This framework assumes that the VTE receives geometrically representable hazard zones. The landscape model contributes to realism by providing real surroundings. The requirements for the landscape model only concern the geometry for rendering purposes. For instance, a mesh from photogrammetry or laser scans may suffice.

3.2 RTLS data processing

The core novelty of this study represents the integration of real-world resources into the VTE to enhance realism through EWK and CO. Such resources include human workers, machinery, or materials. This work focuses on human workers and heavy machinery, such as wheel loaders or excavators. The representation of these resources in the virtual world utilizes geometrical descriptions as well as RTLS sensors to localize the resources in real-time. We expect the framework to function for all types of RTLS systems once the data quality is at a high level.

RTLS data provides spatial-temporal information, which allows us to localize a resource at a timestamp. This information increases the EWK of the virtual environment as the virtual objects are placed at the real location. However, RTLS does not provide further knowledge about the state of the resource (e.g., orientation of the resource). Such knowledge is essential for MR experiences to generate coherent experiences. The real-time processing module generates knowledge about the state of a resource and simulates the motions realistically using technical specifications of individual resources, physics, and logic.

The technical specifications help to create a realistic object of the resource and load it into the MR scene. Besides the correct geometry, it also includes the possible motions of the resource. For instance, how does a machine steer, or can the machine move backward? *The Real-time Processing* module utilizes this information together with physics and logic statements to simulate the motions of the resources realistically. Physics integrates physical laws such as gravity or sound emissions, and the logic statements exclude irrational simulations. For instance, a railway wagon cannot rotate by 180° but changes direction, while a forklift may rotate by 180° without moving the location. The real-time processing module prioritizes realistic visualizations over the accuracy of the sensor data. We would rather misplace the element by a tolerance compared to the recorded data simulating abrupt motions.

3.3 Output: Performance assessment and personalized feedback

The performance analysis module collects data on how the trainee interacts with hazards throughout the training experience. Utilizing the hazard library based on safety regulations, this module constantly checks for violations of safety rules from the trainee. Once such violations are detected, further algorithms can evaluate the severity of the violation. For instance, Golovina et al. (2019b) introduced an approach to classify safety violations. To implement such a method in this framework, the digital twin must provide the location and geometry of hazard zones. Previous research has proposed virtual training for collecting such data (Golovina & Teizer, 2022).

Once the training ends, the performance data is processed, and personalized feedback is generated. Personalized feedback to trainees has various benefits. Among others, learning has shown better efficiency when trainees understand what they did and how they can improve (Pianta et al., 2012). The feedback must summarise and assess the trainee's performance and graphically describe potential improvements. The feedback is also shared with the trainer, who can compare different performances.

4. CASE STUDY

To validate the proposed framework, we conducted an experiment in an infrastructure project in Munich, Germany. The study comprises five steps: (1) Collecting RTLS data from construction resources, (2) generating the game scene in Unity, (3) processing the RTLS data, (4) simulating the resources in the Unity scene using the processed data, and (5) evaluation of the simulation. The following sections describe how we tested the framework and finished with the required changes in order to provide (near) real-time training.

4.1 Reality: RTLS data collection

We collected the RTLS data at the staging area for a subway track replacement project in Munich. The collection lasted for three days during the early stage of the project. During the collection, we observed and tracked multiple tasks, such as unloading materials from the truck and arranging and loading materials onto rail cars. The tasks involved resources of both pedestrian workers and construction equipment.

The RTK-GNSS solution was used for the location data collection as it performs accurately in outdoor environments. The RTK-GNSS solution consists of two components: a base station and rovers. The base station is placed statically in open space, and workers and equipment carry the rovers. Compared to a single GNSS solution whose accuracy is affected by atmospheric delays or clock errors, the RTK-GNSS uses the base station to provide correction for rovers so that the workers and equipment are located with cm-level accuracy (Wielgocka et al., 2021). The accurate location information reduces the work of data processing and filtering when importing it into the training environment. In addition, it can cover a wider tracking area with a simple setup than other locating methods such as BLE or UWB.

Given that traffic from rail cars and construction equipment occurred within a limited area, the logistics at the staging area could be packed and complicated. Therefore, pedestrian workers must receive sufficient realistic safety training to train to work in such an environment. To test the proposed framework, we recorded a task where two construction workers moved materials from a storage area to a rail wagon. Figure 2 illustrates the scenario: One worker operates a forklift, and the other worker assists the equipment operator. The work lasted for 90 minutes. The pedestrian worker carries an RTK-GNSS module, and the forklift has a module mounted on the roof of the forklift, centrally placed on top of the operator's seat.

Fig. 2: The forklift moves material from the loading area to a railway wagon while a pedestrian worker assists.

Figure 3a shows the trajectories of the two resources during the 90 minutes. The RTK-GNSS rovers streamed the location data to a database with a frequency of 5Hz for the machine and 1Hz for the worker. During that time, the worker supported the equipment operator by attaching the material bags to the forklift in the loading area and removing them in the unloading area. Figure 3 shows that frequent interactions between workers and equipment were inevitable when working simultaneously in a limited area. The 3D plot in Figure 3b visualizes the 2-dimensional movements of the forklift and the worker over time within the loading area to stress the close interaction between the forklift and the worker. This visual eases the spotting of proximity events, which entail that the worker was too close to the forklift. In this study, we defined too close proximity once a worker enters a bounding box with a one-meter distance to each side of the forklift. We ran an analysis based on an existing approach to detect such proximity events (Golovina et al., 2019b). The worker entered the 1m bounding box 28 times during the time. We will use this performance as a reference for the trainees in our training scenarios, but the results also indicate that this framework is also applicable for safety monitoring or assessment of construction resources as the game engines provide large libraries for the demand of the previously mentioned applications.

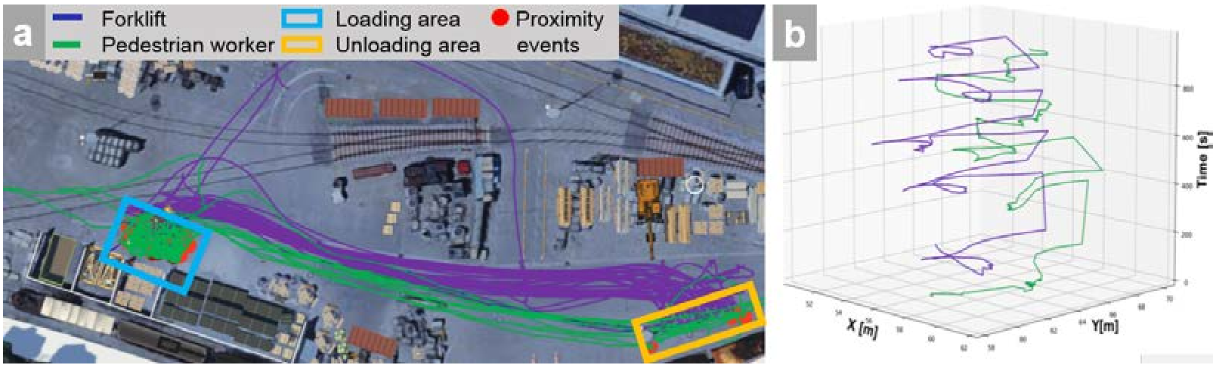

Fig. 3: (a) 2D-trajectories of the forklift and the worker during a work task over 90 minutes with 28 proximity events, and (b) the trajectories, including the time-axis limited to the unloading area for 15 minutes.

4.2 From reality to virtuality: RTLS data processing

The collected data consists of a set of locations (x,y,z) with the corresponding timestamps. The locations refer to the coordinate system WGS84, a common GNSS localization system. As the Unity scene refers to ETRS89, we transformed the WGS84 data into ETRS89 using Pyproj (Pyproj Contributors, 2023). Based on this data, we can visualize the individual states for each recorded point in the Unity scene and locate it at the real-world location. The second component of data processing connects the individual points and moves the resource coherently with a realistic speed, orientation, and motions. For instance, the wheels rotate, or the axle turns once steering. Figure 4 illustrates a problem: The trajectory from a machine implies that the machine first moved forward, then stopped, and returned backward. To include such logic in the framework, we need to make assumptions and technically convert them into an algorithm. This specific forklift steers with the rear axle, which must also be considered when simulating the motions. We make the following logical propositions:

Proposition 1: The forklift only moves forward or backward and not sidewards.
Proposition 2: The forklift changes directions if and only if it is moving.
Proposition 3: The wheel of the forklift spins if and only if the forklift is moving.
Proposition 4: A pedestrian worker only walks forward.
Proposition 5: Distances of less than 10 cm between consecutive points are considered noise.

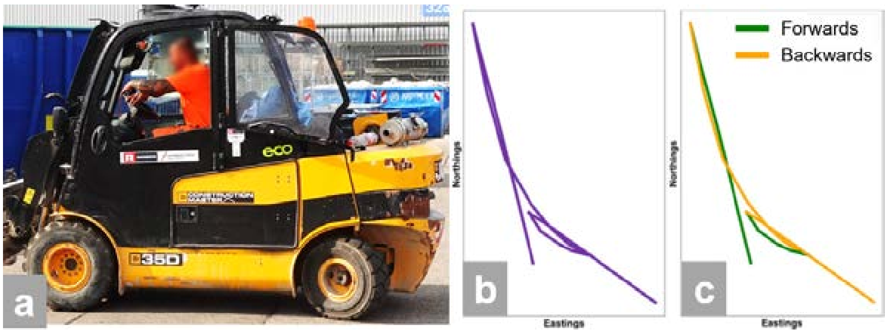

Fig. 4: (a) the tracked forklift, (b) the recorded trajectory, and (c) the directed trajectory after the assessment.

Some of these assumptions are not precise. For instance, humans can walk backward or sidewards, crawl, and jump, but it is rather difficult to detect such behavior purely based on the trajectory of a human. Hence, we limit the scope to forwards walking humans. The last assumption was made after the first implementation, where the authors noticed that the smoothness of the motions appears faulty when considering short movements. For instance, the worker probably standing would constantly change direction and move by a few centimeters. The following algorithm integrates these logical statements and moves the resources in the correct direction at a given speed.

Algorithm 1: Move object

```
Input: Resource, CurrentPoint, NextPoint, CurrentDirection
1    Distance = |(NextPoint – CurrentPoint)|
2    If Distance >= 0.1:
3        NextDirection = NextPoint-CurrentPoint
4        Duration = NextPoint.Time – CurrentPoint.Time
5        Velocity = Distance/Duration
6        If Resource is Machine:
7            If |AngleBetween(CurrentDirection,NextDirection)| > PI/4
8                MoveBackwards(NextPoint, Velocity)
9            Else MoveForwards(NextPoint, Velocity)
10       Else MoveForwards(NextPoint, Velocity)
```

The proposed algorithm moves a resource to the next point with realistic speed and rotation. If the next point is at least 10 centimeters from the current location, the algorithm determines the required direction and the velocity. Depending on whether the resource is a machine or a human, the algorithms move the resource forward or backward. The methods *MoveForwards* and *MoveBackwards* in lines 7, 9, and 10 implement how the resource behaves when moving. Practically, this means that the resource is moved in every frame according to the velocity and distance. The methods also implement additional animations such as rotating wheels of the machine or body motions for the worker (moving the legs, swinging the arms).

4.3 Virtuality: Training scene

The virtual environment was generated in the game engine Unity. We used Unity as it provides a vast selection of assets and is simpler for conceptual work, while other game engines like Unreal outperform Unity with the graphics. The virtual environment comprises the components illustrated in Figure 5: (1) a landscape, (2) the BIM model, (3) additional objects to enhance the realism of the game scene, and (4) the moving resources connected to IoT devices.

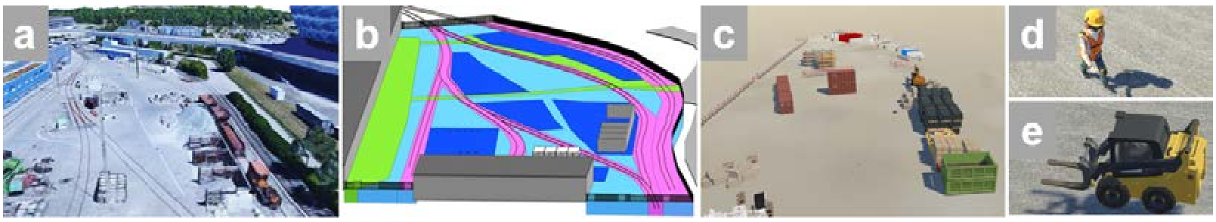

Fig. 5: Scene components: (a) landscape, (b) BIM model, (c) site equipment, (d) human worker, and (e) forklift.

Google's photorealistic tiles were added to the Unity scene using the asset Cesium to visualize realistic surroundings. This asset allows for adding geo-referenced objects and utilizes the WGS84 coordinate system, which is commonly used in GNSS applications. The tiles from Google shown in Figure 5a have two disadvantages: First, it is outdated, and second, the quality is low. For this use case, we consider it sufficient as it is not the focus of this study. A frequently updated mesh generated from a laser scan or photogrammetry may increase realism and ensure up-to-date surroundings. In the next step, we added the BIM model in the form of an IFC file. We envision the digital twin to provide BIM models of high quality. In this case study, a BIM model with few elements and a low level of development was available. The provided BIM model contains the physical structure of the site (see Fig. 5). A modified version of the Unity Asset *IfcImporter* was used to convert the IFC file into a Unity-readable format. The provided IFC file references the geospatial coordinate system ETRS89. Hence, the origin of the BIM model was converted into WGS84 to place it correctly within the landscape model. The local origin of the Unity scene still relates to the ETRS89 origin of the BIM model. In this way, we refer to a Cartesian coordinate system and no longer to the geographic coordinate system WGS84, which eases simulating the resource. In the third step, the scene obtained additional objects to make the environment more realistic. Based on a site visit and a site layout plan, we added elements such as an office trailer, safety guardrails, or material storage. The site layout plan defines, among others, safe paths for the workers and spaces for the machines to operate. In the last step, the tracked resources are added, and the movements will be simulated based on the collected trajectories and the proposed algorithm in the previous sections. The moving resources represent the hazard for the workers, and as they are following the real-world data, the simulation is more realistic.

5. EVALUATION

The introduction described the problem of this research: Generating realistic scenarios for construction safety requires realistic hazards and realistic surroundings. Our framework proposes the use of RTLS data for integrating scenarios based on real tasks. The framework was implemented for the described construction site and tested with the 90 minutes data sample from the previous section in two training scenarios: (1) a training experiment with a student to validate that the created hazards are more realistic, and (2) collaborative tasks where the trainee assists the forklift. Before describing the training scenarios, an accuracy assessment evaluated the algorithm, simulating the motions of the resources.

5.1 Assessment of simulated data

We evaluate the accuracy of the RTLS data integration based on two indicators. First, we measure the deviation from the simulated data to the collected data in the real world. Second, we visually assessed the simulated data and compared it to a video recording.

One of the main objectives of this work was to simulate hazards realistically using RTLS data. RTK-GNSS provides reliable and accurate data. However, the filtering algorithm processes the raw data to visualize motions coherently. This can generate misplaced hazards. Hence, the filtering algorithm was evaluated by comparing both the virtual trajectory to the real trajectory. For collecting the virtual trajectory, a Unity script streamed the location of the resource with 10Hz to a database. The virtual trajectory was then compared to the real trajectory. As the real trajectory was collected with 5Hz and 1Hz for the forklift and the machine, respectively, the time-wise closest point from the virtual trajectory was compared to the real point. There is already a little error in this comparison as the closest point can be up to 100ms apart. With a maximum speed of 30km/h, this can contribute to inaccuracy of up to 8.5cm.

Table 1 summarizes the distribution of the deviation for both the worker and the forklift. The algorithm for the worker provides accurate results. With a standard deviation of 5.9cm and a 99 percentile of 29cm, the performance is very good. However, it is important to stress that the data was collected with 1Hz. The implemented algorithm aims to simulate the movements towards a given point. In between these points, we do not have evidence of what happened. Within this second, we do not know whether the worker turned around. Thus, data should be collected with a higher frequency in order to evaluate the realism of the simulation better. The accuracy of the simulation for the forklift is more meaningful for two reasons: The real-world data was collected with a higher frequency, and the algorithm moves the resource on interpolated paths, which entails a higher deviation. The mean deviation amounts to 13cm, and the standard deviation is 27cm. The median deviation amounts to 6.8cm, and the forklift was at least 40cm accurate during 95% of the time. The inaccuracy of the simulation relates to the low frequency of the collected data points. The authors conclude that a higher 30-100Hz frequency will enable a more reliable simulation.

Table 1: Deviations between the real trajectory from the RTLS data and the virtual trajectory.

Resource	Mean	Standard	Median	95 percentile	99 percentile
Forklift	13cm	27cm	6.8cm	40cm	46cm
Worker	10cm	5.9cm	7.6cm	21cm	29cm

The second measure to evaluate the simulation was conducted manually. We compared 10 minutes of the simulation to a 7-minute video recorded on-site simultaneously. The video reveals that twice during the 10 minutes, the forklift was simulated moving backward while it was actually driving forward. This happened during a total time of 28 seconds, corresponding to 6.2%. Comparing the movements of the worker compared to the simulation seemed realistic.

5.2 Training Scenario 1: Simultaneous tasks

As we mentioned previously, virtual construction safety training requires personalized feedback. Research has proposed methods for collecting such data and can visualize it in a concise way for construction workers. In this research, we use the concept of safety parameters and collect data from the trainees when entering hazards using automatic data collection. In the same way as before with the worker in Section 4.1, a proximity event is triggered once the trainee enters the bounding box around the forklift.

In the first training scenario, the trainee must collect various objects in the training scene and return them to a storage area. Meanwhile, the forklift and the pedestrian worker will follow the trajectories from the real-world data collection. During the training, the trainee needs to ensure that they will not trigger any hazards relating to the forklift. Figure 6a indicates such a situation: The trainee needs to cross while the forklift passes. Should the trainee get too close to the forklift, a close call is triggered, and data will be collected, which is processed for personalized feedback. The created training scenario lasts 10 minutes, where the trainee needs to collect seven objects. Figure 6b shows the results. The trainee crossed the road six times while the forklift was nearby. The visual indicates that the worker always identified the forklift while heading east. However, returning, the trainee was very close to the forklift twice. This data allows us to conclude that either the equipment operator should have more distance to the pedestrian cross or that the trainee could not see the forklift. Figure 6b also depicts the three proximity events of the real-world worker during this 10-minute excerpt.

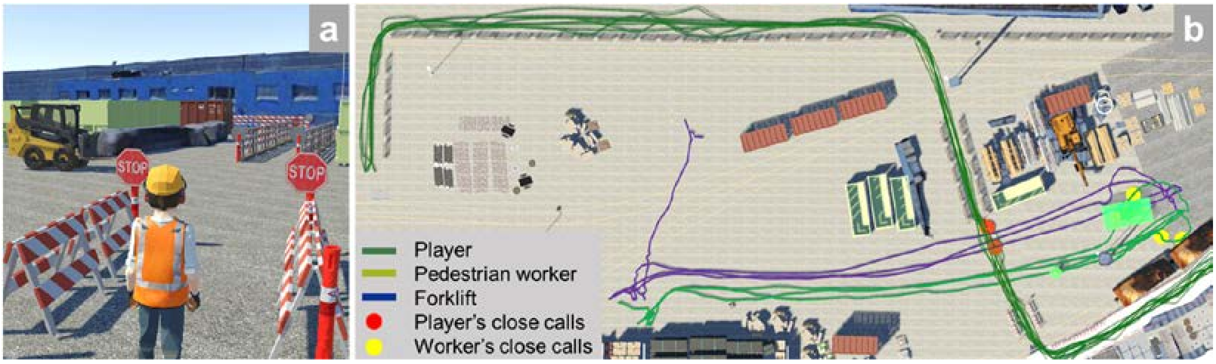

Fig. 6: (a) Results of the first training scene, including the landscape, BIM model, resources, and trajectories from IoT devices, and (b) the trainee crossing the road while the forklift follows the real-world trajectory.

5.3 Training Scenario 2: Collaborative task

In the second training scenario, the trainee takes over the role of the worker. Hence, the pedestrian worker is removed from the game, and the trainee is advised to support the equipment operator in loading the forklift. The trainee must wait for the forklift and assemble the boxes by pressing "C" on the keyboard. To ensure the worker is safe, the trainee is advised to wait in highlighted areas to not collide with the machine. Figure 7b illustrates the safe area, and Figure 7a shows the results from the 90-minute task. During the 90 minutes, the worker followed the forklift to assist in transporting the boxes. We collected the data about the proximity with the forklift using the 1m bounding box described before. When the worker collides with the bounding box, a proximity event is triggered. Figure 7a shows the 37 collisions with the bounding box in yellow and highlights three actual hits in red. The figure indicates that the actual hits occurred not in the loading area but when the forklift was approaching the worker while the worker walked to the unloading area. The forklift was emitting sound, and the game engine increased the volume when coming closer to the sound source. Still, the worker did not avoid the equipment.

However, it is likely that in real-world situations, the equipment operator would have stopped. These collisions are not realistic and reveal one major disadvantage of this approach: The machine is following the trajectory without reasoning. Hence, future work needs to investigate how to include such reasoning as the machine would most likely avoid the machine. Comparing the virtual performance of the trainee to the real-world worker, the trainee triggered more proximity events. There can be different reasons, but all yellow proximity events were triggered at the front. A reason could be that the forklift was stubbornly following the trajectory from the data collection and did not interact with the worker. There was no communication possible between the forklift operator and the construction worker. Hence, if the worker, for instance, did not finish, yet, mounting the box, the forklift will yet continue on the route and almost hit the worker. The authors propose two approaches to tackling this issue. First, the forklift may include intelligence, such as avoiding the worker while driving or waiting for the trainee to finish their task before moving. Second, a multiplayer game where another trainee takes over the role of the equipment operator could enhance realism and improve collaboration between the workforce.

Fig. 7: The (a) results from Training Scenario 2 indicating the trajectories and proximity events, and (b) safe waiting areas where the trainee can safely wait for the return of the forklift until its standstill.

6. CONCLUSIONS AND FUTURE WORK

In this paper, we addressed the challenge of creating realistic virtual training scenarios for construction safety. Despite the advancements in virtual learning, the integration of real-world data from IoT devices was largely missing, hindering the level of realism regarding hazardous situations. Our proposed framework leverages RTLS data to enhance the extent of world knowledge and coherence of VTEs, resulting in more realistic and contextually relevant experiences as the hazards relate to real-world scenarios.

Through a case study conducted at a construction site in Munich, Germany, we validated the effectiveness of our framework. The integration of RTLS data allowed us to accurately represent the movements of construction workers and equipment within the virtual learning environment for safety training purposes. The data processing algorithms and logical propositions ensured realistic motions of the resources, further enhancing the coherence of the virtual environment. Additionally, we demonstrated the practicality of the proposed method by creating a realistic training scenario involving hazardous interactions between construction workers and equipment. The study also indicates potential in creating training scenarios for collaborative tasks between humans and equipment based on real-world data.

Nevertheless, the framework requires a more responsive simulation where the equipment not only follows a real path but can also stop and continue based on the trainees' behavior and feedback or avoid them when having clear sight. It also raises further research questions, for example, whether it would be better to create multiplayer games for collaborative work tasks rather than making equipment follow realistic but, eventually, for human learners, predictable travel routes. As work is underway, expanding our framework to support multiple trainees interacting and collaborating within the virtual environment would foster a more dynamic and engaging training experience, mirroring real-world construction sites' teamwork and coordination.

This preliminary work successfully bridged the gap in virtual training for construction safety by integrating real-world data from IoT devices, but there are several avenues for future improvements: RTLS data should be recorded at a higher frequency than 1Hz, and additional sensors on relevant static or dynamic objects in the scenery could further enhance the realism. For the forklift, additional sensors could detect the vehicle's orientation or the fork's exact location and extension. This would ease the simulation of movements. In addition, a Body Motion Suit (BMS) for the construction worker may provide more information on how the worker executes a specific task, adding a high level of perhaps needed detail of relevance to some construction hazards.

In conclusion, our preliminary research efforts contribute to the advancement of virtual training for construction safety by leveraging IoT data to create more realistic and coherent training scenarios. As we continue to explore and refine the proposed framework, it has the potential to significantly improve safety awareness and reduce occupational injuries and fatalities in the construction industry.

VISIBILITY ENHANCEMENT OF CRANE OPERATORS USING BIM-BASED DIMINISHED REALITY

Roghieh Eskandari & Ali Motamedi

Department of construction engineering, École de Technologie Supérieure (ÉTS), Montréal, Canada

ABSTRACT: *The limited visibility experienced by crane operators in construction sites poses significant challenges, leading to reduced performance and safety concerns. Obstructive elements, such as existing buildings, construction elements, or vehicles, can block the crane operator's field of view, hindering their ability to execute lifting operations with precision and confidence. To address this issue, this study presents a novel approach using Building Information Modelling (BIM)-based diminished reality (DR) to enhance visibility by dynamically removing obstructive objects from the crane operator's perspective in real-time. The research employs a marker-based registration system that effectively aligns BIM data with the physical environment, ensuring realistic and precise DR visualization. Additionally, a semi-automatic selection method that involves minimal intervention from the user is employed to select desired objects. To generate the background, the system utilizes real-time observation data from occluded areas. A validation through a case study demonstrates the practical applicability of the developed system in real-life construction scenarios.*

KEYWORDS: *Diminished Reality (DR), Augmented Reality (AR), Mixed Reality (MR), Crane, Visibility, Building Information Modelling (BIM), HoloLens, Construction industry.*

1. INTRODUCTION

Construction sites are inherently hazardous environments due to the presence of heavy machinery and large equipment. Among these, cranes play a vital role in the construction process. Crane operators may be required to operate when they do not have direct visibility of the load, which is referred to as a "blind lift". This type of lift has been recognized by the industry as one of the most hazardous activities, as it poses a significant threat to both personnel and nearby property. In general, reduced visibility in the working area can lead to lower operator efficiency and have an adverse impact on both the end product's quality and overall productivity (Price et al., 2021).

Diminished Reality (DR) has emerged as an effective solution for overcoming occlusions by recovering background scenes and giving an unobstructed view of the workspace. Meanwhile, Building Information Modeling (BIM), which is a digital representation of the building geometry and information (ISO, 2015), can be beneficial in the DR process. BIM can integrate data from various data-capture technologies, such as laser scanners, Global Positioning System (GPS), and imaging sensors, to provide complete data about a construction project (Alizadehsalehi & Yitmen, 2016). Considering these features, BIM data can be used to create a digital representation of the background scene that is required in the DR process.

In this study, we investigate the implementation of BIM-based DR to enhance crane operator visibility. Our proposed approach aims to facilitate a safer and more efficient construction environment by providing crane operators with a clear and unobstructed view of their work area. By utilizing BIM data and DR technology, we seek to improve awareness, empower operators to make informed decisions, and to elevate safety within the construction industry. The integration of BIM and DR holds the potential to significantly improve crane operations and enhance overall productivity and safety at construction sites.

2. RELATED WORKS

2.1 Occlusion handling in crane operations

Various technologies have been developed to handle occlusion and to enhance visibility for crane operators. The most widespread approach used by the industry is to ensure that the crane operator remains in constant radio communication with either a rigger or a signal person, who can provide guidance throughout the lift. However, these methods of communication can be unreliable and cause various accidents (Mansoor et al., 2023). Many solutions have been developed to overcome this limitation and improve safety and efficiency at construction sites. For example, a crane monitoring system is presented in (Price et al., 2021) that can provide the crane operator with real-time 3D visualization and the ability to give and receive feedback during blind lift tasks. In this study, the safety warning system is also created based on a 3D model of the crane environment. This 3D model is developed

in real-time utilizing sensors, cameras, and laser scanners. An alternative approach involves the visualization of information using transparent displays (Sitompul et al., 2020). This information, which includes important details such as the height and weight of the lift, is displayed through head-down displays, which are installed near the operator's line of sight in the cabin. However, research has indicated that operators often pay minimal attention to the information presented on head-down displays (Wallmyr, 2017). This is primarily due to the placement of these displays far from the operator's line of sight, as they are positioned in a way that avoids hindering the operators' view. A major drawback of using these techniques is that a user is unable to view the information from their own point of view.

2.2 Augmented reality in crane operations

Augmented Reality (AR) can be used to combine computer-generated information with the user's view of the environment. AR systems may give the operator real-time feedback by superimposing valuable information such as the load weight, distance to the target, and other crucial data on their field of view, making AR a valuable tool for improving visibility for the crane operator, the surrounding area, and the operation to be carried out (Sitompul & Wallmyr, 2019). For example, (Yang et al., 2015) developed an AR system to assist operators by providing visual information, such as arrows. The findings indicated that the implementation of AR support led to a significant reduction in task completion time, as it allowed operators to perceive the environment more clearly and effectively. Moreover, it minimized collision frequency and enhanced the overall user experience, demonstrating the usefulness of AR in familiarizing operators with new environments (Yang et al., 2015).

Nonetheless, despite the numerous benefits of AR techniques in crane operations, there are certain limitations that can be overcome by Mixed Reality (MR) techniques. One of the disadvantages of AR is that it may suffer from limited depth perception and occlusion issues. In AR systems, virtual objects are superimposed onto the user's view of the real world, but they may not always appear in the correct position relative to real-world objects, leading to misinterpretations and potential hazards (X. Li et al., 2018).

(H. Li et al., 2022) presents a novel application of MR technology in the form of a night hoisting assistance system, highlighting the potential of MR for enhancing visibility and operational safety in crane operations. This system enables operators to perceive and interact with a virtual model of the hoisting process in real-time. The system offers variety of interaction modalities, including voice interaction, gesture recognition, and gaze tracking, allowing operators to intuitively manage and navigate the virtual environment.

2.3 Diminished Reality

Diminished Reality (DR), which is an advanced visualization technology for removing or reducing the visibility of objects in real-time, can go a step further by visually removing obstructive objects such as buildings, trees, or other equipment that may obstruct the operator's view of the workspace (Mori et al., 2017). Thus, DR can provide new opportunities for more accurate visualization for operators of heavy machinery such as cranes. (Aromaa et al., 2020) introduced the concept of DR for generating see-through visualization, allowing the operator to perceive the machine's physical structure as transparent from their viewpoint (see Fig. 1 (a)). Instead of making the machine's cabin transparent, (Palonen et al., 2017) developed an alternative method for visualizing the view in front of the machine using point clouds (see Fig. 1 (b)).

(a) (b)

Fig. 1. (a) See-through visualization of the boom presented in (Aromaa et al., 2020) , (b) Visualization of the environment using point cloud presented in (Palonen et al., 2017)

Implementing effective DR solutions for operator visibility enhancement comes with a set of challenges that researchers and developers need to address. The main challenge of DR is obtaining reliable and accurate information about the hidden background, especially in dynamic construction sites where the surroundings may change frequently. Since DR aims to remove or reduce the visibility of obstructive objects, it requires access to real-time observation data or an accurate representation of the background scene to create a seamless visualization. Another challenge is the precise alignment of the virtual model with the real-world environment. For effective DR visualization, the virtual model must be accurately registered with the physical scene to ensure a seamless blend between the two. Achieving precise alignment often requires robust marker-based registration methods or other sophisticated tracking techniques, which can be complex to implement and may require specialized hardware or software. Furthermore, in scenarios where the background scene is dynamic and constantly changing, maintaining real-time updates of the hidden background information becomes critical. The DR system must continuously receive and process the latest observation data to accurately reflect any changes in the environment. This real-time processing can place significant computational demands on the system, requiring efficient algorithms and powerful hardware to handle the data in a timely manner. Overcoming these challenges and creating a seamless DR experience for crane operators requires sophisticated data processing techniques and a good understanding of the specific requirements of the construction site environment.

3. PROPOSED DR SYSTEM

The proposed system for enhancing crane operator visibility using BIM-based diminished reality allows for the seamless alignment of physical and virtual scenes, enabling the visualization of occluding objects and their removal from the crane operator's view in an MR environment. This approach aims to enhance visibility, safety, and situational awareness for crane operators in real-life construction scenarios.

Using our proposed system, the crane operator, who controls the overhead crane from the shop floor and is equipped with a head-mounted display, interacts with the system using hand gestures to visually remove the sections where obstructive objects are present. The process begins with scanning the QR code markers, followed by alignment of the 3D virtual model onto the physical scene. Subsequently, specific objects within the virtual model can be selected. Afterward, the system seamlessly integrates the real-time video feed from CCTV cameras, showing the dynamic real-time background and further enhancing the operator's field of vision.

The system architecture consists of three main layers, as illustrated in Fig. 2. The first layer involves data collection. The BIM model provides additional contextual information, such as the physical layout of the construction site, the positions of obstructive objects, the dimensions, and characteristics of the crane. The laser scanning system in combination with the BIM model can create the initial static 3D environment map. Accurate placement of QR code markers in the model ensures precise registration and tracking. Subsequently, real-time data is collected from video streams captured by CCTV cameras placed strategically in the environment. A data integration and processing layer includes both the alignment and DR processing modules. In this layer, the aligned BIM model is integrated with the real-time observation data from the CCTV cameras. Through this integration, the dynamic updating of the DR visualization is achieved, ensuring a seamless and accurate representation of the background scene. The last layer involves the visualization of the enhanced scene in a MR environment. In our implementation, a Microsoft HoloLens 2 headset was utilized to present the MR visualization to the crane operators, allowing them to perceive the virtual and physical elements seamlessly. The visualization module provided the crane operator with an enhanced and contextually accurate representation of the construction site. The headset's advanced hand and gesture recognition capabilities enabled precise and responsive interaction with the MR environment. Crane operators could easily manipulate and navigate the virtual content using natural hand gestures, allowing for efficient and fluid control over the DR visualization.

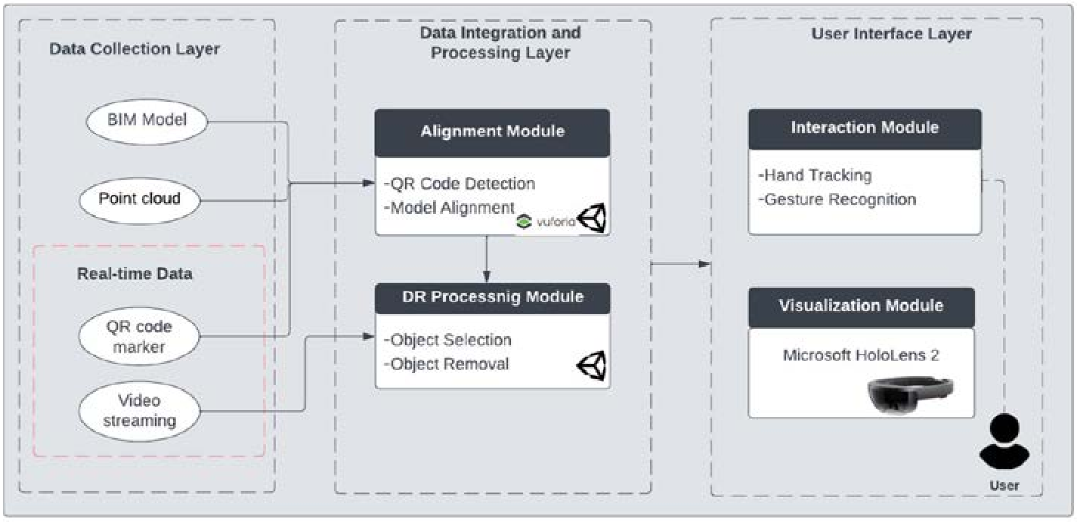

Fig. 2. System architecture for enhancing crane operator visibility

The system is implemented using C# programming in the Unity 3D environment. Unity 3D facilitates integration of video streams into a virtual environment. The OpenCV framework is employed to execute real-time image processing algorithms on the frames, enabling efficient and responsive operations. Additionally, a Wi-Fi connection is established between the HMD (Head Mounted Display) and the CCTV cameras. This wireless network connection allows seamless video streaming to the HMD, ensuring real-time visualization of the environment.

Fig. 3 shows the process flow of the generated prototype system, which will be elaborated in the following subsections.

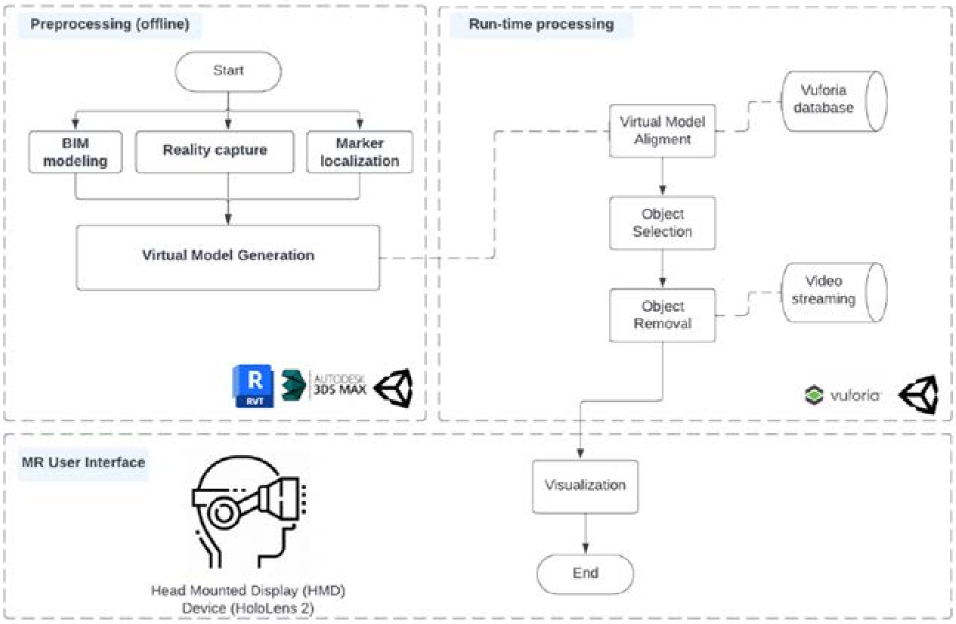

Fig. 3. DR process flow

3.1 Virtual Model Generation

First, the virtual model of the environment is generated using the BIM model in combination with reality capture techniques. The 3D scanner plays a vital role in reality capture by providing highly accurate and precise point clouds of the environment. It captures intricate details and geometries, ensuring that the virtual model is an accurate representation of the real-world site. Compared to the Structure from Motion (SfM) method (utilized in (Inoue et al., 2018)), which heavily relies on the quality and number of images taken to reconstruct the background, the 3D scanner captures data directly from the environment, minimizing the dependency on photo quality and providing a more robust solution. Furthermore, accurate scene reconstruction can be highly challenging when applying the SfM method to complex construction environments. The 3D scanner, with its high precision, can handle such complex environments more effectively, leading to a more reliable and detailed background generation. Then, Autodesk 3ds Max is used to create a high-quality 3D model of the scene using the BIM model and point cloud data. This 3D virtual model can then be optimized and converted into a low-polygon model suitable for real-time rendering in game engine environments. In addition, the location of the QR code is defined in the virtual model in this step for the marker-based registration. The physical QR code marker is subsequently placed in the correct location within the environment.

3.2 Virtual Model Alignment

As indicated in the previous subsection, to adequately align the virtual model in the physical world, QR code markers are used. A Microsoft HoloLens 2 headset tracks the camera's position, ensuring accurate alignment of the virtual and physical scenes. Vuforia image target technology (Vuforia Enterprise Augmented Reality (AR) Software | PTC) plays a crucial role in achieving precise alignment between the virtual and physical scenes in this study. As the user scans the QR code marker using a headset equipped with the Vuforia engine, the system identifies the unique image target and establishes a reference point. By recognizing the image target (the QR code marker stored in the Vuforia database), Microsoft HoloLens gains an understanding of its position and orientation in the real-world environment.

3.3 Object Selection

Users can interact with the virtual model by selecting objects they wish to remove from their view. Upon selection, information about the object, including its metadata transferred from the IFC model, is displayed in the user's view. This interactive process allows for a more user-friendly and intuitive experience.

3.4 Object Removal

The process of object removal involves several steps in an MR environment. First, the system captures real-time video streams from CCTV cameras, which provide a view of the target environment, including obstructive objects. Using the interactive HoloLens interface, the operator can select a region of interest, which includes obstructive objects like walls. The frames captured by the CCTV camera are transmitted in real-time, accompanied by annotation information, including the camera's pose at the time of each frame. After any distortions are repaired, these frames are decoded and uploaded as textures to the GPU (Graphics Processing Unit) of the headset device, enabling the generation of a DR view. The image warping process is then initiated, identifying corresponding points between the selected region in the operator's view and the frames coming from the real-time video stream. By calculating a transformation matrix based on these points, the system precisely aligns the background view with the real-world environment from the crane operator's perspective. As a result, the selected obstructive objects are visually replaced with the corresponding background from the virtual model. The HoloLens application renders this augmented view, providing the crane operator with an unobstructed and clear representation of the environment. The entire process happens in real time, updating when the crane operator moves or changes their perspective, resulting in better awareness of the situation and informed decision-making during complex lifting operations.

3.5 Visualization

The final MR visualization, presented through the headset, seamlessly combines real-world observation data from CCTV cameras with the DR-processed view. Obstructive objects, previously removed using image warping, are no longer present in the operator's field of view, ensuring an unobstructed and clear perspective. This MR visualization empowers the crane operator with real-time and accurate information.

4. CASE STUDY

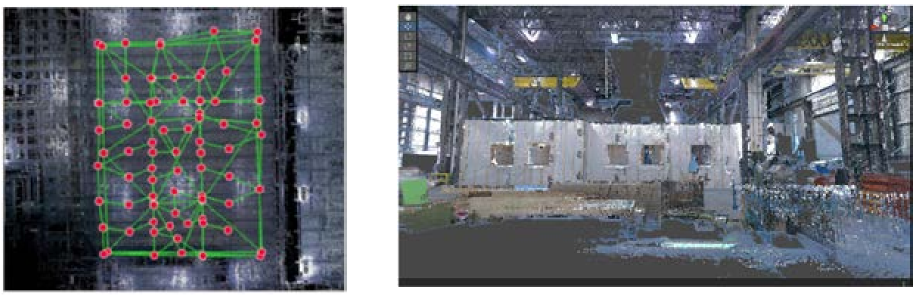
In this case study, we conducted initial steps for the validation of our developed system in a real-world setting at a prefabrication factory's shop floor located in Montreal, Canada. The manufacturing of prefabricated modules is done on the factory’s production floor, with distinct zones and the presence of cranes for material handling (see

Fig. 4 (a)). The type of crane used in this study is an overhead crane, which is defined by its ability to move along rails that are located overhead, thereby offering flexibility in the lifting and handling of material. The system's capabilities in improving operator visibility and safety during crane operations are the focus of this case study. The crane operator is equipped with a remote controller to manipulate the crane's movements and operations. The modules are placed in close proximity on the shop floor due to a lack of space. The operator's viewpoint is obstructed by this setup, which reduces their ability to see crucial parts such as the hook of the crane. In these situations, the operator requires the presence of additional workers near the hook to help manage the entire operation. The integration of the overhead crane with the proposed BIM-based DR system provides a solution to overcome the challenges of limited visibility faced by crane operators. As shown in Fig. 4 (c), the CCTV cameras were strategically placed around the module. Fig. 4 (b) shows the 3D virtual model of the prefabricated module.

(a) (b) (c)

Fig. 4. Experimental area; (a) Physical factory environment, (b) Virtual model of one module, and (c) Factory and camera settings in Unity environment.

Point clouds of the environment are collected by Leica Cyclone REGISTER 360, as illustrated in Fig. 5 (a), (b). The point cloud in combination with BIM model helps us to generate a low-polygon virtual model of the scene (shown in Fig. 4 (b)). The process began by placing a QR code marker at the same location in the physical scene as in the virtual model. When the crane operator wore the HoloLens and scanned the QR code marker, the HoloLens accurately tracked the camera's position and orientation, ensuring precise alignment between the virtual and physical scenes.



(a) (b)

Fig. 5. Point clouds of the environment collected by Leica Cyclone REGISTER 360; (a) Scanning stations; (b) Point cloud data of the target module.

Fig. 6 (b) illustrates the final result of the DR process within the HoloLens 2 environment through a screenshot of the user interface. In the screenshot, the actual prefabrication shop floor is displayed, and obstructive objects are highlighted as regions of interest. Crane operators can use the HoloLens 2's gesture recognition capabilities to select specific obstructive elements by drawing regions of interest around them using natural hand movements. Once the regions of interest are selected (red dash line in Fig. 6 (b)), the DR visualization algorithm processes the data in real-time to remove the obstructive objects from the operator's view.

Fig. 6 (a) shows the operator's view prior to the application of the DR process, providing as a reference point for the visual change affected by DR, as shown in Fig. 6 (b).

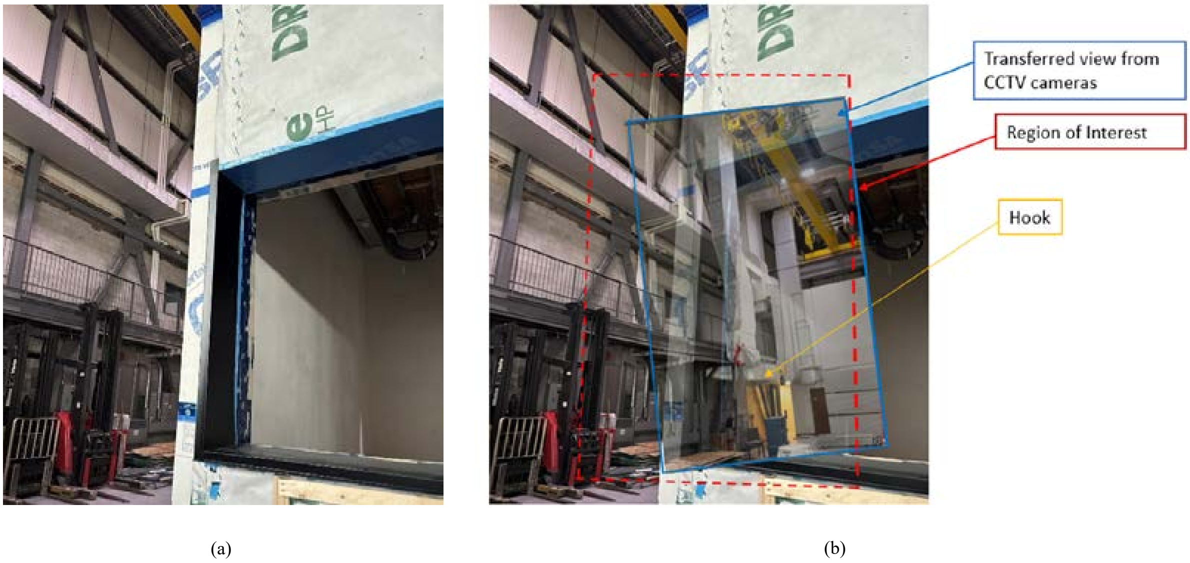


Fig. 6. HoloLens view, :(a) before the DR process; (b) after the DR process.

5. DISCUSSION

The application of BIM-based DR for enhancing crane operator visibility presents a promising solution for addressing challenges related to obstructed views in construction sites. The proposed system effectively combines advanced visualization technologies and real-time data integration to provide crane operators with a clearer and unobstructed view of their operational scene.
The integration of BIM data and real-time observation from CCTV cameras improves the DR visualization's accuracy. This integration tackles the issue of reliable background information by providing a continually updated view of the surroundings via real-time video streams. This ensures that crane operators are provided with a realistic and up-to-date representation of the construction area.

Despite the demonstrated effectiveness of the developed system, some limitations and challenges have been identified. The accuracy and reliability of the DR visualization heavily rely on the quality and availability of real-time observation data. In addition, factors such as changing lighting conditions and dynamic physical environment can influence the accuracy of tracking and registration. Future research can explore potential solutions, such as leveraging advanced imaging technologies or integrating cutting-edge technologies, including sensors and cloud solutions. For example, sensors such as LiDAR (Light Detection and Ranging) can be used to create detailed 3D maps of the environment to help operators in navigating complex environments, detecting obstacles, and improving situational awareness. Position sensors, such as GPS (Global Positioning System), can precisely track the crane's location. Cloud solutions can also be used for data storage and accessibility, providing a centralised and secure repository for storing large amounts of sensor data such as photos, videos, and sensor readings. In addition, cloud-based analytics tools can process sensor data in real-time, providing valuable insights to crane operators. By overcoming these challenges, we can further enhance the precision and reliability of the system, opening up new possibilities for improved crane operator visibility and safety at construction sites.

6. CONCLUSION

This research investigated a BIM-based DR approach to enhance crane operator visibility and safety at construction sites. By dynamically removing obstructive objects in real-time, the proposed system offers crane operators an unobstructed view of the construction scene, significantly improving their visibility and decision-making. The seamless integration of BIM data and real-time observation data enables a realistic and accurate DR visualisation. While our developed system shows promising results, further investigation is needed to address limitations such as the quality of real-time observation data and challenges related to registration and tracking.

ADAPTING BIM-BASED AR POSITIONING TECHNIQUES TO THE CONSTRUCTION SITE

Khalid Amin, Grant Mills, Duncan Wilson & Karim Farghaly
University College London, UK

ABSTRACT: *While Building Information Modelling (BIM) can support the management and visualisation of construction projects, Augmented Reality (AR) holds great promise to enhance interaction with these complex models. The accurate positioning of BIM-AR models in construction sites is critical to ensure that the virtual and real-world environments are correctly aligned. Through a literature review, this paper presents a review of state-of-the-art positioning techniques. It explores the different techniques used to position BIM-AR models and understands the interconnections and differences between them, with an emphasis on their applicability to the construction industry. The review also explores the challenges and limitations of each technique, in terms of the trade-offs between accuracy, computational efficiency, and robustness in varying environments. By providing an overview of positioning techniques in BIM-AR, this paper aims to guide researchers and practitioners in assessing the suitability of these techniques in the context of construction sites. The insights gained from this review may inform the development of efficient BIM-AR platforms that are more aligned with the dynamic and complex nature of construction sites.*

KEYWORDS: *BIM, Augmented Reality, Positioning*

1. INTRODUCTION

The construction industry is constantly looking for innovations and new methods to improve collaboration and productivity (Schiavi et al., 2022). Building Information Modelling (BIM) is a recent innovation in information systems that has proven its value for the construction industry. Currently, the use of BIM is a common practice in the built environment (Amin & Abanda, 2019), although its use in the construction stage is limited (Nassereddine et al., 2022; Sidani et al., 2021). Recent advancements in immersive visualisation technologies have created new prospects for exploring the potential of site-based BIM settings. The research on immersive visualisation technologies such as Augmented Reality (AR) and Virtual Reality (VR) has been growing with the aim of improving collaboration, productivity, and output quality of construction projects (Schiavi et al., 2022). In particular, the integration between BIM and AR can bridge the gap between the site and the office by enabling access to the BIM models onsite (Schiavi et al., 2022; Sidani et al., 2021). The potential of BIM-based AR integration is attributed to the potential improvements in collaboration and onsite information retrieval and representation (Wang et al., 2014). However, the majority of studies tend to investigate general AR applications that do not depend on the utilisation of BIM. The implementation of BIM-AR depends on complex software architecture and sophisticated positioning techniques which are not necessarily needed in general AR applications (Amin et al., 2023). The focus on BIM-AR should provide a deeper understanding of the specific benefits and limitations of the technology in the context of the practical requirements of real-life situations.

In the context of BIM-AR in the construction stage, the accurate positioning of 3D models onsite remains a major challenge and remains one of the most active research subjects (Azuma et al., 2001; Servières et al., 2021; Van Krevelen & Poelman, 2010). Positioning refers to the system's ability to accurately localise and track the BIM model with the proper alignment, orientation, and elevation (Amin et al., 2023). Numerous studies have explored a multitude of positioning techniques, employing different hardware and software components (Nee & Ong, 2023). The choice of the suitable technique is usually driven by a trade-off between accuracy, computational efficiency, and the region of space in which the system should work properly (Rolland et al., 2001; Servières et al., 2021). To decide whether a specific positioning technique is more effective for a specific use case, it is important to have a global understanding of the enabling technologies of positioning. In addition, it is important to explore how the effective management of positioning BIM-AR models in construction sites can have implications on the existing responsibilities and skillset of existing BIM roles. Hence, we adopt a literature review to survey state-of-the-art positioning techniques in the construction stage and develop a better understanding of their uses and limitations in the context of construction sites.

The motivation is to gain a comprehensive overview of the various positioning techniques in BIM-AR to capture the nuances and interconnections between them. This should help better understand their uses and limitations in the context of the dynamic and complex nature of construction sites. Such an understanding should provide insights into the development of BIM-AR platforms that are tailored to meet the demands of such challenging environments.

In addition, we discuss how the effective management of positioning BIM-AR models in construction sites requires revisiting the existing structure of BIM roles including prospects for new responsibilities and skillsets.

2. LITERATURE REVIEW

AR encompasses a wide range of positioning technologies and methods, each with its own set of intricacies and considerations. Capturing the subtle differences and interconnections of these techniques requires a global understanding of Computer Vision, sensor technologies, and algorithm development. Positional tracking systems can be grouped under Outside-In and Inside-Out (Gourlay & Held, 2017). Outside-In systems utilise external stationary sensors or cameras (trackers) to track feature points -such as light emitters- that are mounted or assembled into the tracked device (Gourlay & Held, 2017; Pustka et al., 2012). The main drawback of Outside-In systems is that the accuracy and stability of tracking are limited by the space the trackers can cover (Gourlay & Held, 2017). On the other hand, Inside-Out, the system uses the cameras and sensors that are assembled in the device to map the environment and estimate its local pose (Figure 1). It is believed that Inside-Out systems have an advantage over Outside-In in AR because the former requires less environmental setup and enables a more dynamic experience (Gourlay & Held, 2017). Inside-Out is the dominant positioning technique used in smartphones and modern AR headsets. However, grouping positioning techniques of AR into inside-out and outside-in only partially describes the vast pool of approaches, hardware and software components used. It is more common to group AR positioning techniques under three categories based on the type of sensors: sensor-based, vision-based and hybrid (Amin et al., 2023). This classification is adopted by others (Rolland et al., 2001; Zhou et al., 2008), however, positioning techniques need to be understood with a wider BIM-AR function focus (Amin et al., 2023). Williams et al. (2014) provide an important application case study, which we update and extend in this study. This study expands on the systematic literature review in Amin et al. (2023) to develop and update a comprehensive map of BIM-AR positioning techniques in the construction stage. We provide a detailed description of each category and develop an understanding of the interconnections and differences between them in the context of the nature and requirements of construction sites.

Figure 1 Inside-out systems rely on a group of cameras and/or sensors manufactured into the headsets. These systems do not depend on any external sensory information.

3. RESULTS

3.1 BIM-AR Positioning Techniques

Regardless of the selected technique, any BIM-AR positioning system will need to do two tasks: estimate the local pose (location and orientation) of the user and construct a map of the surrounding environment (Wang et al., 2014). This happens through a two-stage process: a learning stage and a tracking stage. The learning stage comprises understanding the surrounding environment and recognising its features to create a spatial map that serves as a foundation for accurate tracking (Nee & Ong, 2023). The tracking stage is where the system initialises the coordinate system, localises the model in six degrees of freedom (6DOF), and monitors the changes to its location and orientation relative to the environment (Choi & Park, 2021; Zhou et al., 2008). To achieve accurate positioning of BIM-AR models, many techniques and approaches have been developed. Positioning techniques in BIM-AR can be grouped under three categories: sensor-based, vision-based and hybrid (Azuma et al., 2001; Billinghurst et al., 2015; Palmarini et al., 2018; Servières et al., 2021). Manual mapping is an additional technique that is not frequently mentioned in the literature due to its limitations (Amin et al., 2023). The dependency map in Figure 3 shows the different positioning techniques used in BIM-AR and the interconnections among them. The next subsections discuss how the technology works in each category in detail and describe the associated techniques and their limitations.

3.1.1 Sensor-based systems

Sensor-based tracking refers to the process of determining the position and orientation of a user or device within a real-world environment by utilizing various sensors (Rolland et al., 2001, Williams et al., 2014). Compared to vision-based tracking methods, sensor-based tracking is faster and more robust in determining the pose of the device, however, they are analogous to open-loop systems whose output could accumulate errors (Zhou et al., 2008). Several types of sensors are commonly used in sensor-based tracking in BIM-AR:

1. Inertial Sensors: Inertial sensors are commonly used in tracking systems for BIM-AR, usually as complementary sensors to visual ones. The most common inertial sensor used for pose estimation is Inertial Measurement Unit (IMU) (Nee and Ong, 2023). IMUs can provide accurate information for all six degrees of freedom about the pose of the device, usually by fusing information from integrated gyroscope, accelerometer and magnetometer (Ahmad et al., 2013). While inertial sensors provide high accuracy in short-term tracking, they suffer from error accumulation over time and need to be combined with other sensors for accurate tracking (Rolland et al., 2001, Williams et al., 2014, Nee and Ong, 2023). IMUs have become an essential component in all smartphones and modern AR headsets.

2. Laser-based Depth Sensors: also referred to as optical sensors, utilise different kinds of light in the infrared spectrum to measure depth information to understand the geometry of objects and surfaces in real-time, also known as depth sensors. Among several types of depth sensors, the Time-of-Flight (ToF) and Light Detection and Ranging (LiDAR) are the most commonly used techniques in BIM-AR (Amin et al., 2023). A ToF laser sensor emits an infrared laser beam and measures the time it takes to reflect back to measure the distance to an object (Rolland et al., 2001, Williams et al., 2014). LiDAR scanners are usually more expensive because they can cover larger areas and provide higher accuracy.

3. GPS: is a widely used sensor for outdoor localization. It leverages a network of satellites to determine the latitude, longitude, and sometimes altitude of a device. GPS enables location-based AR where digital elements are superimposed based on where the user stands as in Williams et al. (2014). Very few studies have utilised GPS to position BIM-AR models (Fenais et al., 2018; Williams et al., 2014) due to its low accuracy and low performance indoors.

4. Wireless Network Sensing: such as Wi-Fi or Bluetooth. They can be utilised for determining the location of the device but have significant limitations related to setup, coverage and accuracy (Craig, 2013, Williams et al., 2014). A single study utilised Wi-Fi for BIM-AR positioning (Degani et al., 2019).

Other sensors that are frequently mentioned in general AR literature but are not used in BIM-AR in the construction stage are magnetic sensors and acoustic sensors. Magnetic Sensors, also known as magnetometers, detect changes in the Earth's magnetic field to determine the orientation of the device. Due to the existence of magnetic fields apart from the earth's soft iron effect and temperature changes, magnetometers are highly susceptible to magnetic disturbances. As a result, their use is often disregarded in various applications, particularly in industrial settings as construction projects (Rolland et al., 2001, Nee and Ong, 2023). Acoustic Sensors utilise the principle of ToF used in optical sensors but use sound waves instead of laser beams. The speed of sound varies with environmental conditions and sound waves can be easily obstructed, so acoustic sensors are not a reliable tracking technique (Rolland et al., 2001, Nee and Ong, 2023). It is argued that the sole reliance on sensor-based techniques would introduce significant error variables (Craig, 2013). This is due to some requirements that are not always available on construction sites such as network coverage, and due to their sensitivity to some environmental conditions such as temperature, humidity, and noise. In addition, measurement errors are accumulated over time and need continuous calibration because pose estimation is evaluated based on the previous position (Craig, 2013).

3.1.2 Vision-based systems

Vision-based techniques rely on different computer vision methods to locate and track targets within a video sequence or a series of images (Jinyu et al., 2019; Servières et al., 2021; Williams et al., 2014; Zhou et al., 2008). A major advantage of vision-based techniques is that they rely on cameras which provide an affordable solution to capture lots of information, in addition to being available in many forms and types (Song & Kook, 2022; Yang et al., 2023). Vision-based tracking techniques use image processing methods to estimate the pose of the camera relative to the real world and so are analogous to closed-loop systems which correct errors dynamically (Zhou et al., 2008). However, they suffer at higher movement speeds and are dependent on the uncontrolled condition of the environment they are operating in such as scene complexity, lighting, and weather (Servières et al., 2021; Yu et al., 2016; Zhou et al., 2008). In addition, because vision-based techniques rely on recognising and tracking visual cues within the surroundings, it becomes challenging in an unknown environment as the system takes more time to collect enough data to analyse the surroundings to deduce the user's pose (Servières et al., 2021; Siltanen, 2012). To overcome this challenge, predefined signs (markers) that are easily detectable by the visual tracking system can be placed in the environment. This approach is called marker-based, where the marker is used as the reference for the positioning system to superimpose the virtual objects onto the real world (Nee & Ong, 2023; Siltanen, 2012; Williams et al., 2014). However, a major drawback of marker-based techniques is that tracking requires the markers to be always visible in the coverage area of the camera for a stable experience (Nee & Ong, 2023). A multi-marker tracking method that involves distributing a group of markers for the camera to detect to expand the coverage area has been developed. Yet, marker-based approaches are generally considered obtrusive and can be easily obstructed in construction sites (Song & Kook, 2022; Wang et al., 2013).

To overcome the limitations of marker-based tracking, markerless tracking can recognise and track natural features in the environment such as edges, corners, and textures, and use them as location references to overlay virtual elements and determine the pose of the user (Nee & Ong, 2023; Servières et al., 2021; Siltanen, 2012). Markerless tracking offers several advantages, such as flexibility and ease of use since it doesn't require physical markers. However, because the term "marker-based" implies the need to do some preparations in the environment before initialising the coordinate system, the term "markerless" implies a misleading perception that it can work anywhere without previous preparations. Globally, markerless tracking is often perceived as a universally capable technology, however, its practical implementation presents numerous challenges in terms of computational requirements, noise reduction, and user-friendly interaction techniques (Servières et al., 2021). The majority of research in BIM-AR adopts either a marker-based or a markerless approach, overlooking "extended tracking" approaches which allow tracking of digital elements to persist in the user's field of view even when the initial target is no longer in the frame of the camera (Vuforia.Com, 2023; Wikitude, 2023)

Differences among vision-based techniques can then be divided into model-based and Visual SLAM (Simultaneous Localisation and Mapping), also referred to as V-SLAM (Figure 3). While both techniques depend on feature tracking and matching between a series of images, the difference mainly lies in the system's knowledge of what it should track. Model-based systems use pre-existing information about the environment. In other words, the system has prior knowledge of what it will track which can be fiducial 2D features such as images and QR codes (marker-based approach), or a group of edges, corners, and textures that define a 3D object (object tracking approach) (Palmarini et al., 2018; Siltanen, 2012). In contrast, V-SLAM systems gradually reconstruct their environment while tracking the user's pose (Nee & Ong, 2023; Yang et al., 2023). V-SLAM techniques do not have prior knowledge of what to track, and so they continuously create information about surroundings utilising an "ad-hoc" visual tracking method (Palmarini et al., 2018; Servières et al., 2021). V-SLAM relies on principles from "Structure from Motion" (SfM) to create a 3D structure of an unknown environment and then expands by incorporating the aspect of real-time pose estimation through a set of algorithms that optimise computational efficiency (Nee & Ong, 2023; Yang et al., 2013). However, because the environment map is required for the pose estimation and vice versa the main challenge of V-SLAM approaches is the accumulation of small errors in the estimated poses which can lead to larger errors in the map information, etc. The development of hybrid systems, that fuse different kinds of sensory information, was designed to create more accurate results.

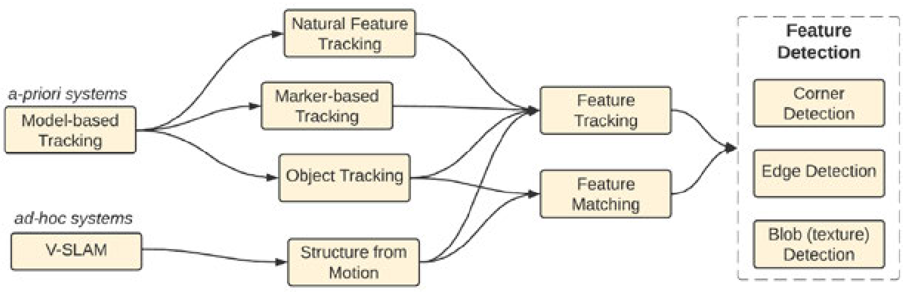

Figure 2 Interconnections between vision-based positioning techniques

3.1.3 Hybrid systems

Hybrid systems fuse information from different sensors and cameras to compensate for the limitations of each technique. In particular, the fusion of visual tracking systems and inertial sensors has gained significant popularity. Cameras excel in providing precise measurements by leveraging visual feature matching and multi-view geometry. However, in scenarios where image quality is compromised due to factors like rapid motion or sudden changes in lighting, purely visual tracking systems often encounter failures (Nee & Ong, 2023; Williams et al., 2014). In contrast, inertial sensors remain unaffected by image quality issues and demonstrate particular proficiency in tracking high-frequency, fast motion. Nevertheless, the measurements obtained from an IMU are subject to high noise levels and drift over time (Nee & Ong, 2023; Zhou et al., 2008). By fusing visual information from cameras and inertial information from IMUs, the system is more able to dynamically correct errors and provide more accurate results in constructing a 3D map of the environment while estimating the pose of the device. This is known as Visual-Inertial SLAM (VI-SLAM) which is the technology used for fusing the information from the different sensors for environment mapping and 3D pose estimation (Jinyu et al., 2019). VI-SLAM can be considered a subset of multi-sensor fusion techniques. Multi-sensor fusion is a broader concept that encompasses the integration of data from multiple sensors, which can include cameras, inertial sensors, GPS, LiDAR and more (Figure 3). Challenging aspects in hybrid systems are the need to perform calibration between the cameras and sensors to ensure that their measurements are aligned within a shared coordinate system, a process commonly referred to as hand-eye calibration (Nee & Ong, 2023).

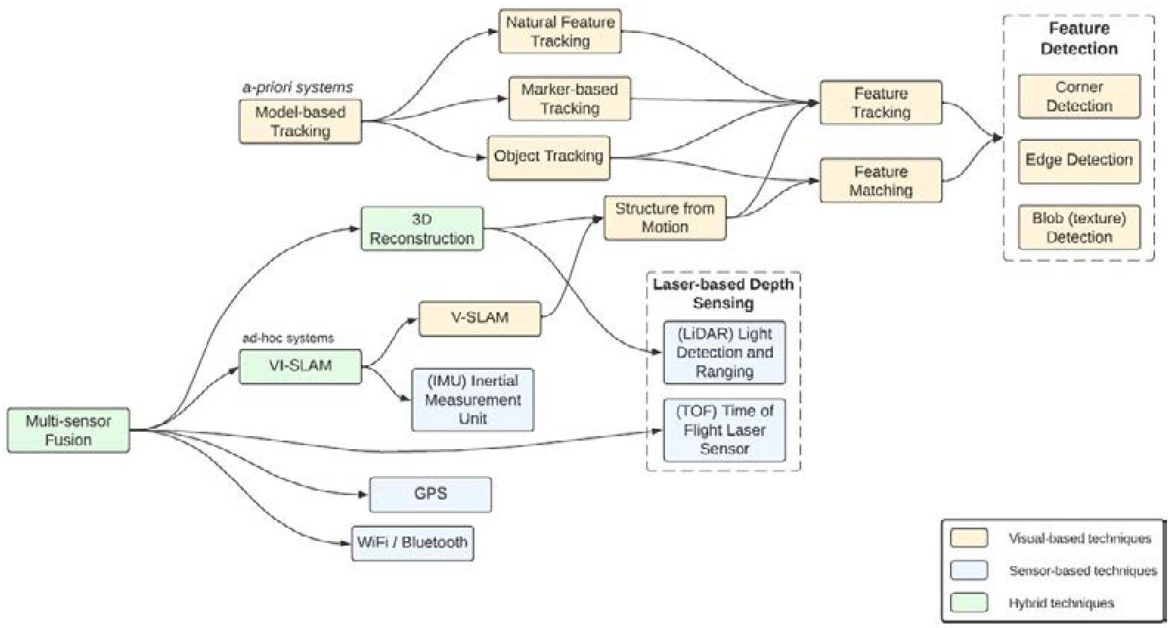

Figure 3 A comprehensive map of the positioning techniques used in BIM-based AR

3.1.4 Manual Mapping

To minimise the complexity of the dynamic real-time update of user movement relative to the surrounding environment, some studies used manual mapping techniques. Manual mapping involves using matrices to create a relation between world space and camera space and use this relation to overlay digital elements on physical objects (Amin et al., 2023). The world space represents the coordinate system that corresponds to the physical environment where objects have specific positions and orientations. On the other hand, the camera space refers to the coordinate system of the camera within an AR device which captures the real-world scene (Figure 4). By creating a similar situation using a virtual camera and a 3D model, the positioning system is then able to properly overlay and align digital elements from the 3D model by converting the coordinates from the world space to the camera space (Amin et al., 2023; Nee & Ong, 2023). Manual mapping techniques do not provide a dynamic experience as the user is restricted by the location of the camera. Few studies have experimented with this technique as in Dai and Lu (2010), Lin et al. (2020) and Gomez-Jauregui et al. (2019).

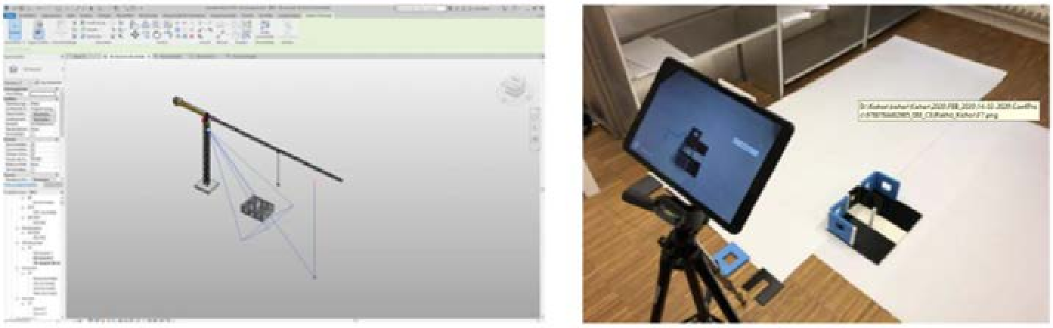

Figure 4 Demonstration of the concept of manual mapping from Lin et al. (2020)

3.2 Dominant techniques and devices

BIM-AR is used for four main applications in the construction stage: site assistance, construction planning, progress tracking, and inspection. Figure 5 shows the techniques used in the mentioned applications. Various methods and techniques are used across applications with the exception of LiDAR. And so, the development of BIM-AR platforms that are capable of supporting different positioning techniques may be required. In addition, more research is needed on the effectiveness of these techniques from a practitioner perspective. While several studies have been carried out in real-world construction sites, the focus has been on the technological aspects of BIM-AR not on the practical implementation of the technology.

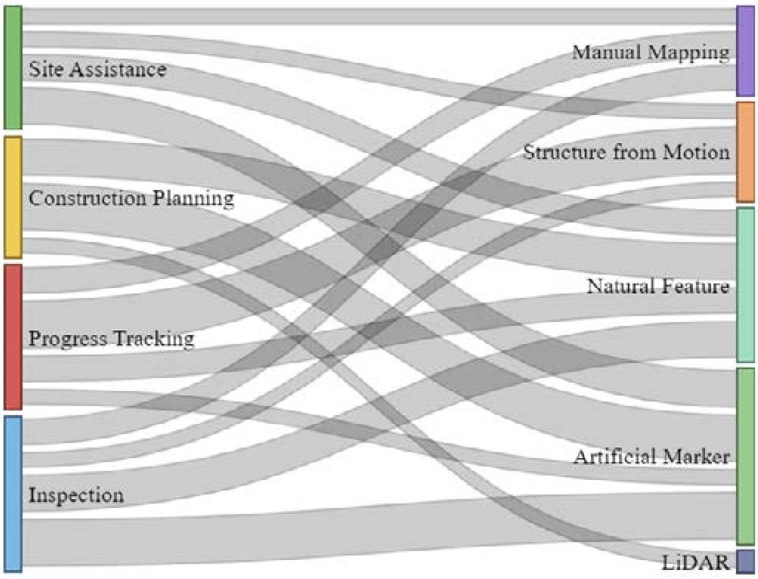

Figure 5 Positioning techniques used in different construction applications

4. DISCUSSION

Common in BIM-AR positioning is the need to map anchor points between digital models and the physical environment. The positioning system will always require a physical reference in the real world that can be mapped to a reference in the digital model. In BIM-AR applications that utilise natural features for positioning, users are usually asked to select a vertical wall edge and a horizontal edge representing a horizontal direction, then select the corresponding edges in the digital model. The same process occurs with artificial markers; the locations of the physical markers are mapped to digital ones in the digital mode. The dynamic nature of construction sites requires that the locations of these anchor points will perhaps change frequently as the project progresses. Studies that used marker-based indicated that in the context of construction sites, there is a considerable possibility that markers will get obstructed by other objects (Kwon et al., 2014; Lin et al., 2020). Studies that used natural feature tracking have argued that they could be obstructed due to other construction activities or disappear because site scenes keep changing (Lin et al., 2019; Mirshokraei et al., 2019). It is critical therefore to understand how construction activities unfold and assess the accessibility of reference physical elements before selecting the most suitable positioning approach. The locations of anchor points need to be coordinated and updated accordingly to ensure continuous alignment between the BIM model and the evolving site conditions.

The continuous coordination of anchor points between the physical site and the digital model necessitates revisiting the responsibilities of existing BIM roles. Existing BIM roles are usually oriented around generating and managing information across different stakeholders for design activities. We envision that a new responsibility will emerge to manage the accurate positioning of BIM-AR models onsite. This new responsibility, dedicated to BIM-AR coordination, will coordinate the anchor points between the site and the digital model and manage the communication with site personnel and their safety. Therefore, more collaboration between BIM and site professionals is needed to consider factors such as site constraints, logistics, and project stages. Adapting BIM-AR positioning techniques to the nature of construction sites is a crucial step in leveraging the technology. In addition, it is necessary to revisit the skills of BIM roles and workforce training programmes in the context of BIM-AR requirements.

5. CONCLUSION

We have provided insights into the positioning techniques used in BIM-based AR for construction projects. By exploring the different positioning techniques used in BIM-AR, their interconnections, and their differences, this study aimed to provide insights to researchers and practitioners for assessing the suitability of these techniques in a construction site context. The results of the review identified three main categories of positioning techniques: sensor-based, vision-based, and hybrid systems. Sensor-based systems utilise various sensors like IMUs, laser-based depth sensors, and GPS to track the position and orientation of the device. Vision-based techniques rely on computer vision methods and can be further categorised into model-based and V-SLAM approaches. Hybrid systems combine information from different sensors and cameras to compensate for the limitations of individual techniques. VI-SLAM is the core technology of multiple-sensor fusion. Additionally, manual mapping techniques were discussed, although they are not commonly used due to their limited dynamic capabilities. The review highlighted the challenges and limitations of each technique, such as accuracy, computational efficiency, and robustness in varying environments. It became noticeable that the choice of positioning technique depends on the specific requirements of construction applications, and there is no one-size-fits-all solution. Hence, we proposed guiding the research on BIM-AR to involve flexible positioning systems that can adopt more than one technique. In addition, the findings shed light on the need for continuous coordination of anchor points between the physical site and the digital model considering the evolving nature of construction sites. Consequently, a new responsibility, dedicated to BIM-AR coordination, will emerge to manage the positioning of BIM-AR models onsite and communicate with site personnel. This calls for more collaboration between BIM and site professionals, as well as revisiting the skills and training programs of existing BIM roles to accommodate BIM-AR requirements.

SAFETY TRAINING FOR RIGGING USING VIRTUAL REALITY

Rafik Lemouchi, Mohamed Assaf & Mohamed Al-Hussein
Department of Civil and Environmental Engineering, University of Alberta, Edmonton, Alberta, Canada

Khaoula Boutouhami & Ahmed Bouferguene
Campus Saint-Jean, University of Alberta, Edmonton, Alberta, Canada

ABSTRACT: *Tower and Mobile Cranes are some of the most commonly used heavy equipment in all construction sites, and any crane failures could lead to significant human and monetary losses. Moreover, rigging configuration determination is a critical task that requires the rigging crew to have significant experience and knowledge of various failure modes that can be encountered when performing lifting operations. However, despite the criticality of training riggers, there has yet to be a comprehensive tool used to train and guide inexperienced riggers, and hence, more practical tools are needed. This paper proposes a framework for using Virtual reality (VR) and simulation to train riggers to identify the optimal rigging configurations based on the lift type and the external conditions. Through 3D modeling, the critical components of the rigging system are modeled to accurately simulate the rigging system and their performance when faced with critical loading scenarios. The developed framework is expected to allow inexperienced riggers to identify critical failure modes and enhance construction operations' overall safety performance and productivity. Furthermore, several scenarios are assessed based on historical evidence for rigging configuration failures, and the efficiency of the training tool is assessed through real-life scenarios and tests.*

KEYWORDS: *Crane Operations, Lift Planning, Rigging, Safety, Training, Virtual Reality.*

1. INTRODUCTION

Globally, construction and industry-related incidents account for significant human and material losses; as a result, the construction industry is considered one of the most hazardous industries for workers. According to the Occupational Safety and Health Administration (OSHA,2020), in 2019, 1061 worker fatalities occurred in the construction industry, accounting for 20% of deaths in all industries. A contributing factor to the increased number of incidents is the use of heavy pieces of equipment, where many fatal injuries were a result of using heavy equipment." For instance, in Australia, Safe Work Australia 2019 reported that there are, on average, 240 serious injury claims reported from crane safety incidents". Furthermore, the current construction trends, such as Off-Site construction (Lingard et al.,2021), are gaining more traction for project execution. Moreover, Off-site construction is heavily reliant on cranes, and thus, an increase in crane usage is inevitable. Fatal incidents would increase exponentially with the increased use of crane construction projects. Thus, it is critical to understand the underlying reasons for incidents related to crane operations and to develop the necessary tools required to mitigate the number of incidents.

Much research has been conducted to understand the causes of crane incidents. (Milazzo et al ,2016) Analyzed 937 crane incidents and identified that the leading cause of incidents for different cranes is overturning and collapse, mainly due to structural failures caused by overloading. Another contributing factor is human error (Milazzo et al., 2016) found that one-third of crane incidents were triggered by human error, resulting in either weight underestimation or improper operation of the crane. (Lingard et al.,2021) Identified that the main types of incidents in crane operations are those related to electrocutions and tip-over incidents. On one side, electrocution incidents result from improper planning, unsafe working conditions, and human negligence. On the other hand, Tip-over incidents are mainly caused by overloading, loss of center of gravity, and outrigger failure. Finally, (Tam and Fung,2011) identified four main factors causing safety incidents in crane operations: negligence and misjudgment, inadequate training, subcontracting, and pressure from deadlines. Thus, to mitigate crane-related on-site incidents, it is necessary to eliminate human error, avoid overloading and structural failures. (Zhang et al.,2023) the overturning and loss of center of gravity can be prevented by securing the lifted loads; this prevention is a major duty of rigging personnel whose performance can be enhanced through adequate training.

Training has been a primary focus for crane operations, where many tools were used to provide operators, riggers, and signalers with the proper procedure to perform lifts. In most cases, only traditional training methods were used, which centered around textbooks, video tutorials, and a limited amount of hands-on experience, which is less immersive. (Wu et al.,2020) argues that learning by doing has been recognized as a more effective training method. Furthermore, they argue that traditional lecturing courses are less effective in transmitting learning

knowledge. Luckily, recently, with the rise of VR, more research is being conducted to understand the impact of VR training on construction workers. For instance, (Joshi et al., 2021) used VR technology for safety training in the precast/prestressed concrete industry and found that knowledge gained through traditional methods is lower than that gained from VR training methods. (Song et al.,2021) developed a VR crane operator training module and reported that VR training effectively enhances crane control skills competence.

Crane operations and VR training procedures are scarcely represented in the literature, where only a limited set of works were published regarding crane-related operations and VR training. Previous works focused on using VR to visualize crane lifts and hazard identification through clash detection. (Shringi et al.,2022) for instance, developed a hazard identification training model for crane operators, which focused mainly on tower cranes. (pooladvand et al, 2021) Used interactive VR to evaluate mobile crane lifts. While (Song et al, 2021) developed a VR crane operator training module but did not take into consideration the rigging personnel training. Regarding rigging, (Zhang et al., 2023) developed a collaborative training model for crane operators, riggers, and signallers. However, the main focus was on collaboration between the different project participants. Furthermore, for rigging, only a semi-immersive CAVE system was utilized for collaboration and communication between the different project participants taking part in operating, and guiding cranes. However, a training system which takes into consideration the elaborate and complex properties of rigging components is yet to be tackled by any work.

Thus, this work identifies the need for developing a fully immersive and engaging tool to train riggers and mitigate on-site incidents. To do so, the authors propose a fully immersive VR-based training framework for riggers to tackle the main causes of crane-related on-site incidents. The proposed methodology is expected to improve the overall safety of crane operations as well as decrease the number of incorrect assemblies and improving the overall performance of crane related operations.

2. METHODOLOGY

The overall methodology proposed by the authors is summarized in Figure 1.

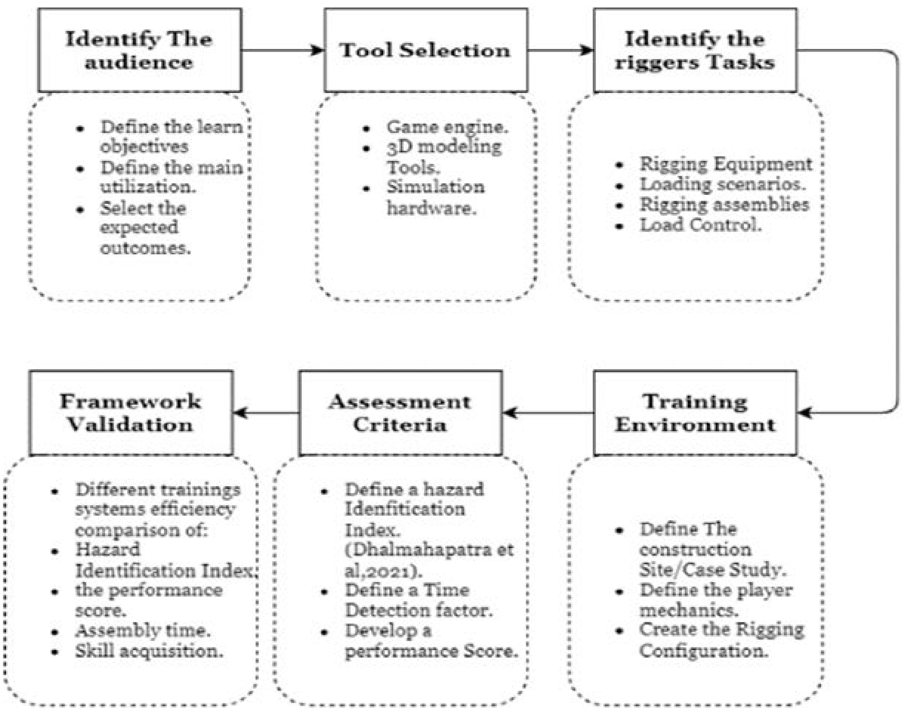

Fig. 1:Research Methodology

The initial step is to identify the audience of the VR tool. Later, tool selection is vital in any VR environment; a set of decisions are needed to select the game engine and the VR hardware to improve the overall experience. Next, the main issues encountered on-site are identified to enable the development of a realistic model capable of accurately representing the real working environment. Moreover, to assess the training progress, a set of assessment criteria is needed to estimate the trained personnel's overall performance objectively. The next step is to build the training environment by initially creating 3D models of the rigging components using 3DSMax and

SolidWorks. Then, to represent the construction site, a BIM model of a real project is exported to the VR environment, and a set of training scenarios are selected appropriately. Finally, a set of validation tools are implemented to validate the methodology, and the results are discussed.

2.1. Identify The Audience

The primary focus of this study is to utilize the Virtual Reality (VR) training tool to teach novice and inexperienced riggers the best practices for safe crane operations. The tool aims to enhance the overall safety of crane operations by addressing critical aspects such as better rigging assemblies, identification of erroneous assemblies, secure load lifting, and identification of faulty equipment. Additionally, civil engineering students seeking to learn crane operation concepts can also benefit from this tool.

2.1.1. Define the learning objectives.

The learning objectives of the training module are as follows:

- Enhancing skills in rigging assemblies: Trainees will learn how to select and assemble the appropriate slings, shackles, hooks, spreader bars, and bolts according to the specific load being lifted.
- Identifying and avoiding hazards: Trainees will be educated on identifying potential hazards during rigging operations and how to avoid accidents by adhering to safety guidelines such OSHA.
- Securing loads during lifting: Trainees will gain insights into load calculations, determining the center of gravity, and ensuring the load is securely balanced and lifted correctly.
- Detecting faulty equipment: Trainees will learn how to inspect rigging equipment prior to assembly and identify any faulty components that may compromise safety.

2.2. Tool Selection

To develop a fully functioning and accurate training module, it is first necessary to select the necessary tool to develop the module. The following sections will discuss the selected Game engine,3D modeling tools and the hardware used throughout this work, as well as the reasoning behind selecting these tools.

2.2.1 Game Engine and 3D modeling Tools

As for the game engine, Unity3D was selected due to its ease of implementation and the availability of a diverse set of libraries and tools which can be used for simulation purposes. The 3D modeling software selected are 3DS max, and SolidWorks.3DSMax was used to import and design some of the necessary components of the raining environment. While SolidWorks was used to create 3D models for the rigging components, such as the hooks, spread bars, slings, and eyebolts. Both 3D software were also chosen since they are compatible with the selected game engines, where it is advisable to use the previously mentioned software alongside a rendering software to provide a more realistic and engaging training environment.

2.2.2 Hardware Description

As for the hardware, an HTC Vive Headset was used for training. The headset was used to allow the user to explore the environment. two Wireless controllers were also used, their utility lies in allowing the user to move through the environment and interact (grab, assemble and dissemble) the relevant rigging components. The movement of the player was detected using two HTC bases. The overall system was run on a supercomputer, with an I9 CPU, and NVIDIA RTX A2000 GPU and 32Gb of RAM.

2.3. Rigger Tasks

After thorough analysis of crane operators training guides such as (ATP 2013), as well as analyzing relevant research such as (Zhang et al, 2023) works riggers tasks were identified as follows:

- check the rigging equipment, in other words, select the appropriate slings, shackles, hooks, spreader bars and bolts in accordance with the module to be lifted.
- load calculations, and center of gravity determination of the loads to be lifted.
- Rigging equipment inspection prior to assembly.
- rigging assembly, by ensuring that each component is secured and respects the angular limits.

- Load Control by ensuring the load is balanced and lifted properly throughout the lift. Ensure the center of gravity and hook are aligned.

2.4. Training Environment

In order to accurately model a construction site, and its properties. The Unity3D engine is used to develop a realistic construction site as well as the user interaction with said environment. The following section will delve into detail and discuss both the construction site and the human interaction within the environment.

2.4.1 Construction Site and Rigging Configuration

A virtual construction site was created to provide the trainees with a sense of dimensions and realism when training which can be seen in Figure 2. The site is populated with various interactable items similar to a real construction site. The rigging components and other items in the virtual training environment are modeled on 3D software with accurate dimensions and physical properties to those used in real operations. However, the interactable items the trainees can interact with, and use are mainly those required to assemble a rigging system. Additional components that are either faulty or unneeded are added to render the tasks more challenging and, eventually, more rewarding. Furthermore, to enhance immersion, audio, and interactive interfaces were used to imitate a real-life learning environment and provide an optimized training process.

Fig. 2: Training Environment.

2.4.2 VR Controls

Replicating human interaction in a virtual environment is often a complex task, specifically when the Virtual environment is large in scale. The main difficulty encountered is regarding the locomotion system which is related to the ability to roam and use to environment.to tackle this issue, two different systems of movement are used to replicate the movement of workers on site. The first system, which is generally used in serious desktop based serious games where the user inputs the direction continuously through a touchpad. The second system is through a teleportation system, where the user can teleport to any accessible location in the construction site. The user is given the option to use one or a mixture of the systems according to their preferences. However, it is preferable to use the second system if the user is more likely to encounter VR dizziness.

As for the interaction system, the user can grab, assess, assemble, and disassemble any rigging components, which is the main feature used to create a realistic interactive training system. Finally, after assembling the rigging, the user can evaluate the efficiency and accuracy of their assembly by performing a lift. The lift is subjected to the environmental conditions present in a construction site, which are accurately replicated in the Unity environment.

2.5. Assessment Criteria

In order to assess the performance of the participants and the efficiency of their training, a hazard identification index inspired by (Dhal Mahapatra et al,2021) is used to grade and measure their performance. The scoring system identifies the primary and secondary tasks to be executed by the participant. Each task is given a score ranging from a one to three scale where one is a basic task that is fundamental but is not critical to the overall safety, and 3 is an advanced task critical to ensuring crane operations. The score system is also affected by a time factor or a time detection factor to put an emphasis on completing the tasks within the allotted time. Table 1 illustrates the different training levels and their assessment criteria.

Table 1: Training Assessment Criteria for different.

Level	Task Description	Score Range
Level 1 - Basic Task:	Fundamental actions and responsibilities contributing to the safety and smooth functioning of crane operations. These tasks require moderate skill and understanding but are not considered critical or highly complex.	1-3
Level 2 - Intermediate Task	Moderately complex actions that are more crucial to the overall safety and efficiency of the crane operations. These tasks require a higher level of skill, attention to detail, and decision-making.	4 to 7
Level 3 - Advanced Task	Critical to ensuring crane operations' utmost safety, accuracy, and effectiveness. It involves handling challenging scenarios and potential emergencies and making critical decisions promptly. These tasks demand a high level of expertise, problem-solving abilities, situational awareness and timely decision making.	8 to 10

2.6. Framework Validation

(Harris et al, 2020) defined validation as the extent to which a test, model, measurement, simulation, or other reproduction provides an accurate representation of its real life equivalent. Furthermore, (Salinas et al, 2022), defined evaluation methods as either objective or subjective.

2.6.1 Objective methods

Objective methods are those methods which evaluate efficiency based on factual data. (Salinas et al, 2022) found four main objective methods used in literature. For safety training, they are defined as follows:

- safety improvement: by comparing the behavior under training with the recommended behavior defined by safety requirements.
- performance time: measuring the time needed by a trainee to preform the required tasks, while also considering the impact of making a wrong decision. This method is used to measure the consequences of timely decision making on the overall on-site safety.
- number of errors measures the number of errors committed by the participants. And for this case study, compare the results for different groups of participants to gain a deeper understanding the VR tools impact on decreasing the number of errors made.
- measurement of vital signs: based on monitoring vital sings of trainees to understand the physical and psychological impact of stressful and dangerous scenarios on the overall performance of the trainees.

2.6.2 Subjective methods

Subjective methods are those methods which evaluate efficiency based on the trainees' feelings and preferences. (Salinas et al, 2022) mentions 4 major subjective evaluation methods which are sensory user emotions, expert analysis, user field workload and interviews and questionnaires.

Thus, and in order to validate the proposed framework, different validation techniques are used in the initial trials, both objective and subjective. As for objective methods, two validation techniques were deemed appropriate, which are performance time and number of errors, these two methods were selected to measure the learning of the trainees as well as understand the impact of timely decision making on the overall performance of crane operations. The rest of the objective methods were not used for this work; However, the developed model allows the inclusion of these methods in future studies.as for subjective methods, questionnaires and interview were used to validate the overall experience the users had when interacting with the training environment.

3. MODEL DEVELOPMENT AND TRAINING PROCEDURE

When developing the training procedure, a natural progression from more manageable tasks to more complex tasks was selected to increase the efficiency of the overall training. The training procedure was inspired by relevant training manuals such as the ATP 2013 and crane safety-related standards. The training consists of four primary levels, starting from a basic introduction to the crane safety problem. Then, a components identification module for rigging assemblies, followed by a basic assembly and secure rigging module. The training procedure is finalized with an advanced assembly and simulation concluding module. The four are explained in more detail below.

3.1 Basics Introduction

Briefly explain the importance of proper crane rigging techniques and the potential risks associated with incorrect rigging. Emphasize the need for a comprehensive training program to ensure safe and efficient rigging operations. A sample of the GUI is shown in Figure 2.

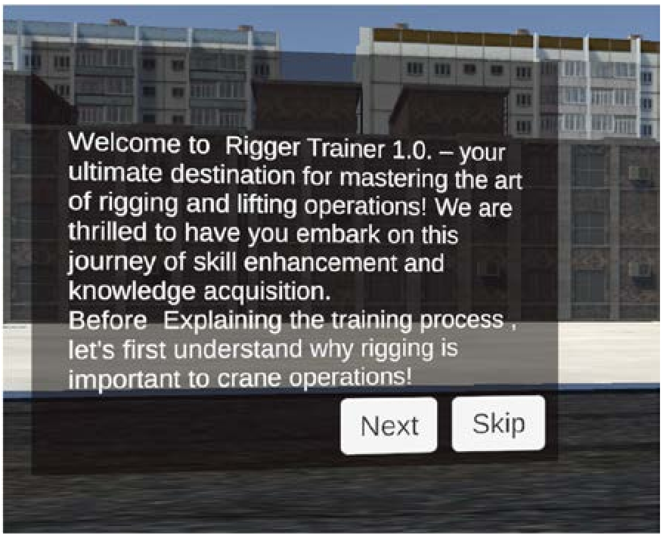

Fig. 3: The Introduction GUI.

3.2 Level 1 - Component Identification

At the outset of the VR training program, we prioritize establishing a strong foundation for trainees by focusing on providing a comprehensive understanding of the fundamental components that make up a rigging system. Through engaging 3D models and interactive hands-on exercises within the virtual environment, participants will delve into the intricacies of identifying key elements such as slings, shackles, hooks, and spreader bars. The VR experience offers a realistic and immersive environment, allowing trainees to explore lifelike representations of these vital components. By interacting with the 3D models, they will gain invaluable insights into the unique features and applications of each component. This in-depth comprehension is critical for ensuring safe and effective rigging practices in real-world scenarios. As trainees virtually manipulate the slings, shackles, hooks, and spreader bars, they will receive instant visual and auditory feedback, fostering a dynamic learning process. This hands-on approach within the VR environment enables them to internalize the knowledge effectively, bridging the gap between theory and practical application. By the end of Level 1, participants will have honed their ability to recognize and differentiate between various rigging components accurately. Equipped with this essential knowledge, they will be well-prepared to progress to Level 2, where they will practically assemble these components into basic rigging configurations, all while harnessing the power and potential of VR technology.

Fig.4 Rigging System Components

3.3. Level 2 - Basic Assembly and Secure Rigging

With a solid understanding of rigging components acquired in Level 1, trainees progress to Level 2, where they embark on the practical application of their knowledge in a virtual setting. In this stage, participants will immerse themselves in the VR environment to virtually practice creating various basic rigging assemblies, honing their skills in a risk-free and controlled space. Within the VR environment, trainees will have access to an array of virtual rigging components, including slings, shackles, hooks, and spreader bars, similar to what they encountered in Level 1 as can be seen in Figure 4.

They will have the freedom to select and manipulate these components to create different rigging configurations, such as single-leg slings, double-leg slings, and bridle slings. Real-Time Feedback: As trainees assemble the virtual rigging configurations, the VR system will provide real-time feedback on their actions. Visual indicators and audio cues will ensure that they correctly balance loads and securely fasten each component, enhancing their understanding of proper rigging techniques. This immediate feedback mechanism reinforces safe practices and encourages trainees to adjust until they achieve accurate rigging setups.

One of the feedback mechanisms used to enhance the learning process, is through highlighting the proper location of each component within the overall assembly as can be seen in Figure 5. This to ensure that the trainee would not require the aid of external factors and their learning journey would be self sufficient using the rigging training model only.

Fig. 5: Different Basic Rigging Assemblies

To enhance engagement and challenge trainees further, the VR program will introduce interactive challenges. These scenarios could include lifting differently shaped loads, coordinating multiple rigging components simultaneously. By navigating through these challenges, participants develop a deeper understanding of rigging complexities and learn to adapt their skills to diverse situations. Throughout Level 2, the VR training program follows a progressive approach, starting with simpler rigging configurations and gradually advancing to more complex setups. This gradual increase in difficulty ensures that trainees build their skills step-by-step, instilling confidence and proficiency in rigging operations.

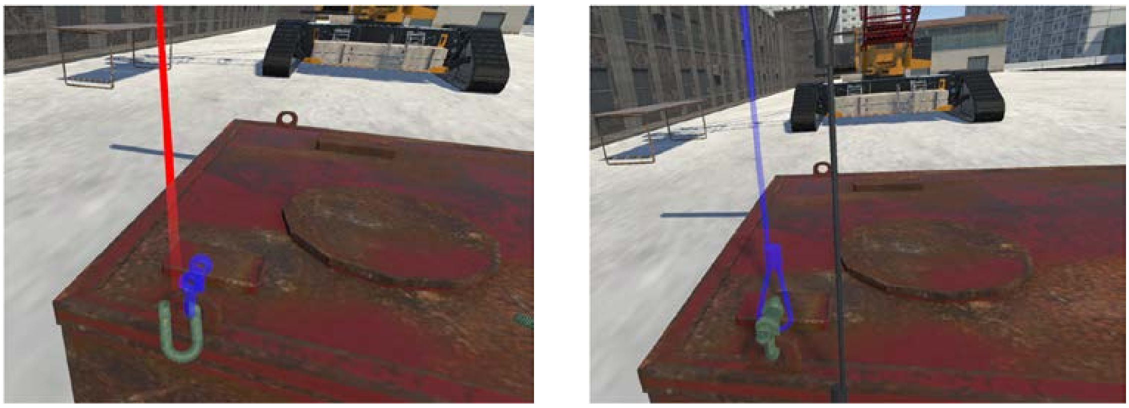

Fig.6: Training Feedback Mechanism

3.4. Level 3 - Advanced Assembly and Simulation

Level 3 represents the pinnacle of the VR Crane Rigging Training Program, where trainees are exposed to advanced rigging assembly exercises and sophisticated simulations. In this stage, participants take their skills to new heights as they tackle complex rigging scenarios, further solidifying their expertise and decision-making abilities.

In level 3, trainees are tasked with creating complete rigging modules from scratch within the virtual realm, similar to those shown in Figure 6. These modules involve intricate configurations and incorporate multiple components, without any guidance, applying what they learned in the previous levels. The VR environment provides an extensive library of rigging equipment, allowing trainees to experiment with various combinations to achieve the best setups.in some scenarios, the participants are not provided with the optimal component and are expected to produce rigging assemblies with the available components, preparing them for unpredictable scenarios in the field.

An integral part of level 3 enables trainees to evaluate the structural integrity and safety of their virtual rigging setups. After assembling and selecting a rigging configuration, a lifting simulation is used to assess the system's stability and provide immediate feedback on potential weaknesses or hazards. This invaluable feature allows trainees to identify and rectify errors.

Fig. 7: Different Advanced Rigging Assemblies

Through out the training process, the VR system records their performance metrics, allowing for detailed analysis and evaluation of their skills and decision-making capabilities. This data-driven approach enables trainers to identify areas of improvement and tailor further training to meet individual needs.

3.4. Level 3 - Advanced Assembly and Simulation

After developing the training procedure, a set of tests were done by the authors and other research team members at the University of Alberta to assess the effectiveness of the training and optimize the movement and interaction systems used throughout the training. Furthermore, the trainees were asked to choose which locomotion system was to be used when moving, and the teleportation movement system was deemed more user-friendly than continuous movement. Other concerns were tackled, and the overall quality was enhanced. In terms of interaction, some users had some difficulties getting used to the interaction system, but this issue was mitigated with more system usage.

Finally, the participants expressed that realistic graphics and environment improved their understanding and feeling of the tasks. However, they would eventually get fatigued when exposed to longer durations of using the model.

4. CONCLUSION

In conclusion, in this work, a framework for training inexperienced riggers using fully immersive VR was developed; the developed framework is expected to enhance the overall safety in crane-related operations as well as mitigate the number of incidents on construction sites that are caused by inadequate training, inappropriate rigging assemblies and human error. The expected improvements result from customizable and realistic training procedures that follow the health and safety regulations and the relevant training standards currently being used to train riggers and crane operators.

The framework performance was tested on a limited number of students and researchers with experience in crane-related operations. However, further plans to have a more extensive and detailed assessment of the performance of the training module are planned in the works to follow.

Furthermore, Future works include using other objective methods to further assess the developed model's validity. These objective methods would be used to provide a detailed comparison of the behavior of workers under training using VR and traditional methods—moreover, the measurement of vital signs to understand the impact of stress on their performance. This research can also be expanded on by creating a digital twin of the construction site and the rigging assemblies and then assessing the validity of the rigging assembly in real-time, allowing the workers to validate the lift in the virtual environment and modifying the actual assembly to minimize the possibility of an incident.

APPLICATION OF DIMINISHED REALITY FOR CONSTRUCTION SITE SAFETY MANAGEMENT

Alessandra Corneli, Berardo Naticchia, Massimo Vaccarini, Alessandro Carbonari & Francesco Spegni
Department DICEA, Polytechnic University of Marche

ABSTRACT: *Safety management in construction sites has always been one of the most sensitive aspects of the AECO industry and a problematic that recalls the complexity of such a multifactor domain. The high number of work accidents that occur on construction sites is also caused by the fact that not all the information to work safely is always available. For instance, visibility during some maneuvers is a key aspect of safety in operations, and this is often impeded due to the layout of the construction site and working methods, especially in the use of some equipment. The latest approaches in order to overcome complex situations is represented by the Digital Twin paradigm. This approach has among its main criticisms:1) the way of connecting physical reality and its digital replica and 2) the system for exploiting the combination of real-time data and digital applied intelligence for supporting operations on site. This paper proposes a framework for the development of digital twin of the construction site. An application of augmented reality that exploits the concept of diminished reality and workers location detection will improve visibility during critical operations.*

1. INTRODUCTION

Safety in construction has always been a major issue that impacts the industry in terms of efficiency and cost. Construction is in fact one of the most hazardous industries due to its dynamic, temporary, and decentralized nature (Li et al., 2015). Among all economic activities, with the exception of oil, coal, and mineral extraction, the highest shares of serious incidents are recorded precisely in the construction divisions, which record rates above 35 percent. In the five-year period 2014 - 2018, compared to cases that occurred in other sectors, events in construction showed a higher prevalence of risk factors related to the predisposition of work environments (19% vs 12%) and procedures implemented by the injured (40% vs 47%) (Inail, 2022). These statistics focus our attention on two aspects: 1. The worksite is a place that by its conformation and nature carries a high percentage of risk; 2. The proper execution of procedures is a critical aspect that should be worked on to reduce its percentage of risk that is the highest among all (Li et al., 2015).

The traditional approach to safety also referred to as Safety-I (Martins et al., 2022) involves working to reduce the number of adverse events as much as possible. This most often involves using methods to counter or prevent the occurrence of misbehavior (e.g., audible warning systems on machinery) or to limit the effects should they eventually occur (e.g., individual and collective prevention devices). This approach involves having to envision all possible adverse scenarios so as to provide methods to counteract possible adverse outcomes. This is a continuous chase that however struggles to take into account a fundamental aspect that characterizes construction sites: their high complexity (Fang and Wu, 2013). Difficulty in standardization of procedures, complicated production processes, temporary organizational structure, relationships between stakeholders, and variable workplaces are some of the factors that contribute to the deep diversification between construction sites and other industrial production sites (Li et al., 2015). All these factors provide the backdrop for another crucial aspect that is encompassed in the concept of complexity and that is the need to manage the unexpected, which in terms of safety can be translated as dealing with new, variable and real-time risks and hazards.

In this context, the use of new technologies to collect and analyze real-time data from the construction site can be a disruptive innovation (Teizer et al., 2022). A push in this direction is also provided in the Italian context by Law 36/2023, which in Annex I.9, article 12 letter m states: *"In the formulation of information requirements by contracting stations, specific uses, operational methodologies, organizational processes and technological solutions may be defined as objects of evaluation for the purpose of rewarding, with reference to the execution phase of works, to digitally increase health and safety conditions at construction sites."* However, there are still unresolved issues in this regard that prevent widespread and pervasive use of these methods in the real environment. On the one hand, real-time on-site data collection itself encapsulates within it several problems: the sensorization of construction sites (workers, vehicles, materials), methods for collecting images that can be

exploited to apply artificial intelligence, the possible need to have to provide power in the open environment to IoT devices, and the lack of a unified framework where to channel and integrate the collected data. On the other hand, information derived from analyses, short-term simulations or application of artificial intelligence should increase the knowledge of the stakeholders involved and thus in the interest of safety management they should be made immediately available on site in order for being used by operators, safety managers and site managers. This aspect represents a great complexity because making content usable on site requires finding quick and effective methods of communication both in terms of sending the data and visualizing it at the construction site. Augmented reality is a technology that has great potential in terms of visualization. Indeed, the use of holograms superimposed on the real-world view makes it possible to add an information layer that can show aspects not visible to the human eye or enrich knowledge with information from analysis of previously submitted data. In some cases, however, what is needed is not so much to add a layer of knowledge as to remove something that impedes the view. There is for this purpose a specific class of augmented reality that is called diminished reality (Cheng at al., 2022).

The purpose of this research is to apply the concept of diminished reality to construction sites in order to support operations with regard to risks related to operator safety. The proposed framework and the first experiments developed involved moving loads with a crane work scenario, including work at height, where the operator of the vehicle has a not fully unobstructed view. The application of see-through diminished reality allows the crane operator to visualize any worker placed in the vicinity of the load through the use of a depth camera and artificial intelligence. Innovations of the proposed system include: 1. Visualization by the operator not only of the relative position between workers and load but also of the orientation of the workers' bodies. This information makes it possible to understand whether the worker is aware that he or she is near a moving load or whether there is a risk of catching the worker by surprise (in case it is shown that the subject is with his or her back to the load). 2. An automatic procedure that transforms the visualization from solid to wireframe of objects that are opposed between the machine operator and human figures detected by the depth camera. In this way through a two-way line of communication and interaction between the actual construction site and a digital representation of it, a Digital Twin (DT) type approach will be achieved in which data obtained are processed and sent back, after the necessary analysis, directly to the site real time use. The system proposed in this article makes more sense at large, complex construction sites where the expected safety costs are higher and therefore allow for the implementation of new technologies.

2. LITERATURE REVIEW

The use of innovative technologies such as virtual (VR), augmented (AR) and mixed reality (MR) in the construction industry has found different levels of application due to the differences between them. Applications using augmented and mixed reality have long since found their use in construction sites. Chalhoub et al., 2018 proposed a method for electrical system component's location visualization on site using mixed reality and head-mounted displays. A similar way of exploiting MR is proposed in recent times also by Dallasega et al. (2023) for MEP components installations in general. A number of applications of AR and MR in construction sites still refers to way for showing design information or building components specifications in a more straightforward and easy understanding way (Carbonari et al., 2022; Yoon et al, 2022; Sabzevar et al, 2023; Pendersen et al, 2020; Um et al., 2023).

As far as worksite safety is concerned, however, most applications focus on the possibilities of leveraging these technologies for operator training. Boschè et al. (2015) proposed a novel MR system uniquely targeted for the training of construction trade workers. One of the aims of this paper was to enable trainees to experience construction site conditions, particularly being at height, in different settings. Anyway, the majority of these applications makes use of VR or Augmented virtuality (Wolf et al, 2022) which means that the operator is transported completely into the virtual world to carry out serious game-like experiences but without testing in the real world or with operations carried out live. Jelonek et al. (2022) developed a VR application for training operators in the use of cutting equipment on site introducing in the serious game procedures to follow in order to be sure that all the involved personnel is following all safety prescriptions. Wolf et al. (2022) developed a serious game for inspector job simulation in a complete virtual environment. Speiser and Teizer (2023) tried to move forward introducing the concept of digital twin for construction safety training in order to link various data sources to generate a Virtual Training Environment (VTE) automatically. However, few applications are yet attempting to bring these technologies on site to provide real-time assistance. Nguyen et al. (2022) started to work on skeleton recognition for action recognition on site but they have not developed an AR visualization on site yet. Eiris Pereira et al. (2019) combined training and augmented reality but directly on site for reporting situations with danger of falling from height.

One aspect that is still underemphasized in the construction world is that sometimes it can be very useful that information is taken away rather than added, and in this sense the application that should be considered is that of Diminished Reality (DR) (Mann et al., 2002). While AR and MR superimpose virtual objects on the real world to enhance reality by placing new objects among real objects or extending real objects with virtual objects (Mori et al.,2017), DR deliberately removes parts of a real-world scene or replaces them with computer generated information (Mann & Fung, 2001) and it can be considered a subtype of AR. Based on computer vision techniques, unwanted image elements are detected and replaced by other image elements, creating an overall plausible and consistent impression for the viewer. The idea in diminished reality is to virtually remove something from the view. There can be identified different techniques for diminished reality implementation. In one kind of approach the object to be removed needs to be detected and the corresponding image area needs to be filled in with a texture that seems to belong to the background. In image processing terms, this kind of filling-in operation is called image inpainting (Siltanen, 2017). Another approach discusses a way of representing occluding objects as semi-transparent. This visualization technique is called AR X-ray vision, see-through vision, or ghosted views. Semi-transparent representation is useful for seeing through car interiors and walls (Mori et al., 2017). In automotive settings, a number of see-through displays have been incorporated. In Samsung's Safety Truck, for example, live video images were displayed on the back of the truck, effectively granting trailing drivers the ability to 'see through' the truck.

The very first approaches to DR aimed to lower the saturation of some areas to force an observer to face other regions and virtual objects overwrote undesirable real objects to hide the real information (Mann, 1994). After that this technique was used for different purposes: to remove a person from Google Street View pictures to protect his or her privacy, to remove a person in a video, to remove a vehicle in front of the driver, to remove a baseball catcher to visualize the view of the pitcher from a view behind the catcher, and to generate a panoramic stroboscopic image (Mori et al, 2017). In the case of see through applications one of the methods to provide the current state of the hidden area in the main view is the same as that used by Zokai et al. (2003) that used two additional cameras as hidden background observers to erase from the main view pipes in a factory. Mori et al. (2017) constructed light fields with a real time multi-camera system and removed a viewer's hand from the perspective to visualize the viewer's workspace occluded by his or her own hand. Queguiner et al. (2018) presented a diminished reality application running live on consumer mobile devices. In their pre-observation-based approach, the clean 3D scene, free of undesired objects, is scanned beforehand and reconstructed as a high-resolution textured 3D model. Many see-through DR literature tends to investigate more computationally efficient approaches focusing on compensating real–virtual boundary in screen space. Thereafter, semi-transparent or wireframe representation is performed to improve user depth perception. These representation methods will be useful for avoiding the danger of a collision with the diminished objects. In this regard, Peereboom et al., 2023 presented a system that exploits DR for avoiding collisions between pedestrians and cars caused by poor visibility, such as occlusion by a parked vehicle. In one of the solutions, they proposed the occluding vehicle has been made semi-transparent. Still recently, Cheng et al. (2022) proposed a study on users' perception of diminished reality and its possible applications.

However, the concept of DR is still little exploited in construction although Klinker, Stricker and Reiners (2001) develop the first examples of diminished reality in the field of construction with two very significant examples: in the first one TV antennas located on a hill are removed from the view within which the work that will replace them is later placed so that it can be visualized in its chosen location. In the second case given as an example, the installations below a wall are shown in the form of holograms.

This research aims at exploiting the concept of diminished reality for construction sites operations efficiency and safety. The innovation of the system proposed lays in the combination of skeleton recognition, which provide operators position and field of view, and the automatic procedure that detect obstacles and made them visualized as a wire frame model. The integration of different technologies for onsite application is also another key aspect.

3. DR FOR CONSTRUCTION SITE SAFETY MANAGEMENT SUPPORT

The system proposed in this research is a diminished reality application for supporting safety management at construction sites. The development focused on a specific case and that is load handling by crane. In the case of cranes maneuvered from the ground, but not only, there are situations in which visibility can be reduced: work at height in which the support is not clearly visible, maneuvers on the construction site in which the placement of material takes place beyond already built constructions. For this reason, a viewer that supports the operations coordinator in visualizing possible hazardous situations can assume great value (Fig. 1). To this end, we focused in this work on visualizing workers in locations hidden from view.

It was decided to proceed with localization and visualization through depth camera with a twofold advantage: on the one hand, this instrument returns the skeleton that allows us to understand how the worker is placed and oriented; on the other hand, the fact that only the skeleton is communicated removes a number of privacy issues. In this system then it was planned to also instrument moving loads, with sensors (UWB inside and RTK outside) in order to be able to communicate this data to the operations coordinator as well. Finally, the developed application involves the transformation of the obstacle object visualization from solid to wireframe. Such a system finds its application not only in the highlighted case but also in many other site operations such as demolitions where knowing what lies beyond certain elements could be crucial.

Fig. 1: Diminished reality for construction site.

4. METHODOLOGY

The methodology followed in this research for improving the safety of workers in construction sites through the exploitation of DR is shortly described in Figure 2.

The first step is setting up a localization framework covering the entire construction site. Such framework should be a *real-time system* capable of attaching spatial coordinates to any entity, object or person, moving around in the construction site. The specific technology employed for this step can vary depending on several aspects, e.g. whether the construction site is outdoor or indoor, or whether we are considering an existing facility to be recommissioned or instead a new building or infrastructure to be built. For complex scenarios, multiple technologies may coexist at the same time to localize objects and people in different areas of the overall construction site. In such a case a problem arises of allowing a seamless integration of different localization systems to provide a homogenous notion of localization on the construction site. The core idea behind the localization framework is to support the detection of safety hazards so as to prevent incidents.

A second step of the methodology is the setup of a heterogeneous network of sensors continuously monitoring the activities in the construction site. The sensor network may employ very different devices both for their technological characteristics and for the kind of data collected (e.g. temperature sensors, cameras, NFC tags, etc.). The basic requirement for each sensor in our methodology is that it must be able to attach a precise timestamp and a precise set of coordinates relative to the localization framework set up. This would witness when and where the information was sensed in the construction site.

A third step is the setup of a DT Platform integrating several sources of information operating on and off the construction site. For instance, interpolating information coming from the construction design together with data collected by the network of sensors the platform can provide the most updated "picture" of the building or infrastructure being realized. The DT Platform is also responsible for managing and harmonizing the several data models used to express the information coming from the different (internal and external) sources, e.g. by using linked data or ontology-based semantic data integration procedures.

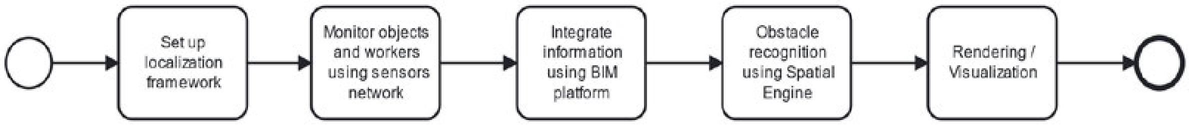

Fig. 2: Methodology for applying Diminished Reality to construction site safety.

Next, a Spatial Engine should be implemented that processes all the spatial information from the BIM models, the persons equipped with DR viewers, the sensors deployed through the site, the vehicles and all the various agents acting within the site. Given the position of a person using a DR viewer, its main role is to determine which agents and BIM objects are of interest for him/her and to provide the corresponding data streaming. Moreover, by exploiting the information stored in the CDE, the Spatial Engine is the place where possible spatial interferences can be detected, forecasted, and notified at run time to the involved agents in order to prevent injuries.

Finally, a DR visualization tool is in charge of rendering holograms mixed with the real objects of the construction site in order to allow the observer to view also those hidden objects that can be involved by the ongoing operations. The obstruction is determined in real-time based on the observer's point of view and the position of the moving objects given by the sensory data: when a BIM object is hit by the ray joining the observer with a moving object, this BIM object is classified as obstructing and it is rendered as wireframes thus making visible the virtual objects behind it that reproduce their invisible real twins.

In the following sections this methodology is applied starting with the indoor localization framework. The sensor network has been set up with a depth camera and two location tags. The former is a special computer camera with two "eyes". By merging the visual information coming from them, it can compute the distance (or depth) of objects and bodies w.r.t. its point of view, when they appear in the picture. The chosen depth camera also provided advanced artificial vision software capable of recognizing the position of core joints in the skeletons. This information can be exploited to know the real-time position and orientation of an individual or of a crew of workers. As a consequence, it is possible to relate this information the one coming from the tag attached to the load lifted by the crane in order to know the exact relative position and the risk of the workers to be hit. A mixed-reality head-mounted display (HMD) is used as visualization tool where the BIM model of the construction site and signals coming from the sensor network (e.g. the position of the workers in the construction site coming from the depth camera, as well as the position of the depth camera itself, and of the crane load) are downloaded from the DT platform together with the spatial simulation results. Also the head-mounted display DR application can download from the DT platform information about the 3D objects that hinders the view of workers and the load when the crane is operating thank to ray-tracing data transmission. The ray-tracing technique uses basic geometry in order to select all the 3D objects (e.g. walls, doors, columns, etc.) that lay in between the user viewpoint and the objects returned as obstructions (i.e. the workers and the crane load) and then the platform sent them back made transparent in a wire frame visualization.

5. SYSTEM ARCHITECTURE

The architecture of the system proposed in this paper is the one depicted in Figure 3. In accordance with what was previously described in the methodology paragraph in this section the specific devices and components of the system will be made explicit. For what concerns the localization of the operators, we chose to use a depth camera and specifically a ZED 2i. This device made possible two things: 1. recognize the skeleton of the workers; 2. place the skeleton in the virtual space once the position of the camera in the real space is known. The ZED 2i camera provides the streaming of the joints of the skeleton, which were set equal to 18 points.

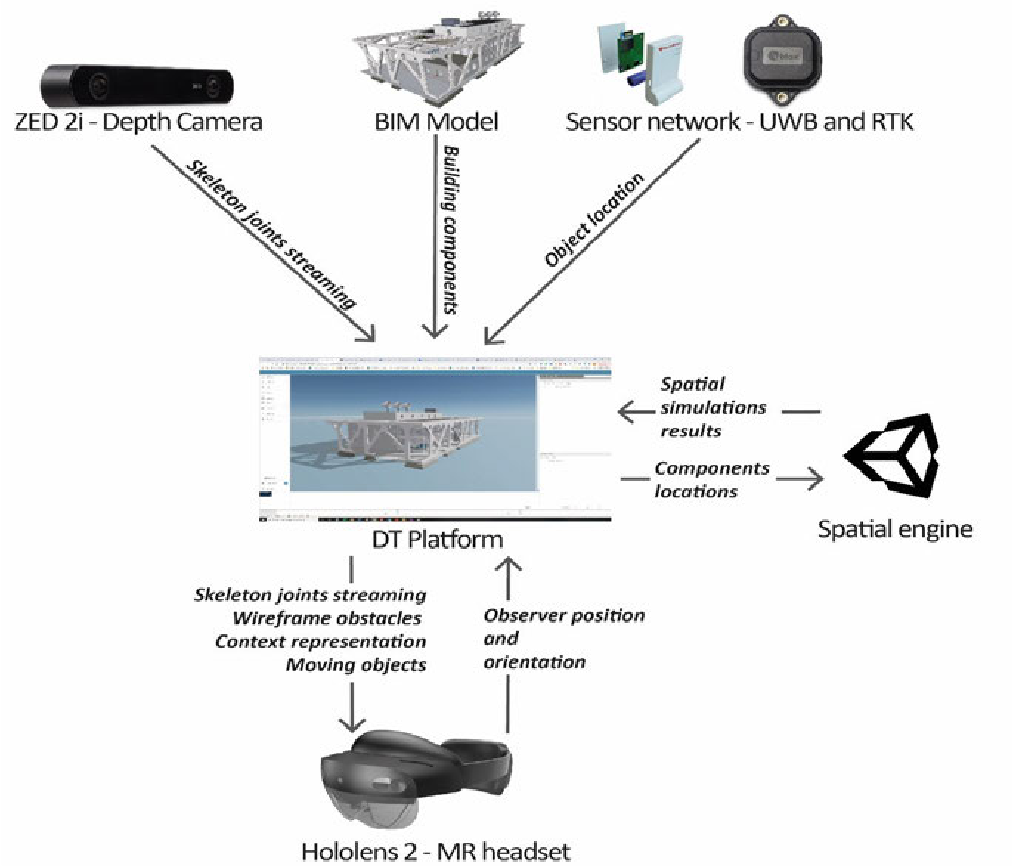

Fig. 3: System architecture and data flow.

For space modelling it can be used a BIM model provided in ifc format. This type of space modelling contributes in modelling the different building components enabling at a later stage to go and select one by one the objects that represent obstacles to workers visualization. In the development here proposed, Autodesk Revit was used for BIM modelling. Moreover, in the case of the construction site where the presence of the elements is dependent on the progress of the work, the combination of ifc files with a timeline also makes it possible to analyse what would be visible and what would not be visible at a precise moment in the construction.

Finally, since not only the workers need to be located but there are other components of the worksite whose location is important to know, a number of sensor networks can be implemented. These vary as needed. In the case taken as an example in this article, two types of sensors were referred to: GPS RTK tags and UWB tags. Although the GPS RTK localization system could not be integrated into the indoor tests reported in section 6, its suitability for outdoor applications is shown by its quite high accuracy reported by technical sheets [Datasheet], which was confirmed by very preliminary trials performed by the authors. But this is going to be used in future research developments. For the purpose of the indoor tests subject of this paper, contextual infrastructure was monitored by means of UWB anchors. In any case, it is worth remarking that both types of sensors can be used to communicate position data.

Moving on to the other components of the system, a platform, resulting from the development of the research project "A Distributed Digital Collaboration Framework for Small and Medium-Sized Engineering and Construction Enterprises" (PRIN 2017), is used. This platform uploads BIM models in ifc format, allowing browsing and querying. The platform then allows the integration of data from a variety of heterogeneous sources (in this case skeleton joints from ZED 2i and location data from sensors) allowing them to be located in space or linked to components (e.g., modeled building objects). In this way it is configured as a real DT platform.

As for the spatial engine, this receives the necessary information and thus the positions of workers and moving objects (provided by UWB or GPS-RTK). The purpose of the spatial engine is to perform real-time processing about spatial interference and then transmit it to the platform, which will also relate it to the components of buildings in space so as to identify objects of obstruction to operator's view.

Finally, the last component of the system is an MR head-mounted display whose use has two purposes. The first is to enable the display of holograms for a diminished reality visualization. The second is to provide the position and orientation of the observer. The Microsoft Hololens used as the MR provider receives the information directly from the platform and thus the visualization of the skeleton joints, the model of the surrounding environment, the positions of moving objects, and objects identified as obstacles and whose representation is then modified by the procedure to change from solid to wireframe. In order to achieve a consistent visualization, the Hololens transmits to the platform the position of the operator with respect to the modelled space and information about the orientation of the head. In this way it is possible to precisely calibrate the sample scenario.

6. DIMINISHED REALITY APPLICATION

The experiment was conducted using a Python application sensing the skeleton information coming from the depth camera ZED 2i through the Python SDK. In this application, the camera acquired two video streams at 30 fps, and once every 3 frames the skeletons information where encoded as JSON objects and published using the MQTT protocol. For debug purposes, the position of workers' skeleton joints where highlighted in a live video stream (Fig. 6 b). This resulted in 10 MQTT messages sent per second. The DT Platform subscribed the topic on the MQTT broker, thus receiving the skeleton signal from the Python application. The DT platform was in charge of sending the skeleton signal as well as the BIM design and the location of the camera, the Head Mounted Display, and the object moved by the crane, to the Spatial Engine. The latter was responsible for detecting in real-time the list of obstacles in the BIM design and passed it to the Head Mounted Display, together with the position of the workers and the crane load w.r.t. the Head Mounted Display.

The logic behind the Spatial Engine detects obstacles using ray-casting, a technique implemented by the Spatial Engine which returns a list of objects hit by a hypothetical ray departing from a source position towards a given direction, and having a length bounded by a given maximum value. To reach our aim, we need to use the user's viewpoint as source position of the ray-to-be-casted, next we need to cast a ray on each direction corresponding to each joint of the workers skeletons detected by the depth camera and each object moved by the crane; finally, we must set as maximum length of the casted rays the actual distance between the user and the joints or moved objects.

7. DEVELOPMENT AND CASE STUDY

Feasibility tests of the developed application were carried out in the DC3 laboratory of the DICEA department of the Polytechnic University of Marche. In this case since a crane was not available, the overhead crane carriage inside the laboratory was used to simulate the suspended load in motion. The hook of the bridge crane was instrumented with a UWB position sensor which sends data to the platform (Figure 4). The laboratory is equipped with UWB anchors placed at the corners of the room for precise position sensing.

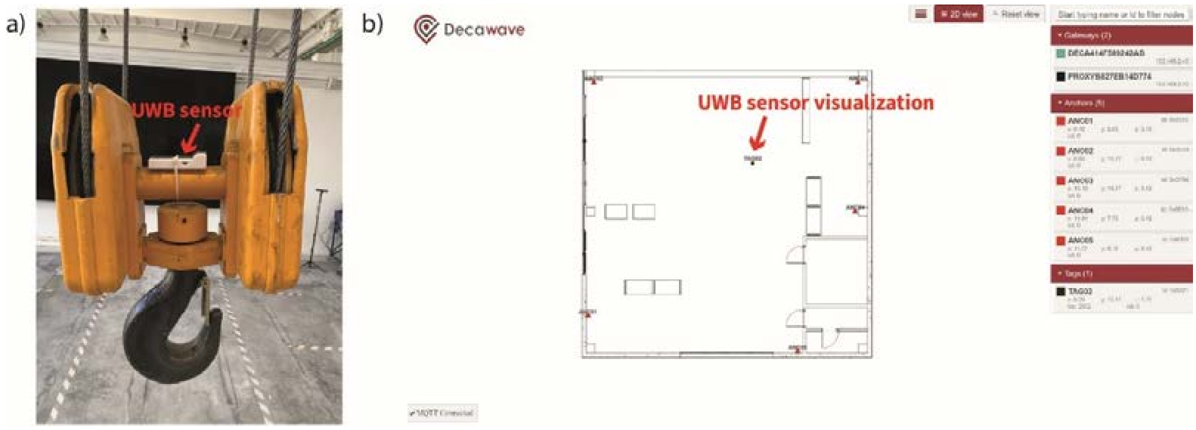

Fig. 4: a) Bridge crane hook instrumented with UWB sensor; b) UWB sensor visualization in the space inside the platform.

Next, the ZED 2i camera was placed as seen in Figures 5 and 6 a). The information that the chamber returns through the recognition of the skeleton joints is as in Figure 6 b). The orientation of the worker is also detected as the blue joints detect the left side of the body while the red joints detect the right side. In this way it is possible to understand which direction the worker is looking at and thus whether in the presence of a moving load he is presumably aware of the presence of the load or whether his being from behind identifies a situation of greater danger as he may not have noticed that something is moving in his vicinity.

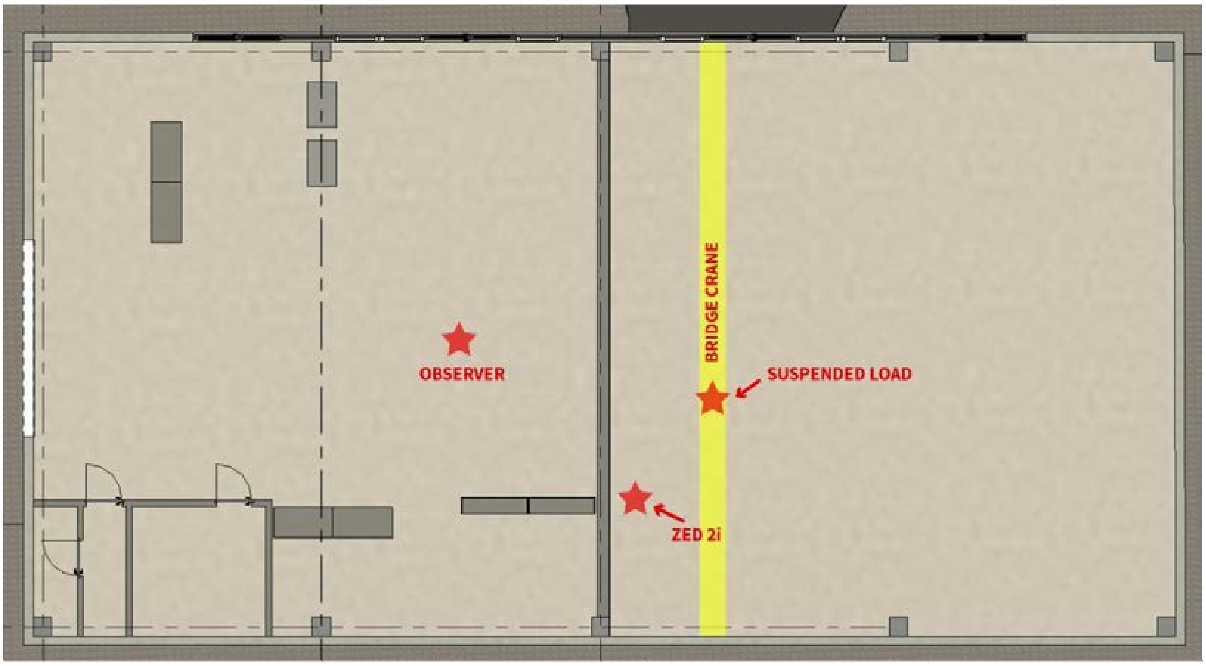

Fig. 5: Components position inside the laboratory.

The test performed reproduced the same conditions shown in Figure 1. The laboratory is placed in a shed divided in half by a wall 3.5 m high, about half of the total height of the structure. Figure 5 shows the location of all components for the experiment in the laboratory. In order to verify the actual operation of the application for the developed diminished reality, the operator wearing the HoloLens stood on the left side in the floor layout of the shed. Looking toward the partition wall (Fig. 7 a)) the HoloLens showed the wall in wireframe visualization and the skeleton points of the operator who was moving around the load on the other side of the room. In this first processing the positioning of the load was not implemented in the hologram visualization although it was present as data in the platform. Again, it is possible to observe the differentiation of blue and red colours for the left and right side of the body respectively which allows the worker observing the scene to understand the orientation of the worker.

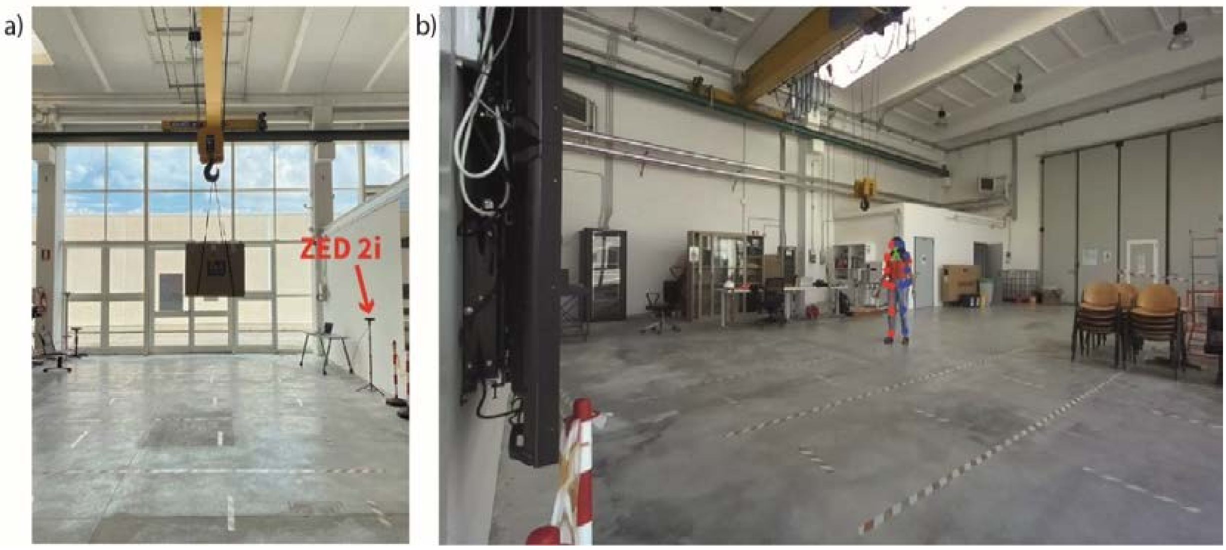

Fig. 6: a) Load position and ZED 2i location; b) Depth camera vision and skeleton joints recognition.

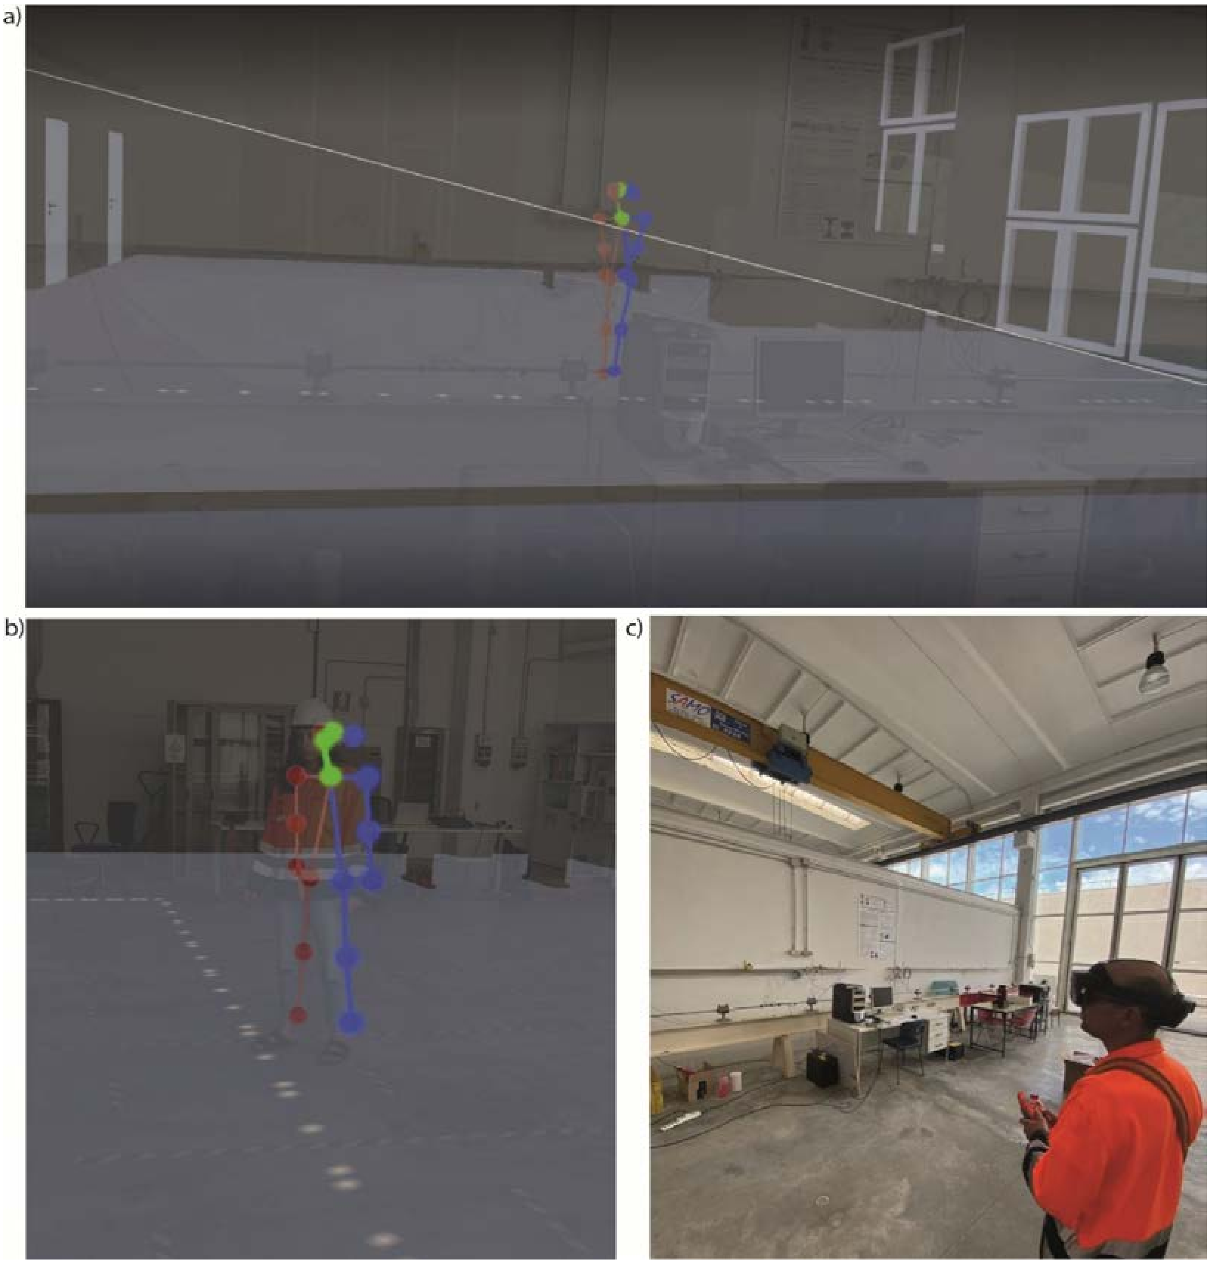

Fig. 7: a) Vision from inside the HoloLens (other side of the wall) ; b) Vision from inside the HoloLens (same side of the worker framed); c) operator with the HoloLens and the bridge-crane remote control (other side of the wall).

8. CONCLUSION

This paper presents an application of diminished reality for safety management support during operations at a construction site. The proposed system involves the use of depth camera and sensors for locating components of interest and implements the development of a DT platform for real-time management. The system thus developed allows for optimization in the number of sensors that can be placed in strategic areas (depth camera) and alternately on moving loads or equipment to be monitored at the stages when they are expected to be utilized. Initial experiments of the application of this development were carried out in the laboratory by reproducing conditions similar to those at a real construction site. The next steps will concern the implementation of the visualization inside the HoloLens of the position of the moving load and tests in outdoor construction sites thus having the possibility to test also the visual rendering of holograms in the open air that could be an obstacle to the optimal visualization for operators.

DRIVING SIMULATOR FOR ROAD SAFETY DESIGN: A COMPARISON BETWEEN VIRTUAL REALITY TESTS AND IN-FIELD TESTS

Meocci Monica, Alessandro Terrosi, Andrea Paliotto, Francesca La Torre & Irene Infante
University of Florence, Florence, Italy.

ABSTRACT: V*irtual reality simulations conducted by driving simulators represent a methodology to assess both the quality of road design and road safety in a safe, controlled, and replicable environment.*

Nowadays, there are numerous studies that use driving simulators to analyze the driver's response when specific road safety treatments are planned before these are implemented. This approach allows the road designer/scientist to estimate the potential safety effectiveness of the countermeasure/design configuration considered.

However, although virtual reality simulations are potentially extremely useful in the evaluation of road configuration design and treatments effectiveness, they also have cons. The two most important are the limitations in the reproducibility of the realworld environment and the difference in drivers' behavior due to the awareness that they are conducting a test.

In this context, our research compared the data collected during virtual reality experiments with those collected in the field with an instrumented vehicle, after a few years from the implementation of the specific safety measure on a real road. Statistical analyses were conducted to compare the results of the two experiments to demonstrate the reliability of the virtual simulations and to identify the limitations.

KEYWORDS: *driving simulator, road safety, virtual reality, road safety treatments, road safety measures effectiveness, in-field test*

1. INTRODUCTION

Making safe roads and decreasing the number of accidents, deaths and injuries on the roads is one of the greatest challenges of this century.

Nowadays technology allows scientists, engineers, and technicians to approach road safety including also human behavior. Virtual reality represents one of the instruments that allow road engineers to understand and evaluate in a safe and controlled environment how both road configuration and other contingent factors, affect human behavior.

When an unsafe road section is identified as a "black spot", e.g., through an analytical accident analysis, the Road Administration (RA) works "to change" the road configuration, improving aspects related to road traffic safety. The solution selected is then implemented on the road and only a few years after the intervention, it can be observed whether the proposed countermeasure has been effective (or not). This type of reactive approach requires investing high budgets to correct the road deficiencies and waiting years to see if the solution proposed was useful in the accident mitigation phenomenon (not always proving its effectiveness).

The use of virtual reality approach, instead, allows to investigate the described phenomenon in a proactive manner (before the accident occurrence), using a controlled, safe and ethical test environment (Calhoun and Pearlson, 2012). Virtual reality also allows to perform a safe, controlled, reproduceable and standardized experiment (de Winter et al, 2012). In fact, the researchers define the "road environment" within a scenario able to describe the main phenomena to be studied, for example, different road geometry (Bassani et al., 2019b; Bobermin at al., 2021; Montella et al., 2018), different intersection layout (Danaf et al., 2018; Kekez et al., 2022) or different cross section organization (Bella, 2013; Ben-Bassat and Shinar, 2011; Mecheri et al., 2017; Domenichini et al., 2018); or introducing events describing specific road users' interactions or limited sight distance (e.g., driver-pedestrian with occlusion, etc.) (Bassani et al., 2019a; Domenichini et al., 2018)

Unfortunately, the use of driving simulators also has cons to be considered. Limited physical, perceptual, and behavioral fidelity of the instrument (driver simulator) affect both the experimentation reliability and the driver's interest in the test, especially if the vehicle cannot reproduce the vehicle performances in an accurate way (de Winter et al, 2012; Boda et al., 2018; Pawar et al, 2022). The possibility to transfer the study results to "an actual road safety countermeasure construction" needs the results to be evaluated in terms both of fidelity and validity. The first validation processes were defined since the last century (Blaauw, 1982; Klee et al., 1999). The term

Referee List (DOI: 10.36253/fup_referee_list)
FUP Best Practice in Scholarly Publishing (DOI 10.36253/fup_best_practice)

"fidelity" has been used to describe the ability of the driving simulator to reproduce the sensory stimuli present in a real driving environment. This ability was strongly dependent on the quality of the equipment (e.g., motion system, projector, screen and display, simulacrum and sound) (Kaptein et al., 1996). Wynne et al. (2019) conducted an extensive literature review concerning driver simulator validation studies. According to the definition given in Blaauw, the word "validity" describes the ability of the study to accurately represent the drivers' behavior in a real world. The study considered two types of validity: absolute validity and relative validity (Blaauw, 1982).

The most used parameter to check the quality of the driving simulator results was drivers' speed (Cao et al., 2015; Bella 2008; Bham et al., 2014; Yan et al., 2008; Branzi et al., 2017). Often the speed was coupled with other parameters describing the drivers' performance such as acceleration/deceleration or lateral position (Blana and Golias, 2002; Chen et al., 2021; Kazemzadehazad et al., 2021) and drivers' reaction time (McGehee et al., 2000; Engen, 2008).

The literature shows that in the analysis of road safety the use of the driving simulator represents a great opportunity for road engineers and scientists to assess preliminary the impact of a specific engineering treatment. The virtual reality evaluation allows also to define the best safety solution with reference to the specific road safety objective and without any implementation cost. The objective of this research is to complete the research conducted in 2017 (Branzi et al., 2017) also investigating the ability of the LaSIS driving simulator to reproduce the drivers' behavior when different safety countermeasures were present along the road. This validation study compared the speed profiles of the driving simulations and the real world drivers, evaluating where the results are similar and which effects could instead cause differences in drivers' behavior and in virtual reality results exploitation.

2. METHODOLOGY

2.1 Research history and overview

Via Pistoiese was studied by our research group in recent years, especially concerning pedestrian safety. Statistics on accidents in Florence always placed this street in the first places in terms of danger, especially for vulnerable road users (VRUs) (Domenichini et al., 2014).

The safety problems of the street were different, and they included the high speed, the high level of interaction between traffic and VRUs due to the strong traffic demand, the geometrical configuration (a long straight about 4 km), and the high presence of commercial activities, residential areas, and parking stalls along the road.

To improve the road safety of the area, part of the street was interested by a reconfiguration project, where numerous traffic calming measures were defined and implemented with the aim of limiting the speeding phenomena, including:

- introduction of both raised pedestrian crossings and/or raised intersections to control the speed along the section;
- installation of a raised median curb to avoid overtaking maneuvers, but which can be performed only by the emergency vehicles;
- reduction of the lane width to the standard value for this type of street;
- introduction of high perception elements to improve the driver perception of the context.

A few years before the road modification, the entire reconfiguration project was studied in virtual reality. In Domenichini et al. (2018) and in Branzi et al., (2018) the good results obtained from the experimentation were extensively described.

In 2018 the safety solutions evaluated in virtual reality were implemented along via Pistoiese and nowadays are part of the road environment. In this context a new experimentation was conducted by the authors to monitor the effectiveness of the engineering treatments over time, and to understand if the results obtained by the LaSIS driving simulator are reliable.

This latter experiment was conducted in-field with a specific device named V-BOX HD2, which is similar to a black box capable of recording the kinematic parameters of the moving vehicle. The experiment can be considered as a validation experiment for the result obtained in the virtual reality evaluation comparing speed and acceleration/deceleration behavior. Figure 1 represents the research approach and the connection between the two different tests conducted, in virtual reality and in-field.

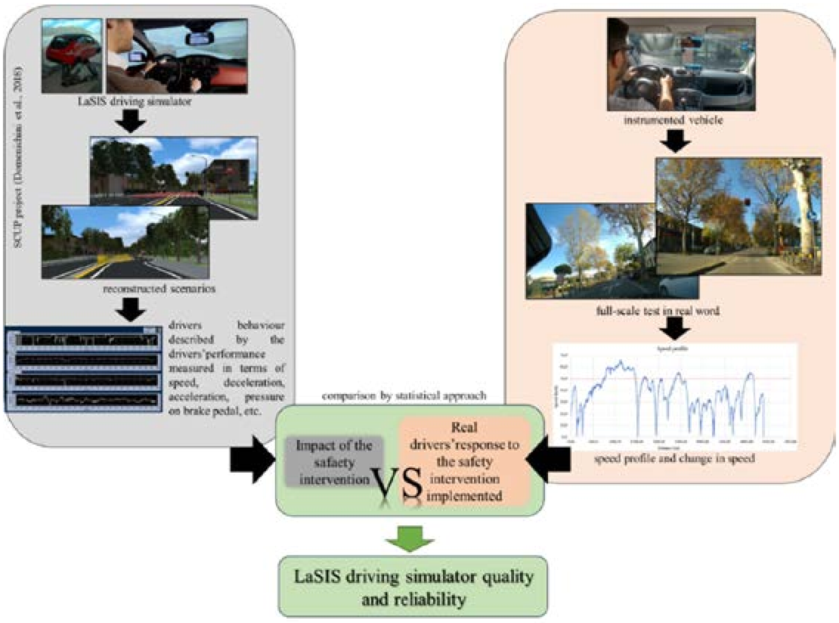

Fig. 1: Overview of the research

2.2 Detailed description of the road context

Via Pistoiese is a street located in the suburban area of Firenze, classified as an urban collector road (it serves penetration movements but also VRUs movements for commercial and residential activities). The road geometry is simple, and it is composed by one curve (R=250 m) that connects two straights which are connected to the road network with roundabout intersections. The road segment is about 4.5 km long (Figure 2).

Fig. 2: via Pistoiese (Firenze)

The cross section is about 18 m wide. On the roadside, a 2.00 m wide parking area and two sidewalks are present (1.50 m wide) on both sides. A wide cross section is dedicated for motorized traffic, and it is organized in different configurations along via Pistoiese as described below:

- different number of lanes (segments with one lane per direction and segments with one lane in one direction and two lanes in the other one);
- presence/absence of a median curb that does not allow left turn maneuvers;
- numerous and different traffic calming interventions (such as raised pedestrian crossing, raised platform in the intersection, chicanes, etc.).

In this paper, the analysis was conducted with reference to the road segment interested by the traffic calming treatments (in orange in Figure 2). In Figure 3 and in Figure 4 some comparisons between the actual street and the virtual scenario are shown.

Fig. 3: via Pistoiese: real world VS virtual reality (1/2)

Fig. 4: via Pistoiese: real world VS virtual reality (2/2)

2.3 Apparatus

Two different apparatus are used in this research, the LaSIS Driving Simulator and the V-BOX HD2.

The LaSIS Driving Simulator is a motion-based simulator, equipped with a full-scale Lancia Y simulacrum fixed on a 6 degree of freedom Stewart's platform. The platform allows roll, yaw and pitch movement of the vehicle. The vehicle interior includes all commands normally available within a car, with a steering wheel with force feedback. The three rear-view mirrors, the central one and the side mirrors, are equipped with displays that project the scenario just traveled and complete the vehicle interior. The cabin is surrounded by a cylindrical screen about 200° wide where 4 projectors reproduce the driving environment. The sounds in the environment and in the participant's car are generated by a multichannel audio system. The data acquisition frequency of the apparatus is 20 Hz. According to the classification proposed by the literature in term of the ability of the device to emulate driving in real world (i.e., vehicle controls, field of view and kinesthetic), the LaSIS driving simulator can be classified as a high-fidelity driving simulator (Goode at al., 2013; Wynne et al., 2019)..

The VBOX HD2 system used for the on-field test consists of a mobile device, like an advanced black box, able to record dynamic information concerning the vehicle movement (such as speed, GPS position, acceleration, deceleration, position in the lane, etc.). The instrument needs to be fixed inside each passenger car used in the on-field experiment. The acquisition frequency is different for GPS and video information and respectively equal to 10 Hz and 60 Hz. The VBOX application allows to read the measurements synchronized and check in a remote analysis the information related to the recorded data (e.g., available satellites, traffic conditions, etc.).

2.4 Participants and procedure

Participants were recruited on a voluntary basis among students, staff, expert drivers and common people.

In both tests, drivers had to meet the following requirements:

- possession of an Italian valid driver's license;
- normal or corrected-to-normal vision.

Two samples were recruited composed of 48 users and 36 users respectively for virtual reality and on-site test. Samples do not contain people who drove in both tests due to the different time frame in which they were conducted (2015-2016 and 2021-2022), but mostly because the selection of the same participants can affect the drivers' behavior in the second experiment due to the previous experience in virtual reality. Table 1 summarizes the participants' characteristics.

Table 1: Participant characteristics

	Virtual reality experimentation		**In-field experimentation**	
	M	F	M	F
Gender	36	12	28	8
Age	42.2 (S.D. 12.7)		40.6 (S.D. 17.12)	

NOTE: S.D. standard deviation

Their driving experience (years of driving license possession) ranged between 3 years and 46 years. Except for 5 participants, all of them declared that they travelled at least 5,000 km in a year.

Each participant was tested individually, according to the two different procedures adopted respectively for virtual and full-scale tests (Domenichini et al, 2018; Meocci et al., 2023). Table 2 summarizes the main steps of the two-procedures adopted for the experimentations.

Table 2: Procedures summary

Virtual reality test	**In-field test**
No payment for the involvements	
Participants were not informed about the research objective	
Test duration about 35-40 min in safe and controlled environment (LaSIS laboratory)	Test duration about 35-40 min in real-word but in a defined path. No restriction of the traffic conditions was defined during the test.
The drivers' performances were recorded by the LaSIS driving simulator	The drivers' performances were recorded by the V-BOX HD2 fixed each time inside the drivers' own car

2.5 Data collection and analysis

To test the validity of the results obtained by the LaSIS driving simulator the comparison was made analysing the speed profiles obtained in virtual reality experimentation and in full-scale test.

A preliminary comparative analysis of the entire average speed profile was conducted to analyze if the simulator results showed the same patterns (and macroscopic effects) as those measured in the real world (relative validity). The comparison was made only with reference to the profile sections where there were no conditions that influenced the drivers' speed (i.e., pedestrians who cross the street in the simulation or traffic congestion in the in-field experimentation). A qualitative comparison was also carried out with reference to the V85 speed.

The absolute validity of the simulation results was evaluated by means of a statistical test. The two datasets consist of the speed measurement along via Pistoiese in virtual reality and in-field. The two datasets were preliminary verified by the Shapiro-Wilk and Levene's tests respectively for normality and homoscedasticity assumptions. In the former test H_0 states that the variable is normally distributed, in the latter H_0 states that the variables we compared had equal variance. Both the tests were conducted with a significant level of 5%.

Subsequently two tests to compare the averages of two groups and determine if the differences between them are more likely to arise from random chance were conducted, the t-Student's test for independent sample when the sample was normally distributed and the U Mann-Whitney's test, a non-parametric test, for the other samples. Both tests were conducted with reference to the null hypothesis H0: the difference in mean is equal to 0. In all cases where the null hypothesis was rejected, also the effect size was determined by the d-Cohen metric. This allows to define the strength of the relationship between two variables compared.

Finally, according to Losa et al., (2013) a regression analysis was conducted to investigate how the driving simulator experimentation reproduces the real-world performances, considering each road segment.

3. RESULTS AND DISCUSSION

3.1 Relative validity: average speed profile comparison

Figure 5 shows the result of the preliminary comparison between the two speed profiles. Specifically, in the chart were depicted the speed profile recorded in virtual reality (in red), the average speed profile recorded the in-field test (in green), the absolute difference between the two speed profiles (in light blue), and the number of lanes in the considered direction (in black). Furthermore, the red dashed line indicates the position of the pedestrian crossing axes where an event was reproduced in the virtual reality simulation (pedestrian who is crossing the street). Finally, green dashed lines indicate the position of the stop lines within the intersection and green dotted lines indicate the position of the pedestrian crossing axes.

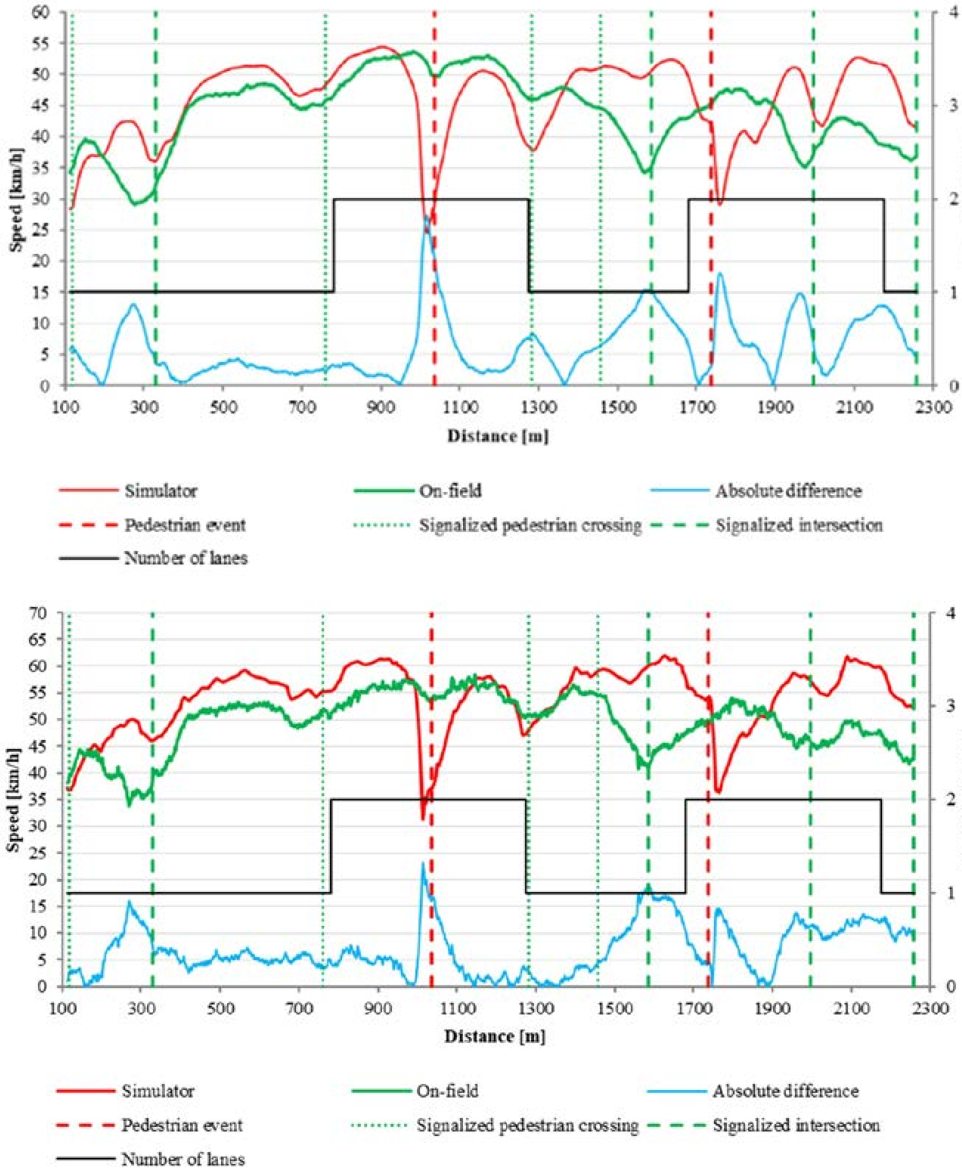

Fig. 5: speed profile comparison (above: average, below: V85)

The trend of the two profiles is similar. However, there are some areas where differences between the two profiles are noticeable. Regarding the simulator tests, the pedestrian who is crossing the street should be mentioned. This event obviously affected drivers' speed and caused significant deceleration, thus influencing the results obtained in virtual reality experimentation. This explains the negative peaks of the average profile in virtual reality (dashed red lines). On the other hand, as far as the field tests are concerned, it must be remembered that the traffic conditions were not restricted or imposed such as in virtual reality where all traffic lights were green. Therefore, drivers' speeds were sometimes reduced due to stationary traffic or otherwise significantly delayed by red lights. In this sense, the indication of the position of both the intersections and the pedestrian crossings are needed to better explain where this type of event could potentially occur. At the same time, information on the number of lanes can help to understand where traffic queues are most likely to occur. Figure 6 shows that in the areas where there were high levels of traffic or traffic queues a negative peak in the green curves was present. To overcome these issues, it seems more appropriate to compare the mean speed profiles only in similar traffic conditions (i.e., where the contingent conditions are the same for virtual reality and in-field tests), excluding therefore all the road segments where speed profiles are strongly affected by external conditions (i.e., pedestrian crossing the street in virtual reality tests (in red) and delays due to high traffic level in real world (in yellow)). Therefore, as shown in Figure 6, eleven (11) different segments were identified.

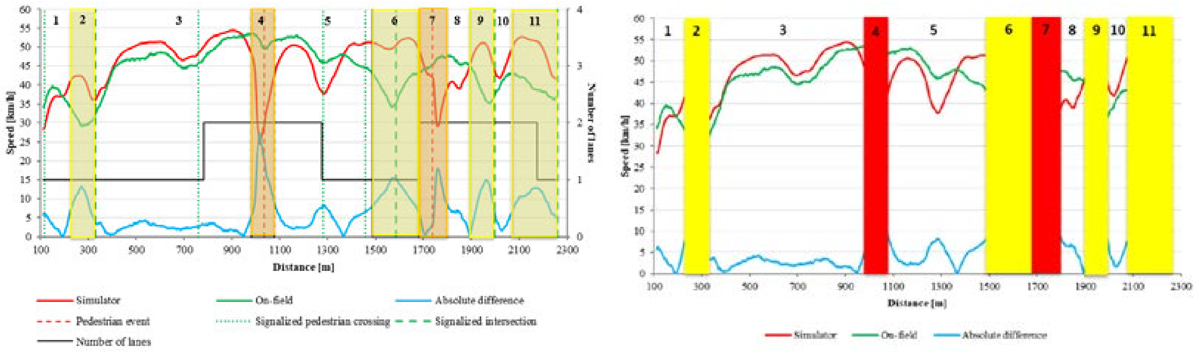

Fig. 6: identification of street segment subjected to different condition between virtual reality and real world

The 1st, 3rd, 5th, 8th, and 10th segments represent the road sections where the "contingent conditions" were the same for virtual reality and in-field tests. Thus, statistical checks of absolute validity were carried out only in these sections. The 2nd, 6th, 9th, and 11th segments represent instead the road sections where the mean speed profile for the in-field test is strongly affected by traffic conditions. These areas were highlighted in yellow. Finally, the 4th, and 7th zones describe the road sections where the mean speed profile obtained in virtual reality is strongly affected by the event where a pedestrian was crossing the street. As indicated in Domenichini et. al., (2018), the pedestrian starts crossing when the vehicle was at a stopping distance from the pedestrian crossing axes (equal about 55 meters). Therefore, the influence of the event begins 55 meters before the event takes place. The end of the influenced area was assumed equal to the one assumed in the previously mentioned study, e.g., in the point at which drivers, after braking because of the pedestrian crossing, recognize that they have regained an adequate driving speed by significantly easing the pressure on the accelerator pedal to a minimum and constant value. These areas are highlighted with a red box.

The preliminary analysis shows a relative validity of the virtual reality analysis, but obviously only where the conditions in virtual reality and in real world were the same (e.g., not strongly affected by the traffic or other events).

3.2 Absolute validity

The absolute validity was evaluated only in the road segments where the same conditions were present (1, 3, 5, 8 and 10). Therefore, segments highlighted in yellow and in red were not considered in the statistical analysis (see Figure 6). Statistical analyses were carried out considering the speed values recorded in the virtual reality and on-fields tests for a given point in the travelled path. The analysis was repeated in 50 points equally spaced out (approximately every 30 m). In Table 3 the results obtained are summarized.

Table 3: statistical test results

Note: boldface indicates statistically significant values with 5% level of significance.

The results in terms of p-value were also depicted in Figure 7. The check describes the result each 0.5 m (for the considered road segment). In blue the segments where the H0 was accepted, that indicate the absolute validity. In grey the opposite result. Where the curve trends were similar, a relative validity can be found, but the absolute validity sometimes is not obtained. However, only the segments close to those strongly affected by traffic (in real world) or events where the pedestrian crosses the street (in virtual reality) present different curve trends and therefore, different drivers' behavior (H0 rejected).

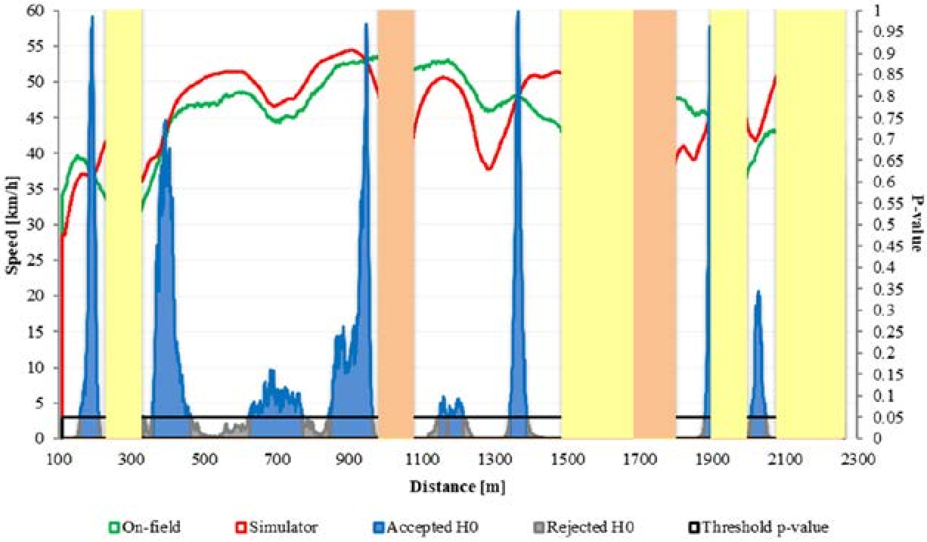

Fig. 7: results of the statistical analysis (p-value estimated each 0.5 m)

Absolute validity was also found in the road segment where a traffic calming measure is present, e.g., around a distance equal to 350 m, 700 m and 900 m where raised intersection, chicane and lane narrowing and raised pedestrian crossing are respectively present. Therefore, the virtual reality study allows to obtain a good description of the drivers' behavior, also in presence of safety countermeasures, partially confirming the finding described by Branzi et al., 2017 with reference to the street before the reconfiguration intervention (i.e., without traffic calming measures). The absolute validity was demonstrated in more than 50% of the entire road segment analyzed.

3.3 Regression analysis for validity

Finally, the regression analysis has been carried out. Figure 11 shows the regression result of the overall street. Table 4 shows instead the R^2 values obtained analyzing segment by segment, as in the previous paragraph. A good correlation among the speed values recorded during the two experimentations was highlighted in segment n.3. Lower R^2 values were instead determined in the other areas.

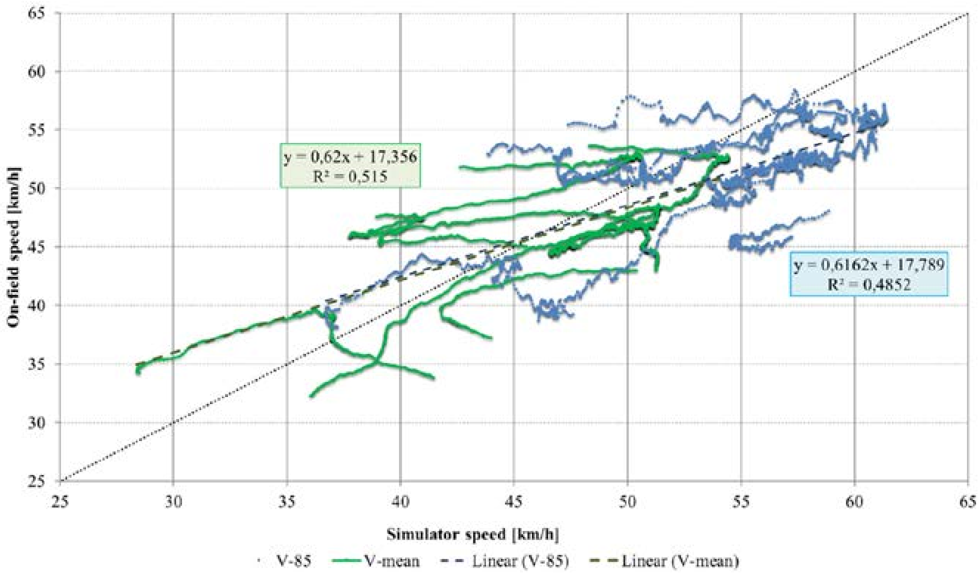

Fig. 11: regression analysis for validity (average speed and V85 speed) – overall path

Table 4: R^2 results – regression procedure for validity

Segment ID	R^2	
	Average speed	V85
1	0.0004	0.0080
3	0.8881	0.9124
5	0.0306	0.3976
8	0.1358	0.5034
10	0.6451	0.3616

The regression analysis showed very good correlation in the segments n. 3. Low values of R^2 were instead found in the other segments. The overall result showed R^2 close to 0.5 both for the average and V85 speed. The result obtained confirmed those obtained in the statistical analysis. It demonstrates also that close to the road segments interested by different "contingent conditions" the validity of the simulation can be only relative or null.

4. CONCLUSION

The analysis conducted allows to observe that drivers' behavior in virtual reality generally differs from the driver behavior in real world due, firstly, to traffic conditions and, secondly, to the different "stimuli's' perception" due to the fidelity of the driving simulator environment. The research conducted has demonstrated that events such as pedestrian crossing the street in driving simulator experimentation or real traffic conditions strongly affected the drivers' behavior. Therefore, to compare virtual reality and on-site experimentation, the same "events" and "traffic conditions" are needed.

The analysis conducted in virtual reality was evaluated both in terms of relative and absolute validity through a statistical test conducted on the entire road stretch observed and interested by different traffic calming measures. In the end also a regression analysis was made to confirm the result obtained. The two average speed profiles (obtained by virtual reality and on-field tests) presented a similar trend, maximum and minimum speed were reached in the same section if the "contingent conditions" of the experimentation were the same. In this sense, the qualitative analysis of the speed profile allows to define the relative validity of the simulation. Moreover, absolute validity was demonstrated in more than 50% of the road section analyzed. Therefore, the analysis conducted allows to demonstrate that the driving simulator study can be relevant to analyze the effectiveness of safety treatments before their implementation on real road. Moreover, this type of analysis allows the road engineering and Road Authorities to select the best engineering treatment as a function of the objective of the intervention.

It can be concluded that the LaSIS driving simulator can be considered as a valid research tool for studying the factors affecting the drivers' behavior and the effectiveness of the different traffic calming measures, confirming also the results obtained in previous research, when the same street was analyzed before the implementation of the safety intervention. The research highlights also the need to check in the "conditions evaluated" that can be quite different in virtual reality and on-field and affect the real drivers' behavior.

ABSTRACT: *An effective design review is critical to identifying changes and/or errors at the early stage of construction projects and reduce the project costs. Traditionally, design reviews are conducted by reviewing the project by reading multiple drawings. The inherent demands of reading project drawings are especially challenging for entry-level built environment learners who often need professional experience and may need more training and skills to fully understand technical representations. Previous research has focused on evaluating the impacts of interactive visualization technologies, such as virtual reality, on the learners' design review thinking skills and showed how such technologies could support learners and industry professionals in performing design reviews. However, such research has yet to assess its impacts on their self-efficacy in engaging in design review thinking skills. Self-efficacy can be defined as one's perception of their ability to perform a task, such as problem-solving and evaluation. To understand how the VR technology can support learners in increasing their self-efficacy in performing design reviews, the researchers hosted a pilot study to evaluate immersive virtual reality design reviews' impacts. Based on the results of this pilot study, the implementation of immersive virtual reality has the potential to positively impact first year-built environment learners' self-efficacy in performing design reviews.*

KEYWORDS: *Virtual Reality, Self-Efficacy, Motivation, Education, Built Environment, Design Review*

1. INTRODUCTION

Experimental learning through hand-on experience is key for the student to gain sufficient knowledge and skills about construction and built environment subjects. However, traditional teaching, which takes place in confined classrooms with occasional aid of online or web-based learning material (Fadol et al. 2018), cannot provide students with such experience. Inaccessibility to construction sites is a main challenge for experimental learning in the construction and built environment field (Ogunseiju et al. 2021). Over the past years, educators strived to use educational technologies to enhance the learning experience of the students. Virtual reality is one of these technologies that has drawn the attention of educators in different fields such as medicine (Duarte et al. 2020), Chemistry (Kader et al. 2020), and art (Serafin et al. 2016). Compared with traditional teaching, training using VR can stimulate students' interest in learning, and promote students' active learning while saving teaching costs and avoiding safety risks (Ding and Li 2022). VR-based learning can improve self-efficacy and motivation of the learners as it allows students to interact with a virtual environment resembling the actual environment and make experiments in a risk-free environment. Past studies showed the effectiveness of VR technologies for teaching different subjects in the Architecture, Engineering and Construction (AEC) industry such as infrastructure management (Arif 2021), earthquake-resistant construction (Kuncoro et al. 2023), offsite construction (Goulding et al. 2012) and safety (Le et al. 2015) (Le et al. 2014).

Design review is one of the critical tasks in the AEC industry because identification of design changes and/or errors at the early stage of construction projects can significantly reduce the project costs. This task requires the participation of various stakeholders and interpretation of multiple engineering drawings, which is often challenging for entry-level built environment learners who do not have professional experience. Therefore, they need training to fully understand technical representations in the drawings and gain pertinent skills in design review. VR-based learning has been used effectively for educating students in design review and enhance their thinking skills (Kandi et al. 2020). However, no research has assessed the impact of this approach on the self-efficacy of learners and engaging them in design review. To bridge this gap, this research aims to understand and evaluate how VR can support learners in increasing their self-efficacy in performing design reviews. To this end, a pilot study was conducted with students at the undergraduate level for teaching design review practices. The

results of the study were then analysed, and the limitations of the research along with directions for future research are presented.

2. LITERATURE REVIEW

2.1. Immersive Virtual Reality in the Built Environment

Virtual Reality (VR) has several potential applications in many fields, including medicine, engineering, education, and entertainment (Hamad and Jia, 2022). VR could be defined as a technology that simulates an environment, which can be interacted with in a manner that appears real or tangible (Sanni Hafiz Oluwasola and Ayinde Munir 2015). The origins of VR technology can be traced back to the mid-1970s, with early experimenters using phrases like "artificial reality" to describe it (Machover and Tice 1994). The term "virtual reality" was coined by Jaron Lanier, founder of VPL Research, and the technology has since evolved from user interface design, flight and visual simulation, and telepresence technologies (Machover and Tice 1994). Freina and Ott (2015) identifies that there are two types of VR: immersive and non-immersive VR. Non-immersive VR is a computer-based environment that simulates places in the real or imagined world, while immersive VR gives the perception of being physically present in the non-physical world. Both types of VR are becoming more user-friendly and economically accessible (Kandi et al. 2020). Kaplan-Rakowski and Gruber (2019) further divided immersive VR (IVR) into low-immersion virtual environments (LiVR) and high-immersion three-dimensional spaces (HiVR). LiVR is a computer-generated three-dimensional virtual space experienced through standard audio-visual equipment, such as a desktop computer with a two-dimensional monitor. The ubiquitous online virtual world Second Life is an example of a LiVR environment. HiVR is defined as a computer-generated 360-degree virtual space that appears spatially realistic due to the high immersion afforded by a head-mounted device (Kaplan-Rakowski and Gruber 2019).

The technology has also undergone significant advancements in recent years, with new displays, input devices, and technologies being developed and introduced to the market (Anthes et al. 2016). VR has the capability to present spatial information in a more engaging manner, allowing for interaction with designed spaces at a human scale (Pacheco et al. 2014). Large screen size and wide field of view are key features of immersive VR systems, while texture, lights, shadows, and objects contribute to the overall VR experience. These VR attributes can further augment the richness of information and enhance the visualization process VR is being increasingly used in architecture, engineering, and construction to support experiential learning, movement through space and time, and interaction with the design (Sala 2013). VR enables a more qualitative representation of spaces from the users' perspective, creating the illusion of depth and immersion (Castronovo et al. 2013).

VR technology has the potential to impact the way users conventionally think and design the built environment promoting it beyond space and time constraints (Paranandi and Sarawgi 2002). The applications of the VR technology in Architecture, Engineering and Construction (AEC) industry are extensive, particularly in simulating environments and creating the feeling of immersion in a virtual world, which can assist architects and engineers in evaluating designs, understanding the needs of different users, especially those who are older or disabled. It can also promote inclusive design by providing in-depth insight into how particular groups of people experience the designed environment and how they interact with it. Nikolić and Whyte (2021) argue that VR can be used as a platform for an interdisciplinary integration of the allied design, social, and environmental disciplines. VR technology can provide easy-to-use communication solutions for all stakeholders in the AEC industry by providing a computer simulated environment with visual, auditory and haptic channels (Kähkönen 2003). VR technologies and computers are being utilized to facilitate the planning and construction of the built environment by aiding in the visualization and simulation of proposed designs, evaluating the visual impact of urban designs, and exploring broader economic ramifications (Whyte 2003). Tytarenko et al. (2023) reconstructed the Kilburun Fortress by monitoring the object's territory, analysing archival, librarian, and cartographic sources, and using various software tools such as AutoCAD, SketchUp, Quixel, and Twinmotion for modelling, rendering, and visualization. The resulting 3D model can be integrated into ArchiCAD and Revit software and showcases the applications of VR in the built environment. Although virtual reality environments (VRE) have enormous potential to engage students in classrooms and aid in construction workers' retention of safety knowledge, the adoption of VRE in the AEC industry remains minimal, as safety professionals still prefer hands-on training (Bhoir and Esmaeili 2015).

VR adoption faces several challenges in architecture and design, including a lack of integrated 3D databases and accurate reality models, technical limitations such as precise monitoring and remote sensors, and challenges in education such as the uniqueness effect, cybersickness, and accessibility (Fakahani et al. 2022). VR is also limited in its ability to create a real-life experience, particularly in conveying appropriate social behaviours and creating convincing virtual characters (Fakahani et al. 2022). Overcoming these challenges requires interdisciplinary efforts and finding the appropriate level of intervention (Fakahani et al. 2022; Hajirasouli et al. 2023; Lach et al. 2020; Zhang et al. 2020). Zhang et al. (2020) proposed future research directions on using the VR technology for the built environment, including user-centred adaptive design, attention-driven virtual reality information system, construction training system incorporating human factors, occupant-centred facility management, and industry adoption.

2.2. Immersive Virtual Reality in the Built Environment Education

Current practices in the built environment education often fall short of adequately preparing students for the complexities and challenges of real-world professional settings (Afacan 2023; Gardner 2022). Conventional teaching methods, which rely largely on textbooks and two-dimensional representations such as drawings and photographs, may fail to convey the multidimensional and dynamic nature of the built environment (Stewart and Baker, 2019). Students may therefore struggle to comprehend spatial relationships, scale, and materiality, limiting their comprehension of the built environment (Stewart and Baker, 2019). In addition, limited access to job sites and real-world initiatives hinders students' ability to gain hands-on experience and understand the practical implications of their decisions (Gibbons et al., 2021).

These limitations underscore the pressing need for innovative approaches that bridge the gap between theory and practice, equipping students with the necessary competencies to thrive in the complex-built environment. Consequently, situated learning is crucial to this field of study, as learning about the built environment requires exposure to a vast array of historical structures and design conditions (Afacan 2023) Situated learning in the built environment refers to an educational approach that emphasises learning within authentic and pertinent real-world contexts. It entails actively engaging students in tasks and challenges that replicate the complexities and requirements of their future professional roles (Bakhteyari et al., 2018; Aggerholm and Misfeldt, 2016). As a means of providing students with hands-on experience, conventional instructional methods utilise various case studies. Steele et al. (2023) assert that case studies are crucial for the education of those who are involved with the built environment. Thus, analysing completed projects allows students to examine the design process, construction techniques, and challenges faced by professionals, facilitating the development of problem-solving abilities and exposure to different design strategies (Hjaltadottir et al., 2018). However, when using case studies, the traditional teaching style encounters difficulties. To begin with, there are difficulties in comprehending projects through drawings and images, which limits students' grasp of spatial relationships, scale, and materiality (Stewart and Baker, 2019). Furthermore, limited access to job sites prevents students from firsthand experiencing the built environment, limiting their comprehension of project context and restrictions (Gibbons et al., 2021). Furthermore, student visits to construction sites are hampered by safety concerns, limiting exposure to construction processes and site-specific difficulties (Liu et al. 2019).

To address these challenges, the emergence of virtual reality (VR) technology holds promise in enhancing situated learning and overcoming the limitations of traditional methods (Elghaish et al. 2021). The advent of VR tools has enabled individuals to begin experimenting with and employing VR (Liu et al. 2019). According to Elghaish et al. (2021), VR is a revolutionary technology that has the potential to improve construction design processes as well as promote education in the built environment. VR provides an immersive platform that enables students to virtually explore case study projects in three dimensions. By experiencing projects from various perspectives, students gain a deeper understanding of spatial layout, scale, and design intent (Ho et al., 2018). VR simulations enhance visualization by offering realistic representations of projects, allowing students to interact with virtual elements and observe the dynamic behaviour of structures or building systems (Lee et al., 2020). Furthermore, VR in the built environment education can help researchers and students simulate real-life, potentially hazardous situations without exposing them to actual danger, making VR experimentations a credible approach for resolving construction clashes and defects (Afzal and Shafiq, 2021). Also, learners can efficiently investigate contextual dimensions associated with a building project using VR by adjusting specific parameters, making variable control simple to achieve (Xu and Zheng, 2020). Young et al. (2021) postulated that VR allows users to have an immersive experience of construction projects, so they can react effectively in real-world situations. Because participants in a lively, evolving situation can better try to remember safety knowledge, technological tools are also applicable in fields such as building risk assessments and safety training (Zhu and Li 2021).

Amidst the propagation of VR in the built environment, its maximum potential is yet to be realized (Safikhani et al. 2020), and there is a significant gap in VR involvement in the built environment between academia and industry (Delgado et al. 2020).

2.3. Self-Efficacy and Motivation

Self-efficacy is a belief in one's ability to perform well on a task and is a core concept of Social Cognitive Theory (Bandura 1997). Bandura (1997) indicated that self-efficacy is a key determinant of behavioural change, and psychological procedures can alter the level and strength of self-efficacy. Self-efficacy is an important factor in motivation, achievement, and accomplishment, and can be influenced by a variety of factors, including personality, motivation, and the task itself (Bandura 1997). Those with a high level of self-efficacy are not only more likely to succeed, but they are also more likely to bounce back and recover from failure (Resnick 2008).

Schunk (2011) describes how self-efficacy influences choice of activities, effort, persistence, and achievement, and how interventions involving models, goal setting, and feedback can affect self-efficacy. Eliyana et al. (2020) found that self-efficacy of entrepreneurial students influences achievement, and motivation significantly mediates the effect of self-efficacy on entrepreneurial achievement. Rodríguez et al. (2014) found that teachers with intermediate self-efficacy perception have more learning-oriented students than teachers with high self-efficacy, and students of teachers who are overconfident of their teaching capacity seem to engage less in studying to learn. Overall, self-efficacy is an important factor in motivating individuals to achieve their goals.

It is well documented that self-efficacy has a positive effect on motivation. Kanfer (1990) described motivation as the "psychological forces that determine the direction of a person's level of effort and a person's level of persistence in the face of obstacles". There are two types of motivation namely: extrinsic and intrinsic motivation (Schunk 2011). Ryan and Deci (2000) defined intrinsic motivation as the natural human propensity to learn and assimilate, while extrinsic motivation can either reflect external control or true self-regulation. Benabou and Tirole (2003) reconciles the economic view that individuals respond to incentives with the psychological view that rewards and punishments can undermine intrinsic motivation. Kuvaas et al. (2017) found that intrinsic motivation was associated with positive outcomes, while extrinsic motivation was negatively related or unrelated to positive outcomes. Overall, intrinsic motivation is driven by internal factors, while extrinsic motivation is driven by external factors, and that the two types of motivation can have different effects on outcomes.

Motivation is crucial in education and can fosters creativity and critical thinking as it cultivates resilience and self-assurance, and improves a student's agency (Schunk 2011). Motivation to learn provides direction, enthusiasm, and persistence in learning (Alfiah et al. 2021). Motivation is important for both students and teachers in achieving desired outcomes in education (Shrestha 2020). The theories of Maslow's hierarchy of needs and expectancy theory shed light on the fundamental aspects of motivation in the context of learning (Shrestha 2020). The application of various methods to motivate students and teachers is crucial and should be tailored to specific situations and requirements, as there is no universal approach (Shrestha 2020). The motivation of both teachers and students holds significance in ensuring an effective teaching and learning process within the field of education (Shrestha 2020).

Low motivation is associated with poor academic performance. Not being motivated was found to be associated with higher levels of stress and a lower Grade Point Average (Rücker 2012). Motivation is a key factor in effective school functioning and academic achievement (Halawah 2006). Fortier et al. (1995) proposed and tested a motivational model of school performance, which found that autonomous academic motivation positively influenced school performance.

Low motivation in education can be caused by various factors. Economic factors, low employment prospects, and educational background can contribute to low motivation in college students (Sahib, 2020). Intrinsic factors, such as a lack of interest in learning activities and embarrassment, can cause low motivation in elementary school students (Alfiah et al. 2021). A lack of interaction between teachers and students, as well as low reading ability, can contribute to low motivation in middle school students (Alfiah et al. 2021). O'Neil et al. (1995) found that offering financial incentives can increase student effort and improve test scores, suggesting that low motivation may be due to a lack of consequences or stakes attached to performance. Therefore, addressing factors such as economic status, interest in learning activities, teacher-student interaction, and incentives may help improve motivation in education.

Educators can increase students' motivation in the classroom by employing various strategies. Pahlavannezhad and Nejatiyan (2013) found that early knowledge of the course syllabus and assessment, rewards and positive reinforcement, and group work and role play can increase students' motivation to learn English. Brophy (2013) suggested that teachers can establish their classes as collaborative learning communities, support their students' confidence as learners, and help them appreciate curricular content as worth learning and applicable to their lives outside of school. Williams-Pierce (2011) identifies five key factors impacting student motivation: student, teacher, content, method/process, and environment, and provides suggestions from each area that can be used to motivate students. Mart (2011) suggested strategies such as providing a positive learning environment, using technology, and incorporating student interests to sustain students' classroom motivation.

Motivation has a positive impact on academic performance. Haider et al. (2015) found that both intrinsic and extrinsic motivation had a positive impact on students' academic performance. Goodman et al. (2011) found that intrinsic and extrinsic motivation were significantly related to academic performance, and that effort mediated this relationship. Afzal et al. (2010) also found that both intrinsic and extrinsic motivation had a positive impact on academic performance. Fortier et al. (1995) proposed and tested a motivational model of school performance, finding that perceived academic competence and perceived academic self-determination positively influenced autonomous academic motivation, which in turn had a positive impact on school performance. Overall, these papers suggest that motivation is an important factor in academic performance.

3. METHODOLOGY

3.1. Research Questions

As highlighted in the literature review, the implementation of immersive virtual reality (IVR) in built environment (BE) requires further research. New research efforts must investigate the impacts that the implementation of this technology has on learners' motivation, and specifically self-efficacy. Furthermore, as highlighted in section 3.2. research in the implementation of IVR in BE education necessitates investigations that leverage rigorous experimental methods. Based on this research gap, the researchers set out a goal of assessing the impacts that an IVR learning activity has on higher education learners in the BE discipline. Therefore, the research was concentrated on measuring the impacts of this activity on learners' self-efficacy and experience.

Based on these goals, the following research questions were posed:

1. Does performing design reviews with immersive virtual reality lead learners to have a higher self-efficacy?
2. Is the learners' experience positive whilst performing design reviews with immersive virtual reality?

Based on these research questions, two null hypotheses were considered. The first hypothesis was that the learners' reported average self-efficacy was going to be the same before and after the learning activity. Meanwhile, the second null hypothesis was that the learners' average experience was going to be neutral.

3.2. Experimental Design and Procedure

To test the hypotheses, the researchers designed a pilot study to test the early impacts of IVR. This pilot study was designed as a one group pre-test / post-test quasi-experiment to assess the impacts on learners' self-efficacy. This pilot study is considered a quasi-experiment due to the lack of randomized assignment to the treatment group. This method is not optimal for the generalization of the data and the impacts of the learning activity might be due to test learning. However, this method is acceptable for running pilot studies and assessing early impacts and identifying early trends (Knapp 2016).

In this pilot study the independent variable or treatment had only one level. This level was the learning activity designed to introduce first year BE learners to the concepts of design reviews while using IVR. The dependent variable measured for this pilot study was the learners' self-efficacy. The assessment instrument designed to measure the learners' self-efficacy is explained further in section 3.4. The procedure for this quasi-experiment can be seen in Figure 1. The participants were students and took part in this learning activity as part of their class time. The students had to participate in the activity; however, they were given the option not to participate in the pre and post-tests. A 10-minute pre-test was administered before the start of the activity. The same 10-minute test was administered as a post-test after the activity.

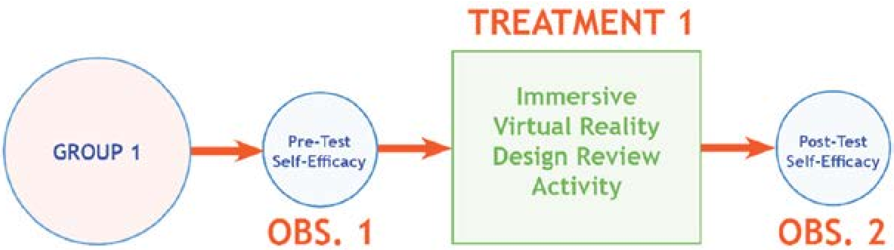

Figure 1. Quasi-experimental Procedure

After the pre-test the participants were provided with a tutorial on how to use the IVR head-mounted system. This tutorial allowed the participants to get familiar with the virtual environment and navigation controls. This tutorial lasted about 10 minutes. Participants that still had difficulty with the controls were provided with additional support and instruction. After the tutorial the participants were asked to navigate through a BIM model of a residential house and identify design mistakes. This residential house was designed in Autodesk Revit to have several design mistakes. The participants were paired in groups of two, where one was assigned the role of "driver" and the other of "note-taker". The driver would wear the headsets, which were casting its video output also to a desktop computer screen. The note-taker was tasked to write down design mistakes that the driver was identifying, on a sheet provided by the team. For every five design mistakes the participants had to switch roles. The total duration of the design review was set to be 30 minutes. This time limitation was also set to limit potential motion sickness of the participants.

3.3. Participants

The participants in the pilot study were first-year students enrolled in an Introduction to the Built Environment module at a university in the south of the United Kingdom. A total of 54 students were enrolled in the module and were asked to participate in the study. Ethical approval was received by the university ethic board to perform the study, and students were asked for consent to collect the data before administering the pre-test. As mentioned earlier, students that did not want to participate in the study were given the option of not answering the pre and post-test, but still had to participate in the class activity.

3.4. Equipment and Assessment instruments

The research team used twenty IVR headsets, the Meta Quest 2. This allowed a total of 40 students to participate in the activity. The video output of the headsets was cast on desktop computer screen over the Chrome web browser. To host the design review sessions the researchers used the IVR Arkio® software. Arkio allows users to host collocate in a virtual environment and perform design review sessions collaboratively. Learners were provided with virtual meeting rooms where the model of the residential house was preloaded.

The measured dependent variable was the participants' self-efficacy and experience. The pre-test was composed of ten questions. The questions were based on the "General Self-Efficacy Scale" (GSS) developed by Schwarzer & Jerusalem (1995). The questions from the GSS instrument were slightly changed to ask the participants about their perceived ability to perform design reviews. The post-test was composed of the same ten questions from the pre-test as well as an additional eleven questions to capture the learners' experience. These questions were based on the instrument developed by Boekaerts (2002), the OnLine Motivation Questionnaire. The participants were asked to indicate their agreement with the statements on a 5-point Likert scale. The questions for the pre and post-test can be found in Table 1.

Table 1. Pre and Post Tests Questions

Pre and Post Tests Self-Efficacy Questions	Post Test Participant Experience
1. How good do you think you are at reviewing design proposals?	11. How do you feel just after finishing the activity?
2. I am able to review most of the design proposals that I am presented with.	12. How easy was this activity?
3. When facing a difficult design proposal, I am certain that I can review it.	13. How well do you think you did in this activity?

4. In general, I think that I can successfully review most design proposals.	14. How useful do you consider this activity in learning about design reviews?
5. I believe I can succeed at reviewing most design proposals.	15. How important do you find it to do well on design reviews?
6. I am able to successfully review design proposals.	16. I felt the time used for the activity was beneficial.
7. I am confident that I can perform effectively design reviews.	17. I saw the value in the activity.
8. Compared to other people, I can do most review design proposals very well.	18. How enthusiastic were you about this activity?
9. Even when the design of a building is complex, I can review it quite well.	19. How pleasant did you find this activity?
10. How difficult did you find the topic of design reviews?	20. How much did you enjoy yourself during this activity?
	21. How much would you recommend this activity to your classmates?

4. RESULTS AND ANALYSIS

In this research, the research questions were answered by conducting two different types of statistical analyses. The first research question, which aimed to evaluate if the learning activity supported the participants in gaining higher self-efficacy, was tested by conducting a Paired-Sample T-Test. The second research question aimed at evaluating the participants' experience while participating in the activity. This question was evaluated by performing a One-Sample T-Test. This analysis aimed to test if the participants' experience was higher than neutral towards the positive. The tests were conducted using the statistics software package, IBM SPSS Statistics. A summary of the results can be found on Table 2 for the Pre and Post-Test, and on Table 3 for the participants' experience. While a total of 54 participants were recruited, only a total of 29 data points were used for the study as the rest either did not participate in activity or did not give permission to use the data.

Using the results from Table 2, a Paired-Sample T-Test was conducted to test if there was significant difference between the pre and post-test for the participants' self-efficacy. No outliers were detected that were more than 1.5 box-lengths from the edge of box in a box plot. Participants reported a higher self-efficacy after participating in the activity (3.890 ± 0.440) when compared to before the activity (3.190 ± 0.0.498), a statistically significant increase of 0.70 (95% CI, 0.885 to 0.536), $t(28) = 8.042$, $p < .0001$, $d = 1.493$. Therefore, the researchers confidently rejected the null hypothesis that the averages for the pre and post-test were going to be the same, as indicated by the significant difference and p value being below 0.0001. Furthermore, the effect size of the sample is quite large as indicated by the Cohen's D being 1.493 (Cohen 1988).

Using the results from Table 3, a One-Sample T-Test was conducted to test if the participants' experience was significantly different than neutral (Likert Scale value of 3). No outliers were detected that were more than 1.5 box-lengths from the edge of box in a box plot. The mean participants' experience score was significantly higher by 0.998 (0.95 CI, 0.7502 to 1.2205) than a neutral score of 3, $t(28) = 8.792$, $p < 0.0001$, $d = 0.606$. Therefore, the researchers confidently rejected the null hypothesis that the average for participants' experience was going to be neutral, as indicated by the significant difference and p value being below 0.0001. Furthermore, the effect size of the sample is between medium and large as indicated by the Cohen's D being 0.606 (Cohen 1988).

Table 2 – Pre and Post Test Average Answers

Question	Pre-Test Average	Post-Test Average
1. How good do you think you are at reviewing design proposals?	3.14	3.90
2. I am able to review most of the design proposals that I am presented with.	3.43	4.03
3. When facing a difficult design proposal, I am certain that I can review it.	2.90	3.79
4. In general, I think that I can successfully review most design proposals.	3.41	4.07
5. I believe I can succeed at reviewing most design proposals.	3.52	4.07
6. I am able to successfully review design proposals.	3.28	4.10
7. I am confident that I can perform effectively design reviews.	3.17	3.86

8. Compared to other people, I can do most review design proposals very well.	3.14	3.76
9. Even when the design of a building is complex, I can review it quite well.	2.97	3.69
10. How difficult did you find the topic of design reviews?	2.93	3.66
Self-Efficacy Average	3.190	3.890
Standard Deviation	0.498	0.440

Table 3 – Participants' Experience Average Answers

Question	Average
11. How do you feel just after finishing the activity?	
11.A How relieved do you feel after the activity?	3.62
11.B How at ease do you feel after the activity?	3.90
11.C How nervous do you feel after the activity?	2.97
11.D How satisfied do you feel after the activity?	4.14
11.E How worried do you feel after the activity?	3.38
11.F How confident do you feel after the activity?	3.90
11.G How concerned do you feel after the activity?	3.34
12. How easy was this activity?	3.97
13. How well do you think you did in this activity?	4.00
14. How useful do you consider this activity in learning about design reviews?	4.24
15. How important do you find it to do well on design reviews?	4.31
16. I felt the time used for the activity was beneficial.	4.31
17. I saw the value in the activity,	4.34
18. How enthusiastic were you about this activity?	4.07
19. How pleasant did you find this activity?	4.55
20. How much did you enjoy yourself during this activity?	4.45
21. How much would you recommend this activity to your classmates?	4.48
Participants' Experience Average	3.998
Standard Deviation	0.606

5. CONCLUSION

The ability to review and evaluate proposed design proposals is a key skill that BE learners must have once they graduate from their higher education institution. As discussed in the literature review, several studies have shown the positive impacts that IVR has on students' learning and their ability to meet learning objectives. However, the role of instructors is not just about meeting learning objectives, but it is also to support learners in developing their self-belief and confidence necessary to enter the industry.

This research conducted a pilot study to evaluate the effectiveness of using IVR in improving self-efficacy of students in engaging in design review thinking skills. The results and analysis have shown that, at a pilot study level, an IVR learning activity has potential in impacting students' self-efficacy while also being a positive experience. When looking at the first research question, the learning activity supported students in increasing their self-belief that they can perform design reviews while immersed in a virtual reality environment. This pilot study can give an early insight into what are the impacts that IVR has in the classroom beyond meeting learning objectives, supporting students in their confidence levels.

The next steps of this research efforts are to mitigate the limitations of sample size by recruiting a larger number of participants to support the researchers in scaling the findings and improving the generalization of the results. Additionally, one group pre-test / post-test quasi-experiments have experimental limitations and threats to internal and external validity. Therefore, the future research can include additional treatments to tackle the validity of the results. To address this limitation, the research has already started collecting the impacts a different medium, non-immersive VR, has on learners. By adding an additional treatment, a repeated-measure experiment and a two-way mixed ANOVA analysis can be conducted. To conclude, this study reports an initial result of an on-going research and the researchers will share further information on the research results in future publications.

COGNITIVE DYNAMICS FOR CONSTRUCTION MANAGEMENT LEARNING TASKS IN MIXED REALITY ENVIRONMENTS

***Xuanchang Liu* & Ivan Mutis**
Illinois Institute of Technology, USA

ABSTRACT: *Technologies to communicate construction project information (engineering designs, schedules) have evolved into a wider range of innovative ecosystems for engineering practices (e.g., cloud-based 3D representations and advanced immersive environments). There is a lack of exploration of effective user interaction for learning and training in relation to how presented information influences cognition in these ecosystems. The presented research investigates the users' cognitive and attentional differences using the interactive capabilities of Mixed reality (MX) technology. The enhanced user-situation interactions are analyzed by measuring cognitive dynamics with an emphasis on two processes (attentional focus and cognitive load) in relation to the challenge of the engineering learning task— defined by its complexity (limited time frame for observations of the situations, number of required observations) and nature (episodic). Cognitive dynamics were measured using an electroencephalography (EEG) device that senses electrical activity in response to changing levels of cognitive stimuli via electrodes placed on the scalp. Measuring fluctuations in cognitive processing (related to the intensity of various task demands) allows associating efforts on semantic information processing for learning and training tasks (e.g., walkthroughs for safety checks in job site in MX). The approach enhances opportunities to design technology that best adapts to the user needs for engineering practices with an efficient comprehensive performance assessment.*

KEYWORDS: *Electroencephalography (EEG), Dynamics of attention, Cognitive load, Cognitive processing*

1. INTRODUCTION

Construction sites are characterized by their dynamic nature, as they are filled with a multitude of activities and potential risks. Safety in construction is a critical aspect of production activities and a major priority effort for successful implementations in construction organizations (Guo et al., 2017). Construction safety training is of the highest priority across the industry, and the use of technology intervention has facilitated such efforts (Frank Moore & Gheisari, 2019). The provision of construction safety training plays a pivotal role in cultivating a safety-oriented environment within the construction sector. Ensuring optimal safety in the construction industry necessitates a collaborative endeavor involving various stakeholders, including owners, designers, construction companies, workers, regulators, and educators (Sacks et al., 2013). Typically, prior to commencing work on a construction site, workers are mandated to complete an Occupational Safety and Health Administration (OSHA) 10-hour construction training program. This program is delivered online and encompasses safety-oriented lectures, videos, and slides.

The efficacy and significance of this training program, as well as its adequacy, are continually pertinent inquiries (Wilkins, 2011). There have been efforts focused on implementing a more effective construction safety training program using different methods like personalized training programs or training with virtual reality devices (Jeelani et al., 2020). However, VR technology implementations generate potential risks for the user. For example, they don't easily enable representing at-scale safety requirements in the VR environments for the users' own exploration in training. Another possibility of risk is that VR applied to OSHA safety training may become a new source of distractions to users (Asish et al., 2022), impacting the intended outcome of training.

Despite the widespread use of technologies in training (including VR and AR as interventions), methods that reveal the effectiveness of the technologies as training approaches are not incorporated into the training programs. For example, methodologies for assessments employ paper-based exams or supervised self-reports—which have considerable limitations— to determine subjects' performance before and after the training program (Jeelani et al., 2020). It is critical, therefore, to comprehensively assess the effectiveness of inventory training tasks with the use of technology by considering the individual characteristics of the trainee (technology user) as they factor or are subrogate into the overall performance. There is a need to find alternative methods to assess the efficacy and benefits of implementing safety training interventions due to individual differences and self-report methods' disadvantages—ranging from response bias, recall bias, and subjectivity to cultural and language barriers. The researchers anticipate that incorporating the users' individual performance front and center might facilitate a smooth path to successful training programs.

Xuanchang Liu, Ivan Mutis, *Cognitive Dynamics for Construction Management Learning Tasks in Mixed Reality Environments,* pp. 231-241, DOI 10.36253/979-12-215-0289-3.22

The presented work uses Mixed Reality (MX) technologies. MX combines real and virtual worlds for the creation of environments where users can function and interact in the physical and virtual worlds. MX has facilitated the consolidation and analysis of activities in the physical space, such as in production processes involved in the manufacturing of goods or services—i.e., the activities for converting raw materials into finished products. The co-existing of real and virtual interaction allows connections and reactions between virtual objects and the physical space, undoubtedly facilitating the enhancement of the study of construction activities, including training programs in the industry. For example, by "moving" the construction site production activities into just a small physical space for training.

This study presents a novel assessment method utilizing electroencephalography (EEG) technology. The EEG is used to measure electrical activity in the brain, which output data brings insights into the timing and nature (rhythms in brain activity across frequency bands— delta, theta, alpha, beta, and gamma) of the underlying cognitive processes. The presented research proposes the utilization of the EEG technique for safety training and problem-solving tasks. The method enables the automatic collection of data from individual trainees to study the effectiveness of training tasks. The approach collects the neural response when learners attempt to address challenges in training tasks under conditions of complexity, such as the cognitive effort involved in solving a question. By conducting an analysis of the EEG data, this technique provides information to assess the training or problem-solving tasks through cognitive load and attention degree analysis for individuals, providing information on which task the user performs well or has deficits. The outcome can easily correlate to individual differences (cognitive abilities such as memory, attention, perception, and problem-solving skills) to find the effectiveness of the overall training tasks. For example, what is the impact of attention deficits on particular training tasks?

The presented study focuses on the problem-solving process in order to develop a more effective, precise, and unbiased approach to assessing performance in training.

2. BACKGROUND

Since the early 20th century, scientific studies using electroencephalography techniques have experienced a considerable evolution. Mainly these efforts involve the detection and analysis of minuscule electrical signals emanating from the human brain during its various activities (Sanei & Chambers, 2007). Electroencephalogram (EEG) signals are categorized into distinct power bands corresponding to various brain wave frequencies, facilitating the identification of different states or conditions of ongoing brain activity in humans (see Table 1) (Fernandez Rojas et al., 2020; Klimesch, 1999; Zietsch et al., 2007).

Table 1: Frequency and statements of brain waves.

Brain Waves	Frequency (Hz)	Statement
Delta	0.5-4	Idling and sleep
Theta	4-8	Mental fatigue and mental workload
Alpha	8-13	Mental workload, cognitive fatigue, and attention or alertness
Beta	13-30	Visual attention, short-term memory, and working memory

The literature has established the meaning of spectral powers of various EEG waves and cortical locations in evaluating cognitive load during problem-solving tasks. Researchers observed an increase in the power of both theta and alpha bands as task difficulty escalated, suggesting a direct association between these bands and cognitive load (Sarailoo et al., 2022). More specifically, the augmentation of theta spectral power serves as an indicator not only of heightened task complexity but also of enhanced working memory capacity (Borghini et al., 2012). Additionally, the beta band can potentially serve as another indicator of cognitive load and working memory during tasks. In visual working memory tasks, there has been an observed augmentation in beta activity within the parieto-occipital channels (Mapelli & Özkurt, 2019).

Building on early definitions of attention from William James, in his book *the Principle of Psychology*, James states that attention "is the taking possession by the mind, in clear, and vivid form, of one out of what seems several simultaneously possible objects or trains of thought."(James, 1890). As a condition of selective awareness, attention degree controls the quality of one's task-solving. Enhancing one's ability to regulate attention pertains to the domain of executive attention, also known as controlled attention. This cognitive process encompasses functions such as planning, decision-making, and problem-solving (Fernandez-Duque et al., 2000). Executive attention refers to the cognitive ability to deliberately redirect one's focus from one task to another or to inhibit the processing of extraneous information. This study focuses on the focus degree, as known as the intensive of attention, as one of the layers of information that help with analyzing performance. To indicate the state of attention degree, delta, theta, and alpha waves are the most used (Kaushik et al., 2022).

Multiple studies have documented an elevation in mid-frontal theta activity, a reduction in central and parietal delta activity, and a decrease in frontal and parietal alpha power during states of attention (Kaushik et al., 2022). Additionally, the relative magnitudes of spectral power across various waveforms can serve as an indicator of attention levels. As per the findings of the researchers, the attention ratio, referred to as the theta/beta ratio, possesses significant utility as an indicator for the analysis of attention. Moreover, it has been demonstrated by researchers that a robust association exists between attentional degree and the ratios of theta/beta, theta/alpha, and alpha/beta (Derbali & Frasson, 2011; Ghasemy et al., 2019; Hillard et al., 2013). More specifically, a larger ratio of alpha/beta indicates a more concentrated situation, in the meantime, there is a negative correlation between the ratio of theta/beta and the focus degree (Derbali & Frasson, 2011).

While EEG is commonly associated with medical and neuroscience applications, it also has some interesting and potential applications in the field of construction. Applications like worker cognitive load or stress level monitoring could help to improve construction on-site workers' health, well-being, and productivity (Jebelli et al., 2018; Saedi et al., 2022). The productivity of construction workers is not solely determined by their individual workload but is also greatly impacted by their emotional state, particularly when encountering hazardous work conditions or confined spaces. The utilization of wearable EEG headsets for monitoring the emotional state of on-site construction workers is a potential avenue for construction managers to enhance control and optimize the overall workflow of building projects (Hwang et al., 2018).

Given that construction workers consistently operate under conditions of high stress and heavy workloads, the matter of safety is a critical domain that researchers seek to enhance. The studies on the EEG in the construction site may lead to the optimization of the construction safety programs. For example, assessing the on-site worker's mental workload via EEG could help managers identify individuals who are not in their best mental status and better arrange human resources to reduce risk and hazards (Chen et al., 2016). On the other hand, ensuring that personnel remain focused on their hazardous tasks and that they are not easily distracted by external factors is consistently crucial. Wearable EEG devices promise to identify factors of distractions of construction workers in hazardous tasks and to improve construction site safety (Ke et al., 2021).

In addition to calls for its application in on-site construction workers, EEG has been utilized in laboratory studies based on virtual reality (VR) to enhance the performance of building or construction environments. The utilization of virtual environments offers a valuable opportunity to replicate real-world scenarios. By incorporating EEG band power scalp mapping into machine learning models, it becomes possible to assess the authentic responses of individuals residing in a building space. This analysis can encompass several aspects, such as comfort, pathfinding, and spatial utilization (Zou & Ergan, 2023). Beyond the analysis of the fatigue level from EEG signals collected in the virtual environment, collected EEG data can help the development of new models to improve the prediction and prevention of construction fall hazards (Tehrani et al., 2022).

3. METHODOLOGY

The presented approach is a model for the performance and assessment of individual trainees' problem-solving tasks implemented in an MX environment combined with an EEG headset. The MX environment will provide a virtual simulation of the training tasks, and the EEG headset will collect EEG signals for cognitive analysis on the problem-solving task. This research work employs the Theta (4-8Hz), Alpha (8-13Hz), and Beta (13-30Hz) frequency bands primarily to assess the cognitive load and attention levels exhibited during a problem-solving task.

Subsequently, the provision of performance feedback entails the comprehensive processing of all collected data. The flow of the feedback methodology process is presented in Fig.1. Detailed steps will be discussed in the following sections.

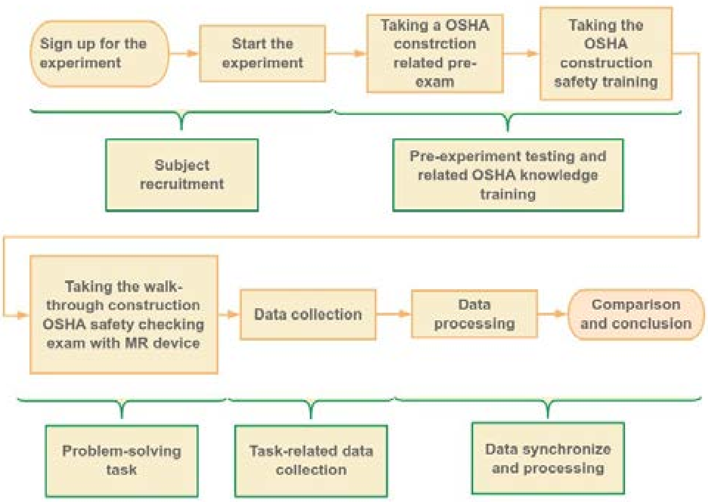

Fig.1: Workflow of the problem-solving task performance feedback process.

3.1 Subjects' recruitment and OSHA safety training

The experiments involve recruiting a sample of fifty individuals aged between 18 and 35 years old, who are enrolled in a university program with a background in civil and construction engineering. The experimental procedure will be conducted within a laboratory area measuring 5 meters by 5 meters.

Upon enrollment in the experiment, participants are required to respond to a pre-test that will inform the knowledge of OSHA construction safety training. After the pre-test, subjects are required to watch the OSHA construction safety training video and then take the OSHA construction safety examination in a virtual environment after becoming familiar with the manipulation of the MX device.

The OSHA construction safety training video refers to the selected OSHA construction regulations (Huang et al., 2003; "Top 10 Most Frequently Cited Standards | Occupational Safety and Health Administration,"). Fig. 2 is an example of the applied OSHA construction standard.

1926.451(e)(1)

When scaffold platforms are more than 2 feet (0.6 m) above or below a point of access, portable ladders, hook-on ladders, attachable ladders, stair towers (scaffold stairways/towers), stairway-type ladders (such as ladder stands), ramps, walkways, integral prefabricated scaffold access, or direct access from another scaffold, structure, personnel hoist, or similar surface shall be used. Crossbraces shall not be used as a means of access.

Fig.2: Example of an OSHA Construction Safety standard applied in this study.

The current approach classified the selected construction OSHA standards for violation identification in the MX environment scene into three tiers. The tiers are designed based on the complexity of violation identification, meaning the user's level of effort required—i.e., the complexity is related to the steps to determine the violation in a virtual scene. Table 2 presents the details of complexity tiers for violation of OSHA standard identification.

Table 2: Tiers and level of effort on OSHA standard violation identification in the virtual scene.

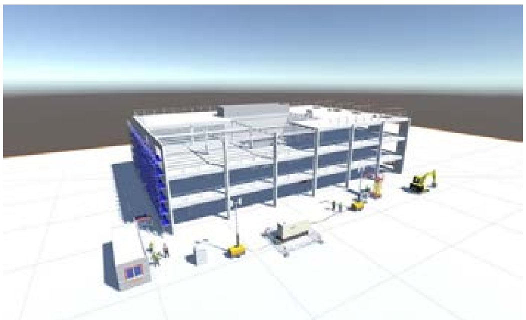
Tiers	Level of effort based on complexity of tasks for violation identification
Tier 1	Direct visual contact with the objects.
Tier 2	Need to search for information to infer a violation.
Tier 3	Need to perform actions in to determine violations

Tier 1 is applied to those violations that can be perceived through direct observation in scenes within the MX environment—i.e., there is minimum learner's effort to perceive the visualizations (visual representations) that produce the stimulus for the learners' identification of the violations. Within this tier, most of the violations could be identified by just a single observation of the virtual objects (visual representations). Typical examples for this tier are conditions that represent personal protection equipment through virtual objects (i.e., visual representation of the worker without properly using protection equipment). Tier 2 is for conditions in the scene that demand the user to search for information to infer the violations. The learners' search for information is possible by triggering actions in the MX environment. The learner's action for information search serves as an additional mediation mechanism for inference to determine violation (e.g., the learners' virtual rotation of an extinguisher in the MX scene to determine the expiration date). Tier 3 complexity consists of additional actions for inference using virtual instruments to determine violations. Using instruments for inference implies an additional level of complexity, as other cognitive capabilities (spatial and reasoning abilities) are required to determine violation (e.g., displacing instruments to measure distances in the virtual space). An example of Tier 3 is the learner's required action of using an instrument to calculate the distance that informs whether it's a violation or not (e.g., the placement of a straight ladder against a wall).

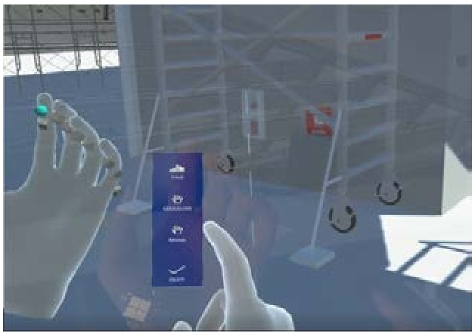
3.2 Problem-solving task design in the MX environment

The design consists of creating an examination of on-site construction OSHA safety checks. The examination is framed as a problem-solving task to draw boundaries of complexity in the search space— the possible configurations, number parameters, and elements in the MX environment that impact the users' decisions and courses of action.

Users (learners, trainees) are required to review the compliance of safety standards of construction of small commercial buildings (3 stories distributed over 40,000 Sq ft) as a project engineer from a local subcontractor company. While wearing the MX device (Hololens 2), users are asked to inspect and label safety standards violations in the first story of the building within 10 minutes. Fig. 3(a) shows the MX ongoing construction site prototype. Fig. 3(b) shows a scene where the user is required to use an additional instrument within the MX environment to determine a violation, like the measuring tape within the problem-solving task.



(a) Virtual construction site.



(b) Integrated virtual commands for labeling virtual objects.

Fig. 3. Virtual environment for OSHA training.

In order to facilitate unrestricted exploration of the entire construction site within a virtual environment, a navigation system was devised to enable virtual movements in the virtual world based on physical displacement in the real world (laboratory space). The navigation system allows unconstraint virtual displacements in the MX environment. Due to the constraints on mobility in the physical environment, individuals are required to physically traverse the laboratory area in order to investigate and examine the construction site comprehensively. Instead of taking the examination totally virtually like a video game, this paper is trying to configure a balance between virtual and reality through this navigation system.

3.3 Data collection

The experiment design includes the collection of video, audio, and EEG data from a MX device and an EEG headset (see Fig.4(a) and 4(b)). The EEG data is collected from an OpenBCI Mark IV headset with a sampling rate of 125 Hz. The OpenBCI Mark IV headset includes 16 channels (with additional reference and ground electrodes in A1 and A2) placed on the subject's scalp according to the international 10-20 system. This paper collects EEG signals by using all 16 channels (FP1, FP2, F3, F4, F7, F8, C3, C4, T7, T8, P3, P4, P7, P8, O1, and O2) as presented in Figs. 5(a), 5(b), and 5(c) (Homan et al., 1987; "Ultracortex Mark IV | OpenBCI Documentation,").

During the implementation of the OSHA construction safety inspection, the researchers collect video, audio, and information on tagged violations by the subjects. All tagged violations will include the real timestamp information, which could help with synchronizing time stamps across different data streams and activities in the MX environment.

3.4 Post-processing

A synchronization task follows. It consists of mapping the generated streams of data collected during the experiment with the real-time stamps associated with each technology device. The timestamps were used to identify the exact occurrence of violations during the experiments. Once violation occurrences are identified, the EEG data will be segmented into 20-second epochs for target sections (20 seconds before each incident violation was labeled or tagged). The researchers post-process EEG data in MATLAB (version 2023a) and the EEGLab toolbox (Delorme & Makeig, 2004). After importing raw EEG data and electrodes' locations correspondingly, a FIR filter is applied to bandpass filter the EEG data to a frequency of 0.5-30 Hz to help to remove low-frequency drifts and power line noise. Artifacts from eye blinks and muscle movement were corrected by applying ICA in EEGLab (Winkler et al., 2014).

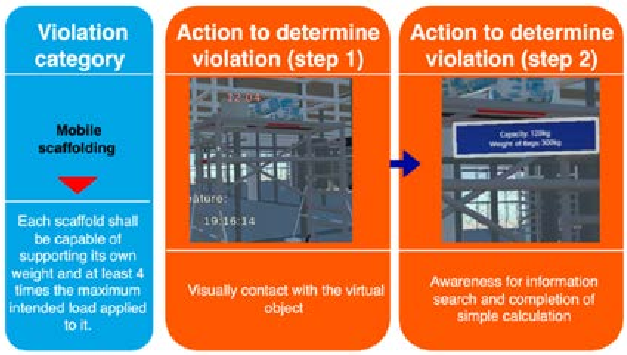
The next steps are the extraction of features of theta (4–8Hz), alpha (8–13Hz), and beta (13–30Hz) to analyze and compare the mental cognitive load and attention degree across different levels of efforts.

4. EXAMPLE OF DATA RESULTS AND DISCUSSION

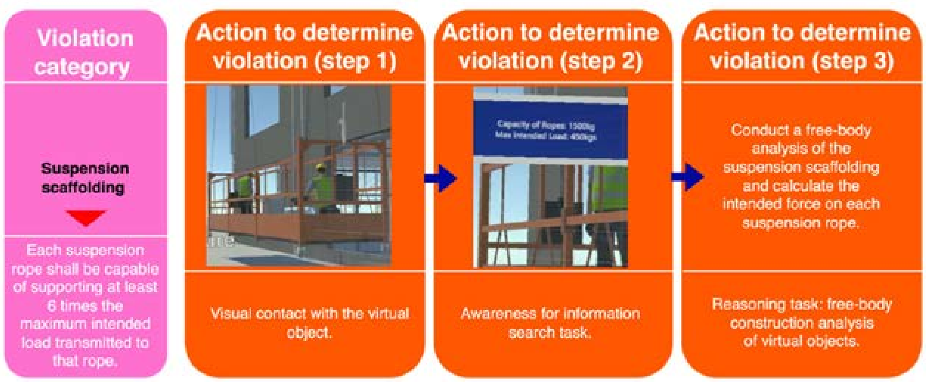
The current experimentations of the treatment and control groups are in progress. The following is an example of the typical experiment and data captured for one subject, including the data processing outcomes for the treatment group.

The presented example shows an experiment with a subject of the treatment group who has never taken any OSHA construction safety-related training. The researchers asked the subject to take a personalized OSHA safety training session. Once the training session was finalized, the researchers asked the subject to be immersed in an MX reality ecosystem by wearing the MX and EEG devices. The immersive environment consists of a virtual construction site with multiple scenes and situations that present safety violations and hazardous conditions based on OSHA standards. Each violation fell into three different tiers of complexity. As an illustration, the violations' type and complexity tier are presented in Fig. 6.

(a) Easy-level complexity violations.



(b) Mid-level complexity violations.

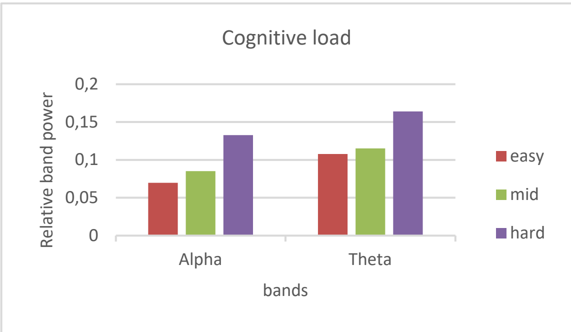


(c) Hard-level complexity violations.

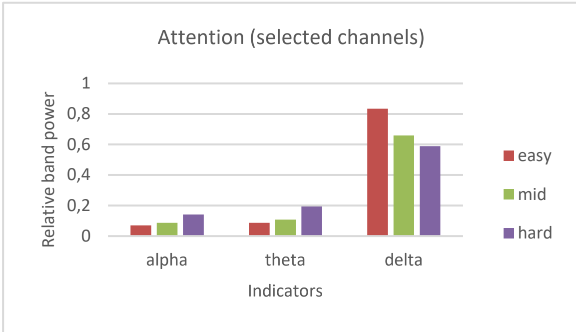
Fig. 6. Example of complexity tier violations used in the experiment.

The easy-level complexity violations (like PPE violations) would only require subjects to visually be in contact with the virtual object to check and determine the violation. For mid-level complexity violations (like mobile scaffolding capacity violation), the subject needs first to be in contact with the virtual object (as a target virtual object with potential violation)—next, the subject searches for information to make inferences and verify a violation. For hard-level complexity violations (like suspension scaffolding capacity violations), the subject requires not only the awareness of an information search task to deduce a violation but also be involved in a reasoning task. The reasoning task demands constructs a free-body analysis of virtual objects.

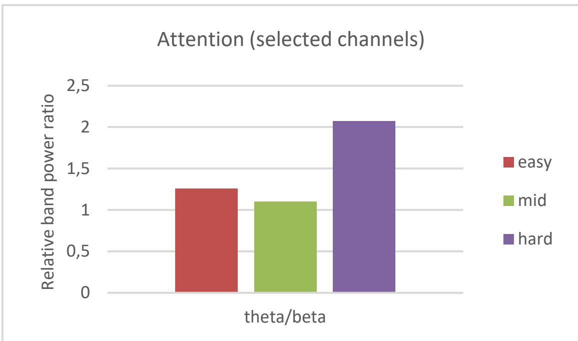
Fig. 7 (a) shows the result of cognitive load when the subject was experiencing different efforts associated with the tiers of complexity violations. As introduced in the previous sections, to analyze the cognitive load, the relative band power of Alpha and Theta was computed (Sarailoo et al., 2022). Based on the result, it can be concluded that to address the increasing complexity of tasks, individuals are required to exert a higher cognitive load to arrive at a solution. Furthermore, since the subject's cognitive load increased with the higher complexity levels when solving a task, it is possible to determine the dynamics of success and failure of each subject (cognitive dynamics of each subject). The dynamic enables the research to correlate the efficiency of the technology for training and individual differences in training tasks.



(d) Cognitive load.



(e) Attention degree (alpha, theta, and delta band).



(f) Attention degree (ratio between theta and beta).

Fig. 7. Data from cognitive processes from one subject involved in MX training task.

To analyze the attention degree when subjects address solutions in problem-solving, the band power of mid-frontal theta, central and parietal delta, and frontal and parietal alpha were computed. Besides, the ratio between theta and beta was also included as an indicator (Derbali & Frasson, 2011; Kaushik et al., 2022). As presented in Fig. 7 (b) (c), with the increase of the task complexity, the related power band of the mid-frontal theta increases, and the central and parietal delta decreases, which indicates a better intense of attention was put into the problem-solving task. However, the relative band power of frontal and parietal alpha exhibited a little increase as the task complexity escalated, indicating a potential decline in attention levels during the problem-solving activity. Besides, the ratio between theta and beta was also not presented as the ideal model. This result may be caused by lost calibration or bad connections between some channels of EEG collecting headset and subject's scalp. Drawing precise reasons on this issue is challenging due to the insufficient number of trials and subjects involved.

Nevertheless, by analyzing the cognitive load condition and the attention degree while the subjects were facing the problem-solving task, the researchers could infer that some mistakes made by the subject were not because of the inefficiency of the training program but due to loss of attention or the lack of ability to keep on a high cognitive load level for a long time. In this example, the subject stayed focused during the whole session and solved all three violations (presented in Fig.6) successfully. However, the presented example contains a short number of decisions with only simple construction scenes and a limited number of violations. It's relatively easy to keep focused on the problem-solving task. For subjects who face a more complex scene and can't solve all violations, the reason for the mistakes (i.e., performance on correct inferences to solve the problem) will become part of the analysis, including the effectiveness of the MX intervention for the training program.

5. CONCLUSION AND FUTURE WORK

The presented research is a successful design and development of a method for the effectiveness of assessment safety training. The approach includes in its development the design and construction documents of the construction project site to build a virtual construction site. The information was used to build an MX environment for the learner's self-exploration using a navigation system, enabling the learner to mimic the real workplace with the advantage of a mixed-reality device. The method uses EEG signals to estimate cognitive conditions that inform the users' effort in decision-making while solving a problem relating to OSHA violation (i.e., virtual safety inspections in the MX environment). The technology consists of an MX device and a 16-channel EEG headset. Subjects could walk freely in the experimental space, as the portable EEG and mixed-reality devices allow them to collect the data wirelessly to a local network set for the experimentation. With the model developed, the researchers could successfully and accurately assess the subject's cognitive load and attention levels while solving the construction safety-check problem. The outcome provides new and comprehensive information that helps to analyze the performance during learning and problem-solving. With the developed method, the researchers could overcome the bias from self-report evaluation or any paper-based test and get a comprehensive and personalized performance analysis. For future work, the researchers will model the effects of the cognitive load and attention degree analysis by applying machine learning algorithms for inference on the subjects' behavior during problem-solving tasks.

EVALUATION OF COMPUTER VISION-AIDED MULTIMEDIA LEARNING IN CONSTRUCTION ENGINEERING EDUCATION

Anthony O. Yusuf, Adedeji O. Afolabi, Abiola A. Akanmu, & Johnson Olayiwola
Myers-Lawson School of Construction, Virginia Tech, Blacksburg, VA, USA.

ABSTRACT: *Due to the practice-oriented nature of construction engineering education and barriers associated with physical site visits, videos are invaluable means to expose students to practical curricula content. Prior studies have investigated various design principles of multimedia pedagogical tools to enhance student learning and reduce cognitive load. These design principles and computer vision techniques can afford the design and usage of a multimedia learning environment with annotated content to teach students construction safety practices. Hence, using subjective and objective measures such as self-reported cognitive load, eye tracking metrics and verbal feedback, this study assesses the effectiveness of a computer vision-aided multimedia learning environment as well as examines variations across students' demographics. Students were exposed to both annotated and unannotated versions of the learning environment. The annotated version of the learning environment was considered more effective in triggering students' attention to learning content, but higher cognitive load levels were reported by participants. The same demographic groups that dwelled longer and on more annotated areas of interest also reported higher overall cognitive load. Keeping with individual differences principle of multimedia learning, demographic variations in participants' cognitive load and effectiveness of the learning environment were reported. The study provides implications for instructors in construction engineering programs on effective use of computer vision-aided annotated videos as instructional materials. This study could serve as a benchmark for future studies on artificial intelligence techniques for signaling in multimedia learning. This study reveals the affordances of computer vision-aided multimedia learning in construction engineering education and the need for adaptation of multimedia learning tools to students' demographics.*

KEYWORDS*: Computer vision, construction engineering education, demographic differences, multimedia learning, video.*

1. INTRODUCTION

Construction-related disciplines are applied science; hence they are rich in practical components which are usually difficult for instructors to cover in the classroom (Gunhan, 2015). The imbalance between theory and practice has been one of the challenges in preparing students for the workplace (Afonso et al., 2012). Hence, academia is in constant effort to achieve a proper blend of theory and practice (Bozoglu, 2016). Site visits are being used to circumvent this challenge by exposing students to real-world examples, spatio-temporal scenarios of construction operations and interaction with practitioners (Eiris Pereira & Gheisari, 2019). However, barriers associated with site visits such as safety, coordination, distance/location, limited what-if scenarios, and concerns for disabled students(Eiris Pereira & Gheisari, 2019) have necessitated the need for new methods of bringing practical examples into the classroom. Videos are now increasingly being widely used as pedagogical tools to address these limitations (Shojaei et al., 2021). Videos enable instructors to bring the real world into the classroom. Videos also allow for experiments, site visits, and demonstrations that otherwise would have been impossible. Beyond knowledge transmission, videos expose students to diverse experiences, attitudes, and emotions and promote interactions and discussions (Ferreira et al., 2013). However, the use of videos also comes with some challenges. For example, if not intelligently designed, videos could be ineffective for learning because they could increase cognitive load, and not capture learners' attention (De Koning et al., 2009). In addition, videos could contain non-essential information which could be distracting to learners. These downsides of videos have been earlier reported (Homer et al., 2008). To circumvent these challenges, the adoption of multimedia learning principles such as removal of extraneous content and signaling of important learning content are effective measures (Mayer & Fiorella, 2014). Signaling involves the use of cues (e.g., arrow, boundary boxes, color contrast) to point out important learning content to learners in a multimedia environment. In other domains, previous studies have demonstrated the effectiveness of these techniques in ensuring that videos are effective pedagogical tools (De Koning et al., 2009; Navarro et al., 2015).

Given the advances in computing, its affordances and wide applications, manual signaling methods which could be laborious, undynamic and time intensive can be replaced with automation afforded by artificial intelligence. By leveraging computer vision (CV) techniques (such as object and interaction detection), construction videos can be automatically annotated to call out specific learning contents. This has been demonstrated in other endeavors such as detecting human daily activities using convolutional neural networks (Zhang et al., 2017). Adopting this in construction engineering education is important given the need to visualize theoretical concepts,

understand the pace and sequence of construction tasks, and spatiotemporal nature of construction activities (Eiris Pereira & Gheisari, 2019). Previous studies (Abdulrahaman et al., 2020; Stark et al., 2018) have highlighted the need to evaluate the efficacy of multimedia learning environments. To evaluate multimedia pedagogical tools, learners' cognitive load level and demographic differences have been suggested as primary considerations (Grimley, 2007). Also, earlier studies have combined objective and subjective measures and compared two or more multimedia learning environments (Abdulrahaman et al., 2020; Stark et al., 2018). Despite the potential of multimedia learning in construction engineering education, it has received little attention in literature, especially the application of CV in multimedia learning. Hence, this study compared two multimedia learning environments from the lens of demographic differences to evaluate the effectiveness of CV-aided multimedia learning in construction engineering education.

2. BACKGROUND

2.1 Application of Computer Vision in Education

Computer vision is being increasingly leveraged in several educational contexts because of its value to conventional educational methods by improving teaching and learning (Savov et al., 2018; Sophokleous et al., 2021). For instance, using a face recognition algorithm, Savov et al. (2018) combined computer vision, and internet of things to provide engaging experience for students. The study demonstrated the efficacy of computer vision through adaptation to learners' facial expression to help instructors tailor the teaching process to learners' preferences. Tetiana et al. (2021) also leveraged computer vision and augmented reality to allow students to interact with and obtain additional virtual information about research objects. This helped to promote effective interaction between students and educational material. Similarly, using facial emotions, pose estimation, and head rotation, Poonja et al. (2023) developed a computer vision-based system to detect students' engagement in online learning. Computer vision has been adopted in other educational context such as enhancing the teaching of mechatronics (Tudić et al., 2022), in distance education of new generation labor productivity (Zhao & Li, 2021), as well as educational robotics in K-12 education (Sophokleous et al., 2021). Interaction and object detection techniques of computer vision can be leveraged to signal essential learning contents in videos for teaching purposes. For example, Tang et al. (2020) used Faster Region-proposal Convolutional Neural Network (Faster RCNN) to detect workers and materials for safety monitoring. Using deep residual learning network, Hashimoto et al. (2019) used computer vision for automated operative step detection during Laparoscopic Sleeve Gastrectomy. Similarly, Aronson (2018) demonstrated the efficacy of computer vision for signaling violation of human right in videos. However, there are scarce studies that demonstrated the effectiveness of computer vision for signaling in multimedia learning.

2.2 Evaluation of Multimedia Learning Tools

To evaluate multimedia learning tools, a comparison approach which involves comparing two or more multimedia pedagogical tools is a common method (Abdulrahaman et al., 2020). For example, Chiu et al. (2018) compared the efficacy of annotated and unannotated versions of a video to teach cardiopulmonary resuscitation. Using pre and posttests, eye tracking metrics, satisfaction and self-reported cognitive load questionnaires, the study reported that students that learned with annotations had lower cognitive load, concentrated more on the critical parts of the instructional video, and thus learned more effectively and easily. Also, combinations of objective and subjective measures have been encouraged in usability evaluation (Abdulrahaman et al., 2020). This is due to the limitations of subjective measures such as risk of prejudice, lack of response, and lack of supporting evidence for respondents' ratings (Kelley et al., 2003). Objective measures such as eye tracking metrics (e.g., fixations and dwell times) are widely used in the usability evaluation of multimedia learning tools (Molina et al., 2018; Stark et al., 2018). National Aeronautics and Space Administration Task Load Index (NASA-TLX) is a widely used subjective evaluation tool for assessing cognitive workload. NASA TLX assessed cognitive workload across six subscales: Mental Demand, Physical Demand, Temporal Demand, Performance, Effort, and Frustration (Sharek, 2011). Eye Tracking and NASA TLX have been used in previous studies (Latifzadeh et al., 2020; Law et al., 2010) for the evaluation of multimedia pedagogical tools. Other subjective measures such as think-aloud protocol, interview, and verbal feedback are also being used (Abdulrahaman et al., 2020). Also, to evaluate the usability of multimedia pedagogical tools, demographic differences such as gender (Grimley, 2007), academic level, academic program (Castro-Alonso et al., 2019), ethnicity (Moreno & Flowerday, 2006) and prior experience (Kalyuga et al., 2000) are deemed important considerations.

3. METHODOLOGY

3.1 Overview

The study evaluated the efficacy of an annotated video designed to teach construction students different construction safety practices. A comparison approach was adopted. Students were exposed to two learning environments. One was designed with computer-vision aided signals or cues to call out essential learning content while the other was not. Subjective and objective measures of the participants in the two learning environments were compared. In addition, keeping with individual differences principle of multimedia learning, demographic variations in participants' cognitive load and eye tracking metrics in the annotated learning environment were assessed.

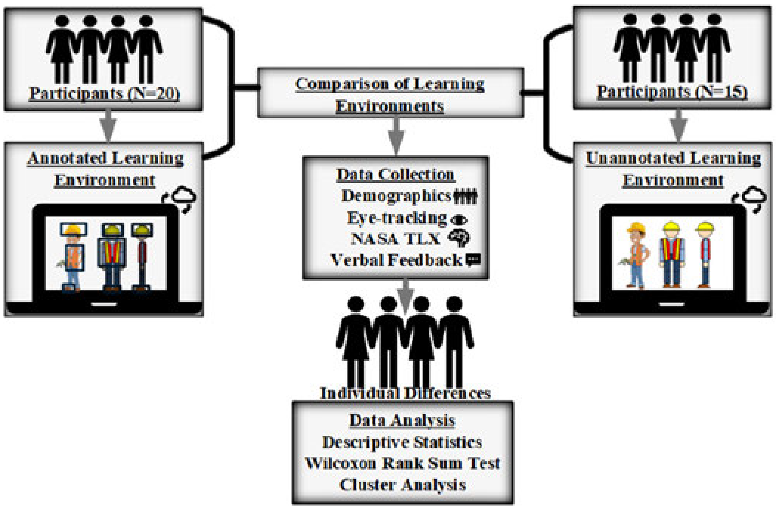

Fig. 1: Overview of Methodology

3.2 The Learning Environments: Annotated and Unannotated Videos

The two versions of the video had the same contents, each about 6-minutes long. The videos contain both visual and audio presentations of eleven (11) construction safety practices. These include Personal Protective Equipment (PPE), Situational awareness (SA), Secure workers at height (SWH), Securing materials (SM), Exclusion zone (EZ), Deep excavation (DE), Signage (S), Fall protection (FP), Mobile phone use (MPU), Ladder use (LU), Ergonomics (ER). These safety practices were identified by Olayiwola, Yusuf, et al. (2023) as critical to complement classroom teaching during site visits. The safety practices represent areas of interest (AOIs). Safety practices were chosen because Pedro et al. (2016) highlighted the need for knowledge of safety practices in preparing the future workforce. The annotated video contains computer vision-aided signals to call-out the safety practices while the unannotated video does not. Both object and interaction detection techniques of computer vision were used in this study. Faster RCNN, a deep learning technique was combined with Visual Geometry Group network (VGG16) (a convolution neural network architecture) to signal the construction safety practices with boundary boxes. Visual translation embedding network (VTransE) was used as the interaction detection technique. The details of the design and development of the annotated learning environment are presented in Olayiwola, Akanmu, et al. (2023). Examples of frames from the annotated and unannotated videos are shown in Figure 2.

3.3 Participants and study approval

After the Virginia Tech Institutional Review Board approved the study, thirty-five (35) participants who are students in construction-related programs volunteered to participate. Twenty (20) of them used the annotated learning environment while fifteen (15) used the unannotated learning environment. All the participants are between 20 to 24 years old. The participants' demographics are shown in Table 1 below.

(a) Sample frame of annotated video

(b) Sample frame of unannotated video

Fig. 2: Frames of Annotated and Unannotated Videos.

Asian	5	3
African American	2	2
Hispanic/Latino	1	1

3.4 Experimental design and Data collection

Before the experiments commenced, every participant was intimated with the workflow of the experimental procedure. Thereafter, the participants signed the informed consent form and completed the demographic questionnaire. A web-based eye tracker (Gaze-recorder) was used in this study. The participants' eyes were calibrated, and then they watched the 6-minute video of construction safety practices. Eye-tracking data was collected as the participants watched the video. Two separate experiments were conducted. In the first experiment, the experimental group (n = 20) was exposed to the annotated video while in the second experiment, the control group (n = 15) was exposed to the unannotated video. After every session, participants completed three subscales of the NASA-TLX questionnaire (i.e., Mental demand, Effort, and Frustration). These subscales have been used to assess cognitive load in multimedia learning (Refat et al., 2020). Finally, the participants' verbal feedback was audio-recorded. Each session lasted for about one (1) hour.

3.5 Data analysis

Dwell times of the participants were collected for the eleven AOIs in the videos. Wilcoxon Rank Sum Test was used to test for statistically significant differences since the comparisons were between two independent groups and independent observations. Descriptive statistics were used for the self-reported cognitive load. MS Office Excel and SPSS were used for the analysis. The verbal feedback was transcribed and analyzed using cluster analysis. The analyses were done by comparing the participants' dwell times on the AOIs of the annotated and unannotated videos and the demographic differences of the participants.

4. RESULTS AND DISCUSSION

4.1 Dwell Time Comparison in Annotated and Unannotated Video

As shown in Figure 3, significant differences in the dwell times were found between the annotated and unannotated videos for seven (7) AOIs of which four (4) had significantly higher dwell times in the annotated video. These include PPE, Situational Awareness, Securing Material, and Signage ($p < 0.05$). The overall dwell time of the participants was higher in the unannotated environment although no statistically significant difference was observed. However, the participants dwelled longer on more of the AOIs in the annotated video. The participants dwelled longer on 7 out of the 11 safety practices in the annotated video. In the unannotated video, the participants only dwelled longer on four (4) safety practices, which include Secure workers at height, Fall Protection, Use of Mobile Phone and Ergonomics. This result shows that although the participants spent more time in the unannotated environment, they did not dwell longer on more AOIs. Whereas the participants spent less time in the annotated environment but dwell longer on the AOIs. This shows that the annotation was effective to direct the learners to important learning content and to stimulate their interest. This finding agrees with Molina et al. (2018) who explained that learners might dwell more on AOIs in multimedia learning. The higher dwell times on the AOIs in the annotated video shows the extent of focus and interest in the AOIs (Bojko, 2013; Carter & Luke, 2020). This result aligns with the findings of previous studies (Molina et al., 2018; Navarro et al., 2015) which underscored the potential of signals to trigger learners' interest, improved learners' visual search efficiency and provide greater visibility for important learning content.

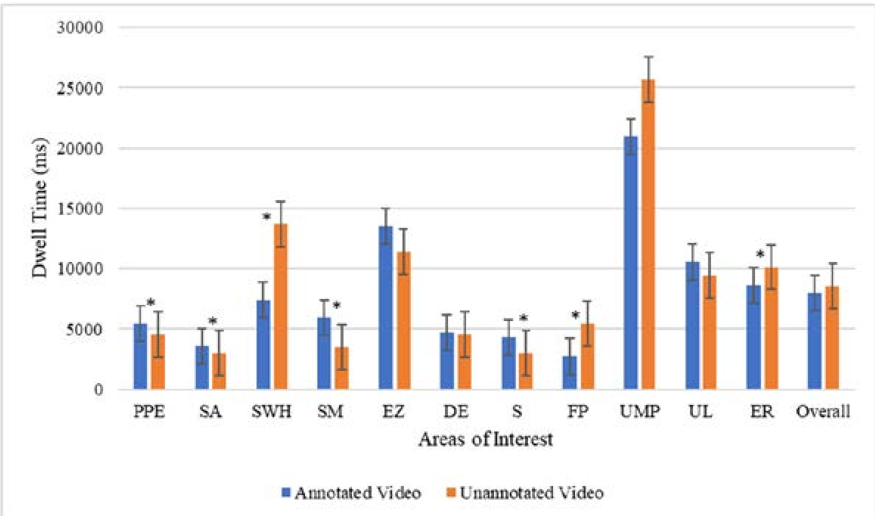

Fig. 3: Dwell Time on AOI

4.2 Comparison of Demographic Differences within Annotated Video

4.2.1 Gender

Within the annotated environment, gender differences were observed, as shown in Figure 4. On the overall, female students dwelled longer on the AOIs than their male counterparts. The overall dwell time of the female students was statistically higher ($p < 0.05$). Also, the female participants dwelled more on each of the AOIs than their male counterparts. This phenomenon reveals that signals were efficacious in drawing the attention and stimulating the interest of female students than male students. The female participants' dwell times on the AOIs were significantly higher for three (3) AOIs, which include Secure Workers at Height, Deep Excavation and Use of Mobile Phone. This could mean that female students prefer to learn with annotated videos than male students. This could be helpful to instructors in their choice of instructional materials. This finding contributes to prior studies (Grimley, 2007; Saha & Halder, 2016) which have shown gender differences in information process in multimedia learning. The finding agrees with Dousay and Trujillo (2019) who reported that females had higher situational interest in multimedia learning than males.

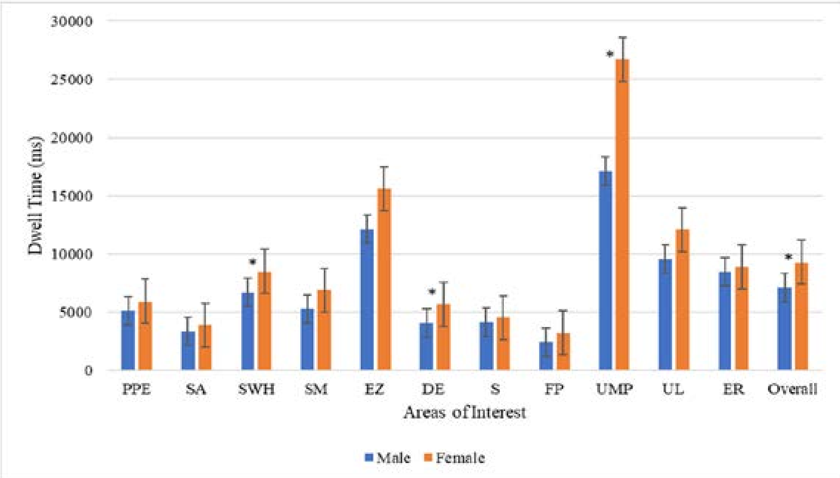

Fig. 4: Male and Female Dwell Time for Annotated Video

4.2.2 Academic Level

On the overall, Figure 5 shows that the senior-level students dwelled longer (although not significant, $p>0.05$) on the annotated video than junior-level students. Also, the senior-level students dwelled more on nine (9) out of the eleven (11) AOIs than their Junior-level counterparts. The Senior-level participants dwelled more on all AOIs except Use of Mobile Phone and Ergonomics. The results showed that the Senior-level participants significantly dwelled longer ($p<0.05$) on Exclusion Zone ($p<0.05$). The academic level of the students could be synonymous with prior knowledge. Although, previous studies (Grimley, 2007; Kalyuga, 2013) have noted that multimedia learning would be effective for learners with lower prior knowledge, the findings of this study differ from Navarro et al. (2015) who reported that students of lower academic levels dwelled more on AOIs while senior students only take a glance. The difference in the finding could be because the participants in this study were college students (aged 20-24 years) while those in prior studies (Grimley, 2007; Navarro et al., 2015) were primary school pupils (aged $\leq$ 11 years). Also, in this study, better than junior-level participants, the senior-level participants might have been more willing to explore the annotated learning environment and found the signaled concepts more engaging which might have been responsible for dwelling on more signaled concepts. This result contributes to earlier studies, e.g., Castro-Alonso et al. (2019), on academic level-based differences in multimedia learning.

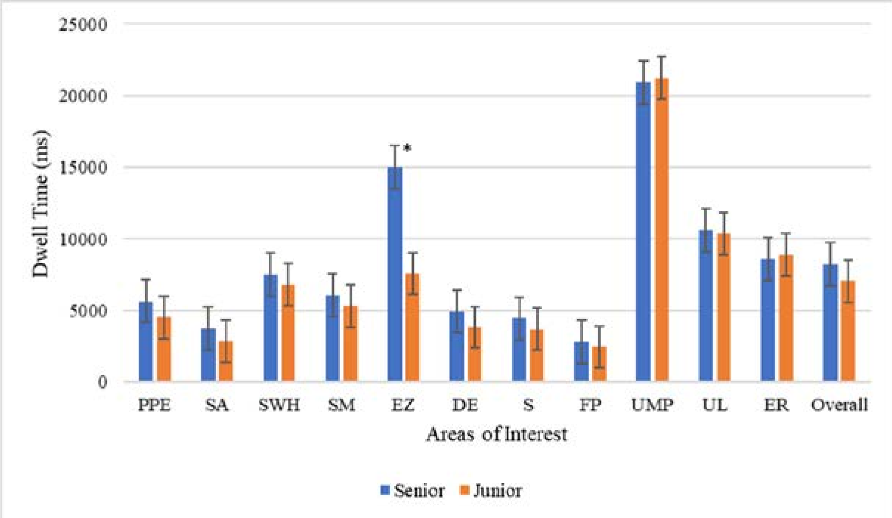

Fig. 5: Junior and Senior Dwell Time for Annotated Video

4.2.3 Years of Experience

As shown in Figure 6, although no statistically significant difference was observed, overall, students with 0-2 years of experience had higher dwell time on the AOIs. The students dwelled more on the AOIs (8 out of 11) than those with 2-5 years of experience. The students with 2-5 years of experience only dwelled longer on PPE, Situational Awareness and Secure of Materials. This result shows that the learners with lower experience would perceive better learning benefits with the annotated learning environment. This study contributes to prior studies e.g., Kalyuga et al. (2000) that have demonstrated differences based on prior experience in multimedia learning.

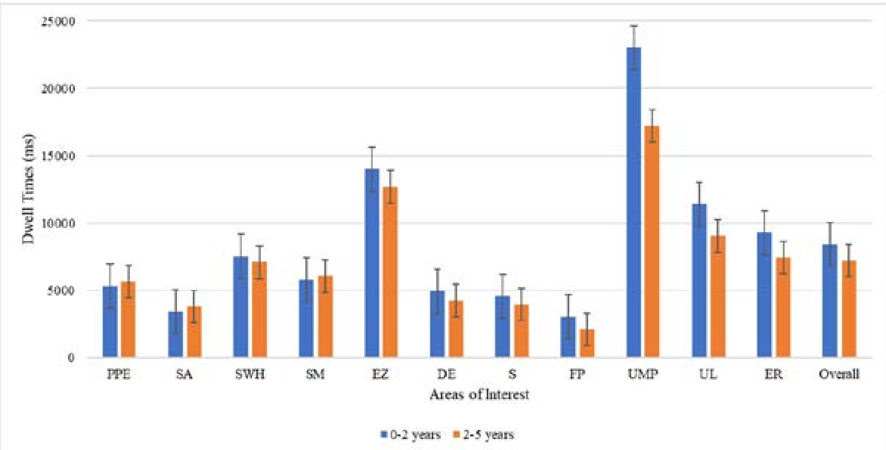

Fig. 6: Dwell Time for Annotated Video Based on Years of Experience

4.2.4 Academic Program

No statistically significant difference was observed in the comparison based on students' academic program. On the overall, students in CEE dwelled longer on more AOIs than those in BC and CEM respectively (Figure 7). For six (6) of the AOIs namely, Situational Awareness, Exclusion Zone, Deep Excavation, Fall Protection, Use of Mobile Phone, Use of Ladder, the ascending order of the increase in dwell time on the AOIs is BC students, CEM students and CEE students. The variation observed based on academic programs could be due to differences in the emphasis of each program even though they are all aspects of construction education. For instance, Abudayyeh et al. (2000) pointed out that the CEE program is focused more on design of facilities; CEM program has concentration on achieving a balance between the engineering and management component of construction, while BC program has emphasis on management and business components of construction. Hence, the differences in the educational background of the students could have been responsible for the variations. For example, since CEE students are in a program that focused on design of infrastructural facilities, they might have been less familiar with the construction safety practices in the annotated video compared to their counterparts in CEM and BC programs. This could account for their higher dwell times on most of the AOIs. This result contributes to earlier studies e.g., Castro-Alonso et al. (2019) on differences based on academic program in multimedia learning.

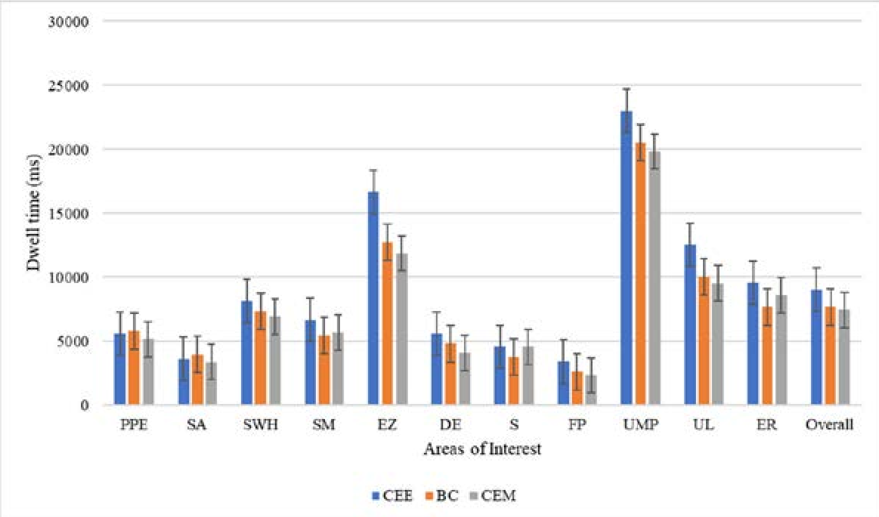

Fig. 7: Dwell Time for Annotated Video Based on Academic Program

4.2.5 Ethnicity

Though without any significant difference, the result reveals that on the overall, White students dwelled longer on the annotated video (Figure 8). They also dwelled longer on more AOIs (6 out of 11) than students of other ethnicities. Studies comparing ethnic differences in multimedia learning are scarce. In this study, due to the small sample sizes, only White students who made up 60% of the participants were compared with other ethnicities. This study contributes to the few existing studies such as Moreno and Flowerday (2006) that have examined ethnic differences in multimedia learning.

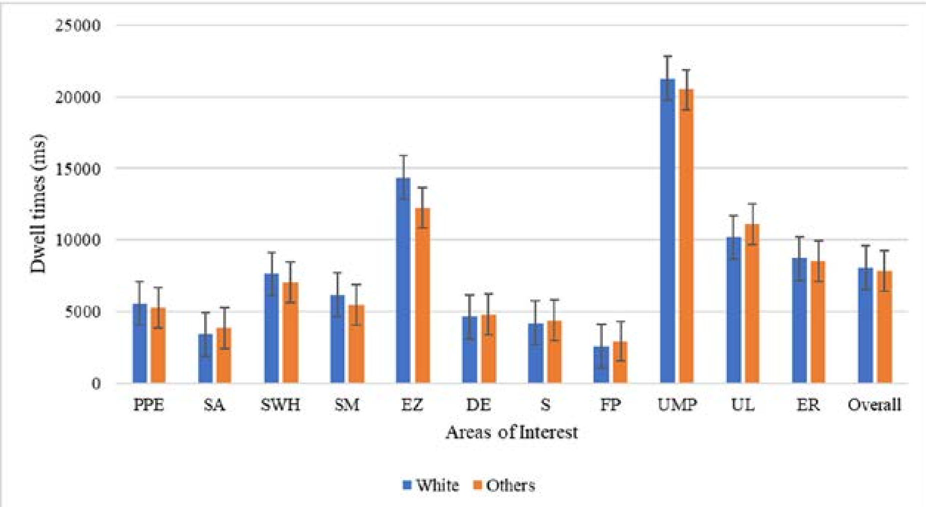

Fig. 8: Dwell Time for Annotated Video Based on Ethnicity

4.3 Cognitive Load

As shown in Figure 9, the participants reported higher effort and frustration for the annotated video, however, they reported lower mental demand for the same. This shows that it was not mentally demanding to learn with the annotated video, but participants put in more effort and experienced higher frustration. This could be because of their unfamiliarity with the annotated video, the effect could be abated as learners get used to the video. Overall, the participants experienced a higher cognitive load in the annotated learning environment. No significant difference was observed between the annotated and unannotated video ($p > 0.05$). This result differs from Chiu et al. (2018) who reported that students who learned with annotated video experienced lower cognitive load. This difference could be attributed to other factors such as participants' ethnicity (Moreno & Flowerday, 2006), visual preference (Homer et al., 2008) and media type (Castro-Alonso et al., 2019) which are moderating variables in multimedia learning. For instance, Homer et al. (2008) reported that low visual-preference learners experienced higher cognitive load than high visual-preference learners in learning with video.

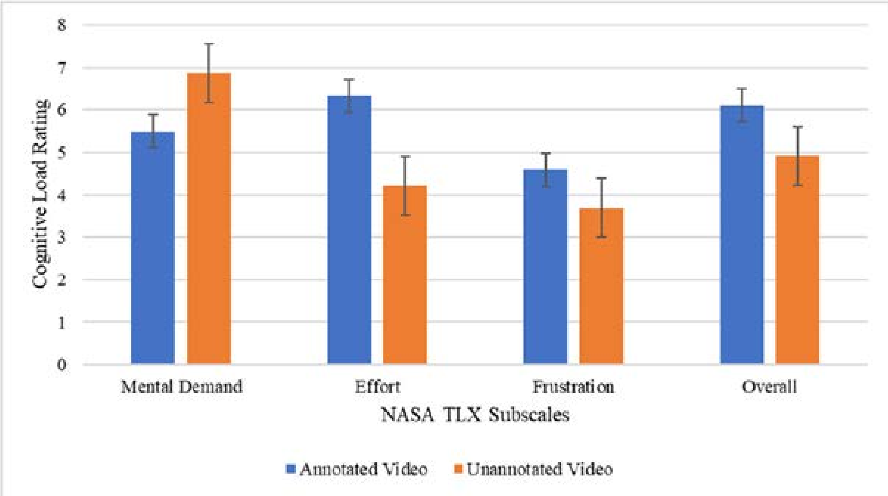

Fig. 9: Participants' ratings of perceived mental demand, effort, and frustration after interaction with both video

The demographic comparison of cognitive load in annotated video is shown in Figure 10. Although no statistically significant difference in any of the comparisons (p>0.05), female participants reported higher cognitive load compared to male participants. Similarly, participants with 0-2 years of experience self-reported higher cognitive load than their colleagues with 2-5 years of experience. For the academic programs, CEE students reported the highest cognitive load, followed by CEM students, while BC students had the lowest cognitive load rating. Demographic comparison reveals variations in the cognitive load level of the students. This variation could help instructors to design and adapt multimedia learning environments to suit learners of various categories. This is especially important to instructors especially those in engineering-construction educational programs, where effort is required to attract and retain female high school students and those from underrepresented groups (Choi et al., 2022).

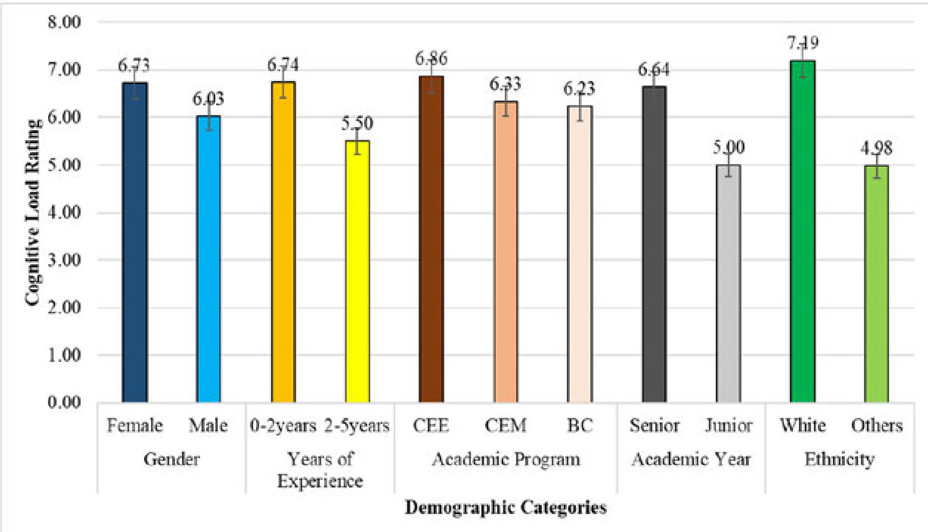

Fig. 10: Demographic comparison of cognitive load in annotated video

4.4 Verbal Feedback

Most of the participants that watched the annotated video opined that the annotation was effective in making them learn easier. The participants reported that the annotation helped them to focus on learning content and their attention was held. This is because in addition to the audio narration, the annotation helped the student to easily identify specific areas to focus on in the video which helped them to better understand the learning contents. Only three participants reported that the signals were distracting. The participants suggested using arrows instead of boundary boxes and highlighting their content because some learners might focus on the boundary boxes more than the contents within them. Some participants also suggested making the video more interactive and reducing the tempo. The students attested to the potential of the video for online courses and helping to learn about more construction practices without having to visit a job site.

5. CONCLUSION, LIMITATIONS AND FUTURE WORK

Characteristics of learners influence cognitive load and the efficacy of designs in multimedia learning. Hence, it is important to evaluate multimedia pedagogical tools to assess their suitability for intended context, purpose, and users. This study evaluates the efficacy of an annotated video which is a computer-vision-aided multimedia learning for teaching construction safety practices. The study reveals that computer vision generated signals were effective in drawing the intention of learners to fixate on AOIs. Within the annotated learning environment, female students, students with 0-2 years of experience, senior-level students, CEE students, and white students dwell longer and on more AOIs than their counterparts. However, these categories of participants reported higher overall cognitive load for the annotated video compared to their counterparts. The study also shows demographic differences in the cognitive load level of participants based on gender, ethnicity, academic level, years of experience and academic program. The results reveal that the demographic classes that dwelled more on the AOIs also reported a higher cognitive load. The results of this study could help instructors in engineering-construction education programs to effectively use annotated videos as instructional materials. This study could serve as a benchmark for future studies on artificial intelligence techniques for signaling in multimedia learning. The study opened a discussion on demographic differences in multimedia learning within the construction engineering education domain as well as the efficacy of artificial intelligence techniques in the design of multimedia pedagogical tools. This study has some limitations which could be the focus of future research. For example, only subjective rating of cognitive load was used, future research could combine both objective and subjective measures to assess cognitive load level in multimedia learning. Also, the small sample size of this study could have been responsible for some lack of significant differences in the comparisons made across the demographics of the participants. The small sample size also limits the generalizability of the findings. Future research could use higher sample sizes. Also, effects of age differences and academic levels (i.e., elementary school, high school, and college) of participants in multimedia learning could be the subject of future work.

Witt Emlyn D.Q
Tallinn University of Technology

Kahkonen Kalle & Poulitaival Taija
Tampere University

ABSTRACT: *In the field of AEC, Architecture Engineering and Construction, Building Information Modelling has increasingly assumed an important role, especially for construction simulation. BIM is needed for various building and management systems, particularly for project construction management. Students, teachers and operators of AEC need to have the availability of data, reports, pieces of information that allows to create BIM. "BENEDICT" is an European Erasmus project that has the aim of developing a web-based platform for BIM teaching that has a tight relationship with the AEC industry. Therefore, a BIM-enabled Learning Environment (BLE) can be used to implement BIM-based project planning and control system for learners and future practitioners, with Open Learning Resources. Open Learning Resources (OLR) are learning, teaching and research materials in any format and medium that are useful for teaching, learning, and assessing and for research purposes. In addition to the BLE platform, a BIM-model repository was developed to store information for each component of the project and of the learning activities. The repository can also store OLR and students' outputs. The BLE repository has the task of helping students and practitioners to implement BIM actual project models by developing an on-line repository of digital models, objects and elements, therefore providing knowledge transfer between different players.*

KEYWORDS: *Building Information Modelling, Benedict project, Open Learning Resources, Construction.*

1. INTRODUCTION

The construction industry is one of the largest in the world economy, with about $ 10 trillion spent every year for construction related goods and services. However, the industry productivity has lagged behind that of other industrial sectors, such as manufacturing and retail, that have implemented digitization and innovation, increasing their productivity over time. This productivity gap has many causes, and Building Information Modelling (BIM) is considered one fundamental strategy to recover the desired level of performance (European Construction Sector Observatory, 2021). Building Information Modelling (BIM) is the use of a shared digital representation of a built object to facilitate design, construction and operation processes to form a reliable basis for decisions (ISO 294811:2016). A built object can be a building, a road, a bridge, a process plant, everything that belongs to the built environment. A building construction information model is a shared digital representation of physical and functional characteristics of a built object (ISO TS 12911), therefore the term modelling addresses the process of managing information related to the facilities and project in order to coordinate multiple inputs and outputs, regardless of the specific implementation. Therefore, BIM is a method or strategy, not a tool. In the construction sector, knowledge transfer between different players, owner, designers, construction specialists, and project operators, together with project procurement take place by data exchange, i.e. information exchange. Among the specific features of the BIM methodology there is the ability to store information for each individual component of the project, including three dimensional properties and data concerning materials, building products, structure, quality performances, construction operations, transformation or installation stages, maintenance, time and cost data, sustainability and health and safety related information. Therefore, the fundamental element of this method is a digital model capable of n-dimensional representation of a building. BIM is considered a powerful approach to improve productivity in Architecture, Engineering and Construction sector. The use of BIM is spreading rapidly in many countries, covering a wide range of project both in the public and private sectors. Digitization of construction sector involves the need of helping students and practitioners to implement BIM actual project models by developing an on-line repository of digital models, objects and elements. Particularly focusing on educational processes, there is a strong need of developing a shared, online BIM models repository to provide an effective and coherent basis for BIM project implementation (Becerik-Gerber, 2012, Boeykens et al. , 2013, Clevenger et al. 2013, Puolitaival, Forsythe, 2016) The BENEDICT project, BIM-Enabled Learning Environment for Digital

Construction, is an Erasmus+ strategic partnership between the Department of Civil Engineering and Architecture at Tallinn University of Technology (Estonia), the Civil Engineering Unit of Tampere University (Finland) and the Department of Architecture at the University of Bologna (Italy). The BENEDICT project deals with how to teach courses at university level with BIM tools, in particular through the use of an IT platform for BIM models (Olowa et al. 2022, Ruutman et al., 2022, Witt, Kahkonen, 2019). The fundamental needs of Real Estate and Construction professionals and students, Architects, Engineers, Construction Managers, concerning Building Information Modelling involve the design, development and implementation of various building and management systems, for instance:

- Architectural systems and space coordination: i.e architectural layout and spatial units (size and coordination, proximity relationships, internal partitions),
- Structural systems: i.e foundations, poles, structural slabs and basement structures, superstructure, reinforced concrete framework, GLT and solid timber frame, CLT and prefabricated panels, floors and roof structures;
- Enclosure systems: i.e. architectural language and facades, doors and windows, architectural finishes, waterproofing, roofing;
- Mechanical /Electrical / Plumbing - MEP systems: i.e. connection systems i.e. elevators, mobile staircases,
- Construction project systems: i.e construction site provisions and equipment (e.g. scaffoldings, tower crane, formworks etc.).
- Project Construction Management systems: i.e project control methods and tools concerning project description, integration and implementation, project planning and time management, project risk management, project cost, quality and resources management.

The needs of BLE users – learners, teachers, system administrators – consist in having the availability of data, reports, pieces of information concerning architecture – engineering systems. The technical data and information concerning design, development and installation of the building and its project management allows BLE users to create the Building Information Model. For example, construction management students will need a set of case studies to be tested with practical exercises and the Open Learning Resources will be supplied as actual case studies - each case study consisting of a building or facility that has been designed and engineered in industry or in previous courses. Learning experiences using these will greatly enhance BIM-enabled learning where BIM-based workflows will provide immersive learning and training opportunities. BIM – enabled learning can use a virtual platform, a web site and repository, where all BIM models, examples and data can be stored and used. This creates a BIM enabled Learning Environment, BLE. The BLE provides the learning environment or web platform specifically designed to support this type of learning. Key resources for the use of the BLE are Open Learning Resources.

2. OPEN LEARNING RESOURCES AND VIRTUAL DATA ENVIRONMENTS

The simulation of actual design and project management activities that takes place in teaching AEC modules with BIM as a media has the need of a common data environment. A Common Data Environment CDE is a single source of information for any given project, used to collect, manage, and disseminate all relevant approved project documents for multidisciplinary teams in a managed process (BS EN ISO 19650). A CDE has four different environments where models and data can be stored: the work in progress area, the shared area, the published area and the archive. With the aim of creating a virtual environment for learning and teaching activities two different virtual environment were developed, the BLE platform and the OLR repository. The OLR repository is not a CDE because does not fulfill the requirements of ISO 19650, but was developed with the aim of storing BIM models and data. The BLE platform and repository create a virtual environment where teachers, learners and system administrators can store data, reports, pieces of information concerning architecture and engineering systems of the built object under design. All of these technical data and information concerning the different stages of production of a building, design, i.e. concept design, space coordination and technical design, construction and installation, operation and maintenance allows user to create the Building Information Model. Construction Management students, as an example, will need to use a set of case studies to be tested with practical exercises.

Open Learning Resources (OLR) or Open Educational Resources (OER) will be supplied as actual case studies – each case consisting of a building or a facility that has been designed and engineered in industry or in previous courses. The BLE, will be used to store and manage both OLR and BIM models, output of the students' work. Therefore, the BIM – Enabled learning environment will provide a virtual environment where educational activities in the AEC sector can be performed using BIM-based technology. Open Educational Resources (OER) are learning, teaching and research materials in any format and medium that reside in the public domain or are under copyright that have been released under an open license, that permit no-cost access, re-use, re-purpose, adaptation and redistribution by others (UNESCO, 2019). Open educational resources (OER) are freely accessible, openly licensed instructional materials such as text, media, and other digital assets that are useful for teaching, learning, and assessing, as well as for research purposes. The term "OER" describes publicly accessible materials and resources for any user to use, re-mix, improve, and redistribute under some licenses. These are designed to reduce accessibility barriers by implementing best practices in teaching and to be adapted for local unique contexts. The BENEDICT project has the aim of promoting a new concept of learning/training in the REC sector. The Open Learning Resources are essential for users to benefit from the BLE as they provide real (or near-real) project data for learners to work with and this will demonstrate the practical implementation of BIM workflows. The BIM-enabled learning environment creates a repository of OLR that can be descriptions of projects, technical BIM models, and project plans (table 1).

Table 1: Type of Open Learning Resources.

OLR	Examples	File format
Descriptions of projects	project objectives; site description and analysis; media concerning the site; building overall concept description; statement of work (SOW); building systems reports, drawings and calculation	.docx; .xlsx; .pdf; .dwg; dxf; xml; mp4; JPG; (…)
Technical BIM models	BIM objects; BIM model	.ifc
Project Plans	architecture and envelope layout; structure layout; MEP systems layout, construction process. bills of quantities; budgets; schedules; resource estimation, procurement documentation concerning materials, products, components and other supplies; safety plans	docx; .xlsx; .pdf; .dwg; dxf; xml; mp4; JPG; (…)

Open learning resources for BLE need to be checked before model processing. BIM models should be checked also concerning the achievement of the desired level of detail / level of development (LOD) and quality assessment consisting in code checking and model checking. The purpose of defining the level of information need is to prevent delivery of too much or too little information (ISO 19650-1:2018). In particular, the project information requirements (PIR), in relation to the delivery of an asset indicate for what, when, how and for whom information is to be produced. The Level of Information Need (LOIN) has to be set by applying the BS EN 17412-1 that indicates the framework to set the LOIN. Firstly, four pre-requirements addressing the context needed to identify the information content have to be set: BIM uses, milestone, actors, object. After this stage, the level of information need must be set concerning geometrical information, alphanumerical information, and documentation (BS EN17412-1:2020) (figure 1, figure 2). In the specific case of construction management – oriented applications, Open Learning Resources will be supplied to students and applicants as actual case studies. Each case study consists in one or more than one building or civil engineering facility that has been designed and engineered in previous courses of the university programme, or provided by teachers or by the BENEDICT project associated partners. As an example, the following documentation / information can be produced by the students of construction engineering and management courses with Building Information Modeling.

- Project Planning, job site design & safety planning;
- Work Breakdown Structure;

- Construction project schedule;
- Construction site design;
- 4D BIM animation.

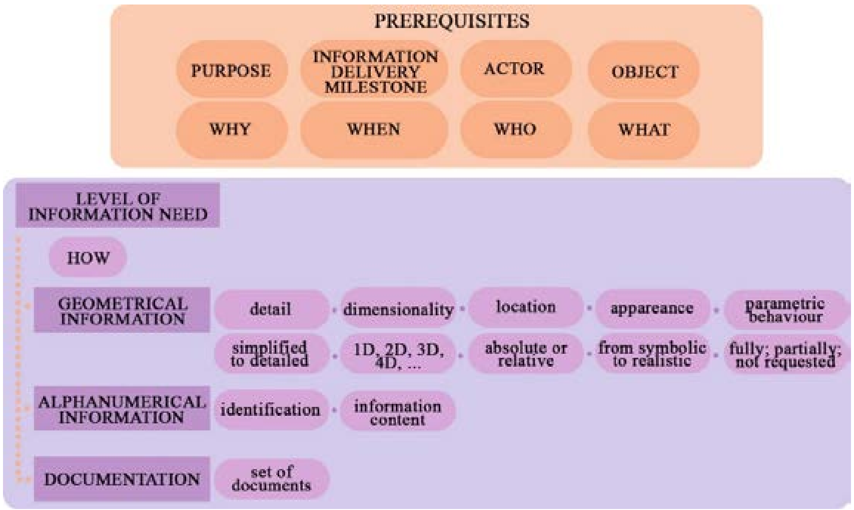

Fig. 1: Relationship diagram on level of information need.

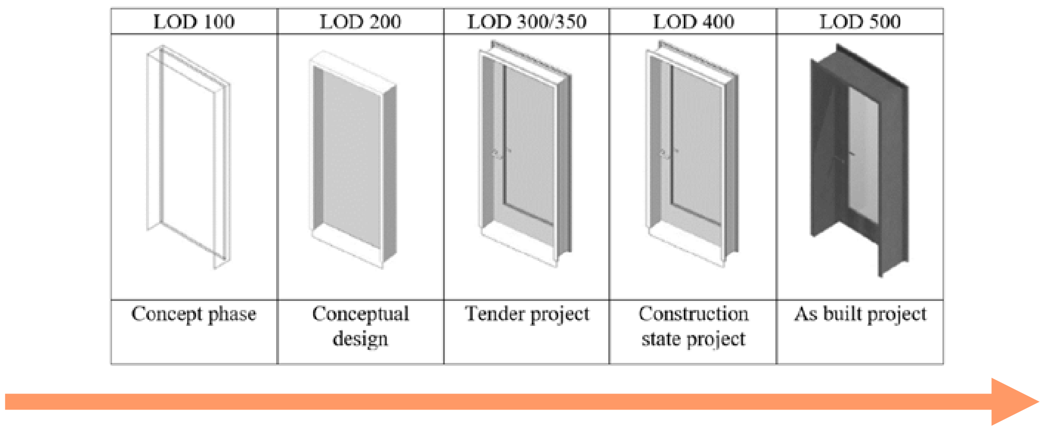

Fig. 2: Example of the concept of "continuum" associated to the detail of a door.

3. BIM ENABLED LEARNING ENVIRONMENT AND OLR CATEGORIZATION

The BLE (BIM enabled learning environment) virtual environment has the task of integrating BIM strategy and technologies into curricular activities, i.e. course modules. The BLE environment consists of the BLE Platform, that hosts pilot modules OLR and a repository that includes a Content Management System and a server that hosts BIM models and other OLR (fig. 3). The pilot modules section addresses the different pilot modules of the BENEDICT project: integrated design module, risk management module and time management module (fig 4). The repository includes a Content Management System CMS and a Data base DB for storage of OLR and students'outputs, (fig. 5). Both sections can be used by different actors, with different navigation capacities, depending on the type of user, teacher, learner, and system administrator (fig. 3).

The navigation capacity is of capital importance as depends on data and BIM object categorization. BIM models can be classified as types of models and model elements. All models are composed of model elements that have properties and attributes. Each native BIM authoring tool, as well as IFC, uses its own unique terminology to describe these components. It is therefore important to first understand what is considered an element and how elements relate to one another in order to discuss them.

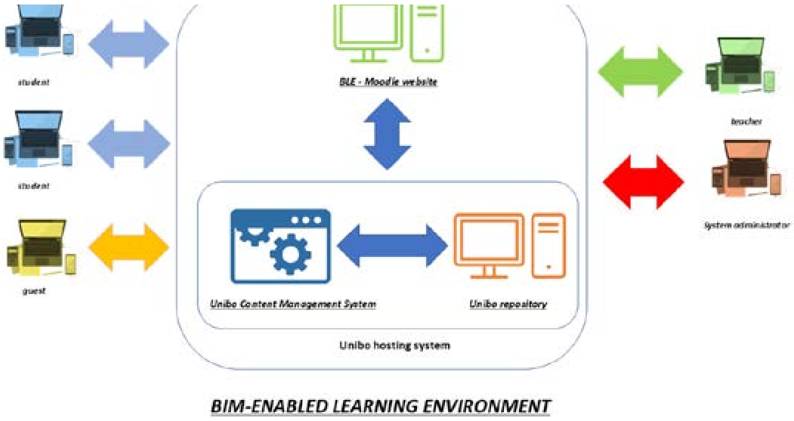

Fig. 3: BIM-enabled Learning Environment (BLE) – system architecture.

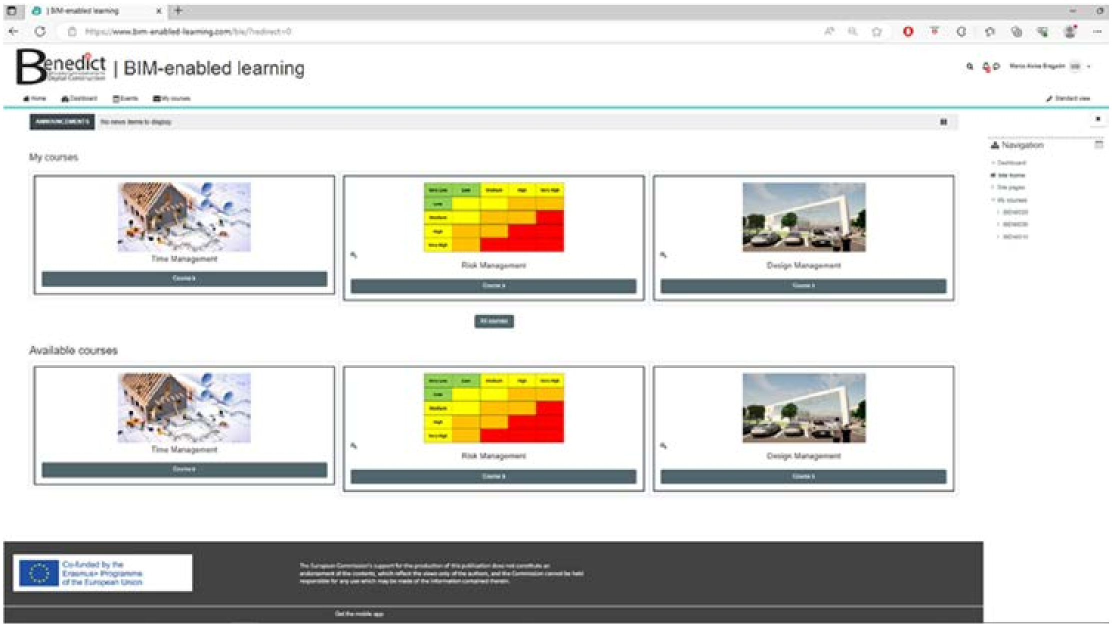

Fig. 4: BIM-enabled Learning Environment (BLE) – BLE platform.

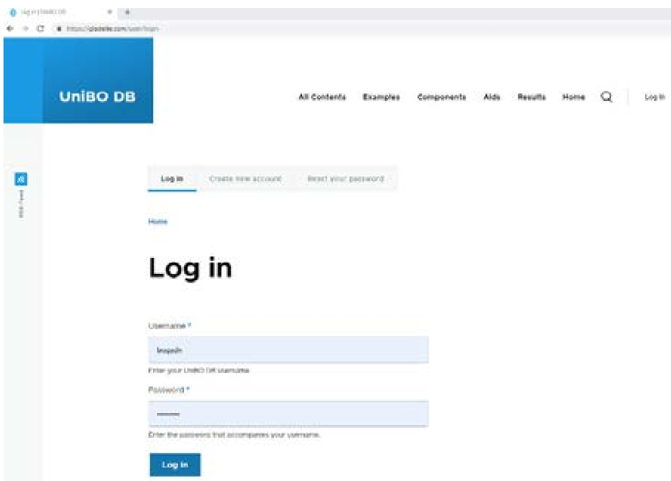

Fig. 5: BIM-enabled Learning Environment (BLE) – OLR repository.

Due to the complexity of buildings and BIMs, a simple hierarchy does not suffice to describe the relationship between model elements (US GSA BIM Guide 07). A sophisticated ontology is required to develop an understanding of how model elements may relate to one another. All the levels in the model ontology have properties associated with them, and thus the properties of one model element are associated with related model elements. A BIM ontology is an informal, semi-structured, conceptual domain ontology used for knowledge acquisition and communication between people.

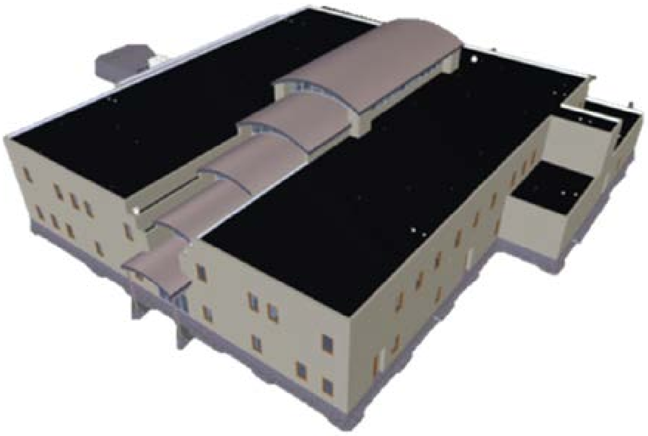

Fig. 6: Federated Model (from US GSA BIM guide 07).

A federated building information model is an assembly of distinct discipline models to create a single, complete model of the building. A federated model is a model composed of multiple linked models that contains architectural, structural, and mechanical, electrical, and plumbing (MEP) information of a building (US GSA BIM guide 07). Federation is the creation of a composite information model from separate information containers (ISO 19650 -1). A stand-alone model is a single discipline model, an information model that is a set of structured and unstructured information containers (ISO 19650 -1). The Association of General Contractor of America, AGC, in the AGC Consensus Docs 301- BIM Addendum (AGC, 2015) defines a federated model as a model consisting of linked but distinct component models, drawings derived from the models, texts, and other data sources that do not lose their identity or integrity by being so linked, so that a change to one component model in a federated model does not create a change in another component model in that federated model. A single federated model is useful for design co-ordination, clash avoidance and clash detection, approvals processes, design development, estimating and so on, but the individual models do not interact, they have clear authorship and remain separate. This means that the liabilities of the originators of the separate models are not changed by their incorporation into the federated model (fig. 6, fig. 7).

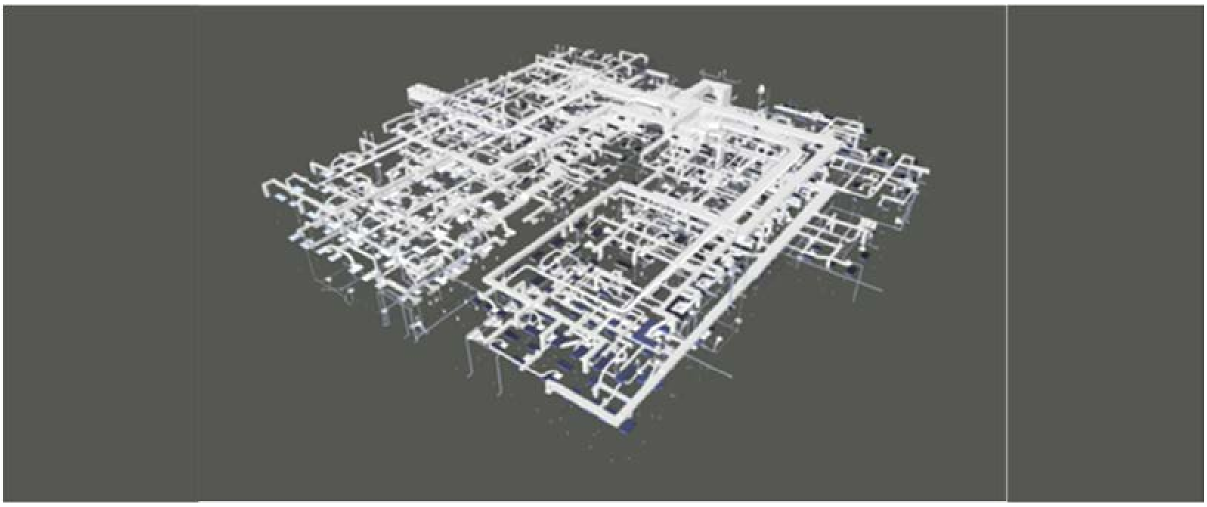

Fig. 7: Single discipline model- stand alone MEP Model of the Building (from US GSA BIM guide 07)

Categorization is of capital importance to achieve effective information management. Classification can be defined as: 'The act or process of dividing things into groups according to their type. Uniclass is based on the general structure described in ISO 12006, which promoted the use of classification classes, each of which relates to a classification need. As well as products (or objects), some of the other classes suggested by ISO 12006 are:

- Entity e.g. a building, a bridge, a tunnel;
- Complex (a group of entities) e.g. airports, hospitals, universities, power stations;
- Space e.g. office, canteen, parking area, operating theatre;
- Product e.g. boiler, door, drain pipe;
- Facilities, this combines the space with an activity which can be carried out there, for example, an operating theatre;
- Other classes can be added, such as 'system', which works very well in an MEP environment. Similarly, an 'activities' class would be very helpful for defining a range of activities which might be able to be done within a particular space, as an alternative to using the 'facilities' class.

The organization of information about construction works is of capital importance for Building Information Modelling, therefore a framework for classification is proposed by ISO 12006 standard as showed in the following tables (table 2). Information are relevant to particular stages in a building construction project, therefore, life cycle stages should be defined on a common basis. Building life cycle stages proposed by ISO standards are the following: inception; brief; design; production; maintenance and demolition. These principal stages are further decomposed to provide a meaningful set of stages for exchange requirements.

Table 2: Standard principal and decomposed life cycle stages (ISO 12006-2:2015).

Life cycle stage	**Principal life cycle stage**	**Decomposed life cycle stage**
Pre-life cycle stages	Inception	Portfolio requrements
	Brief	Conception of need
		Outline feasibility
		Substantive feasibility
Pre-construction stages	Design	Outline conceptual design
		Full conceptual design
		Coordinated design and procurement
Construction stages	Production	Production information
		Construction
Post-construction stages	Maintenance	Operation and maintenance
	Demolition	Disposal

Different classes of information are proposed by ISO 12006 standard, related to resources, as construction information, products, agents and aids; or relatated to process as management and construction process; related to result as construction complex, entity, built space, element and work result; or related to property (table 3).

Table 3: Framework for classes of information about construction works (ISO 12006-2:2015).

Class	**Classified by**
Classes related to resource	
Construction information	Content
Construction product	Function or form or material or any combination of these
Construction agent	Discipline or role or any combination of these
Construction aid	Function or form or material or any combination of these
Classes related to process	
Management	Management activity
Construction Process	Construction activity or construction process life cycle stage or any combination of these
Classes related to result	
Construction complex	Form or function or user activity or any combination of these
Construction entity	Form or function or user activity or any combination of these
Built space	Form or function or user activity or any combination of these
Construction element	Form or function or user activity or any combination of these
Work result	Form or function or user activity or any combination of these
Classes related to property	
Construction property	Property type

The framework for classification of ISO 12006 about construction works also introduces a set of different relationships between the different classes of information. The organization model or user activity of the built asset uses the built space that is defined by a construction result, that is part of a construction complex. A construction complex is an aggregate of construction entities, composed by construction elements. A construction results is developed by a construction process that is divided in pre-design, design, production and maintenance processes. Construction process uses construction resources that can be construction product, construction aid, construction agent and construction information (ISO 12006-2:2015). Classifying data means structuring it in an agreed way so that different actors can easily find what they need and understand it. A classification system is like a common language. In BIM, classification lets people, software and machines share and use building information efficiently and accurately. Different classification systems have been developed for different types of BIM data and actors, and for different geographic areas and situations. In table 4 some other examples of BIM classification are presented.

Table 5: Metadata of BIM education Models.

Information Category	**Value Type**	**Values**	**Description**
Model Language	Text	English, Finnish, Estonian, Italian	The language(s) used in the model to describe the content
Building Type	Text	Office, Teaching, Care, Residential	Property used to describe the dominant function/use case for the facility
Discipline	Text	Urban, Architecture, Landscape, Interior Design, Structural Engineering, Building Services Engineering (HVAC and MEP), Construction Engineering, Facility Maintenance	The model discipline prepared by or for the purpose of the given discipline.
Program	Text	Small, Medium, Large	Reflecting on the size of the building, relative to its building type.
Model Categorization	Text	Mass, Room/Space/Zone, and Element models	The type of model content
Life-Cycle Stage	Text	Strategic Planning, Brief, Programming, Schematic Design, Preliminary Design, Design Development, Detailed Design, Pre-Construction, Construction, Commissioning, Hand-Over, Use, Renovation, Disassembly, Demolition	The stage of the model prepares in or for
Model Use	Text	Gather, Generate, Analyze, Communicate, Realize	Penn state classification for BIM uses
Model Maturity	Text	Initial, Defined, Managed, Integrated, Optimized	The mature of the model in any specific stage.
Geometry Maturity	Text	Symbolic, Generic, Detailed, Fabrication	Average accuracy of geometry in the model.
Model Information Reliability	Text	Preliminary, Proposed, Coordinated, As-Built	The state of the information in the model, its reliability with respect to itself and others in the process
Content Classification	Text	CCI, Uniclass, Masterformat	

As a first approach the following classification systems for Open learning resources OLR were proposed for the BLE platform: metadata, building type, size of the project, different plans, life cycle period, model categories, model functions, language/country. Metadata classification was chosen as the easiest way of OLR categorization. Many metadata of BIM models can be detected, and different categories of information can be listed in the repository for each piece of OLR. Again, a list of metadata of BIM education models is presented in table 5.

The BIM-enabled learning environment is a prototype for online BIM models repository (fig. 5; fig.8). The proposed categorization system of BIM models is based upon five categories: discipline, type of building project, life cycle stage, model use and BIM dimension (fig. 9).

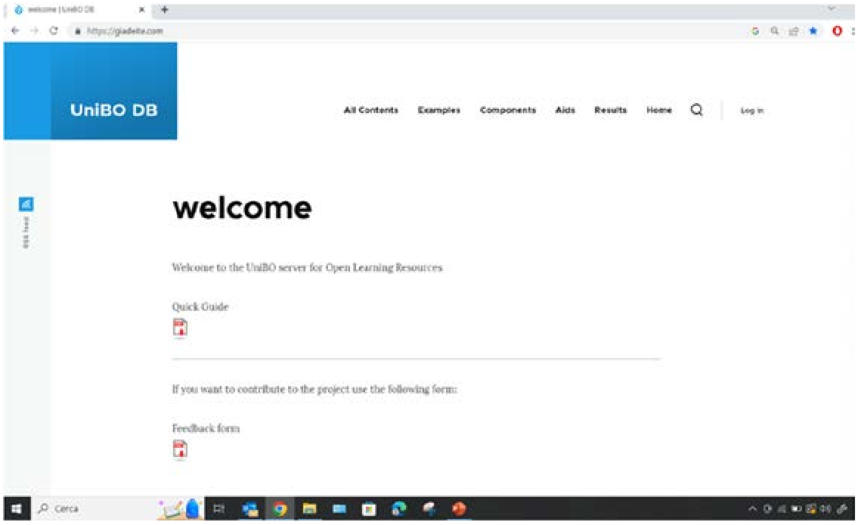

Fig. 8: BENEDICT DB – Unibo server and project data repository.

A prototype for Unibo server that host the CMS and the OLR database was developed for the proposed online BIM models repository of the BENEDICT project (http://ble.unibo.it). In the welcome page (fig. 8) it is possible to download a guideline to help end users better use the platform . From the home page, end users also could access several sub-pages including “Examples”, fully solved BIM solutions that students can use as examples, “Components” or BIM objects, “Aid” including BIM documentation, standards, project data, and “Results” where students’ outputs are stored. The repository also provides a powerful searching engine to help quickly find useful information from the repository.

4. CONCLUSIONS

In conclusion, Building Information Modelling (BIM) has become increasingly important in the field of Architecture Engineering and Construction (AEC), particularly for construction simulation and project construction management. The availability of data, reports, and information is crucial for students, teachers, and operators in the AEC industry to create BIM models. The BENEDICT project, a European Erasmus plus KA2 project, aims to develop a web-based platform for BIM teaching that is closely connected to the AEC industry. This platform, known as the BIM-enabled Learning Environment (BLE), provides a repository for BIM models, open learning resources (OLR), and students' outputs that includes a Content Manaagment System CMS and a Data Base. The CMS and the DB are freely accessible to registered users that can access OLR are essential for BIM-enabled learning processes and provide real-life project data for learners to work with. The BLE platform categorizes BIM models and elements, allowing for effective information management and knowledge transfer between different players in the AEC industry. By incorporating OLR and BIM workflows, the BLE platform enhances learning experiences and supports the implementation of BIM-based project planning and control. Ultimately, the BENEDICT project and the BLE platform contribute to bridging the productivity gap in the construction industry by promoting the use of BIM and providing a collaborative learning environment for students and future practitioners.

ABSTRACT: *In recent years, technology has been playing a transformative role in the field of built environment, architecture, and construction education. It can be argued that the emergence of digital technologies has revolutionised the approach to teaching and learning in higher education in these fields. Digital technologies, such as Artificial intelligence (AI), additive manufacturing, robotics, 3D laser scanners, and Immersive Realities (IR), have played a crucial role in enhancing sustainability and efficiency in the industry. However, the opportunities provided by the use of these technologies (as a single tool or combined) in higher education and within the field of Architecture, Engineering, and Construction (AEC) are still relatively unexplored. To address this gap, this work presents a novel pedagogical framework aimed to enhance students' literacy on emerging technologies, and increase their criticality, and understanding of professional practices along with the related ethical challenges. Furthermore, to assess its effectiveness regarding the integration of immersive VR technologies in the teaching practice, a learner-centred evaluation approach is proposed, based on the collection and correlation of both qualitative and quantitative data. Concerning the former, a dedicated questionnaire is developed to collect students' subjective feedback. For the latter, a method for tracking their use of space in the virtual environment is discussed. Both the immersive pedagogical framework and evaluation approach presented in this work will be implemented in diverse architecture and civil engineering master classes in Australia and in Italy, and their comparative outcomes and validation will be the object of future joint contributions.*

KEYWORDS: *Digital and Immersive Pedagogy; Digital Technology; Architectural Higher Education; Immersive Reality, Evaluation, Questionnaire, Spatial tracking.*

1. INTRODUCTION

Over the past decades, there has been a rapid growth in urbanisation and development of urban areas across the world. This has resulted in a considerable increase in the demand for new buildings, structures and infrastructures, which, in turn, brings along a number of environmental, social and economic challenges. The nature of such challenges has become increasingly complex, so much so, that the traditional and conventional methods of construction cannot address them. Emerging technologies and digital tools have been increasingly applied in this field to address such challenges and achieve a more sustainable, safe, efficient and optimized practice (Alsafouri & Ayer, 2018; Alsafouri & Ayer, 2019; Ardito et al., 2019; Davila Delgado, Oyedele, Beach, et al., 2020; Davila Delgado, Oyedele, Demian, et al., 2020; Fazel & Izadi, 2018; Hajirasouli & Banihashemi, 2022; Hajirasouli et al., 2022; Hamzeh et al., 2019; Mandolla et al., 2019; Moon et al., 2015; Nåfors et al., 2020; Rohani et al., 2014; Valero et al., 2015). Among such technologies, Immersive Realities (IR) such as Virtual Reality (VR) and Augmented Reality (AR) have proven to be very advantageous in various areas of built environment. When considering architecture discipline and the required spatial qualities, capabilities and understanding required for it, VR seems to be a more appropriate tool to incorporate in its pedagogy, with multiple advantages (Getuli et al., 2020; Hajirasouli & Banihashemi, 2022; Hajirasouli et al., 2022; Rahimian et al., 2019). Despite the emphasis that have been made by a number of studies and scholars regarding the development of digitally enhanced and technology-integrated teaching methods (Aydin & Aktaş, 2020; Bashabsheh et al., 2019; Ceylan, 2021; Hajirasouli

Referee List (DOI: 10.36253/fup_referee_list)

& Banihashemi, 2022; Shirazi & Behzadan, 2015), a number of studies conducted by authors have identified that the current teaching and learning practices in the AEC higher education does not adequately embrace and incorporate such digitally enhanced methods and, therefore, are yet to respond to the industry's demand in this area (Getuli et al., 2020; Hajirasouli & Banihashemi, 2022; Hajirasouli et al., 2022; Pour Rahimian et al., 2019). More importantly, when developing such pedagogies, how would this affect students' perception of their education and impact their teaching and learning experience.

This study aims to provide an in-depth understanding of student's needs and requirements and, more importantly, their perception of the integration of new technologies in their courses and curriculum. For this purpose, in Section 2, a theoretical framework was developed to establish a novel immersive pedagogy. Building on the constructivist assumption of active learning for a digitally enabled pedagogy, a problem-based learning process fostered by immersive technologies is conceptualized. Furthermore, to assess the framework's effectiveness, an original mixed method for the evaluation of VR-based teaching experiences for AEC students is discussed in Section 3. This comprises a dedicated questionnaire to be administered to the students after the immersive learning experiences to collect their subjective perceptions and feedback. Complementarily, the tracking of their virtual position and its restitution in the form of contextualized heatmaps is proposed to objectively evaluate their use of the virtual environment in relation to the learning objectives. In Section 4, the implementation plan of the proposed pedagogical framework and evaluation method is then presented with reference to the architecture and civil engineering master classes which will be involved both in Australia (Western Sydney University) and Italy (University of Florence). Eventually, the discussion of the limitations and outlook of this study is provided in Section 5.

2. PEDAGOGICAL FRAMEWORK

To develop the proposed theoretical model a critical literature review was conducted, including the relevant works related to previously developed models in this area. From their analysis, constructivism philosophy emerges as the most appropriate teaching philosophy to be adapted to this framework, due to the constructive nature of immersive technologies and their implementation in teaching and learning activities. In fact, constructivism philosophy is correlated with creating and constructing new knowledge based on the learner's already existing knowledge, therefore implying an active and continuous participation in the process of learning (Behzadan et al., 2015; Behzadan et al., 2011; Biggs & Tang, 2007; Bruning et al., 1999; Lord, 1999; Luo & Mojica Cabico, 2018; Tynjälä, 1999; Von Glasersfeld, 1995). Hence, the constructivist approach was used as the principal philosophy for the developed model.

Choosing the right approach for implementing this model was the next step of this work. It is suggested that the concept of digital pedagogy does not only reflect upon using digital tools and technologies, rather, it is also about cautiously considering their effects and implications from a critical pedagogical point of view. Therefore, the decision about their integration within the teaching approach or not, depends on the desired learning outcome of a course or subject (Anderson, 2020; Barber et al., 2015; Croxall, 2013; James & Pollard, 2011). Problem-based learning approach was also used in this model as an integral part of the application and integration of immersive technologies. The selection of this approach was also due to its suitability for complex real-world situations where there is no right or wrong answer to the problem (Barber et al., 2015; Savin-Baden, 2007; Word, 2003), which is the main focus of AEC discipline and industry. This approach helps students to work collaboratively in groups, to identify the problems and gaps, and to develop solutions and knowledge, through self-directed processes (Barber et al., 2015; Savin-Baden, 2007; Word, 2003).

Eventually, immersive learning was also used as the last stage of this model. Using this method, the creation and construction of knowledge occurs through virtual immersion into a context, dialogue and/or situation. Immersion occurs in two different ways: immersion through narrative (cognitive aspects), and immersion through technological devices (technical aspects). This study focuses on immersion through technical devices, hence requires various tools and technologies, such as AR, VR, and Virtual Learning Environment (VLE). The choice of tools and technologies in this model depends upon the level of immersion required for a learning objective. VR, which is the subject of this study, is mainly being used when a fully immersive experience and a sense of presence in the virtual environment is required for the learning process.

3. IMMERSIVE VR LEARNING EXPERIENCE EVALUATION

The proposed pedagogical approach theorises the beneficial impact that the adoption of immersive visualization technologies can provide in AEC master classes. To support this claim and assess its effectiveness in upcoming case study implementations (see Section 4), an original method for the evaluation of immersive VR learning experiences is developed, considering both qualitative subjective data and quantitative objective observations. As shown in Figure 2, a questionnaire to be administered to the student after the immersive experience and divided into five inquiry areas is provided. Besides, the student's use and understanding of the virtual environment in relation to the learning objectives is evaluated with the acquisition of their spatial track during the VR experience and its sequential visualization of a BIM environment in the form of a heatmap.

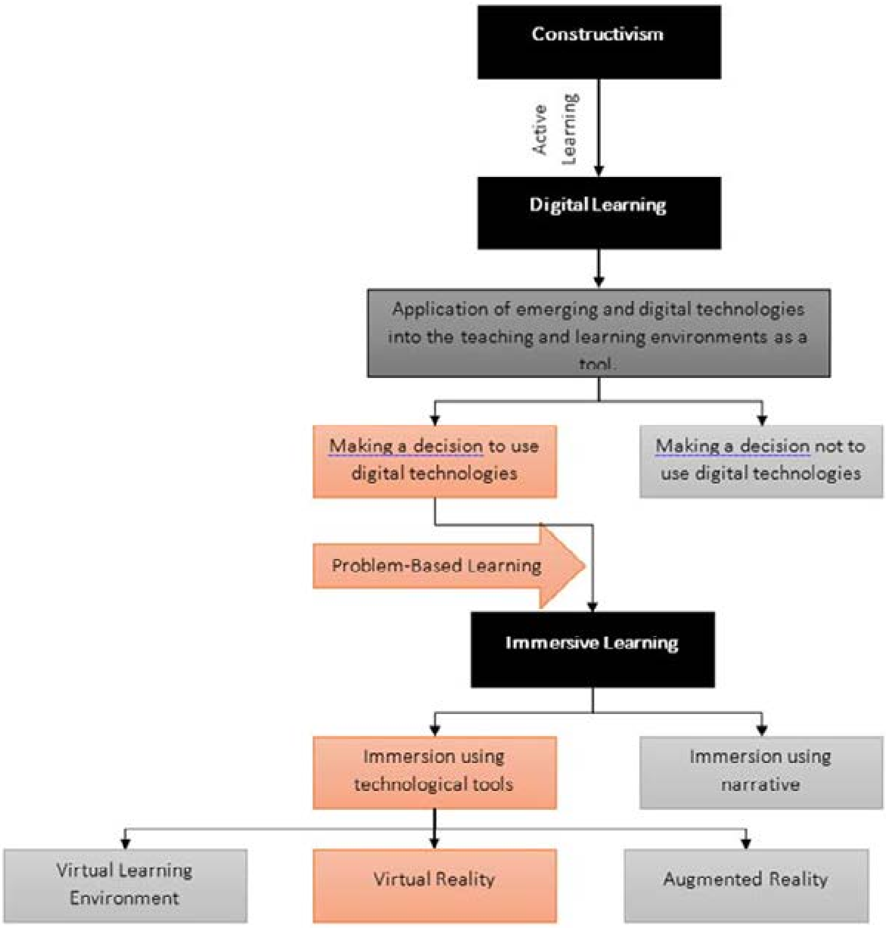

Fig. 1: Pedagogical framework designed for BIM-enabled VR-based technology application into architectural design studio.

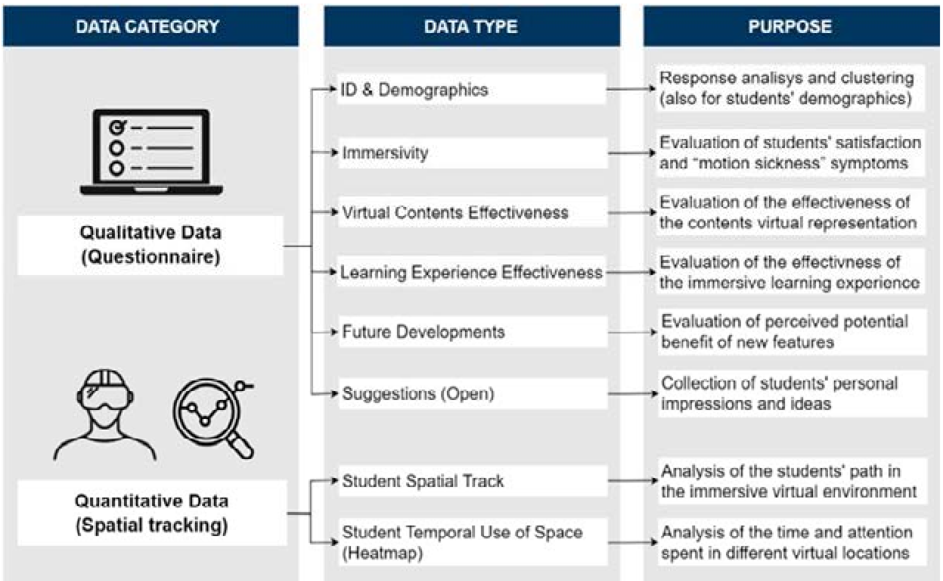

Fig. 2: Immersive VR learning experience evaluation approach – Data schema.

3.1 Post-experience evaluation questionnaire

To collect students' subjective feedback, a dedicated questionnaire has been developed to be administered directly after the immersive learning experience. First, data necessary to classify, analyse and classify the questionnaire responses based on students' demographics are collected. Then the experience is evaluated against the student's perceptions, concerning: the engagement with the virtual environment (*immersivity*); the reproduction of the virtual contents (*contents effectiveness*, e.g., graphical realism compared to the objective of the session); the gained self-efficacy and competency (*learning experience effectiveness*); the opinion on suggested additional features that could be implemented in the experience and that were currently missing (future developments). For the cited criteria the responses are collected according to a scoring system ranging from one to five, where five correspond to the maximum agreement with the statement or satisfaction with the experience. Furthermore, an open textual field (*suggestions*) is provided to enable the collection of personal remarks, impressions, and ideas, involving and empowering the student in the improvement and evolution of a learning approach based on ever-changing technologies and that will need to keep up to learners' expectations and needs to be future proof. In Table 1 the data type and the description and purpose of data collection are reported along with explanatory examples.

Table 1: Questionnaire data type description and prompt example

Data type	Description	Example
ID & demographics	Data necessary to analyse and classify the responses collected through the questionnaires with reference to the occurred immersive learning experiences, and to cluster their results also with reference to the students' demographics (anonymized). [Various]	Questionnaire ID: (Text) Immersive experience: (Text) Date: (yyyy/mm/dd) Age: (Number) Gender: (Multiple options) Course: (Text)
Immersivity	Questions related to the student's ability to get immersed in the virtual experience. They are useful for assessing how engaged the students were in the virtual world and to evaluate their satisfaction in terms of both ease of use and comfort (also related to the possible onset of symptoms of "motion sickness"). [Single rating – Likert scale]	How much did you like the experience? [min 1; max 5]
Contents effectiveness	Questions regarding the virtual representation of the learning contents, aimed at evaluating the effectiveness of the experience against the objectives of the session. [Single rating – Likert scale]	How efficiently and clearly does the content of VR help you to perceive the discussed subject better? [min 1; max 5]
Learning experience effectiveness	Questions pertaining to the overall effectiveness of the experience, aimed at investigating the actual usefulness of the immersive VR learning session compared to traditional methods, especially concerning the learning objectives. [Single rating – Likert scale]	Do you think this experience is useful in understanding the qualities of the designed spaces? [min 1; max 5]
Future developments	Questions concerning the introduction of new features (e.g., content animations, audio and visual effects, etc.) or virtual content aimed at enhancing the immersive VR learning experience through the inclusion of greater realism and/or interactivity. [Single rating – Likert scale]	Would you like to be able to grasp and interact with objects in the VR environment? [min 1; max 5]
Suggestions	Open questions to collect personal impressions and ideas from the students. [Text box]	Suggestions

3.2 Student's spatial tracking and use of space visualization

In the previous paragraph, it has been discussed how the students are actively involved in providing data for a qualitative evaluation. Here, the second, complimentary, data acquisition method is presented which is based on the objective observation of the virtual positions covered by the students throughout the experience. In turn, this involves capturing the position of the student in the VR environment during the entire course of the simulation in order to analyse their actual use of the tridimensional space. For this purpose, the student's virtual position shall be recorded with a data acquisition rate of at least 1 Hz. The 3D point sequence resulting from this process shall be transferred in a BIM environment and converted for the generation of heatmap visualization, within which the position of the student is represented, weighted by the time spent, with a colour gradient. In this way, the relevance of different areas of the experience can be evaluated based on the time spent in certain virtual locations by the students. As with the questionnaire's development, the student spatial tracking and visualization procedure to be performed during the learning experience is explained with reference to the collected data type in Table 2.

Table 2: Student's spatial tracking and use of space visualization characteristics

Data type	Description	Example
ID & demographics	See Table 1.	See Table 1.
Learning experience duration	The duration of the experience from start to finish, excluding a possible tutorial or time required to the student to get used with the immersive VR system and controllers. This is necessary to allow for the later heatmap visualization of the student use of the virtual space weighted on the overall elapsed time. [time in seconds]	Duration: (number) sec
Student spatio-temporal track	The student position in the virtual environment is collected as 3D point with 1 Hz frequency. The corresponding spatial track is then graphically represented against a model of the experienced environment (e.g., BIM model) both as a 3D path (polyline) and with an heatmap representation, with the colour gradient weighted on the time spent in a certain location.	Colour gradient representation of the student's followed path (weighted by time) [min. green, max. purple]

4. FRAMEWORK IMPLEMENTATION PLAN

The theoretical approach of this paper is built upon previous research projects, undertaken by authors in Australia and Italy, to create an innovative approach and prototype protocol for the design, delivery and evaluation of a number of subjects for AEC students in higher education, based on an interactive and immersive learner-centred approach. The outcome of this work will be implemented in a number of course subjects at the University of Florence, Italy and Western Sydney University, Australia. The nominated subjects for the implementation of this model are reported in Table 3.

Table 3: Immersive VR learning approach for AEC higher education - Implementation plan

Institution	Course (Academic Year 2023/2024)	Expected attendees
Western Sydney University, Australia	• Advanced Design Communication (ARCH7007) • ARCH7015 Practice Research Studio Civic (ARCH7015)	50 50
University of Florence, Italy	• BIM and Information Modeling of the Construction Process (B028836) • Design and Safety of Workplaces B030584 (B063)	50 50

The implementation of the proposed pedagogical model will engage the students in providing indications and opinions regarding the environment in which they are exploring and studying. This approach will help with validating both the pedagogical framework, as well as, the designed environments, by gathering the user's experiences and observations. This, in turn, will assist in enhancing the entire framework developed in this study. For this purpose, and according to the principles discussed above, a prototypical questionnaire implementation comprising 16 questions has been developed and is represented in Figure 3.

In addition to the questionnaire, a prototypical implementation of the student spatial tracking restitution in form of heatmap is proposed in Figure 4. As it can be seen, the more relevant areas of the virtual environment for learning purpose could straightforwardly be inferred based on the time spent, providing useful information in the development of further immersive teaching material (e.g., virtual environments).

Student Data

ID:	
Age:	
Course:	
Gender:	

	Questionnaire	min - max
Immersivity	1) Did you enjoy the experience?	1 2 3 4 5
	2) Were you comfortable during the experience?	1 2 3 4 5
	3) Was it easy to use the viewer and controller?	1 2 3 4 5
	4) Did it bother you not being able to see your body in the virtual world?	1 2 3 4 5
Contents' Effectiveness	5) Are the signal arrows helpful in figuring out where to go?	1 2 3 4 5
	6) Does the virtual building spaces sufficiently replicate the real one?	1 2 3 4 5
	7) Did you need less time to understand the content displayed in VR compared to a face-to-face power-point presentation?	1 2 3 4 5
	8) Were your learning skills affected by the VR experience?	1 2 3 4 5
	9) Do you think this experience can replace the role of the educator?	1 2 3 4 5
	10) Do you think this experience is useful in getting to know a subject before it is explained to you by an educator ?	1 2 3 4 5
Learning Experience's Effectiveness	11) Do you think this experience is useful in understanding the building and its technological aspects?	1 2 3 4 5
	12) Is this type of learning useful for an inexperienced student?	1 2 3 4 5
	13) Is this type of learning useful for a student without any knowledge on the subject?	1 2 3 4 5
	14) Do you prefer to interact with an avatar or a teacher?	1 2 3 4 5
Future Development	15) Would you like to listen audio explanations of the virtual scenarios?	1 2 3 4 5
	16) Would you like to be able to interact with virtual objects?	1 2 3 4 5

5. CONCLUSIONS

This study, which was a successful collaboration between University of Florence and Western Sydney University aimed to provide a comprehensive understanding of student's perception and demand of the newly developed pedagogical framework. This framework aimed to create a more engaging learning environment, while responding to the industries needs and requirements, and prepare students for the future of their careers in AEC. To achieve this, this study was developed in two stages. In stage one, a qualitative approach was used to develop a novel pedagogical framework, based on the constructivism method, followed by a problem-based approach and immersive learning method. To test the effectiveness of this developed model and student's perception of it, a mixed-method approach was used to develop an in-depth questionnaire. Furthermore, a contextualized heatmap recording is accompanying the developed survey to ensure the robustness of the results of this study.

The outcome of this research will be tested internationally at the architecture and civil engineering master classes which will be involved both in Australia (Western Sydney University) and Italy (University of Florence) in early 2024. The outcome of the experiment will form another joint publication and collaboration between the two institutions.

A FRAMEWORK FOR REALISTIC VIRTUAL REPRESENTATION FOR IMMERSIVE TRAINING ENVIRONMENTS.

Caolán Plumb, Prof. Farzad Rahimian & Dr. Diptangshu Pandit.
Teesside University, UK

Dr. Hannah Thomas & Nigel Clark.
The Faraday Centre LTD, UK

ABSTRACT: *As mixed-reality (XR) technology becomes more available, virtually simulated training scenarios have shown great potential in enhancing training effectiveness. Realistic virtual representation plays a crucial role in creating immersive experiences that closely mimic real-world scenarios. With reference to previous methodological developments in the creation of information-rich digital reconstructions, this paper proposes a framework encompassing key components of the 3D scanning pipeline. While 3D scanning techniques have advanced significantly, several challenges persist in the field. These challenges include data acquisition, noise reduction, mesh and texture optimisation, and separation of components for independent interaction. These complexities necessitate the search for an optimised framework that addresses these challenges and provides practical solutions for creating realistic virtual representations in immersive training environments. The following exploration acknowledges and addresses challenges presented by the photogrammetry and laser-scanning pipeline, seeking to prepare scanned assets for real-time virtual simulation in a games-engine. This methodology employs both a camera and handheld laser-scanner for accurate data acquisition. Reality Capture is used to combine the geometric data and surface detail of the equipment. To clean the scanned asset, Blender is used for mesh retopology and reprojection of scanned textures, and attention given to correct lighting details and normal mapping, thus preparing the equipment to be interacted with by Virtual Reality (VR) users within Unreal Engine. By combining these elements, the proposed framework enables realistic representation of industrial equipment for the creation of training scenarios that closely resemble real-world contexts.*

KEYWORDS: *Digital twin; 3D reconstruction; Virtual reality; Laser scanning; Photogrammetry; Training simulation; Unreal Engine.*

1. INTRODUCTION

In recent years, the increased availability of mixed-reality (XR) technology has spurred the exploration of virtual reality training environments, which showcase their immense potential in enhancing training effectiveness across various domains(Abulrub et al., 2011). By reducing expenditure associated with travel and physical resources, safety training that has been delivered via virtual methods is predominantly more cost-effective than non-virtual alternatives, without sacrificing training effectiveness (Adami et al., 2021) (Stefan et al., 2023).

Virtual Reality (VR) can present us with realistic replications of real-world situations with a high degree of accuracy, and immersive virtualised training scenarios can significantly improve participant engagement when compared to equivalent training using conventional methods (Sacks et al., 2013). Trainees presented with a virtual environment can engage with high-risk scenarios without actual danger. The elimination of risk fosters confidence and risk-free experimentation, which has a significant positive impact upon post-training technical proficiency (White & Jung, 2022). Regarding the attitude of trainees towards professional learning content, Loosemore and Malouf (Loosemore & Malouf, 2019) suggest that there is “a need to adapt safety training to create more emotional connection” between the trainees and their learning within the construction industry, and that “New technologies such as virtual reality may be useful this context since through [life-like] immersion in the work environment and simulation of workplace accidents, they are able to create a stronger emotional connection with the subject matter.” This suggestion is supported by Newton, Wang and Lowe (Newton et al., 2015) who find that “incongruously, results indicate that user’s reporting their experience of virtual reality score that experience higher in presence terms than users experiencing the physical world,” indicating that virtual experiences may be more emotionally engaging and more impactful for trainees than real-world experiences alone. This calls us to re-examine our approach to training and education as we begin to see XR technology as an effective tool to enable trainees to connect theoretical knowledge and practical application.

The standard of these simulations is influenced by the quality of virtual representation. High-fidelity 3D illusions bridge the gap between physical and digital environments and enhance the task-oriented performance of the

trainees (Slater, 2009) and so highly-realistic virtual assets may improve the effectiveness of the virtual experience.

1.1 3D Scanning Methodologies

To elevate the authenticity and realism of virtual training, exploring 3D scanning methodologies (such as photogrammetry and laser scanning) present exciting possibilities as potential solutions for highly realistic representation within VR scenarios. By employing advanced 3D scanning technologies, we can capture with accuracy the dimensions and intricate surface details of real-world equipment and environments. After sufficient data has been captured with scanning hardware, the data will be manipulated through a pipeline of various specialized 3D modelling software to create a mesh that may be rendered by a games engine.

There are practical challenges associated with the application of 3D scanning techniques which must be addressed, such as site-access for data acquisition, followed by noise reduction and asset optimization. To conduct the training, the user will be expected to manipulate the asset, or parts of the asset, using virtual reality hardware. Therefore, not just aesthetic accuracies, but realistic interaction and functionality will also be essential. Equipment which has independently moving components will have to be separated into dynamic and static bodies to facilitate independent movement and interaction within the virtual environment.

1.2 Goals of this Article

Our effort to establish a framework that adheres to industry best practices has been in collaboration with The Faraday Centre, recognised for their expertise in electrical engineering training. Ordinarily, The Faraday Centre delivers training using out-of-service switchgear that has been refurbished or donated to the Centre, so that trainees can receive hands-on practical training with switchgear up to 33kV. A significant challenge presented by electrical engineering equipment is that there are high costs associated with the newer, higher-voltage switchgear, thus making their acquisition impractical. A virtual training environment (VTE) offers a cost-effective alternative to simulate operation of this high voltage equipment for training purposes. Our data-driven approach hopes to ensure that the virtual representations closely mirror their physical counterparts.

Therefore, we believe that establishing a framework encourages the integration of virtual technologies for industrial training scenarios. Our objective is to provide insights into the scanning methodologies, challenges faced, and available solutions in capturing the details of real-world environments, equipment, or other assets. To achieve this, this paper will review the current technology and methodologies used to emulate real-world equipment and their processes within a virtual context. Drawing inspiration from methodologies employed in data-driven digital twinning pipelines (Pan et al., 2022), both photogrammetry and laser-scanning applications are integrated within this framework and their compatibility with the development of contemporary professional training for high-risk environments is discussed. The framework proposed is capable of systematically addressing each obstacle, thereby ensuring a seamless transition from physical equipment to the creation of highly realistic virtual training environments.

This paper is organized as follows: **section 2** will look review production pipelines, methods and motives for the creation of such data-driven virtual assets. **Section 3** presents an overview of the technology required to scan a 3D object and recreate it as 3D virtual asset. **Section 4** will report the framework we have developed as a solution to the challenges presented when developing realistic VR-ready assets from high-voltage switchgear scan-data.

2. METHODS FOR REALISTIC VIRTUAL REPRESENTATION

Virtual representation encompasses the creation of digital reconstructions of real-world subjects, including those with glossy surfaces like switchgear equipment. Specular (mirror-like) reflections can challenge 3D data capture methods like laser scanning and photogrammetry, reducing the usefulness of output models (Frost et al., 2023), therefore we will review approaches designed to address issues associated with capturing accurate data.

Another challenge involves minimizing the computational power required for rendering our results in a real-time application. Two viewpoints (one for each eye) must be rendered, making VR susceptible to difficulties with framerate, which will be affected negatively by superfluous model complexity. Therefore, our review will be extended to provide an overview of various methods to clean and simplify our results.

2.1 Photogrammetry

Photogrammetry is a 3D surveying and modelling method which has the major advantage of being low-cost, portable, flexible and is capable of delivering highly detailed reconstructions. Three-dimensional information about objects or environments is obtained by analyzing a dataset of two-dimensional photographs.

Photogrammetry relies on the identification of feature points on or within the object being scanned. Areas of the subject with aspects like colour variation, surface imperfections, or details such as dust and grime must be adequately captured to be reconstructed. Significant overlap across multiple images in the dataset is crucial to ensure an ample supply of contrasting, unique points. Observed similarities across images is used to reinforce the confidence of the photogrammetry software in determining the 3D positions of each point. Available photogrammetry software options are discussed in Section 3.

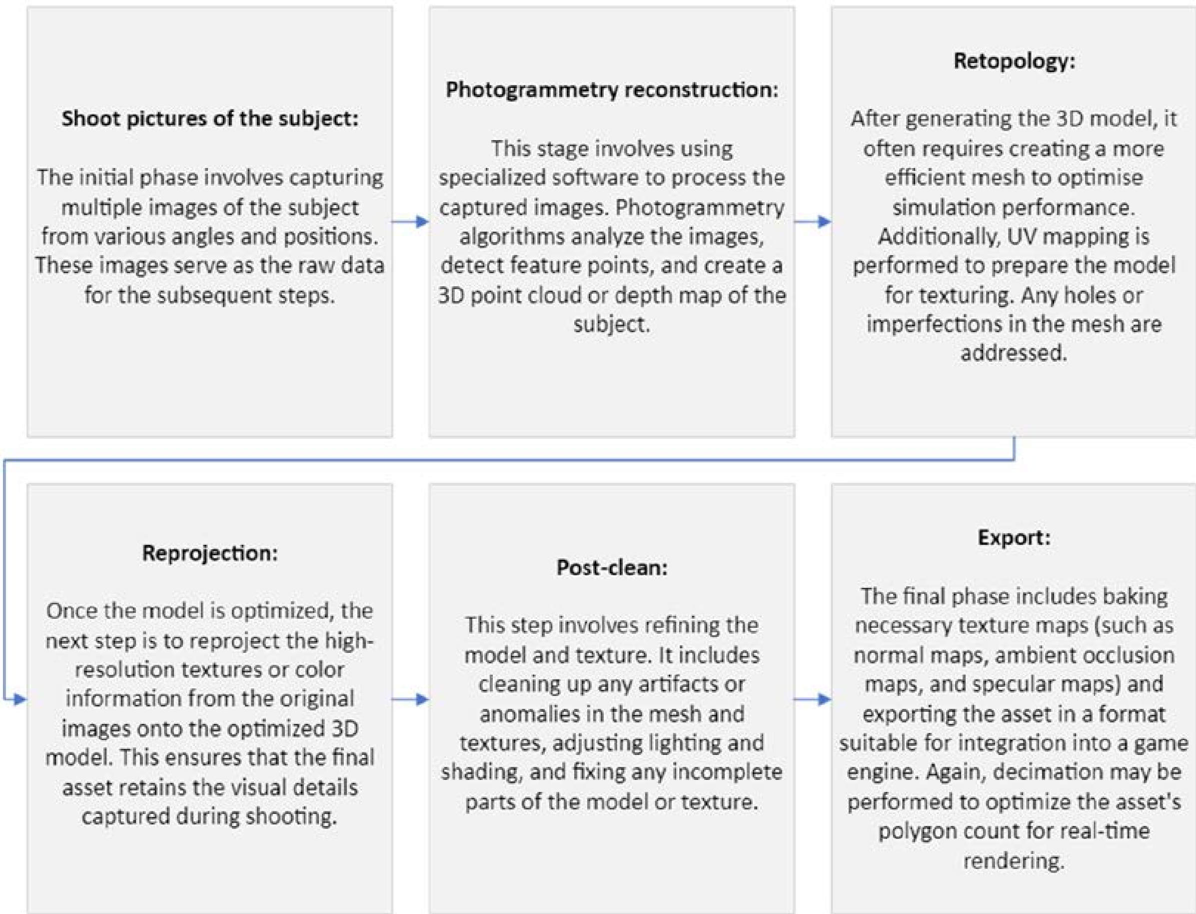

Fig. 1: A Photogrammetry process diagram showing an overview of the various stages from data capturing to a simulation-ready asset

The accuracy of camera alignment and the quality of the created asset is determined by consistency across the data obtained from the input images. In cases where the object's surface lacks distinctive features, challenges arise in achieving accurate surface reconstruction. According to Schiach, the objects best suited for automated image-based 3D reconstruction methods feature amorphous geometries, structured surfaces, numerous edges, and exhibit inhomogeneous colouring. Objects that yield poor or no results typically have monochrome, translucent, reflective, or self-resembling surfaces (Schaich & Fritsch, 2013). Dark materials, insufficient lighting, and changes in lighting can all have detrimental effects on the image quality and may prevent the photograph from registering as correctly aligned. Methods we may employ to optimise the conditions in which we capture data include strategic distribution of light sources to eliminate shadows, applying a coat of spray to make the surface more responsive to scanning, cross polarisation techniques, or by using some combination of these methods (Noya et al., 2015; Porter et al., 2016).

2.1.1 Capture methods

To capture a static object, the photographer moves around the subject, taking multiple pictures from various viewing angles. Collecting every angle may be made difficult if the object is quite large and/or positioned inconveniently for photo-scanning purposes, meaning a complete scan may be impossible without repositioning the object. For the feature detection algorithms to run correctly, the features of the input images must remain consistent. Therefore, if we wish to reposition the object, we must take the additional step of separating desirable features of our subject from undesirable inconsistencies from background visual information. Typically, this involves manually applying masks to each input image, a potentially time-consuming process (Farella et al., 2022), even with expediating background removal features like semantic segregation (Chen et al., 2017; Kang & An, 2021; Ronneberger et al., 2015).

Alternatively, a camera configuration with strategic lighting can be set up to automate the masking process. Background interference may be avoided by ensuring the scanned object is well-lit against a dark, featureless background. This allows for the target to be rotated and repositioned in front of a camera which may remain fixed, providing sufficient captured data from various viewing angles, without the feature detection algorithms being disrupted by undesirable information. The effect of this method may be improved by strengthening the lighting of the foreground to heighten the contrast between the foreground and background. This lighting can be provided in different ways, the object may be homogenously lit with LEDs from various angles, or a piece of equipment such as a ring light may be employed; both may sufficiently eliminate shadows.

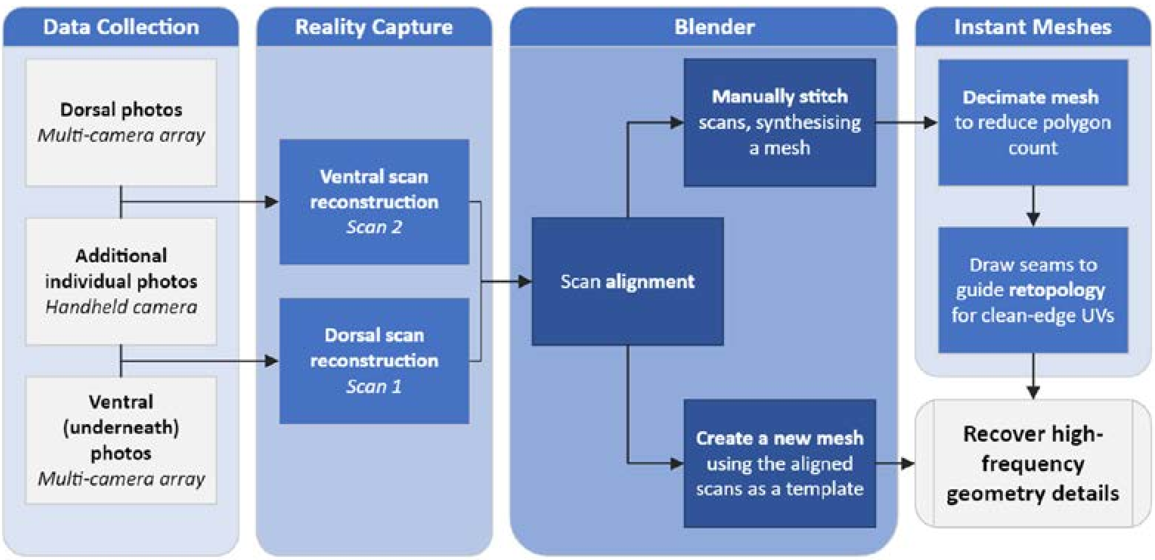

Fig 2: A flowchart describing the process used to create a clean asset from a photogrammetry reconstruction using a multi-camera array to capture a turtle (Bot et al., 2019). The software used is included. Recovering high-frequencies geometry details will be expounded upon in Section 2.3.

To capture dynamic objects, a single camera is unsuitable as it presents a high risk of capturing inconsistent data due to movement of the subject. Therefore, a multicamera array is used, which typically consists of 4 to 30 cameras on tripods or metal rods, with all of them pointing towards a central area. This "rig" of specially calibrated lights and cameras permits efficient and simultaneous data capture from various angles to ensure consistency across source images. An alternative method is the use of synchronized video with a common motion (e.g., a clapper or a ball drop in view of all cameras). Figure 2 shows the methodology employed by (Bot et al., 2019) when using a multi-camera array to scan and create and asset that captures the likeness of a turtle.

2.1.2 Cross polarisation and reflectance acquisition

VR is capable of simulating realistic lighting and accurate material properties. Reflectance acquisition techniques are used to measure an object's reflectance properties under varying lighting conditions. One such approach using polarisation techniques is outlined by figure 3, below. Numerous images are taken with different lighting conditions to sample the appearance of specular highlights under a dense sampling of lighting directions, which can be data-intensive and time-consuming, particularly when dealing with highly specular surfaces.

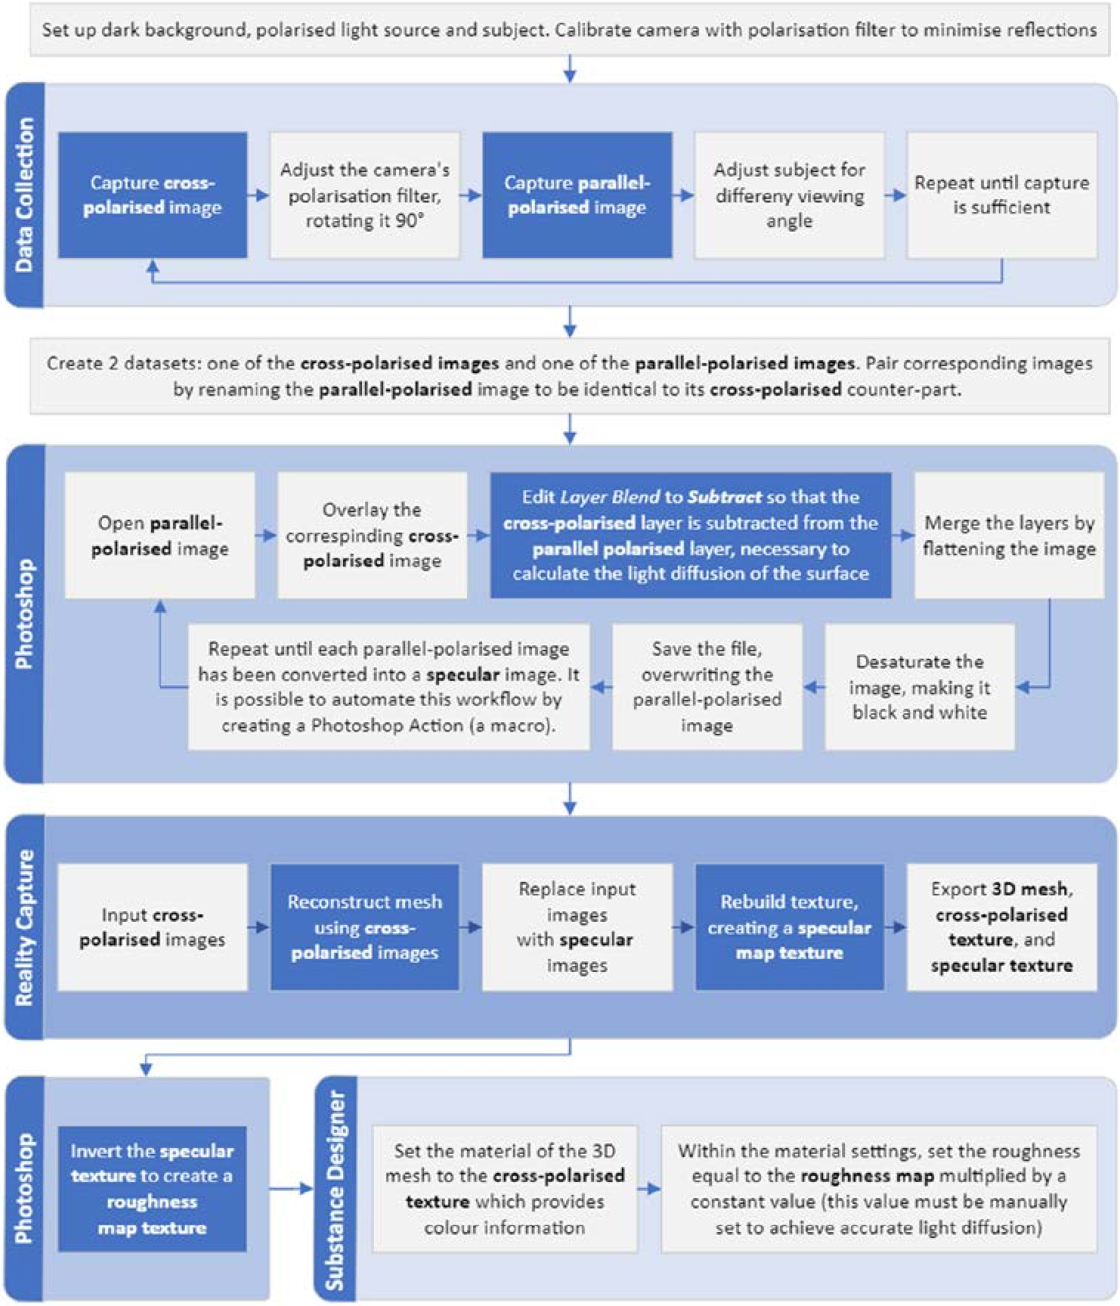

Fig. 3 A flowchart showing an overview of the data processing required to prepare what information is collected in a cross-polarisation method (Frost et al., 2023) to acquire reflective data, including the software employed.

Cross polarisation methods produce an image where most of the specular data is removed using two orthogonal polarisation filters. One filter is placed on the camera lens, and the other is a polarising film positioned in front of the light source to illuminate the target with polarised light. Cross-polarised images are highly effective for photogrammetry reconstruction as they minimise disruptions caused by reflections (Frost et al., 2023).

The polarisation filter on the camera lens can be adjusted to be parallel rather than orthogonal, thus producing a corresponding image which preserves specular information. Subtracting the cross-polarised image from the parallel-polarised image yields a specular image. Collecting specular images from multiple camera positions allows us to create a specular map by replacing the cross-polarised data with the specular data during the reconstruction process. This map represents the reflectivity of the object's surface at different locations on the mesh. However, achieving this in uncontrolled environments, where ambient lighting is beyond our control or with large equipment that requires camera movement, can be challenging and result in inconsistencies.

2.1.3 Colour correction

To ensure the accuracy of the model texture, especially for its use in a games engine for simulation, managing lighting conditions is crucial. If lighting affects the color of the captured images, a Look-Up table (LUT) can be applied to the input images to correct their colour accuracy. Software like Houdini (SideFX, 2022) or Photoshop (Adobe, 2022) can generate this LUT from an image of a colour checker taken at the site under the same lighting conditions as the photos, and then batch process the input images, correcting colour information.

Most games engines have their own lighting systems. Depending on the 3D objects being rendered, most 3D games engines simulate realistic shadows for objects in relation to in-simulation light sources. These shadows can be dynamically calculated at runtime, adjusting with user interactions or object movements. In some cases, shadows might be baked into the scene if they are not expected to change. If shadows were captured in the source photos due to non-flat lighting during image capture, they could inadvertently become part of the object's texture information. To address this, the shadow information should be removed. This can be achieved by opening the texture data from the UV maps in software like Photoshop, where adjustments can be made to minimize or eliminate the shadows. This process homogenizes and evens out the lighting affecting the texture, allowing the games engine's lighting to handle shadows appropriately.

2.2 LiDAR

In recent decades, point clouds obtained through light detection and ranging (LiDAR) have become a significant data source for various mapping applications within the photogrammetry, remote sensing, and cultural heritage communities among many others (Leberl et al., 2010) (Wang et al., 2018). There are two primary LiDAR methods to consider, laser scanning and structured light scanning. Both make use of time-of-flight (ToF) calculations, the scanner can determine the distance and create a point cloud of the object's surface. Their advantages include their noninvasive nature, high precision, and interoperate easily with supporting software.

Aerial laser scanning (ALS) and Terrestrial laser scanning (TLS) are two examples of long-range scanning methods that rely on laser beam emission. The emitted lasers can reflect off of surfaces up to 130 meters away, and can be used to scan large objects such as airplanes. The Focus3D S120 (FARO) is a laser scanner employed by (Wang et al., 2019) as described in figure 5, so this method may be fit for our purposes, however, long-range can be more expensive and may require more time for data processing.

Structured light scanners project patterns of light (such as grids or stripes) onto the surface of an object. The deformation of these patterns on the object's surface is captured by the scanner's cameras. The distortion of the patterns is then used to calculate the 3D coordinates of the object's surface points. Cui, Tao and Zhao acknowledge that the 3D light-section reconstruction method (depicted in figure 4) is a common and applicable way to obtain point cloud data for the needs of 3D reconstruction potential accurate to the millimeter. Structured light scanners are generally faster than laser scanners and are well-suited for capturing medium-sized objects with moderate to high surface details.

However, like photogrammetric methods, structured light scanners struggle with reflective, transparent, or homogenous surfaces. Their accuracy can vary based on the complexity of the object's surface; for example the performance of these scanners suffers when there is a distinct lack of points of interest on the surface, as it makes it difficult for the algorithms within the software to accurately track the lasers position frame by frame. Consequently, the scanner will “slip,” leading to inaccuracies in scanning surfaces. We may mitigate some of these issues by scanning the surface multiple times, or by introducing additional features to aid 3D registration.

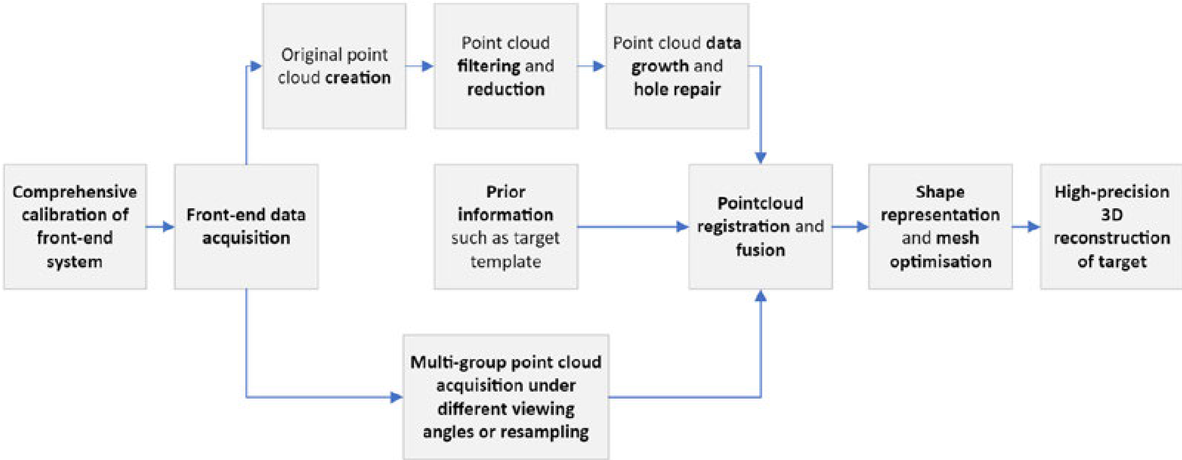

Fig. 4 A process diagram showing the light-section method for a structured light scan. (Cui et al., 2021)

2.3 Model Synthesis for Virtual Reality

To achieve realistic virtual representation, it's crucial to capture high-frequency details. However, this often results in high-polygon count 3D models generated by scanning methods, which can slow down real-time simulations, especially in virtual reality. Mesh decimation helps reduce the complexity by simplifying the mesh to a target polygon count, although some detail is lost in the process. As depicted in figure 2, in cases where the scan data has inconsistencies, further reconstruction and cleaning with 3D editing software might be necessary. Alternatively, the scan can serve as a reference for creating a new, more accurate mesh.

High-frequency detail can be restored by generating normal maps from the complex mesh, which are used to create detailed shadows and highlights. Unwrapping the mesh's topology into UVs is required to store this data as a texture file. Specialised software such as InstantMeshes as mentioned in (Bot et al., 2019) or similarly specific tools like those of Houdini (SideFX, 2022) called Sidefx Labs which contains the AutoUV as used in (Triantafyllou et al., 2022). After retopologising the mesh, any available texture information can be reprojected. If the captured

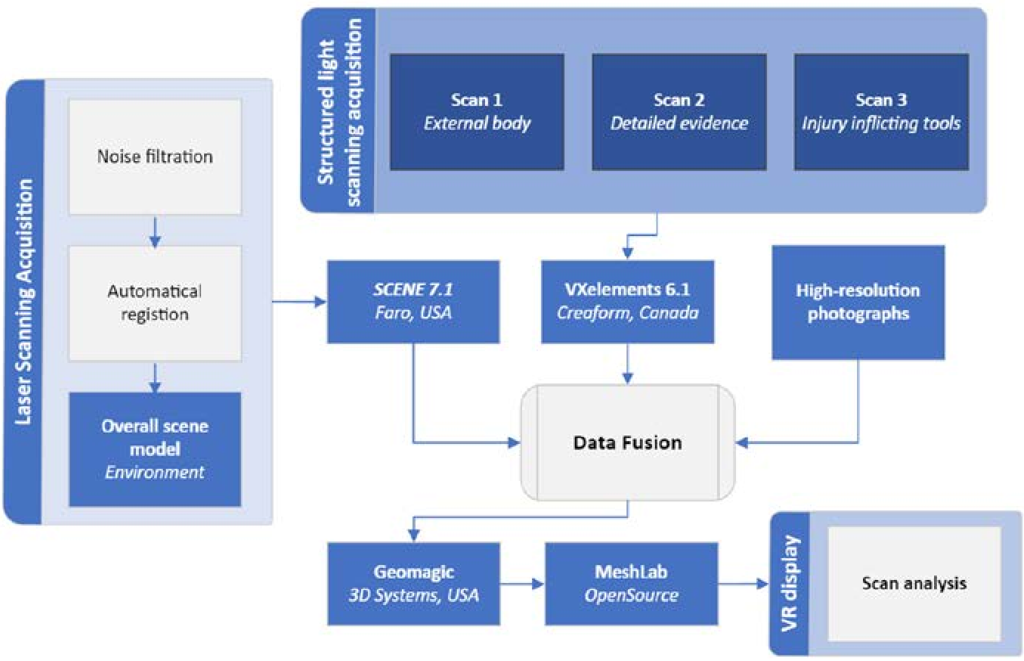

Fig. 5: A diagram showing an overview of methods being used to reconstruct a detailed environment for VR (Wang et al., 2019)

texture data is insufficient, libraries like Quixel Megascans provide high-quality textures for approximating the surface material.

One example (Alexander et al., 2009), involves the use of a stereo-camera rig with strategically placed lights. This rig is calibrated to capture multiple images simultaneously, each providing various lighting information: cross-polarized, parallel-polarized, and spectral line measurements for diffuse albedo, specular albedo, and 3D geometry, respectively. To aid data calibration, makeup dots on the target are used, ensuring they don't obstruct data while allowing precise realignment. By contrast. (Wang et al., 2019) merge laser scan point clouds using registration software. Ground control points (GCPs) and other scene features' known locations are used to combine scan data, creating a comprehensive indoor environment reconstruction. Additional scans made with structured light scanners add more detailed information to specific areas of interest for analysis.

Once the data from these various methods has been combined, the next key challenge lies in effectively separating these components to enable interaction within the virtual environment. Advanced VR interactions, characterized by direct manipulation, diverse input devices, and high degrees of freedom, demand the division of the unseparated scan-data model into distinct, potentially modular components. 3D modeling software will play a pivotal role in separating the components for independent simulation of their interactions.

For training purposes, equipment behaviors will also require virtual recreation. While the best approach is to have firsthand expert demonstrations of the equipment, this is often not feasible due to factors like high risks and limited accessibility. In such situations, an alternative approach is to attach recording equipment to a professional who can perform the necessary operations. This recorded footage can then be used as a reference for replicating the equipment's behavior in a virtual environment.

3. TECHNOLOGY

A standard asset creation pipeline involving scanning processes will require several pieces of hardware to collect data, with the appropriate software to process the information. We will also consider hardware and software required to develop functionality and render the equipment as interactable models within a VTE. The most effective solutions will be discussed below.

3.1 Software

Each step in this process necessitates specific software tools. Initially, images must be prepared for alignment, followed by running photogrammetry algorithms to construct textured models from these images. The subsequent phase involves processing the data obtained through 3D scanning to create a 3D model that faithfully represents the physical geometry of the scanned subject. This model must be optimized for seamless integration into a games engine for virtual interaction, and various texturing solutions will be evaluated. It's common to encounter multiple software options for each stage of the scanning process. Some software packages bundle applications to be used in tandem with diverse workflows, and open-source alternatives may also be available. (see Table 1). For the software upcoming to be listed, the minimum processing requirements would be a 2GHz CPU and 16GB or more RAM.

Table 1. Depicts a selection of software available from the Geomagic application suite, and corresponding open-source applications

Geomagic software	Description	Open-source alternative
Geomagic Capture	Scanner specific registration software	
Geomagic Design X	Rebuild CAD data reverse engineered from scans	OpenCAD
Geomagic Control X	Visualising and analysing data for quality control	Volume Graphics
Geomagic Freeform	Manipulate and manage large unstructured meshes	MeshLab

3.1.1 3D scanning software for 3D scanners

To process the results of the scanning process, various specialized software solutions are employed to manage scan data and enhance scenes. For this type of 3D scanning software, it's often bundled with 3D scanning hardware, and many developers have created their own software packages to accompany their laser scanners. Faro utilizes Faro Scene for scan registration and cleanup of collected geometry data, whilst Faro Zone 3D is used for tasks like importing high-res photos, utilizing registration targets, and performing metrics calculations within 3D reconstructions (Wang et al., 2019). Creaform's VX Elements is used to calibrate data collected from structured light scanners, while VX Model serves for more detailed scene modeling or measurements. Artec offers a comprehensive set of tools within Artec Studio, tailored for scan reconstruction and will be suitable for processing scan data. Additionally, CloudCompare (Open source) is an open-source solution that allows us to compare and edit point clouds or meshes (Dewez et al., 2016). It provides the capability to transform scan data to ensure alignment with our photogrammetry reconstructions.

3.1.2 Photogrammetry software

RealityCapture is renowned as one of the top choices for photogrammetric reconstruction for speed, accuracy, and format compatibility. Due to its exceptional capabilities, it is available at a premium price point. Other popular premium software includes Metashape (Agisoft) and Recap Pro (Autodesk).

There are many free photogrammetry software, the most popular of which includes Meshroom (AliceVision) which has been integrated as a free plug-in for 3D processing software such as Houdini (SideFX) and Maya (Autodesk). Other open source solutions include 3DF Zephyr, Colmap, and Regard3D.

3.1.3 3D mesh processing/modelling

3D mesh processing is a fundamental component of the 3D scanning and modeling pipeline, used to manipulate, refine, and optimize the three-dimensional mesh models generated from various data acquisition methods, such as laser scanning and photogrammetry. Most have access to various plug-ins which augment and enhance the capabilities of the software, unlocking a multitude of functionalities that cater to diverse project requirements.

Premium solutions include 3DS Max, Maya (both Autodesk), Houdini (SideFX), and ZBrush. Zbrush is well known in the professional industry for its many highly advanced tools for tasks like cleaning, healing, and texturing. 3DS Max offers cloth, light and liquid simulations and its own scripting language (MAXScript). Houdini’s procedural modeling solutions may provide scalability of modular components, enhancing the flexibility and efficiency of the asset creation and simulation process.

Blender is a remarkable free and open-source 3D modeling software known for its exceptional versatility. It offers a wide spectrum of capabilities, making it a powerful tool for cleaning up scans and repairing meshes. While Blender has a learning curve, due to its wide availability, there is a wealth of learning resources online for techniques such as hard surface modelling. There are also plug-ins which allow you to create highly detailed materials, like Substance Designer (Adobe), or create powerful renders of 3D objects. For tasks like modelling switchgear equipment, Blender’s extensive features make it an ideal choice for this purpose.

Among other open-source solutions are weaker options such as Autodesk TinkerCAD and Vectary. These free tools operate directly in your web browser, however, are primarily designed to educate entry-level users. For instance, TinkerCAD is often integrated into 3D printing processes and has limitations, such as restricting OBJ uploads to models with up to 300,000 faces.

More open-source options include OpenSCAD, FreeCAD, and Sculptris: OpenSCAD requires a bit of previous skill as you have to code your objects and it works with primitive geometric shapes and reads the code to modify and render them creating 3D models a with constructive solid geometry (CSG) which can be beneficial when it comes to 3D printing your projects. FreeCAD is a 3D modeling software was based on Python language which allows you to add new specialized features. Similarly Sculptris modifies pre-existing shapes with brushes of different strokes.

3.1.4 Games Engines

Lastly, the software we must consider is running the simulation so that it may be viewed and interacted with by a VR user. Unreal Engine 5 (Epic Games) natively supports VR development and also has the Quixel Bridge feature, giving easy access to tools and resources which may be beneficial or time saving for to the project, saving development labour. Similar plug-ins are available for Unity and the open-source Godot Engine. These games engines provide the necessary framework for creating immersive and interactive virtual environments based on the 3D models and assets generated during the scanning and modeling process.

3.2 Hardware

Hardware plays a significant role in capturing visual data and running the software necessary for asset visualization. To achieve accurate photogrammetric reconstruction, the quality of the captured images is essential, motivating us to explore several camera options, including the Mattterport Pro, DSLR cameras, and due to their wide availability we will also consider mobile phone cameras. For highly accurate metrology of our scanning targets, we shall review Lidar and structured light scanners. Lastly, we will address hardware that may be used to provide user interaction within a virtual environment, such as head mounted displays (HMDs) and review processing requirements.

3.2.1 Cameras and registration

Standard photographic equipment is often more accessible and cost-effective compared to other 3D scanning methods like LiDAR or structured light scanning. The camera will be used to gather input images to create a 3D model from photogrammetry with an accompanying texture. When aiming for the greatest accuracy, images with a higher resolution are preferred, therefore, to opt for a camera of superior quality is justified.

Various cameras may differ in quality, varying in number of pixels, sensor size, and field of view. Many pixels help to boost the image resolution to capture fine detail, most noticeable when zoomed in. Different lenses can be used with different DSLRs to correctly calibrate the cameras for scanning purposes. Conversely, smartphones may not have as many customisable options or similar fine-controls over the image capturing process, however as can be inferred from table 2, smartphones can often offer sufficiently high-quality visual data, as well as being widely available, highly portable and very accessible. Some smartphones have a single camera, others have dual sensors, quad sensors, however, frequently, high-megapixel cameras being used on market smartphones don't output photos as high as the camera is capable of because of pixel-binning.

Using a camera will be essential to capture texture and colour detail, as well as for providing proper reference for registration within the 3D processing software.

Table 2. Comparing the Megapixel value of various available camera devices.

Device		**Megapixels**
Mobile Phone	iPhone 14 Pro Max	48MP
		12MP
		12MP
	iPhone 11	12MP
		12MP
	iPhone 6	8MP
	Samsung Galaxy Fold 5G	16MP
	Google Pixel 7	50MP
DSLR Camera	Nikon D3300	24MP
	Cannon EOS ID Mark III	2.11MP
	Sony X7R	61MP

3.2.2 LiDAR Scanners

Table 3. Illustrating the range in available LiDAR scanners depending on the required range of the scan.

Manufacturer	**Short range**		**Medium Range**			**Long Range**	
Artec	Micro	Space Spider	Eva Lite	Eva	Leo	Ray II	
Faro	Gage FaroArm		Freestyle		Vantage	Focus	
Creaform	R-series		Go!Scan	HandyScan	MetraScan	MaxSHOT 3D	
Sick			S300 series			Tim-S	OutdoorScan 3
Leica					BLK 360	RTC 360	Scanstation

LiDAR scanners are known for their high accuracy and ability to capture intricate details. For the purposes of this project, they will be used for capturing complex geometries and surfaces with varying textures. Different scanners with different features are better suited to various scanning tasks depending on the object size and the necessary scan quality. Faro are well known for their mid-long-range scanners, and Creaform have also been used for their handheld scanners by similar project. Other scanners include the Geomagic capture and capture mini, ideal for "desktop scanning" of small objects up to the size of a shoebox, as well as the EinScan product range from Shining3D.

Certain scanners integrate both camera components and structured-light sensors. This grants the scanners the ability to gather supplementary colour information, which is particularly valuable for laser position-tracking and registration processes. Some artec scanners include cameras, allowing colours that the texture camera has captured to the 3D mesh being created. The quality of this texture is sufficient for a majority of metronomic applications. The quality depends of the generated geometry depends on the selection of the scanner, on the scanning distance, the lighting conditions, and the general execution of the scanning routine.

3.2.3 Matterport

Matterport is a company specializing in 3D scanning technology and software to capture and render 3D models of physical spaces. Their Matterport Pro Camera utilizes depth-sensing cameras and imaging sensors to create 3D point clouds of environments. The Matterport Pro2 3D camera offers 36MP images with a scan accuracy of +/- 50mm, while the Pro3 improves accuracy to +/- 20mm at a 10m distance. This tripod-mounted device captures comprehensive visual data by rotating 360 degrees in a short time. However, there are privacy concerns regarding detailed models unintentionally capturing sensitive information.

Matterport provides an iPad app for camera control, offering a "Dollhouse" view to identify unscanned areas. Users can navigate 3D models by selecting points within the model, making it popular for virtual property or office tours. They also have a mobile application using LiDAR sensors in phones to scan objects and generate 3D meshes in .obj format. While convenient, these scans may lack the precision needed for high-fidelity virtual assets, particularly in capturing intricate surface details.

For this project, Matterport services have drawbacks. They can be costly due to hardware expenses, service charges, and the need for additional payment to access the metadata folder (MatterPak). The generated point cloud format (.xyz) lacks widespread compatibility, often requiring conversion to more universally accepted formats like .e57. Furthermore, Matterport's scanning technology might not provide the required accuracy and detail for the project, especially in capturing nuanced surface features necessary for high-fidelity 3D models.

3.2.4 VR Hardware

Different head-mounted displays have been designed for slightly different purposes. While most headsets come with controllers, not all controllers are the same. Because the head-mounted display is the hardware through which the student interfaces with the training environment, the controller will dictate the possible depth of interaction In the context of this research, the emphasis is on a cost-effective and immersive VR solution. Many VR headsets can run the proposed simulation. However, a mid-range specification HMD with stand-alone capabilities is preferred over more powerful and expensive headsets such as the HTC Vive Pro line of HMDs. This choice imposes certain technological limitations on the performance of the 3D virtual representation.

For this project, the target headset will be a Meta Quest 2 VR headset. As well as its performance capabilities, the oculus link cable accessory allows the HMD to interface easily with a PC for development and testing purposes. The Pico Neo line of HMDs boasts similar specifications as the Meta Quest 2, both headsets have previously been used for virtual training and education purposes (Cowie & Alizadeh, 2022; Han et al., 2022; Moolman et al., 2022).

4. EXEMPLIFYING THE FRAMEWORK: HIGH-VOLTAGE ELECTRICAL SWITCHGEAR

Photogrammetry excels in capturing high-detail visual information, although as mentioned the resulting three-dimensional information may be susceptible to gaps, noise and inaccuracies. To use a fixed-camera or a multicamera set-up is feasible only for objects compatible with the rig in scale and shape, meaning they are mostly applicable only for small-to-medium objects. We shall be capturing objects on the site of their professional environment, therefore lighting conditions may not be perfect. Because of this the geometry that will result from our photogrammetry effort will likely have inconsistencies and not be very robust. For this reason we shall not rely on geometry data obtained this way, however, efforts will be made to retain any worthwhile texture information generated by the photoscan.

The 3D geometry obtained from LiDAR scan will likely be more robust however due to poor exercise of control over the lighting conditions, a complete and consistent scan cannot be guaranteed. As mentioned in section 2, we shall seek to mitigate these inconsistencies by employing the light-section method and performing multiple overlapping scans. To avoid incongruities caused by erroneous position tracking, a consequence of featureless scanning geometry, one solution emerged as notably effective: affixing ping pong balls or golf balls onto the surfaces of the equipment using blue tack. This addition of texture intricacies facilitated a more precise registration of the scanner's position during the scanning process. As the scanner traversed the modified surfaces, the intricate texture details provided the necessary points of reference for the algorithms to accurately determine the scanner's movement. Consequently, the scanner's accuracy improved significantly, and the issues of slippage and positional loss were effectively mitigated.

After combining the LiDAR and photogrammetry data into a unified 3D visualization, we suggest employing Blender to refine and optimize this asset. In case the resulting asset falls short of the realism required for real-time VR, the reconstructed data will serve as a reference template for generating a new mesh. By utilizing the scan data as a guide, the precise measurements obtained from the scan data can inform the development of an equally accurate 3D object. Furthermore, we have access to suitable replacement textures to maintain our goal of photorealism. While this process may demand additional time and effort, it is essential for achieving an immersive virtual reality experience.

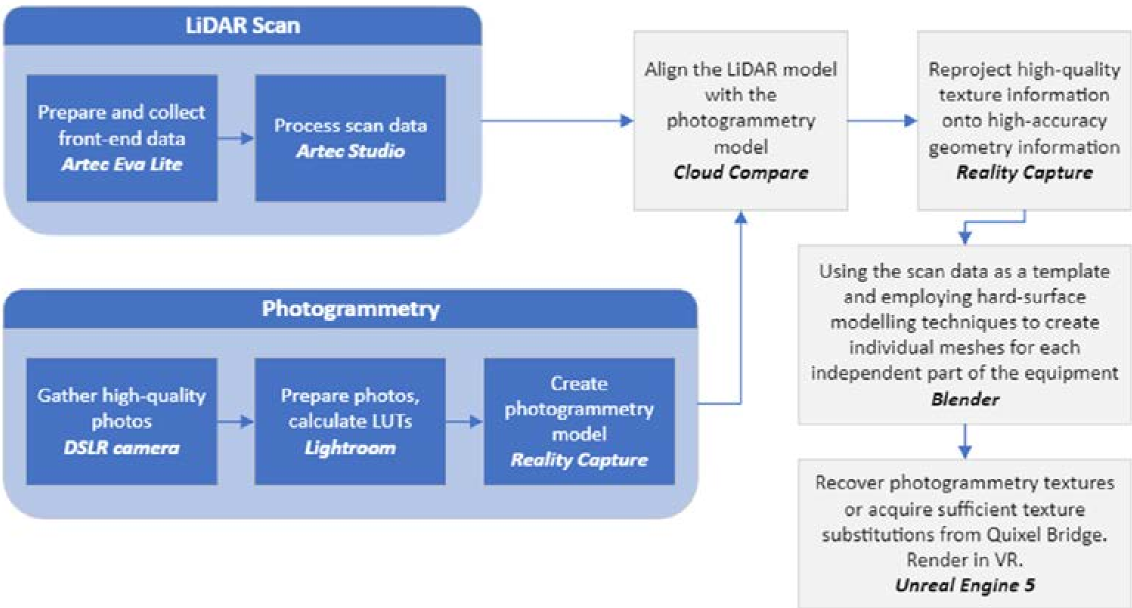

Fig 6:. Shows a process diagram outlining the methodology best suited to meet our needs of reconstructing a piece of equipment for virtual representation

5. CONCLUSION

This paper is structured to detail the methodological approach used in each stage, its limitations, and to empirically evaluate its effectiveness. By integrating advanced technologies and methodologies, this research strives to simplify the development of immersive training environments by reviewing and optimising the process of virtual representation. The framework presented is designed to methodically overcome various challenges, highlighting opportunities for automation of repetitious tasks associated with the necessary data processing, and facilitating a smooth shift from physical equipment to the production of highly lifelike virtual training environments.

ABSTRACT: *The diffusion of Building Information Modeling (BIM) and advanced visualization technologies in the increasingly digitalised construction sector is fostering the development and implementation of disruptive approaches for workforce Health and Safety (H&S) training. Project-specific risks, safety procedures and information can be administered through immersive Virtual Reality (VR) experiences where construction site environments and activities are reproduced without exposing the trainees to real hazards. However, despite numerous research and industry applications demonstrating the potential benefits of these technologies, a standardized framework and methodology for the evaluation of VR safety training effectiveness for construction workers is still lacking hence hindering its large scale-adoption and recognition from policymakers. Within the scope of previous authors contributions on the development and implementation of BIM-based VR experiences for construction workers' safety training, this paper aims to address the evaluation of their effectiveness proposing a novel semi-qualitative approach based on the integration of trainees' subjective and objective data. A post-experience evaluation questionnaire is developed to collect trainees' direct and qualitative feedback about the experience immersivity and perceived safety content transfer. Furthermore, the integration with trainees' spatial tracking data is proposed to complement the qualitative feedback with the quantitative evaluation of their use of the virtual space for safety training purposes. The application of the presented approach in case study is currently undergoing and the related results will be subject of future contributions.*

Keywords: *Virtual Reality (VR), Construction worker, Safety training, Evaluation, Spatial tracking, Heatmap visualization, Survey*

1. INTRODUCTION

Despite recent technological innovations and policy improvements in workforce Health and Safety (HS) are contributing to a low but steady reduction in accident rates, the construction industry is still one of the most dangerous, accounting for one fifth of yearly workplace fatal accidents in the European Union alone (Eurostat, 2022). In this regard, the growing adoption of real-scale immersive visualizations of complex site scenarios and construction activities enabled by Building Information Modelling (BIM) and Virtual Reality (VR) technologies are supporting HS managers in the early identification and mitigation of safety risks (Babalola et al., 2023). Moreover, since their early applications, it has been acknowledged that immersive VR simulations of project-specific site layouts and activities can improve the transfer of safety contents and preventive procedures to the trainees, while empowering their awareness in later real-site hazardous contexts (Rokooei et al., 2023). However, the administration of VR experiences for construction workers safety training is far from substituting traditional methods (e.g., slides) and is still confined to a minor share of early adopters. In fact, while economic and technical barriers have progressively shrunk, the lack of standardized frameworks and methods for the evaluation of the effectiveness of construction site VR training still stands as a major obstacle for its recognition from policy makers

and hence for their large-scale adoption in the industry. In this context, several contributions have shown how the quantification of the trainee's ability to perform cognitive and practical tasks in the VR environment (e.g., hazard identification, activity simulation) can be used to objectively assess the training effectiveness (Li et al., 2018). Nonetheless, the qualitative evaluation of VR training, collected via post-experience questionnaires administered to the trainees, is often overlooked or tailored on a specific application, so that its reuse in other case studies is impractical.

To address the mentioned open issues in the evaluation of VR safety training experiences for construction workers, this paper proposes a novel approach based on the integration of trainee's subjective perception and objective VR spatial usage. The former is collected through a questionnaire administered to the trainee after the experience and divided in five inquiry areas. For the latter, the acquisition of the users' spatial track during the VR experience and its restitution in a BIM environment through an heatmap visualization is proposed to evaluate the trainees' use and understanding of the virtual environment in relation to safety training purposes. The present work stems from previous authors' contributions in the development and administration of BIM-based immersive VR site simulations to construction workers for HS training and management purposes and is currently being tested in an infrastructure project case study whose results will be subject of future contributions (Getuli, Capone, Bruttini, & Sorbi, 2020; Getuli et al., 2018, 2021, 2022).

2. BACKGROUND

The use of virtual reality as a safety training technology is gaining attention in the construction industry. While many of the current studies mainly focus on the development of VR-based safety training programmes, it is noticeable that there is still a lack of research focusing on assessing its effectiveness. In this section, an overview of the state of the art with regard to the use of immersive virtual reality used in the realisation of training sessions for workers is given and, finally, the identified open problems and obstacles to implementation that this research aims to address are reported.

2.1. BIM and Virtual Reality for construction workers' safety training

Increasing use of BIM is favouring the adoption of VR in the Archtiecture, Engineering and Construction (AEC) sector. Typical applications for VR include construction safety planning and training (Azhar, 2017), production planning and design review sessions (Wolfartsberger, 2019).

In recent years, several studies have shown that BIM models can be used to represent construction site layouts and extract data for space and activity optimisation (Tao et al., 2022) and apply automated safety rule checking to simplify hazard recognition and assessment and risk assessment activities (I. Kim et al., 2020). Most of all, the spatial understanding and information visualisation capabilities provided by construction site BIM models have been harnessed to transfer general and project-specific HS knowledge with the implementation of VR technologies for the reproduction of construction site scenarios and activities for worker safety training and site planning (Getuli & Capone, 2018).

Several studies investigated the use of virtual reality to allow construction workers and supervisors to have easy access to the BIM through a simple VR interface and also for the education of students, defining an efficient educational tool by integrating VR application and BIM model information to develop 3D, 4D, and 5D simulations (Esfahani, 2023) and offering suggestions to AEC educators and students in implementing BIM-into-VR in different courses.

The use of virtual reality as a safety training technology is gaining attention in many different fieds: using a fully immersive VR has been shown to offer numerous benefits in terms of the effectiveness of health and safety training including risk assessment, machinery and/or process operation training in various industries (Toyoda et al., 2022).

VR is gaining attention also in the construction industry, but while many of the current studies mainly focus on the development of VR-based safety training programmes, it is noticeable that there is still a lack of research focusing on improving its effectiveness. It has been shown that telepresence experienced through VR and learners' perception of the risk of occupational accidents significantly influence their satisfaction with VR-based safety training, thus influencing its effectiveness (Yoo et al., 2023).

2.2. Construction workers' safety training evaluation

The evaluation of the effectiveness of simulations developed in VR during the training sessions or the validation of the experience carried out is a key step to identify different problems and to be able to solve certain situations by fully improving the training activity for trainees, but while VR-based training has been proven to improve learning effectiveness over conventional methods, there is a lack of study on its learning effectiveness due to the implementation of training modes. It is known that BIM and VR for safety training of construction workers are useful in many contexts (Afzal & Shafiq, 2021), although there is still no standardized method to evaluate the effectiveness of safety content transfer. In fact, most of the proposed methods are specific to individual case studies or applications in different fields, and the effectiveness of the training administered as perceived by the trainee and the spatial understanding of the worksite scenario and activity in VR is often overlooked.

The evaluation of the user experience in virtual environments can be done either with subjective methods, such us questionnaires (H. K. Kim et al., 2018) or with objective methods, like eye-tracking, or brain activity measurements (Hertweck et al., 2019).

Regarding to the evaluation of the VR safety training of construction workers, several survey methods were proposed, including the creation of a questionnaire containing open and closed questions to evaluate various aspects of the VR interface on a scale of 1 (poor) to 5 (excellent) with subsequent collection of further data through observations and conversations with participants during and after the VR tests (Johansson & Roupé, 2019). Questionnaires are a widely used and well-known tool to collect user feedback and changes in mental states during various activities (Robinson, 2018) including VR applications.

Although the use of objective measurement methods is promising, questionnaires are the most frequently used tool in user experience studies for VR. These questionnaires can be used as pre-, real-time, or post-assessment methods. In pre-surveys, the user is not immersed in a virtual environment: this can lead to a less dominant difference between VR and the traditional desktop presentation of questionnaires. After immersion into the virtual environment, however, it is important to investigate the influence of the type of questionnaire presentation on user experience (Safikhani et al., 2021).

Another important topic is the movement or spatial tracking of workers during VR simulation of construction activities, that has been shown to be useful for ergonomic evaluation of workstations or assembly procedures (Getuli, Capone, Bruttini, & Isaac, 2020).

Some studies demonstrate the effectiveness of VR simulations of assembly lines and task scenarios in an ergonomic approach to workplace design, aimed to optimize the production and the human-machine interaction (Caputo et al., 2018). Through the collection and analysis of the position tracking of a worker (Michalos et al., 2018) and human motion and posture tracking systems is possible to obtain reliable and repeatable measures to be used for evaluation of activity and workplace-related working postures.

2.3. Open issues

Although BIM and VR for construction workers' safety training has been proven beneficial in many studies, there is still a lack of a standardized method to evaluate safety contents transfer effectiveness. Most methods are specific to single case studies or applications; they are used to assess the training on objective quantification of the trainee ability to accomplish tasks in the VR environment but overlook trainee's perceived effectiveness of the administered training and spatial understanding of the construction site scenario and activity in the VR, and ignore the subjective worker perception.

Movement or spatial tracking of the trainees/workers during VR simulation of working activities has been proven beneficial for the ergonomic assessment of workstation or assembly procedures but not yet to evaluate the spatial understanding of the trainee in VR safety training experience that could instead be leveraged in the safety content transfer evaluation of HS training VR experience.

3. PROPOSED APPROACH

The aim of this paper is to propose an evaluation method of VR safety training experiences for construction workers that is based on the integration of a qualitative survey of the experience and spatial tracking data of participants. To this end, first a dedicated questionnaire was developed to evaluate both the immersiveness of VR experiences and the effectiveness of the safety content presented. Then a study on the benefits of tracking and visualizing trainees' use of space in the virtual environment is proposed. Finally, the proposed approach was validated within a case study previously developed by the authors and used for BIM-based construction worker safety training in VR.

As mentioned above, the proposed approach is based on the integration of two main categories of data, as illustrated in Figure 1. The overall goal is to collect a set of data from trainees experiencing immersive VR training, aimed at evaluating the effectiveness of the virtual experience. The detailed description of the types of data to be collected and the specific purpose for which they need to be obtained then follows in Sections 3.1 - 3.2.

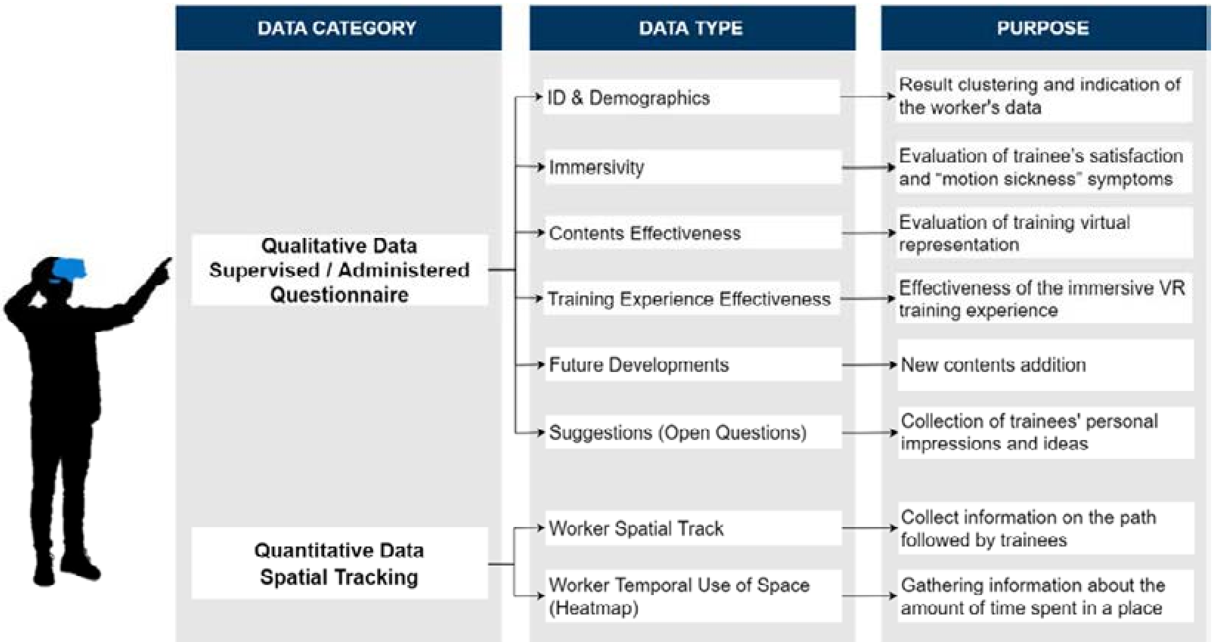

Fig. 1: VR safety training experience effectiveness evaluation approach – Data schema

3.1. Post-experience evaluation questionnaire

The approach adopted for the creation of the evaluation questionnaire led to the distinction of two main sections: the first section includes the trainee's personal data, while the second section corresponds to the actual evaluation part. The latter includes both a series of evaluation questions, for each of which the trainee can give a score on an increasing scale from one to five (where five represents maximum satisfaction), and an open "suggestions" section to collect trainees' personal impressions and ideas. Table 1 shows the sections and subsections with an indication of the purpose for which it was deemed necessary to include them, a brief description, and an explanatory example.

3.2. Trainee's spatial tracking and use of space visualization

From the immersive VR experience, data are collected not only directly, by filling out questionnaires, but also indirectly with the acquisition of the worker's position in the virtual environment. The latter procedure involves capturing the position of the worker in the VR environment during the entire course of the simulation in order to analyse the actual use of the workspace and is recorded with a data acquisition rate of 1 Hz. The 3D point sequence resulting from this process is then converted for the generation of heatmaps within which the position of the worker is represented with a gradient of colour ranging from green to purple.

As with the formulation of the questionnaire, mentioned in the previous paragraphs, an approach was defined to analyse worker movement during the immersive VR experience in order to visualize position tracking. This methodology involves taking into account not only the spatial coordinates, but also the time duration required for the performance of the experience.

Table 1: Questionnaire contents

Data type	Description	Example
ID & demographics	The worker's data, which includes an identification code/number (ID) for classification of the completed questionnaire and an indication of the worker's age, role/occupation and company, with the purpose of clustering the results obtained. [Text]	ID (Number) Age; Company; Role
Immersivity	Questions related to the user's ability to get immersed in the virtual experience, useful for assessing how engaged the trainee actually was in the virtual training scenario. It consists of an assessment of the trainee's satisfaction in terms of both ease of use and comfort (also related to the possible onset of symptoms of "motion sickness"). [Single rating – Likert scale]	How much did you like the experience? [min 1; max 5]
Contents' effectiveness	Questions regarding the virtual representation of the site and security content, aimed at evaluating the effectiveness of the experience against the objectives of the training session. [Single rating – Likert scale]	How accurately does the virtual construction site reproduce the real one? [min 1; max 5]
Training experience's effectiveness	Questions pertaining to the overall effectiveness of the experience, aimed at investigating the actual usefulness of the immersive VR training session and whether it turns out to be as comprehensive and exhaustive as a traditional training session. [Single rating – Likert scale]	Do you think this experience is useful in understanding the hazards present on the construction site? [min 1; max 5]
Future development	Questions concerning the introduction of new automation or virtual content aimed at enhancing the immersive VR training experience through the inclusion of even virtual objects with enhanced interactivity. [Single rating – Likert scale]	Would you like to be able to grasp and use objects from the construction site? [min 1; max 5]
Suggestions	Open question to collect personal impressions and ideas from the trainees. [Text]	Suggestions

Table 2: Heatmap schema contents

Data type	Description	Example
ID & demographics	See Table 1	See Table 1
Training experience duration	The duration of the experience from start to finish, excluding the tutorial that is run at the end to explain the operation to trainees, takes into account how long it takes the user to complete the experience. [time in seconds]	523 sec
Worker spatio-temporal track	The graphical representation is given by a series of points that correspond to the coordinates of where the user was every 1 second and are used to create an image that shows the path followed by the worker distinguished with different colours. [Frequency in Hz]	Image with coloured representation of the worker's followed path. [min. green, max. purple]

4. IMPLEMENTATION

The area in which this paper is located is part of a previous research project in which the authors' goal was to develop a prototype protocol for the design and delivery of safety training to construction workers, based on an innovative and interactive learner-centred approach. This protocol was designed and then tested for validation in a construction project in Italy that served as a case study for the development of VR training session content and implementation (Getuli et al., 2021). During and after the exploration of the site phases implemented, the worker undergoing the experience was invited to provide indications and opinions regarding the work environment in which he/she was working. This was done with the aim of both validating the different site layouts designed and to collect any objections and/or observations from the worker, thus enhancing their experience and giving it due importance within the development process of the virtual reality training experiences covered by this research work.

In order to collect direct feedbacks and suggestions to better drive the decision of the development direction of the implementation of the proposed VR training protocol, an evaluation questionnaire (Fig.4) was administered from a staff member to every trainee involved after they finished their test training session. The authors drawn the questions in relation to the following development areas, weighting the number of the questions for each one according to their research objectives:

- **Immersivity**: (question 1 to 4) Evaluation of the trainee's satisfaction in terms of ease of use and comfort (also related to eventual "motion sickness" symptoms occurrence).
- **Contents' effectiveness**: (question 5 to 10) Evaluation of the site's and the safety contents' virtual representation in respect of the purposes of the training session.
- **Training experience's effectiveness**: (question 11 to 14) Evaluation of the overall effectiveness of the immersive VR training experience.
- **Future development**: (question 15 and 16) Evaluation of the introduction of audio and enhanced object's interactivity as new features to be implemented in future developments.

For each evaluation question the trainee can give a score on an upward scale from one to five, where five represents the highest satisfaction. Furthermore, an open "suggestions" section is added to collect personal impressions and ideas from the trainees. All the results were collected and processed in anonymous form.

User Data	
ID:	
Age:	
Company:	
Role/Job:	

	Questionnaire	min - max
Immersivity	1) Did you enjoy the experience?	1 2 3 4 5
	2) Were you comfortable during the experience?	1 2 3 4 5
	3) Was it easy to use the viewer and controller?	1 2 3 4 5
	4) Did it bother you not being able to see your body in the virtual world?	1 2 3 4 5
Contents' Effectiveness	5) Are the signal arrows helpful in figuring out where to go?	1 2 3 4 5
	6) Does the virtual construction site sufficiently replicate the real one?	1 2 3 4 5
	7) Do the work spaces indicated for the work seem adequate?	1 2 3 4 5
	8) Are the safety and hazard spaces useful in signaling hazardous areas?	1 2 3 4 5
	9) In your experience, are the work procedures reproduced correct?	1 2 3 4 5
	10) Do you think this experience is useful in getting to know the worksite before entering it?	1 2 3 4 5
Training Experience's Effectiveness	11) Do you think this eperience is useful in understanding the hazards present at the worksite?	1 2 3 4 5
	12) Is this type of training useful for an inexperienced worker?	1 2 3 4 5
	13) Is this type of training useful for an experienced worker?	1 2 3 4 5
	14) Would you prefer to see people and machines in motion ?	1 2 3 4 5
Future Development	15) Would you prefer to hear sounds and noises inside the worksite?	1 2 3 4 5
	16) Would you like to be able to grasp and use worksite objects?	1 2 3 4 5

Suggestions

Fig. 2: Scheme of the VR training session evaluation questionnaire administered to the trainees

In addition to the data collected in active form through the questionnaires, an algorithm for recording the position of the worker in the virtual reproduction of the worksite was integrated into the VR training experience applications. In this way, during the training experience, with an acquisition frequency of 1 time per second (1 Hz), the coordinates of the worker's position are recorded in relation to both the work spaces designed for the simulated construction activities, and in general in his movement within the construction site, so that his aptitude for recognising risk areas can be assessed a posteriori at both the site and activity scales.

The interpretation of the movement traces acquired by the VR device during training in the form of sequences of points in the virtual space of the worksite was conducted by developing an additional analysis algorithm capable of reporting this information within the BIM model of the worksite and providing a graphic interpretation by means of heat-map visualisations. These visualisations allow the temporal dimension of the path followed by the worker in VR to be reported in a planimetric elaboration, distinguishing with different colours, in accordance with a pre-set gradient, the areas where the worker spent the longest time (violet, red) from those of short passage (green).

The tracking of the worker's position recorded during the VR activity simulation is done by visualizing the worker's use of space based on a temporal heat map, which consists of a 2D representation of the 3D position points recorded by the worker. The time dimension of the position tracked by the worker is graphically represented through a colour gradient (green to red), so that a red-coloured area represents a previously recorded position (red indicates a position occupied longer during the VR simulation). The heat map is then automatically generated using a custom algorithm specially developed by the authors.

Comparison of the generated heat map with the initial configuration of the workspace, in a BIM modeling environment, allows for early identification of possible planning errors; in fact, the results of the analysis of the obtained data are necessary for the next planning step, i.e., modification of the workspace configuration.

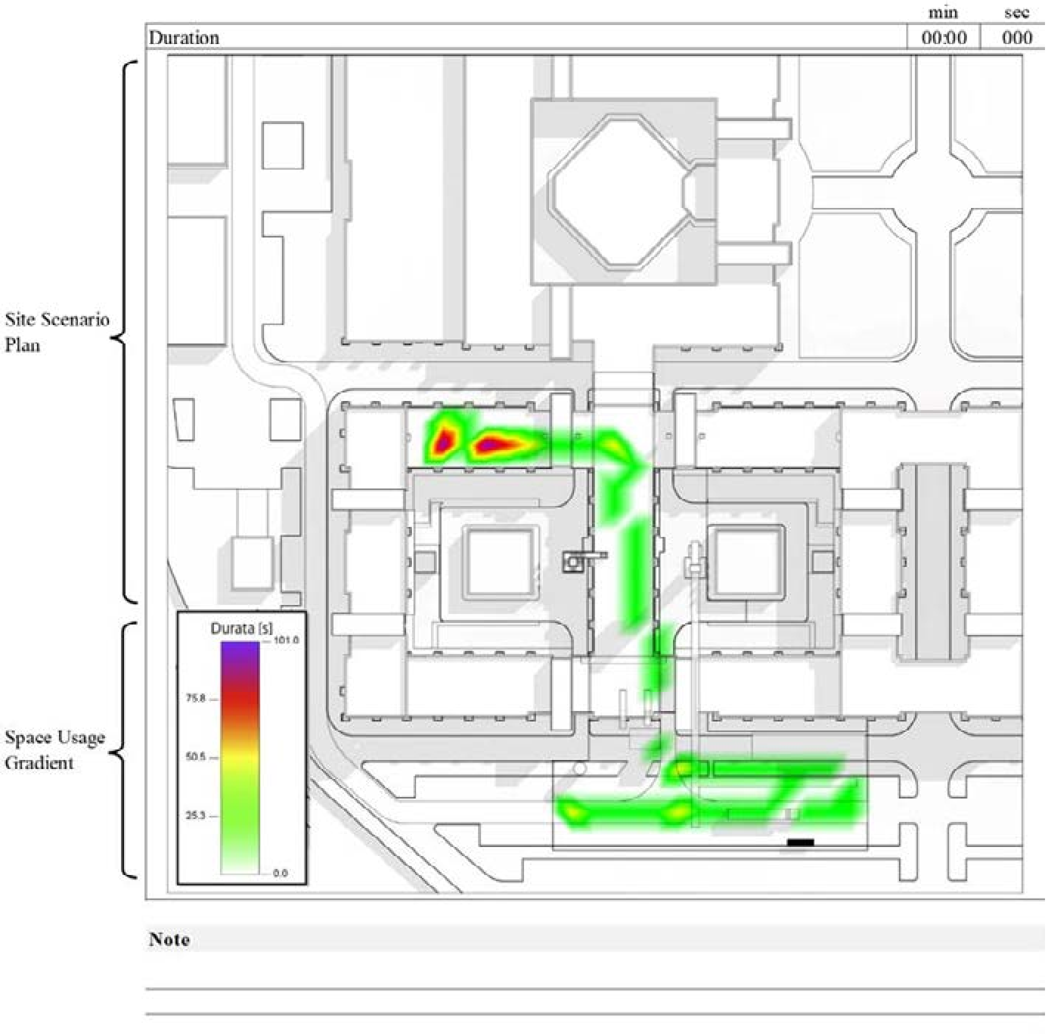

Fig. 3: Heatmap visualization (plan view) of the trainee usage of the virtual training environment

5. CONCLUSIONS

The present work, through implementation of an approach based on the integration of two main categories of data, with the overall objective of collecting a set of data from trainees experiencing immersive VR training to evaluate the effectiveness of the virtual experience, contributes to the development of a standardized method of evaluating the effectiveness of safety content transfer to workers that does not neglect the trainee's perceived effectiveness of the administered training and spatial understanding of the worksite scenario and activity in VR, as is the case with most of the methods proposed in the literature that are specific to individual case studies or applications and evaluate training based on an objective quantification of the trainee's ability to perform tasks in the VR environment.

The developed questionnaire, dedicated to evaluating both the immersiveness of VR experiences and the effectiveness of the safety content presented, and the proposed study on the benefits of tracking and visualization of learners' use of space in the virtual environment, allowed us to conduct an evaluation of safety training experiences in VR for construction workers, based on the integration of both a qualitative survey of the experience and the participants' spatial tracking data. Spatial tracking of trainees and their movement in space during the VR simulation of work activities proved useful for the evaluation of trainees' spatial understanding of the VR safety training experience.

Finally, the proposed approach was validated within a case study previously developed by the authors in which the authors' goal was to draft a prototype protocol for the design and delivery of safety training to construction workers, based on an innovative and interactive learner-centred approach. That protocol was designed and then tested for validation in a construction project in Italy that served as a case study for the development of BIM-based construction worker safety training in VR. During that work, a total of 6 VR training experiences were developed for workers, the contents of which consisted of the 3D models needed to reproduce the construction site scenario of the case study in the first 3 phases of construction: site set-up, installation of the external staircase and erection of the tower crane. At the same time, 4 training days were organized, during which the results of the proposed questionnaires were collected with reference to the different VR experiences carried out.

During and at the end of each VR training session of the 6 different site phases implemented, the worker undergoing the experience was asked to fill out the questionnaire developed to provide input and opinions on the work environment they were in, for the evaluation of the session, in order to enhance the experience and collect useful data for the development of subsequent implementations. The results obtained from the above evaluation and the discussion of the related case study previously mentioned will be the subject of further publication.

ENHANCING COLLABORATION WITH BLOCKCHAIN-ENABLED DIGITAL TWINS: PERSPECTIVES FROM STAKEHOLDERS IN THE BUILT ENVIRONMENT

Nana Akua Adu-Amankwa, Farzad Rahimian & Nashwan Dawood
School of Computing, Engineering and Digital Technologies, Teesside University, United Kingdom

ABSTRACT: *This study explores the potential of Blockchain (BC)-enabled Digital Twins (DT) using qualitative semi-structured interviews to investigate the perception of stakeholders in the Architectural, Engineering, Construction and Facility Management (AEC-FM) industry on the relevance of BC-enabled DTs in augmenting stakeholder collaboration. The findings revealed that most interviewees perceived the potential of a BC-enabled DT in fostering stakeholder collaboration, leading to enhanced project delivery. Some participants viewed affordability drivers, whilst some highlighted the desire to fulfil client demands as influencing drivers for BC-enabled DT implementation in the AEC-FM industry. The study's empirical findings align with evidence from other industrial sectors, proving that BC can ensure data integrity in a decentralised peer-to-peer framework, whilst DTs can leverage that data for effective and reliable decision-making. In the AEC-FM industry, these technologies are nascent; however, their potential integration could tackle critical issues regarding stakeholder collaboration and information fragmentation, leading to value generation in a decentralised and immutable manner. This study offers insights into implementation strategies for a BC-enabled DT collaborative environment and contributes to accelerating the industry's approach to digital transformation.*

KEYWORDS: *digital twins, blockchain, drivers, collaboration*

1. INTRODUCTION

In a project-dominant sector like the Architectural, Engineering, Construction and Facility Management (AEC-FM) industry, collaboration is seen as a critical catalyst in boosting efficiency, promoting information sharing, facilitating effective decision-making, and improving the quality of production processes and project-based performance (Koolwijk et al., 2018). Unfortunately, collaboration in the sector is beleaguered with mistrust, ineffective communication, adversarial relationships, and unnecessary disputes. This has resulted in the industry's fragmented nature and inconsistent activities by different participants, hindering progress towards project targets and creating a significant barrier to success (Li et al., 2021; Prebanić & Vukomanović, 2021).

Fragmentation of the AEC-FM industry is further compounded by the industry's complex activities due to the variety and volumes of entities involved (Chen et al., 2022), the duration of a project, the amounts of relevant data generated and dispersed stakeholders who work at the different phases of a built asset's lifecycle. Therefore, this creates breeding grounds for loss of crucial information, untracked implementation, and, most importantly, the failure to meet client requirements. Given the industry's complexities, it is essential to identify tools or solutions that can improve collaboration and contribute to process efficiency.

There has been an increasing trend in adopting digital technologies in various industries (Pour Rahimian et al., 2022), especially with the advent of Industry 4.0, to overcome industry complexities. However, the AEC-FM industry has slowly adopted, used, or applied emerging digital technologies (Newman et al., 2021). Studies show that applying digital technologies such as Building Information Modelling (BIM), Digital Twins (DT), Distributed Ledger Technologies (DLT) or Blockchain (BC), Internet of Things (IoT), and Augmented or Virtual Reality in the AEC-FM industry can increase productivity, collaboration, quality, and efficiency (Olanipekun & Sutrisna, 2021). Under the concept of Construction 4.0, the AEC-FM industry is making efforts to adopt such emerging technologies and utilise their advanced capabilities (Opoku et al., 2021).

BIM is now widely recognised as an effective way to facilitate collaboration, communication, and management. It is a common tool or process that provides a high level of information depth (Gan et al., 2019), containing all necessary details about objects and processes for the asset's entire lifecycle and the different stakeholders involved (Khajavi et al., 2019). Despite the well-known benefits of BIM in terms of collaboration, issues relating to collaboration persist (Oraee et al., 2021); these might stem from a lack of shared collaborative culture, limited understanding of emerging technologies among project teams, and a preference for traditional methods (Che Ibrahim et al., 2019; Ibrahim & Belayutham, 2019). Furthermore, the multi-level capabilities of BIM are limited to implementation without the inclusion of real-time information to achieve a close-to-"as-built" or "up-to-current"

Referee List (DOI: 10.36253/fup_referee_list)
FUP Best Practice in Scholarly Publishing (DOI 10.36253/fup_best_practice)

state of the built asset being actualised in physical form (Lu et al., 2021). Wang et al. (2020) suggest that the absence of real-time information exchange can lead to fragmented and discontinuous actions among participants. Therefore, a collaborative platform allowing real-time information sharing among all parties is necessary.

DT technology has immense potential to facilitate real-time communication and collaboration among project participants (Lee et al., 2021). DT surpasses BIM by providing more "up-to-current" modelling (Rao et al., 2022; Xie et al., 2020). Integrating IoT sensors and DTs can also transform BIM into a dynamic tool, automatically updating as-built BIM (Dudhee & Vukovic, 2021). Furthermore, DTs can simulate "what-if" scenarios with AI-based techniques to identify potential solutions to issues such as cost overruns and schedule delays, enabling stakeholders to make proactive decisions (Lee et al., 2021). In addition, DT technology offers a shared virtual environment where project participants can visualise the project, discuss options, and ultimately make well-informed decisions (Zhao et al., 2022). Several studies have emphasised that creating and managing DTs is a continuous process relevant throughout a built asset's lifecycle (Xie et al., 2023). However, these studies have also highlighted the importance of ensuring data security, reliability, and improved collaboration (Hellenborn et al., 2023).

BC technology is anticipated to fuel innovation in essential areas such as security, trust, and coordination with unified standards and protocols for information sharing. This decentralised, peer-to-peer framework is based on cryptographic mechanisms (Elghaish et al., 2022; Talla & McIlwaine, 2022) and could be an ideal solution to tackle the challenges of DT concerning security, reliability, and transparency (Kiu et al., 2022). BC enables a secure electronic ledger of digital information, utilising hash values to enhance security. BC uses consensus protocols through a decentralised network to ensure data reliability and encourages collaboration among project participants to record, verify, store, and extract construction project information and transactions without centralised data intermediaries (Kim et al., 2020).

When it comes to the digital transformation in the AEC-FM industry, the integration of BC and DT technology poses the potential to ensure data integrity, security, and trustworthiness, thereby enabling more effective collaboration among stakeholders (Adu-Amankwa et al., 2022); however, only limited studies on its potential integration can be found in AEC-FM literature. Additionally, its adoption and potential integration may be a complex phenomenon which could be influenced by factors considered from multiple perspectives. Hence, investigating and exploring stakeholders' perspectives on the potential of a BC-enabled DT collaborative approach can contribute to designing a framework and informing policymakers towards its successful adoption and implementation. To help contribute to the limited studies on BC-DT integration, this current study aims to explore and understand the perspectives of the industry's stakeholders on the potential applicability of BC-enabled DT collaborative approach using qualitative semi-structured interviews. In line with the aim, the study seeks answers to the following research questions:

- What do industry stakeholders perceive as the potential role(s) of BC-enabled DT collaborative approach?
- What factors would motivate industry stakeholders to pursue a BC-enabled DT approach to collaborative working?

The remainder of the article is structured as follows: Section 2 reviews relevant literature, while Section 3 explains the methodology used. Section 4 presents the results and discusses the perspectives of the study's participants. Finally, Section 5 summarises and concludes the study.

2. LITERATURE REVIEW

The impact of BC-enabled DT approach on collaboration is increasingly studied, particularly in the energy, health, manufacturing, and transportation sectors. For instance, studies by Huang et al. (2020) demonstrated the effectiveness of a data management platform for a turbine using a BC-based DT approach to help curb problems associated with data storage, data access, data sharing, data authenticity, and overwritten data. The results of their approach indicate the potential of BC-based DT to guarantee data storage, access to verified data, sharing efficiency via a peer-to-peer network, and data authenticity through traceability. In another study, EL Azzaoui et al. (2021) created a BC-based DT framework for a smart health city to ensure user identity is secure and data is anonymously available only to healthcare providers and professionals for real-time data analytics, research, and personalised treatment. The framework has the potential to enhance treatment accuracy, predict future diseases, and control them. The authors also suggest that in a COVID-19 scenario, this framework could be used as a collaborative approach to provide a secure, shared database where healthcare providers and professionals can access data anonymously and use that data to improve treatment and prevent future pandemics. In a recent study by Tao et al. (2022), a BC-based platform was proposed for better management of manufacturing services. The platform aims to improve trust among collaborators by ensuring accurate information sources and secure data. The authors explain that despite the challenges posed by the lack of interaction between physical and cyber spaces, the proposed platform offers a reliable solution for cyber-physical integration and addresses issues of distrust commonly associated with such service platforms.

In AEC-FM literature, Lee et al. (2021) developed and tested a BC-DT integrated framework to support accountable sharing of project-related information among stakeholders. According to the authors, integrating BC and DT can ensure authentic real-time construction-related data is traceable, immutable, and shared among project participants without an intermediary. Similarly, studies by Teisserenc and Sepasgozar (2022) posit that BC-enabled DT will allow real-time monitoring of assets whilst supporting data decentralisation and enhancing data traceability, security, and privacy. In another study, Jiang et al. (2022) suggested that a BC-enabled DT collaboration platform can establish a virtual space for real-time monitoring, decision-making, and communication among different parties in a project.

These studies demonstrate that integrating DT and BC can facilitate collaborative work practices by improving stakeholder communication, maintaining secure data integrity, and creating an authentic digital representation of the physical asset or process being twinned. In addition, these studies have management implications that can be useful for monitoring data in real time, exchanging data and information securely, and making trustworthy and transparent decisions. However, despite these studies, only a few have attempted to explore and understand its applicability in the context of the AEC-FM sector. Furthermore, there is a need to test these theoretical promises through empirical research, using both qualitative and quantitative methods to discover robust knowledge. This will help gain a more thorough understanding of their relevance within the AEC-FM industry and increase awareness about their potential benefits. Hence, seeking input from key stakeholders can offer valuable insights into the advantages of implementing a collaborative approach incorporating DT and BC technologies and the driving factors behind its adoption.

3. METHODOLOGY

A qualitative methodological approach focusing on conducting semi-structured interviews was mainly employed for this study. This approach was adopted due to its potential to gather comprehensive data and generate rich insights (Bryman, 2016). Hence, using this approach to explore and understand stakeholder perceptions about DT and BC technologies for the AEC-FM industry will enable participants to provide rich perspectives based on their knowledge and expertise. Through purposeful sampling, participants were sought through online networking websites (e.g., LinkedIn) and peer recommendations (Bryman, 2016). The main areas of interest were those participants with knowledge or experiences about DT, BC, or both in the AEC-FM industry. Nevertheless, flexibility was employed for some profiles which didn't express explicit expertise in those fields but were keen to participate in the study because of their broader knowledge of digital transformation in the AEC-FM sector.

3.1 Data Collection – Semi-structured Interviews

After ethical approval was granted to engage participants for data collection, potential candidates were approached for their consent to participate in this study. According to Saunders et al. (2019), a range of 5-25 participants is adequate for qualitative interviews. Thus, this study included 19 AEC-FM industry professionals and scholars from Asia, Europe, North America, and Africa.

The researchers employed a semi-structured interview protocol to organise detailed and orderly interviews, including open-ended questions to collect meaningful comments from respondents (Yin & Campbell, 2018). The interviews were conducted via web meetings on MS Teams to accommodate a wider reach of participants and allow effective capturing of responses for transcription. Accordingly, before each interview session, participants were briefed on the study's aims, any concerns were addressed, and their consent was formally sought to officially commence the interview process.

3.2 Data Analysis – Thematic Analysis

With the aid of NVivo, the transcribed responses from participants were progressed into the data processing and analysis, where available information within each response sheet was extracted into self-describing categories and held under thematic codes to identify the scope or variety of relevant constructs (Saldaña, 2021). Emerging themes highlighting the potential role of BC-enabled DT perceived by participants and the drivers or influential factors towards its adoption were identified. The emerging themes identified were guided by the study's focus, as suggested by Bryman (2016).

4. RESULTS AND DISCUSSION

4.1 Demography of Interviewees

A total of 19 participants hailing from Africa, Asia, Europe, and the Middle East were involved in this study. These participants were classified according to their field of expertise, which included Academics, Managers, Architects, Engineers, Programmers, and Surveyors.

4.2 Participants' Perspectives on the Role of Blockchain-enabled Digital Twins

During the interviews, individuals were asked to provide insights on a BC-enabled DT approach's role in collaborative working within the AEC-FM industry. Drawing from their extensive knowledge and understanding, they affirmed that a BC-enabled DT would be crucial for four main themed functions on effective collaboration, as it would provide a secure environment for accessing and sharing data, improve decision-making and promote trust and transparency (see Table 1).

Table 1: Summary of Themes about the Role of Blockchain-enabled Digital Twin from Participant

Theme	Descriptions	No of Participants
ENHANCED DATA ACCESSIBILITY	This theme comprises views on the role of blockchain-enabled digital twin in easing stakeholder access to data	9
DATA SECURITY	This theme comprises views on the features of blockchain-enabled digital twin in assuring the security of data	3
ENHANCED DECISION-MAKING	This theme highlights views on the role of blockchain-enabled digital twins in assisting with decision-making	3
TRUST AND TRANSPARENCY	This theme comprises views on the relevance of blockchain-enabled digital twins in ensuring trust and transparency	2

Regarding the popularity of themed responses, it is observed from Table 1 that most participants expressed sentiments about enhanced data accessibility, followed equally by data security, as well as enhanced decision-making, and finally, trust and transparency. Nevertheless, the number of participants is only an indication of interest as some participants may be represented across themes, so in this paper, the contents that comprise these themes are of interest. The subsequent subsections delve into the themes with supporting evidence quotes.

4.2.1 Enhanced Data Accessibility

Most of the interviewees revealed that opting for a BC-enabled DT solution will create a platform where data can be accessed easily by project participants and stakeholders. They expect that BC's added characteristic of a peer-to-peer decentralised network will empower each participant to easily access data without the need to depend on a central authority for data access. Some interviewees believed that accessing data is vital for collaboration as this would allow for timely retrieval of data or information since it is available to all parties. Extracted comments from a participant which align with the view of enhanced data accessibility include:

"I think the timely retrieval of information will be a major aspect that digital twin and blockchain technology eventually would be able to address."

"You need to focus on specific information that you want stored on the blockchain, but once you have stored the information, then it is available to all the parties involved. So, within the blockchain-enabled digital twin, you would have specific information that is useful for managing the overall lifecycle of the building and are

available to all parties."

The expectation of interviewees is corroborated by Sarfaraz et al. (2023), who revealed that BC poses a potential for ensuring the immutability, validity, and confidentiality of recorded data while enabling decentralised storage. Hence, BC's integration with DT can ensure access to information without a mediator, providing a decentralised solution to project participants. Additionally, the integration of BC and DT can enhance data visibility. Thus, all parties involved in a `built asset's lifecycle can access reliable data on a shared distributed ledger (Suhail et al., 2022).

4.2.2 Data Security

Data Security was also indicated as a key relevant attribute that a BC-enabled DT solution can enhance, resulting in improved collaboration. Most interviewees consider data security very relevant while managing a built asset's lifecycle. In their opinion, a BC-DT integration will ensure data security. Interviewees further indicated that data generated throughout a built asset's lifecycle needs to be protected due to the confidentiality of certain data types shared between project parties. In addition, interviewees highlighted that BC-enabled DT's incorporation into the management of a built asset lifecycle would prevent data from being tampered with due to BC's immutable nature. An extracted interviewee comment is presented below:

"*…but we want to protect this data, and not expose it to any cyber-attacks, or to expose it to people who do not have access to that kind of information. So blockchain data, in the end, will create big changes in how we manage assets, the way we manage the buildings by providing some good data, accurate data, real-time data about the buildings, and that is also secured."*

The views expressed on BC-enabled DT's capability in enhancing data security are corroborated by Shen et al. (2021), who confirmed via a secure data sharing framework that BC's distributed mechanism and cryptographic features can guarantee a higher level of security as compared with a traditional centralised solution. Sahal et al. (2021) revealed that the issue of security in collaborative working could be significantly enhanced by BC-enabled DT due to its potential to allow for secure real-time data exchange and analysis among multiple participants. Data breaches in real-life scenarios highlight the importance of ensuring data security and reliability, hence the need to integrate BC-enabled DT throughout a built asset's lifecycle.

4.2.3 Enhanced Decision-Making

The interviewed participants indicated that the unique characteristics of BC and DT will lead to enhanced decision-making. They highlighted that the feature of DT in providing real-time data on a built asset and BC's capability in ensuring secure, immutable data within a decentralised setting can contribute to timely and accurate decision-making. Additionally, participants revealed that using the real-time data available in BC-enabled DT platform can form a reliable base to improve performance and predict future occurrences. A comment extracted from an interviewee is as follows:

"The strengths of digital twin solutions, with real-time information on the built assets plus the decentralised and transparency strengths of the blockchain technology, I believe that will actually help you to manage facilities better and also, perhaps, generate more insights that can also help improve how facilities are being managed."

Studies by Suhail et al. (2022) have also indicated that integrating BC and DT can ensure that actionable insights are driven by trustworthy data. They further pointed out that BC-enabled DT approach can help stakeholders to acquire more thorough and accurate insights into asset performance based on generated reliable data. Sahal et al. (2021) highlight that BC-enabled DT collaboration can enhance decision-making in avoiding risks and proffer solutions to unexpected occurrences. These studies confirm the views shared by interviewees that incorporating BC-DT creates an enabling environment that can facilitate decision-making in the built environment based on reliable data.

4.2.4 Trust and Transparency

Enhancing trust and transparency between stakeholders involved in a project was also a key perspective shared by most interviewees. A participant believed that BC adds a layer of transparency when integrated into a DT depending on the defined protocols and its peer-to-peer network. Furthermore, participants were of the view that the layer of transparency can contribute to enhancing trust amongst stakeholders. One interviewee stated:

"… it would be that you can trust it because project parties would have the same records. Parties will not be

required to go through old extra records because every time data is updated, it is a universal update throughout the network."

Findings from the interviews are consistent with studies by Teisserenc and Sepasgozar (2021), who posit that incorporating a BC-enabled DT platform is crucial in establishing a reliable and secure data audit trail within decentralised ecosystems, from project initiation to completion. This shared data platform guarantees trust and transparency while ensuring data integrity throughout the project lifecycle. Suhail et al. (2022) suggest that by integrating BC and DTs, all parties involved in a product's lifecycle can effectively and efficiently manage data on a shared distributed ledger, thereby addressing data trust, integrity, and security concerns. In summary, a BC-enabled DT system will enhance stakeholder collaboration, improve transparency, and resolve trust-related concerns.

4.3 Drivers of Blockchain-enabled Digital Twins

Understanding the motivations behind the adoption of digital technologies is crucial, as these drivers can significantly impact behaviour and outcomes (Yang et al., 2021a). This study presents the driving factors, as perceived by key stakeholders, that will lead the AEC-FM industry towards undertaking and successfully executing BC-enabled DT approach. In this context, "drivers" refer to the motivating forces (Opoku et al., 2022) that will prompt stakeholders to execute BC-enabled DT projects effectively. After conducting a thematic analysis of interview data, five key themes emerged as the main influencing factors that would encourage stakeholders in the industry to adopt a BC-enabled DT collaborative approach (see Table 2).

Table 2: Summary of Themes about the Drivers of Blockchain-enabled Digital Twin from Participants

Theme	Descriptions	No of Participants
Affordability and Cost-effectiveness	This theme represents views relating to the cost involved in acquiring the approach and the potential value to be gained	8
Stakeholder Awareness of the Potential Benefits	This theme comprises views relating to stakeholder understanding and perceptions of the benefits	11
Standards, Policies and Regulations	The theme represents views shared on the need for rules, guidelines, and policy interventions.	6
Real-life Implementation	The theme revolves around views shared on the need to showcase practical approaches and demonstrate real-life examples	6
Client's Demands and Interests	This theme encompasses perspectives shared on a client's role and interests	4

gr

4.3.1 Affordability and Cost-effectiveness

The participants revealed that stakeholders would be more likely to adopt a BC-enabled DT collaborative approach based on its affordability and cost-effectiveness. They mentioned that the affordability of the approach, especially for small-scale industry players, is considered the main driving force behind its development and implementation. In addition, some participants emphasised that a business's decision to invest in a new solution or innovation is primarily influenced by its cost-effectiveness, as businesses constantly strive to make returns on their investments. One interviewee's extracted comment is as follows:

"The main one is the cost to install a big platform. For a small-scale office, it is another cost. So, it only makes sense if the cost return works out. The equity returns on their investment in that platform should justify that investment and make sense if they scale up to larger scale projects for greater returns."

Considering the novelty of a BC-enabled DT approach, its initial cost and affordability are crucial to its potential adoption. Studies by Cheng and Chong (2022) revealed that perceptions about the costs of adopting and implementing emerging technologies can significantly influence stakeholders' adoption decisions. Suhail et al. (2022) pointed out that adopting emerging technologies can help reduce operational costs, reinforce productivity, and enhance operational efficiency. However, industry players still face high initial investments despite the potential benefits gained from their adoption (Toufaily et al., 2021), which could be an obstacle (Rind et al., 2017). Suhail et al. (2022) further suggest that adopting these emerging technologies would require a detailed cost-benefit analysis; otherwise, they may pose a significant challenge to an enterprise's resources.

4.3.2 Stakeholder Awareness of the Potential Benefits

In the AEC-FM industry, BC and DT are emerging technologies many stakeholders may not yet be familiar with. Hence, to promote their adoption, interviewees believe it is important to spread knowledge about their potential benefits. Some interviewees suggest that stakeholders need to be educated and convinced about the added value of these technologies before they can be implemented. The interviewees also underscored the need for continuous advocacy and education to shift the mindset of industry players, especially in an industry that is slow to adopt new technology and where stakeholders may resist new innovations. A typical view shared by interviewees is as follows:

"I believe people need to be convinced that this approach can save them money, make them more efficient, or maybe make them more competitive against their peers or give them some competitive advantage. So, they need to be convinced that investing in tools or new approaches like this will actually be worth it. In the long run, as a business, you don't want to invest your time and resources into something that would actually drain your limited resources. So, people need to be convinced and encouraged to adopt such technologies."

Perspectives shared by participants are supported by Orji et al. (2020), who indicate that having a comprehensive understanding of the advantages of new technological advancements can inspire stakeholders to invest in digital innovations. Therefore, it is recommended that stakeholders who are well-informed about these emerging technologies should emphasise and create awareness of their benefits, such as their ability to improve productivity based on an organisation's resources and traits.

4.3.3 Standards, Policies and Regulations

During the interviews, it was discovered that industry players are more likely to adopt new innovations if stakeholders or policymakers in the built environment develop and implement standards and procedures to guide the adoption and implementation of BC-enabled DT collaborative platforms. The interviewees also highlighted that implementing standards, policies, and regulations would create an environment that enables the proper implementation of new innovations and encourages their adoption. Additionally, some interviewees suggested that the government could spearhead the use of new innovations by establishing and implementing specific project requirements that make adoption necessary. One of the interviewees intimated that:

"So, if the stakeholders or the policymakers in the built environment can come up with standards and procedures, and also give policies and regulations which motivate or promote the adoption of this technology, then it is imminent that professionals in the built environment would definitely adopt it."

The impact of governmental policies, standards, and guidance on the perceived usefulness and complexity of new technologies cannot be underestimated (Cheng & Chong, 2022). Abideen et al. (2022) pointed out that governmental regulations and laws can influence innovation adoption and further cited the 2016 UK construction strategy as a notable instance of such regulations. Hence, regulatory bodies need to create policies and provide support to drive the adoption of BC-enabled DT platform.

4.3.4 Real-life Implementation

Participants suggested that in addition to communication and raising awareness about the benefits of BC-enabled DT platforms, it is important to demonstrate their real-world applications. Most interviewees agreed that developing case studies showcasing the tangible benefits of implementing such platforms would be an effective way to convince industry stakeholders of their value. Some interviewees also recommended creating prototypes to demonstrate the viability of collaborative working using these platforms. Implementing pilot projects was also suggested to illustrate the benefits and encourage adoption. Finally, interviewees emphasised that showing use cases would also educate people about the necessary resources and requirements for successful implementation, given that these technologies are still emerging. One of the interviewees stated that:

"The development of case studies that showed real application of this technology. So, we have to show how these technologies can be applied, and I think that this is the only way in which we can prove to industry and academia the values and the benefits that we can realise using the integration of BC and DT."

The views expressed by interviewees are further supported by Zhang et al. (2023), who suggest that pilot projects are a practical approach to tackling technical concerns that stakeholders may have and enhance their appreciation of the advantages of implementing emerging technologies. They further pointed out that many stakeholders hesitate to embrace new technologies because they lack real-world case studies to prove their effectiveness. Hence, the deployment of pilot projects cannot be discounted as a driving force during decision-making in adopting digital solutions.

4.3.5 Client's Demands and Interests

Interviewees emphasised the role of the clients or owners as driving forces in adopting innovation. They explained that clients have the potential to fuel innovation through their desire to explore novel approaches and optimise project execution methods. Additionally, interviewees confirmed that some clients often support new strategies that can motivate adoption. However, some interviewees caution that clients without knowledge of new technologies or a clear understanding of their needs may demand unrealistic solutions. An interviewee shared the view that;

"So basically, what I'm trying to say is that professionals and clients that would love to see new ways and better ways of doing things will easily find this approach very valuable to them."

Similar studies on the adoption of digital technologies corroborate the role of the client as an important driver. According to Yang et al. (2021b), increasing market demands for digitalised solutions in many industrial disciplines have driven firms to adopt digital technologies to meet client demands and requirements and maintain client relationships. Abideen et al. (2022) also pointed out that industry professionals are driven by clients' awareness of potential enhancements in the digital built environment, and this usually motivates industry players to achieve competence and excellence when adopting and implementing new solutions.

5. CONCLUSION

This paper explored the perspectives of industry and academic professionals about the potential roles that BC-enabled DT collaborative approach could play in the AEC-FM industry, as well as the influencing drivers that would motivate such stakeholders to pursue BC-enabled DT approach to collaborative working. Emerging themes from respondents revealed that participants perceived that BC-enabled DT could create an enabling environment for enhanced data accessibility, data security, enhanced decision-making, and promote trust and transparency, thus making it vital for collaborative work across the AEC-FM industry. Meanwhile, it was discovered that five main factors emerged from participants' responses as motivational drivers to pursue the path of BC-enabled DT; these are affordability and cost-effectiveness, stakeholder awareness of the potential benefits, standards, policies, and regulations, real-life implementation, and client's demands and interests.

Despite BC-enabled DT solutions being explored in other industries for collaborations, the lack of attention to its combined potential in the AEC-FM leads to the heart of this study's novelty, which lies in its focus on empirically identifying its anticipated roles and influential drivers. By conducting semi-structured interviews with industry and academic practitioners, the findings are expected to resonate with readers who seek to understand key considerations that come into play beyond the promised potential within literature.

A significant limitation of this study was the difficulty in finding participants with knowledge or experience in both BC and DT applications to respond to the study's questions.

Based on the findings of this study, it is recommended that further empirical investigation be conducted to gain a holistic understanding of the capabilities and implications of adopting a BC-enabled DT approach to address the collaboration challenges inherent in the AEC-FM industry as it gears up towards embracing digital transformations.

6. ACKNOWLEDGEMENT

This paper contains research which is part of the lead author's ongoing PhD research project, partially funded by Teesside University.

ABSTRACT: *Implementing blockchain benefits various construction management processes, such as securing payments, enabling traceable design process, and enhancing information transparency in supply chain. However, blockchain implementation in construction is still in its infancy due to weak functionality of smart contracts, which are self-enforceable programs allowing iteration between external data and blockchain. In the context of construction management that embraces complex and dynamic business processes, smart contracts are currently designed based on specific and isolated functional requirements without considering the connection and execution logic between these functions. It leads to inefficient collaboration and even execution errors, thereby corrupting data quality and even causing business failure. Therefore, this paper proposes a Blockchain-BPMN (Business Process Model and Notation) integrated (BBI) framework for construction management. The framework poses two contributions. First, a BPMN-driven method is developed to design smart contracts supporting executing linked and logically connected business activities. Second, an access control strategy is integrated into smart contracts to safeguard the accessibility of sensitive business data in a blockchain environment. The BBI framework is validated in an actual BIM design collaboration scenario, and results show its feasibility and computational performance are acceptable. Several aspects for improvement and future directions are discussed in the end.*

KEYWORDS: *Smart contract; Blockchain; BPMN; Construction business process*

1. INTRODUCTION

Data security is becoming an increasingly concerning issue in the construction industry. With the higher level of digitalization in construction, it is inevitable that data security becomes more important (García de Soto et al., 2022). Several examples highlight the vulnerabilities that exist in the construction business process, such as the lack of records for Building Information Modeling (BIM) changes, fragmented and unaccountable supply chains, and insecure payment systems. These vulnerabilities can result in various negative consequences for construction projects, from delays and cost overruns to compromised safety and quality. Therefore, it is crucial for the construction industry to prioritize data security, traceability, and process automation. By implementing robust security measures, ensuring transparency and accountability in the supply chain, and automating processes, construction companies can mitigate the risks associated with data breaches and cyberattacks. This not only protects sensitive information but also improves overall project efficiency and reduces the likelihood of errors and disputes. The construction industry must recognize the importance of data security and take proactive steps to safeguard their systems and information.

Blockchain and smart contracts have emerged as potential solutions to various challenges in different industries, including the construction sector. Blockchain is a decentralized digital ledger that records and verifies transactions across multiple computers, ensuring transparency, security, and immutability (Leng et al., 2022). On the other hand, smart contracts are self-executing contracts executed in the blockchain platforms with the terms of the agreement directly written into lines of code (Ye et al., 2022a). These two technologies have the potential to revolutionize the way transactions are conducted and contracts are executed.

In the construction industry, blockchain and smart contracts have been explored as solutions to various problems. One example is payment management. Smart contracts can automate the payment process, ensuring that contractors and suppliers are paid promptly based on predefined conditions (Sigalov et al., 2021; Ye & König,

Referee List (DOI: 10.36253/fup_referee_list)
FUP Best Practice in Scholarly Publishing (DOI 10.36253/fup_best_practice)
Xuling Ye, Xingyu Tao, Jack C. P. Cheng, Markus König, *Blockchain-BPMN Integrated Framework for Construction Management,* pp. 309-317, DOI 10.36253/979-12-215-0289-3.29

2021a; Ye et al., 2020). Another example is in the field of BIM change record in the design phrase. By implementing smart contracts, any modifications to the design of BIM model can be automatically updated to blockchain, ensuring that all stakeholders are aware of the changes and can plan accordingly (Xue & Lu, 2020). This can help streamline the design phase and minimize the risk of errors or miscommunication. Supply chain management is another aspect of the construction industry that can benefit from blockchain and smart contracts. With complex supply chains involving multiple suppliers, contractors, and subcontractors, ensuring transparency and traceability becomes crucial. Blockchain can provide a secure and immutable record of every transaction and movement of materials, enabling stakeholders to track the origin, quality, and location of construction materials, where smart contracts can automate the procurement process, ensuring that materials are ordered and delivered on time, and payments are made only after satisfactory delivery (Elghaish et al., 2023). Therefore, blockchain and smart contracts have the potential to revolutionize the construction industry by addressing various challenges and improving efficiency. As more research and implementation examples emerge, these two technologies are not just buzzwords but practical solutions that can drive innovation and transformation in the construction industry. However, the current smart contract implementation is isolated, neglecting task sequence execution, leading to limited automation. Furthermore, the use of code in smart contracts makes them challenging to understand for non-programming participants in the construction industry.

Therefore, the main objectives of this study are to explore the possibility of incorporating blockchain and smart contracts into construction business processes and to improve the automation level using smart contracts in the construction field. To achieve these, we propose a novel BPMN-driven approach aimed at enhancing the efficiency and automation capabilities of smart contracts. The study aims to develop a Blockchain-BPMN integrated framework for connected smart contract execution, enabling seamless interaction and collaboration among different smart contract functions, thereby automating complex construction workflows. Additionally, a smart contract access control strategy is proposed to manage data accessibility, ensuring that sensitive information is only accessible to authorized parties while maintaining transparency.

2. LITERATURE REVIEW

2.1 Blockchain and smart contracts in construction

In the construction industry, many blockchain and smart contract reviews were conducted and their adoption to the construction industry were highlighted. For example, the applications of blockchain and smart contracts in construction were summarized by Li and Kassem (2021), which mainly focusing on information management, payment, procurement and supply chain management. Another smart contract review was conducted, which pointed out that 81 smart contract-related papers were published from 2014 to 2021 in the construction industry, focusing on the areas of contract and payment, supply chain and logistic, and information management (Ye et al., 2022a).

One of the critical pain points in the construction industry is the inefficiency and lack of transparency in payment processes. Smart contract-based payment systems have emerged as a promising approach to tackle these issues. Ahmadisheykhsarmast and Sonmez (2020) investigated the implementation of smart contracts in construction projects to enhance security in payment processes. Their study demonstrated that smart contracts could automate payment release based on predefined conditions, reducing payment delays and disputes significantly. Building Information Modeling (BIM) is a critical component of the construction process, allowing stakeholders to collaborate visually and efficiently during the design phase. Integrating blockchain technology with BIM has the potential to enhance data management and collaboration (Ye et al., 2022b). Tao et al. (2021) explored the use of blockchain and smart contracts for BIM-based collaborative design in construction projects. Their research demonstrated that the decentralized and immutable nature of blockchain improves data sharing and coordination among stakeholders during the BIM design phase.

The current use of smart contracts faces limitations, including their isolated nature and the absence of a coherent approach to developing logical methods that align with construction business processes. In Fig. 1, a comparison highlights the difference between the current practice and the potential capabilities of smart contracts in construction workflows. Presently, various tasks are handled by independent smart contracts, necessitating users to determine which contract to engage. For instance, in Fig. 1(a), tasks are individually managed by separate smart contracts without intrinsic connections, which may cause execution or business logic errors and decrease the automation level of smart contracts. The current practice contrasts with practical expectations where inter-dependencies should be embedded. Fig. 1(b) illustrates the expectation for execution tasks within a smart contract, which enhancing the automation potential of smart contracts.

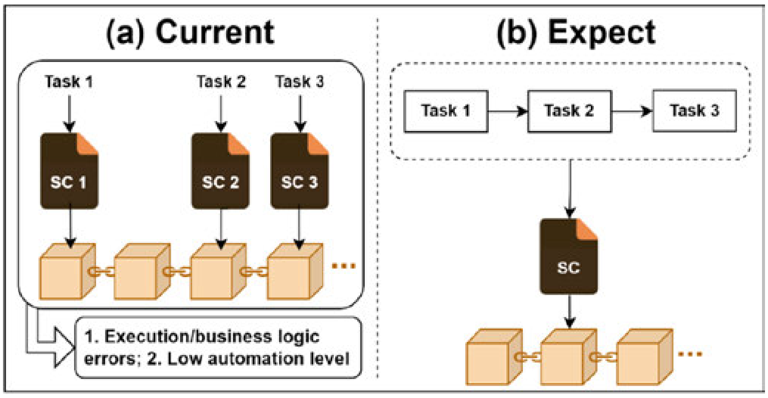

Fig. 1: The limitation of the current usage of smart contracts. (a) Current practice of smart contracts; (b) Expected usage of smart contract

2.2 Combination with BPMN for construction business process management

Business Process Model and Notation (BPMN) is a standardized graphical representation language used to define and visualize business processes (Object Management Group, 2013). In the realm of construction project management, BPMN offers a range of benefits. It provides a clear and intuitive visualization of complex construction workflows, enabling stakeholders to understand processes more easily (Borrmann et al., 2018). This enhances communication, collaboration, and decision-making among project teams. Furthermore, BPMN can facilitate the identification of bottlenecks, inefficiencies, and potential improvements in construction processes, contributing to more effective project management and resource allocation (Borrmann et al., 2018).

BPMN's suitability for connecting smart contracts is noteworthy. With its versatile graphical representation, BPMN can model and illustrate the interactions between different smart contract functions effectively. This enables the design of intricate sequences of smart contract executions, facilitating the automation of multi-step processes (Ye & König, 2021b). For example, López-Pintado et al. (2019; 2022) introduced and implemented a blockchain-based BPMN execution engine called Caterpillar to generate smart contracts using a BPMN-to-solidity compiler. Di Ciccio et al. (2019) proposed an approach to translate from BPMN process models to smart contracts using Caterpillar tool, execute processes through smart contracts, and track activities in the Ethereum blockchain. The other existing study in the construction industry analyzed the possibilities of combining blockchain and BPMN choreographies, and proposed a framework to identify the state of each process in BPMN processes and choreographies (Spalazzi et al., 2021). Additionally, BPMN can be coupled with access control mechanisms, ensuring that only authorized parties can engage with specific smart contracts or process steps. This integration strengthens security and transparency, both crucial aspects in the construction domain.

However, the current research focuses on direct translation from BPMN to smart contracts, without considering the real-time connection and visual execution of BPMN and smart contracts. One reason is the relative novelty of blockchain and smart contract adoption within business processes. As a result, the exploration of BPMN's capabilities for this purpose is limited. Moreover, incorporating access control mechanisms in this context presents challenges, as construction projects involve various stakeholders with differing levels of authorization. Balancing data visibility and access becomes intricate, given the diversity of involved parties and the need to maintain data integrity and security.

This paper addresses these gaps by presenting two significant contributions. Firstly, it introduces a groundbreaking Blockchain-BPMN integrated framework designed for the connected execution of smart contracts. This framework allows for the seamless interaction and execution of interconnected smart contracts, enabling the automation of complex construction workflows. Secondly, the paper proposes an innovative smart contract access control strategy that caters to the diverse data visibility needs of various stakeholders in the construction process. These contributions collectively aim to revolutionize the construction industry's approach to business process automation, improving efficiency, transparency, and collaboration through the integration of BPMN and blockchain-powered smart contracts.

3. METHODOLOGY

The research methodology, illustrated in Fig. 2, comprises three key steps. Step 1 involves designing a Blockchain-BPMN integrated (BBI) framework by firstly defining the framework's logic and workflow, and then explaining how the connected smart contracts are executed in the framework. Step 2 focuses on developing a strategy to control data access. This includes determining who can see which data level based on permissions and setting rules for accessing data stored both inside and outside of the blockchain. In Step 3, the logical smart contract algorithm is developed, by defining the mapping from BPMN to smart contracts, and developing the smart contracts based on the BPMN execution logic. The output of Step 1 is a concept explanation of the BBI framework, and its functionalities are detailed further by the development of the data access control strategy in Step 2 and the logical smart contract algorithm in Step 3. Step 4 tests the feasibility of the BBI framework using a case study. This includes building and putting the BBI framework into action, and then assessing its effectiveness using a BIM-based design collaboration scenario.

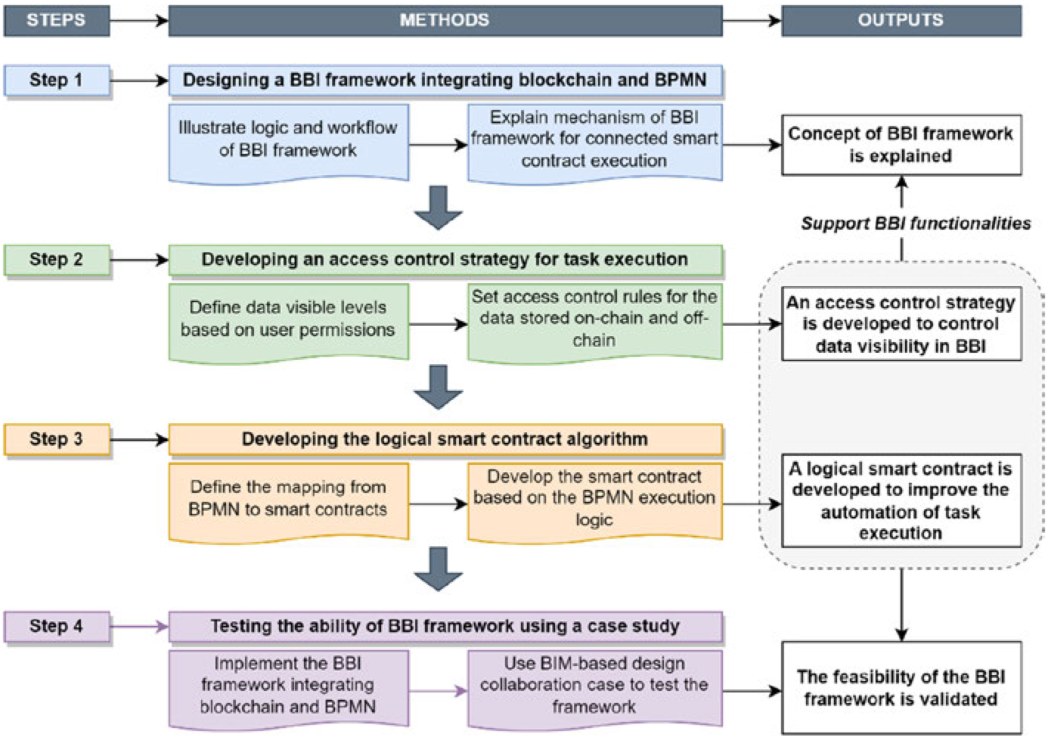

Fig. 2: Research methodology

3.1 Blockchain-BPMN integrated framework

The overview of the proposed BBI framework is shown as Fig. 3. Process-embedded smart contract list (PeSCL) is proposed in this paper for storing all the process-required data in a construction project to be executed via the smart contracts, which includes such as project information, participant information, process units, and the linkage to the BIM model. The PeSCL and the BIM model are the inputs for the framework (Fig. 3①), where BIM model is displayed in a BIM viewer, and PeSCL is displayed as table. They are linked via the GUID of each BIM elements that stored in the PeSCL (Fig. 3②). These two input data are further linked with the construction business process, which is represented by BPMN (Fig. 3③). Each BPMN task is mapped to a corresponding smart contract function. Real-time process visualization and execution are then realized (Fig. 3④). During the task execution, an access control strategy is developed for controlling different data permissions for different participants of the construction project. Such strategy controls the visible level of both on-chain and off-chain data (Fig. 3⑤). The logical smart contracts automatically execute the tasks represented via BPMN with their execution logic, and their transactions are stored in the blockchain (Fig. 3⑥). Such framework can not only visualize BIM and real-time construction business process execution status with an improvement of business process automation, but also build trust and realize data access control.

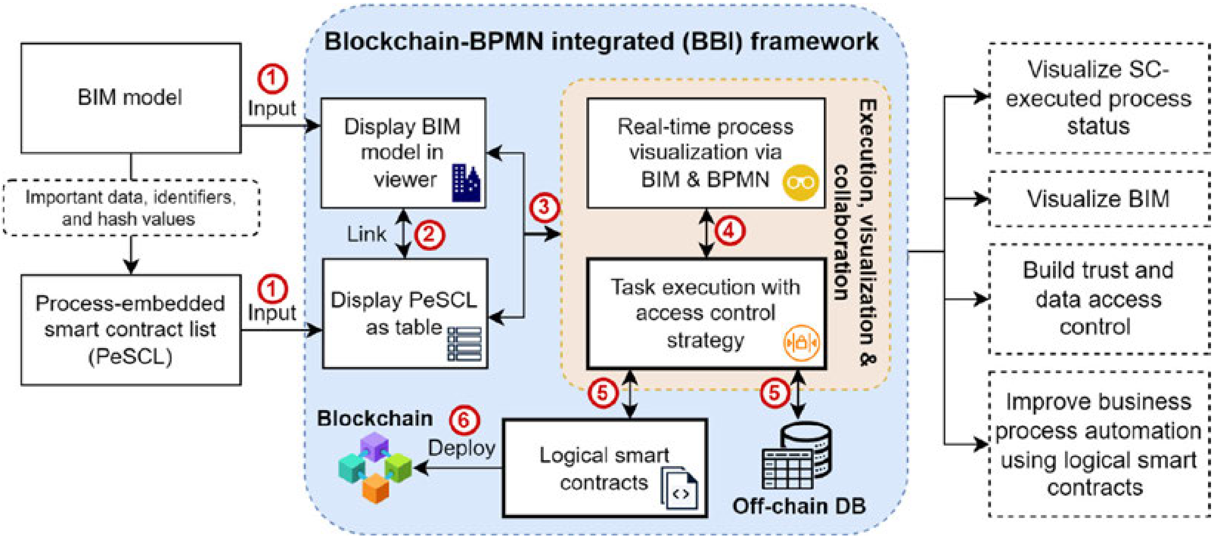

Fig. 3: The overview of the proposed Blockchain-BPMN Integrated (BBI) framework

3.2 On-chain and off-chain access control strategy

The access control strategy can be divided into two parts, namely on-chain and off-chain data access permission (see Fig. 4). All the project-related documents are stored in the off-chain storage, where the permission level of each document is also stored. When users request to check or modify the off-chain data, their username (as identifier) and permission level will be firstly checked. All the sensitive or valuable data are stored on-chain (i.e., on the blockchain), and only specific user can call specific smart contract functions. When users request to view or modify the blockchain (BC) data, their BC account identifier will be firstly checked in their called smart contract function for viewing or modifying request. Further detailed example about the access control strategy is shown in the case study section (Section 4).

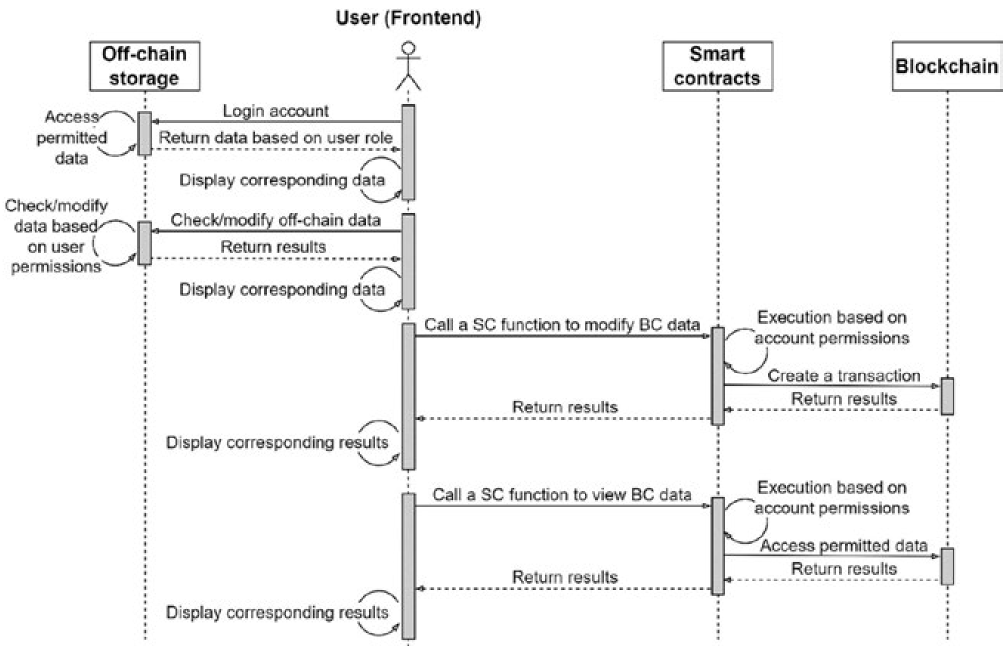

Fig. 4: Access control strategy among users, smart contracts, blockchain, and off-chain storage

3.3 From BPMN to logical smart contract

To solve the problem of current isolated smart contract usage, this paper proposes a way of implementing smart contracts, which is defined as logical smart contracts. Such logical smart contract, which is interpreted based on the BPMN components, not only automates the BPMN tasks based on the execution logic in BPMN, but also further automates the inner actions of some specific BPMN tasks. The mapping from BPMN to the logical smart contract is shown as Fig. 5. In BPMN, there are three main components, namely participants, tasks, and flows. BPMN participants are interpreted into P.StateVariables and P.Modifiers, where the former is used to store the information of the participants (such as identifier and role) and the latter is used to restrict that only specific participant can execute specific smart contract function (for access control strategy). BPMN tasks include task participants and inner actions, where the former is from the BPMN participants with the specific task execution permission and the latter is to indicate what actions could be done within the tasks. BPMN flows are used to indicate the execution logic of BPMN tasks, which is further interpreted into F.StateVariable, Enum, F.Modifiers and F.Functions. Further example of the generated logical smart contract is shown in the case study.

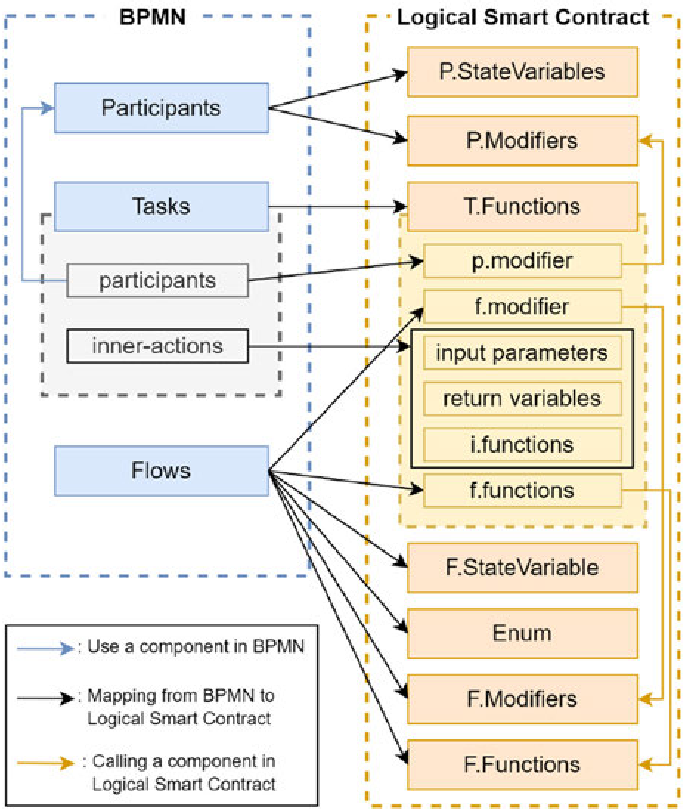

Fig. 5: Mapping from the logic of BPMN to the logical smart contract

4. CASE STUDY

Validation of the proposed BBI framework was achieved through the implementation of a decentralized application, where a React frontend was seamlessly integrated with the Ethereum blockchain. This implementation was rigorously tested against a real-world BIM design collaboration case from Tao et al. (2021). In Fig. 6, the comparative analysis between their original smart contract solution and our enhanced logical smart contract is presented, revealing the improvements achieved by integrating process logic into the smart contract. Following this comparative analysis, the testing results of the case within our implementation are diligently presented in Fig. 7, providing a comprehensive view of the real-world applicability and efficacy of our proposed framework.

In Fig. 6(a), the BPMN workflow was meticulously designed based on the case elucidated by Tao et al., encompassing three distinct roles of participants and a comprehensive set of seven BPMN tasks. Fig. 6(b) depicts the original smart contract solution, which was rather limited, accommodating only two smart contract functions, namely UPLOAD and INQUIRE. In this solution, real-time process status updates were unavailable to participants, and the execution of smart contract functions required manual intervention from the participants themselves, lacking the seamless automation sought after. Conversely, in Fig. 6(c), our proposed logical smart contract solution represents a significant advancement. Execution logic and access permission are ingeniously incorporated directly into the smart contract, improving its ability for automation and collaboration. Furthermore, execution permissions are elegantly restricted by this design, significantly mitigating the potential for errors and associated challenges, thus providing a more robust and efficient solution for BIM design collaboration in the smart contract system.

Fig. 7 serves as a comprehensive visual representation of the final case outcomes, encapsulating a multitude of crucial components that harmoniously contribute to the success of our BBI framework. Within this illustrative figure, Fig.7(a) provides an immersive real-time visualization of the BPMN process status, meticulously denoting task execution through distinct markers, with yellow indicating completed tasks and green designating those currently in progress. This dynamic display offers stakeholders an intuitive and up-to-date overview of project progression. In Fig.7(b), the logic of BPMN tasks is revealed through the logical smart contract functions, showcasing how these functions govern the execution of critical project activities.

Meanwhile, Fig.7(c) introduces the access control strategy with strict user authentication via blockchain login accounts. This authentication process ensures varying levels of data visibility across the frontend, catering to the unique needs and privileges of individual users. Furthermore, it plays a pivotal role in safeguarding sensitive smart contract functions, allowing access only to authorized stakeholders. The BIM model is displayed in Fig.7(d) through the BIM viewer, providing stakeholders with a comprehensive visual representation of the project's architectural intricacies. This model is intimately linked to the PeSCL shown in Fig.7(e) , which is used for storing and listing project-specific details. Finally, Fig.7(f) focuses on on-chain data and blockchain-related information, demonstrating the transparent and immutable nature of data stored in the blockchain. Together, these components provide project participants with valuable insights into the structural and organizational dimensions of the project, offering a holistic view of how blockchain-based smart contracts enhance transparency and data integrity in the BIM design collaboration case.

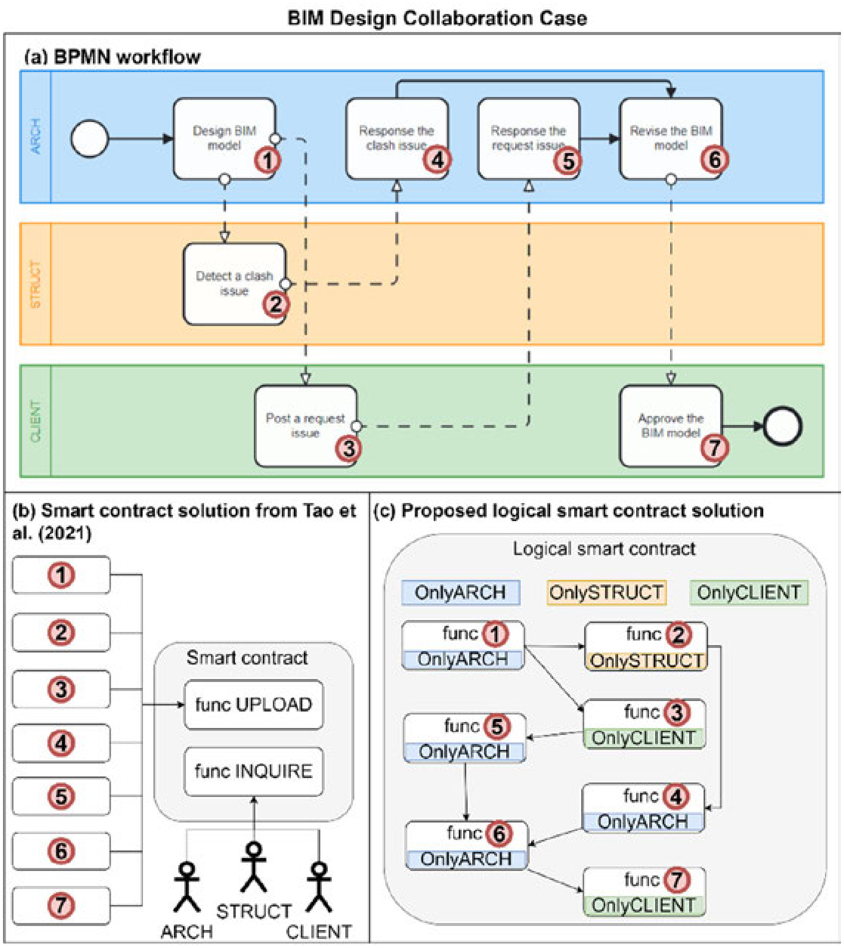

Fig. 6: The comparison of (b) the smart contract from Tao et al. (2021) and (c) the proposed logical smart contract

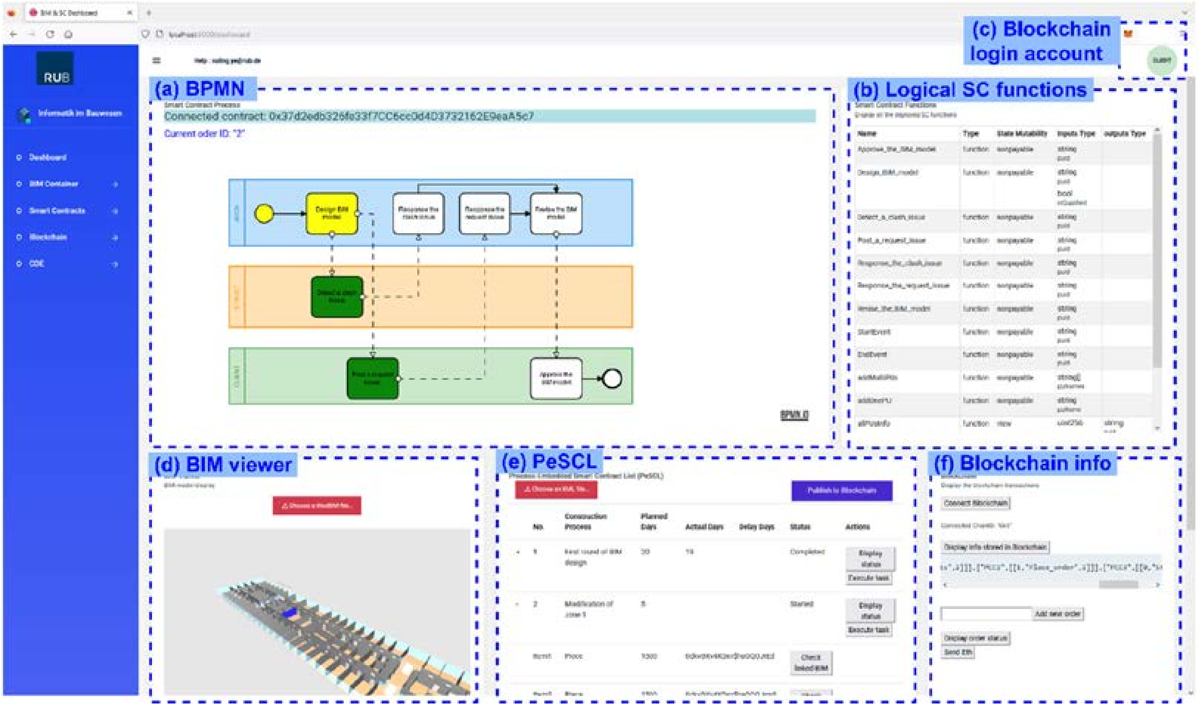

Fig. 7: Results of the BIM design case in the BBI framework

5. CONCLUSION

In summary, the escalating concern for data security in construction business processes has spurred the search for innovative remedies. While the potential of Blockchain and smart contracts is evident, they grapple with substantial drawbacks, notably the isolation of current smart contract implementations and the difficulty non-programming participants face in comprehending smart contract codes within the construction industry. This study has confronted these challenges head-on by pioneering a BPMN-driven approach, seamlessly integrating blockchain and smart contracts while remedying issues related to automation and participant understanding. The introduction of the Blockchain-BPMN integrated (BBI) framework marks a significant advancement, revolutionizing the automation of intricate construction workflows, fostering seamless collaboration, and enhancing visualization across diverse smart contract functions. The strategic inclusion of an access control strategy fortifies data security while preserving transparency. The innovation of logical smart contracts, enhancing automation by embedding task execution flows, is a notable contribution. The feasibility and efficacy of the BBI framework are demonstrated through practical implementation and rigorous testing in a BIM design collaboration scenario. However, a lingering limitation pertains to the immutability of smart contracts. Future endeavors should focus on enriching the framework's adaptability and addressing this issue by incorporating an upgradable feature into the proposed logical smart contracts, paving the way for more refined solutions to the multifaceted challenges inherent in the construction field.

Zheng Chengliang
Wuhan University, Wuhan, China

ABSTRACT: *A crucial action of COVID-19 combat is the quick design and building of makeshift hospitals (MHs). Although adopting building information modeling (BIM) promotes the digitalization and communication of design collaboration, data security vulnerabilities (e.g., lacking traceability and transparency) are detected and have inevitably impeded the efficiency and productivity of the MH project. Such problems often lead to rework and unnecessary disputes, wasting valuable time on projects requiring ultra-fast construction speed. The emerging blockchain technology offers an immutable and traceable collaboration environment. However, limited studies have integrated blockchain in the BIM design process, especially design in emergency projects like MH. Therefore, this paper proposes a blockchain-enabled collaboration (BEC) framework for fast and secure BIM design. The framework is illustrated in an actual MH project in Hong Kong, and results show that: (1) it supports secure and automated BIM data exchange and (2) it saves 23 % of the time in a design coordination case.*

KEYWORDS: *Covid-19, BIM, Blockchain, Makeshift Hospital, Smart Contract.*

1. INTRODUCTION

The COVID-19 pandemic seriously threatens the global public medical and health system. By January 2023, there had been over 750 million confirmed illnesses and over 6 million documented fatalities (WHO, 2023). Governments launched many emergency construction projects to meet the enormous demand for patient quarantine facilities, establishing multiple makeshift hospitals (MHs) (Luo et al., 2020). A makeshift hospital, also referred to as Fangcang hospital or mobile cabin hospital, is a type of emergency service that assembles modular medical units to form a temporary hospital to address the ongoing scarcity of medical supplies. Two examples in China, Huoshenshan hospital and Leishenshan hospitals, built and delivered in 10 days and 18 days, respectively, have proved that the suppression of epidemic outbreaks is made possible by establishing temporary MHs, which are crucial for lifesaving and improving recovery rates (Zhou et al., 2022).

MHs have challenging tasks, intricate specifications, and condensed design and build times. Therefore, building information modeling (BIM) technology is introduced because these criteria present additional difficulties for design work (Tan ey al., 2021). BIM is essential in streamlining coordination by combining organizational and procedural data into a shared repository. According to (Luo et al., 2020), BIM benefits the MH design in three aspects. First, MH design needs significant optimization work by reducing changes during the building phase by visualizing all conflicts. Additionally, designers can use integrated BIM data to speed up construction for parallel scheduling, improving design simulation, like predicting the transmission of viruses in negative pressure wards. Finally, BIM is a platform everyone can use to easily create, exchange, and collect digital data to promote collaboration.

However, some data security concerns still exist in the MH BIM process, causing reworks and time waste, hindering efficiency and productivity. For example, in contrast to general construction projects in which BIM models from various disciplines are created sequentially, models in MHs are made independently and concurrently. When BIM information is synchronized amongst teams, there is a danger of data omission and inconsistency, which eventually leads to design errors because there are no referenced models for the untransparent collaborative environment. Besides, there are no routine meetings for BIM coordination due to time constraints. Instead, a "peer-to-peer (P2P)" communication model is used, wherein project members contact accountable designers directly and personally through virtual meetings or phone calls. However, because it lacks verifiable and traceable records, this method can occasionally be disorganized and ineffectual, making collaboration time-consuming.

Blockchain is a distributed database technology that leverages peer-to-peer networks, cryptographic hash algorithms, and consensus mechanisms to secure data integrity (Tao et al., 2020). The blockchain prevents a single

administrator from controlling the entire network because each peer keeps an identical and append-only data copy (also known as the blockchain ledger). The benefits of blockchain in construction payment (Das et al., 2020), supply chain management (Tezel et al., 2021), and design collaboration (Pradeep et al., 2021) have been preliminarily investigated. However, incorporating blockchain into MHs is still in its infancy for two barriers: (1) The mechanism of embedding blockchain in an MH BIM process is unclear. Problems like which activities need blockchain and what data should be transferred are still awaiting solutions. (2) Key technical elements, like smart contracts supporting blockchain data interaction, have not been developed.

Therefore, this paper proposes a blockchain-enabled collaboration (BEC) framework for fast and secure BIM design. The primary scientific contributions of this paper are: (1) identified three main security risks in the MH BIM design process, (2) proposed a BEC framework to alleviate harms brought by the security issue, thus improving design efficiency, and (3) developed three smart contracts to automate the data exchange in a blockchain. Finally, the framework is demonstrated and evaluated in an actual MH project in Hong Kong.

2. METHODOLOGY

2.1 Identification of BIM security vulnerabilities in MH

Locating the risks is the fundamental step in developing the BEC framework. In this study, one BIM manager and two BIM designers who had a direct hand in an MH project and were familiar with the intricate steps of BIM-based design were interviewed four times each. Data collection took place over one month in 2022, from March to April. A BIM collaborative design workflow is in Figure 1.

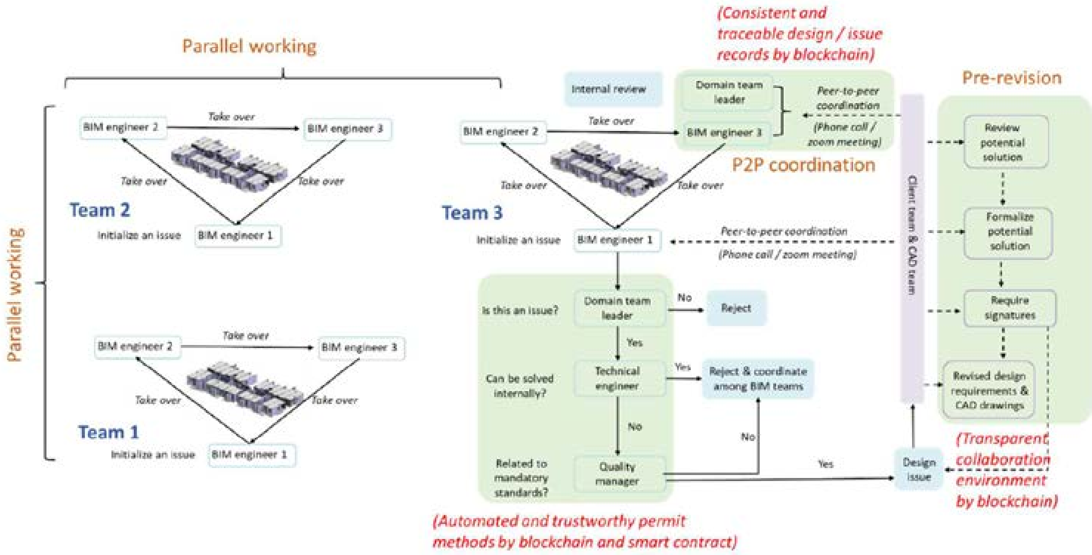

Fig. 1: BIM-based design workflow in MH

Three factors account for how the workflow quickens the BIM design process. The parallel design is the first benefit. Several models are produced simultaneously in this MCH project, reducing time compared to normal construction projects in which BIM models from several disciplines are developed sequentially. P2P communication is the second advantage. There are no scheduled meetings for BIM coordination because of scheduling constraints. Instead, a P2P communication model is used, in which accountable designers are contacted directly and personally by project members during virtual meetings or phone calls when design issues arise. This is an effective method for facilitating communication since it prevents pointless meetings and enables responsible individuals to identify design concerns promptly. Pre-revision refers to addressing design or BIM model issues before the client issues formally amended drawings or documentation, saving waiting time. Content marked green in Figure 1 indicates the steps that can be improved by blockchain.

However, security flaws are also caused by such unique collaboration methods. The risks and merits provided by blockchain are presented in Figure 2. For parallel work, the absence of a visible path for updating information causes differences across models, mistakes in design, and even delays. Blockchain guarantees data transparency and consistency thanks to its distributed architecture. In the course of the discussion, the BIM manager bemoaned the fact that they frequently wasted time looking up design records to identify problems because ECPs lacked adequate logging facilities, leaving out certain previous data. Additionally, several designers collaborate to develop a model in a "relay race" fashion, with each team member finishing a section of the model in turn. The designer contacted during the P2P collaboration may not be aware of the specifics of the issue if they recently took over the contract from another designer (the issue proposer). All design logs and actions can be immutably recorded using blockchain to improve collaboration traceability.

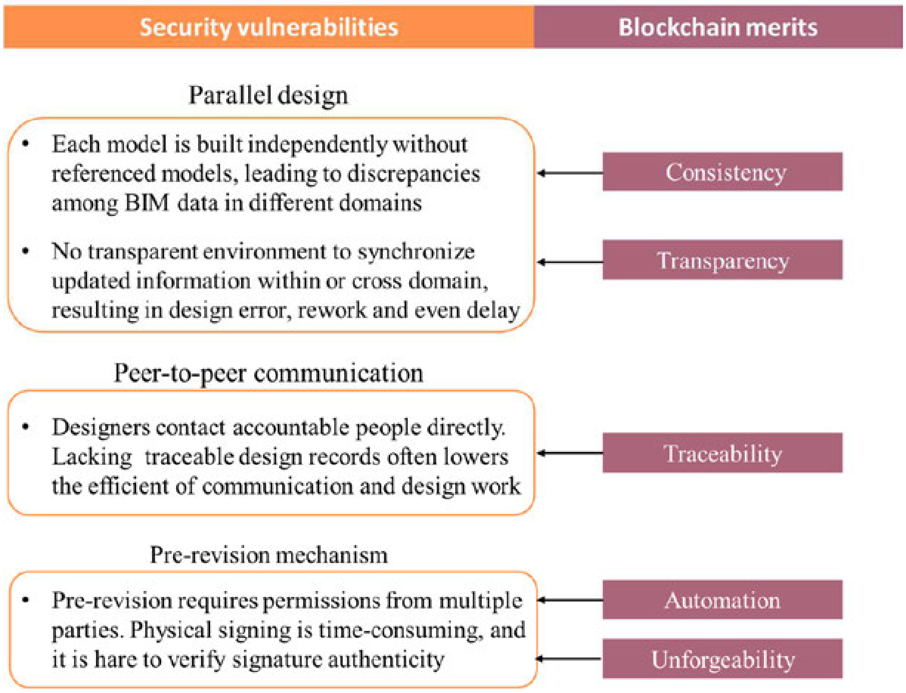

Fig. 2: Blockchain merits in MH

2.2 Blockchain-enabled collaboration (BEC) framework

The BEC framework in Figure 3 shows the logic of implementing blockchain in an MH BIM design and offers a technical stack for data flow. The seven-layer architecture serves as an example of the technical stack used to create a BEC framework. Through the application layer, which provides an interface for user management, users in the user layer can sign up for the blockchain. User operations may be documented in the blockchain in this manner. These "one-stop" registration processes make it easier for consumers to use blockchains because they simply need to complete standard registration processes. The interaction between the front-end inputs and the blockchain databases on the backend is carried out through smart contracts at the smart contract layer. Blockchain smart contracts, machine-readable pieces of code, can self-execute business logic (e.g., payment) on blockchain ledgers, thus empowering automatic and unforgeable collaboration actions (Li et al., 2022). Event transactions will represent collaboration actions, such as permission transactions (metadata of permission execution), issue event transactions, and model event transactions (metadata of events pertaining to BIM models). Large-sized data like BIM models and non-graphic documents are also stored in off-chain databases, which can be local servers or cloud servers like Autodesk BIM 360. This is in addition to on-chain data (transactions). This layer has a digital signature generator that generates digital signatures using the 256-bit secure hash technique (SHA-256). These fingerprints are spread across the blockchain network. The infrastructure layer serves as the foundation and provides necessary services, including cloud data storage, operating systems, and hardware (e.g., GPU and CPU).

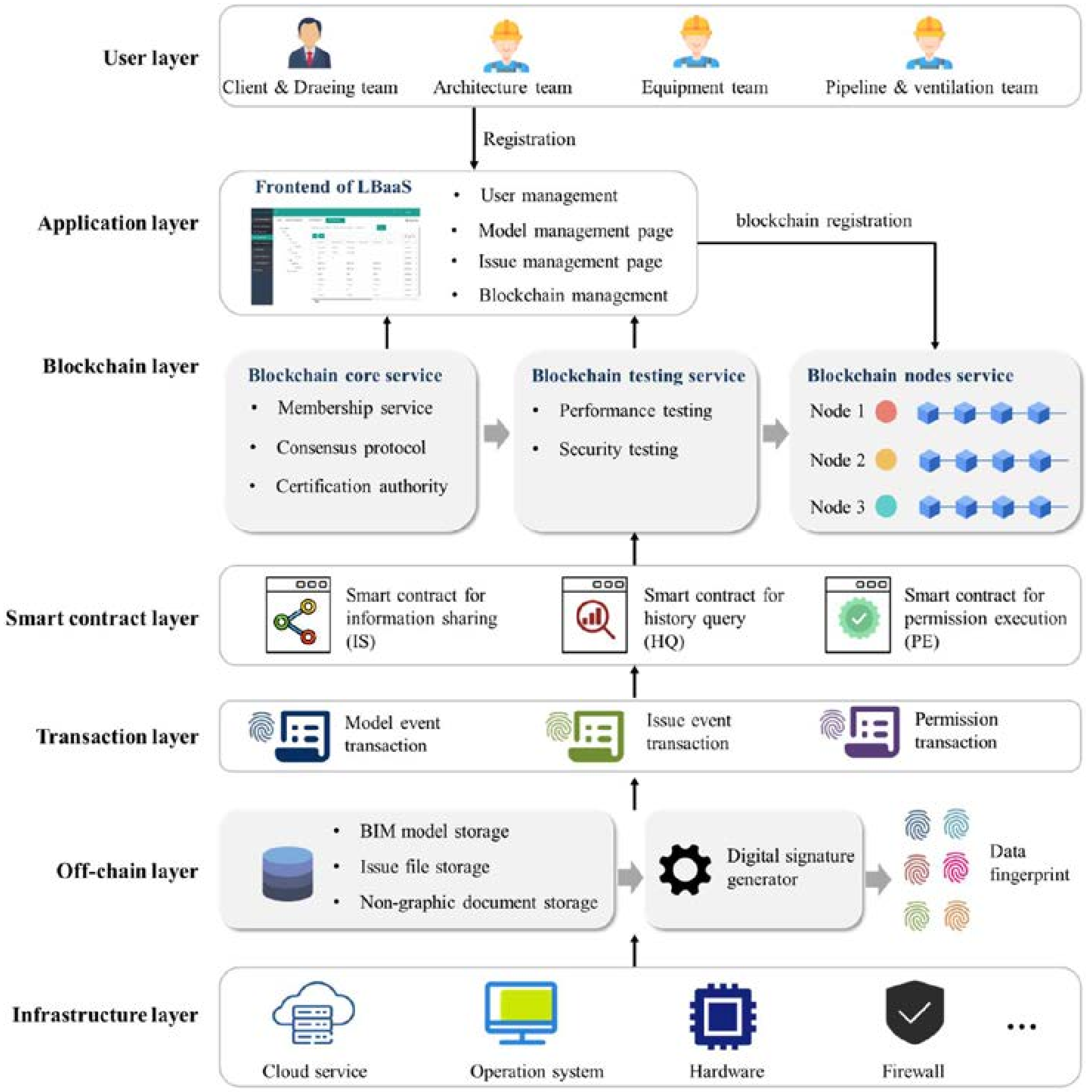

Fig. 3: Architecture of BEC framework

2.3 Smart contracts for BIM data interaction

In the BEC framework, three smart contracts have been coded. The pseudocodes are shown in Figure 4. A transaction comprising the model ID, fingerprint, user ID, and timestamp will be transmitted to the IS (information sharing) smart contract whenever a user uploads a new model (or issue). An endorsing node will verify this transaction by examining the legality of the transaction (Step 1). Illegal transactions will be denied, or they can go through and be sent back to the smart contract with endorsing signatures. An example of an illegal transaction would be one where the transaction data model is not required to follow a key-value structure (Step 2). In Step 3, the smart contract hands the transaction off to an ordering service that will chronologically group the transactions that occurred within the specified time into a new block. All blockchain nodes will receive it through the smart contract, and upon obtaining it, they will verify the block (Steps 4 and 5). The ledger will be updated with confirmed blocks as immutable records.

The rationale behind PE (permission execution) smart contracts is similar. One distinction is the smart contract input, and the other is the status results. After reviewing an issue, a project member (such as a domain manager) can decide. An endorsing peer will receive a new transaction from the PE smart contract along with all essential metadata (such as issue ID, issue decision, reviewer comments, etc.) so they can verify that the input complies with the regulated data model. Then, the project member will update the blockchain world state, a database that displays the most current status of various files and is built on top of the blockchain ledger. Besides, the PE smart contract creates and stores the digital signatures of the user to ensure the integrity of outcomes, saving time by doing away with the laborious physical permit process. The HQ (history query) smart contract will retrieve previous transactions (e.g., file ID) based on the provided key.

Pseudocode of information sharing (IS) smart contract

```
Input: IS transaction data, IS function
Output: New block in blockchain
Step 1: IS function proposes the transaction for legality checking
    if input data model = pre-defined IS data model
        Function name = IS
        generate endorser signatures
    else
        validation fails
Step 2: Get back endorsing signature
        return pre-execution results ← transaction data||read-set||write-set||signatures
Step 3: Sent to ordering service for new block packing
    new block ← pre-execution results||block hashes||Merkle tree||timestamp
Step 4: Broadcast the new block to all nodes
Step 5: Verify and add to ledger
    if validation results = true
        return new block ← block number "N+1"
        notification message ← "Transaction has been successfully shared"
    else
        IS transaction sharing fails
Step 6: Notification
End
```

Pseudocode of permission execution (PE) smart contract

```
Input: PE transaction data, decision, PE function
Output: New block in blockchain, issue status change
Step 1: PE function proposes the transaction for legality checking
    if input data model = pre-defined PE data model
            Function name = PE
            generate endorser signatures
    else
            validation fails
Step 2: Get back endorsing signature
        return pre-execution results ← transaction data||read-set||write-set||signatures
Step 3: Sent to ordering service for new block packing
        new block ← pre-execution results||block hashes||Merkle tree||timestamp
Step 4: Broadcast the new block to all nodes
Step 5: Verify and add to ledger
        if validation results = true
            return new block ← block number "N+1"
            notification message ← "Transaction has been successfully shared"
            New issue status ← reviewer ID||decision
        else
            PE transaction sharing fails
Step 6: Notification
End
```

Pseudocode of history query (HQ) smart contract

```
Input: Target file ID, HQ function
Output: Transactions details of a given ID
Step 1: HQ function checks if the given ID exists in blockchain
    if ID exists
        query results ← transaction value of this given ID
    else
        reject the query
End
```

Fig. 3: Architecture of BEC framework

3. VALIDATION AND EVALUATION

3.1 Validation scenario

The roadmap for the validation scenario, which aims to confirm the viability of the smart contract and the authorization workflow, is shown in Figure 5. The AR-01 presents a concern regarding the current window size of a medical block, which is 600*1200mm, although the standard suggests a 900*1200mm window. The problem is then generated, along with a design document, for review. The domain team leader AR-0 reviews the issue detail and approves it with the remark that "this is an issue." The technical engineer (TE-1) notes that this problem cannot be resolved internally and requires the client's additional input. The quality manager (QM-1) approves this issue because it relates to requirements that should be accepted by the client and drawing team. All these permissions are carried out by calling the PE smart contract. Results indicate that every authorization action was carried out automatically and stored in the blockchain. Each transaction records the following information: (1) the user ID executing the action, (2) the judgments (in this case, "approved") made by various users, and (3) the precise remarks made by various parties.

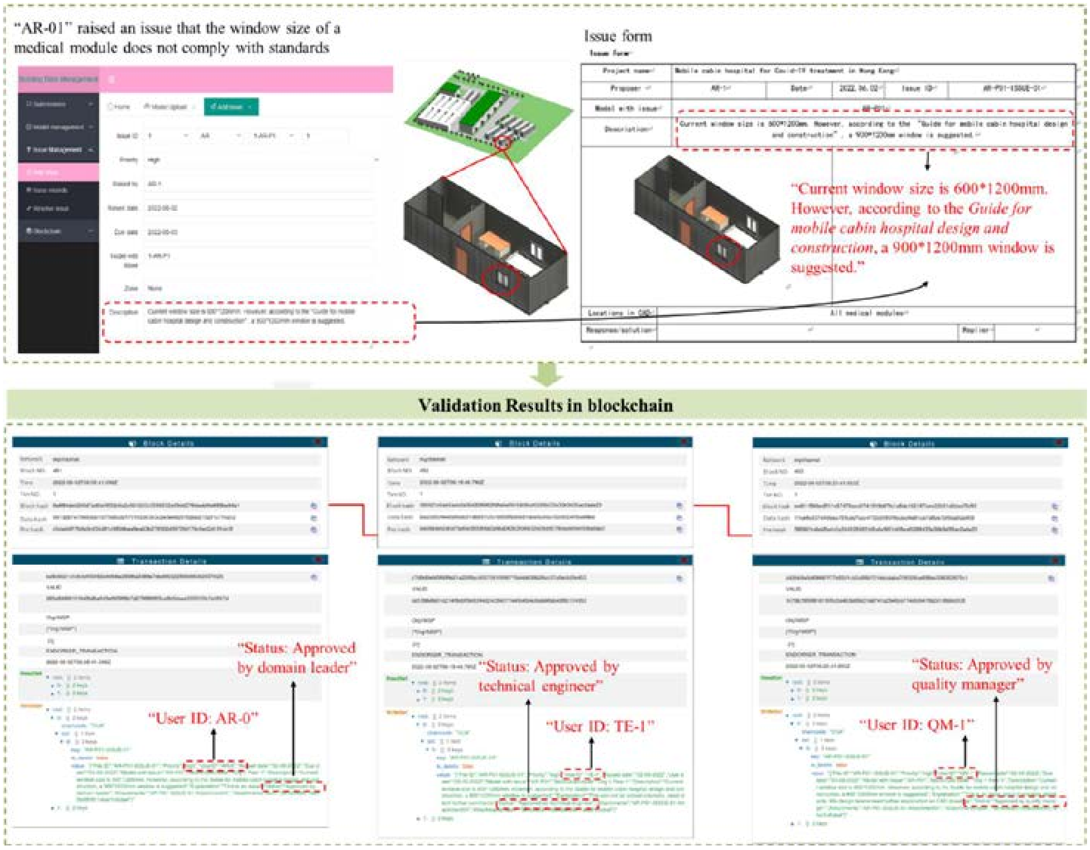

Fig. 5: Framework validation in a BIM permission execution scenario

3.2 Framework evaluation

The evaluation includes two parts. The first is BEC computing performance testing, aiming to see if the proposed framework meets the basic data processing requirements. High latency, like what is in the Bitcoin blockchain, is not acceptable in construction design. The second is a comparison evaluation to test if the BEC framework advances existing BIM solutions regarding design efficiency.

Blockchain latency measures the time required for a smart contract to register a transaction in the blockchain (Ciotta et al., 2021). To determine whether a blockchain's "speed" meets business needs, latency is a crucial statistic in the evaluation process. In MHs where rapid information sharing is required, high latency is problematic. The latency of three smart contracts is measured in this research. To prevent abnormal findings, the repeated test is run ten times. The results in Figure 6 demonstrate that all latency is millisecond-level. No latency standard has been established in construction, because the blockchain is currently being built. Consumers won't notice the delay if the blockchain application's maximum reaction time is less than 1 second, according to Fatokun (2021). Recommendations and best practices from studies (Sheng et al., 2020; Tao et al., 2021) state that millisecond-level blockchain latency is acceptable for design and construction procedures. The BEC framework latency is, therefore, permissible.

The quantitative analysis of how automated smart contracts in the BEC framework could promote efficiency is shown in Figure 7. Three project participants from the MH project—one BIM manager and two designers—were requested to conduct a BIM design coordination case in both the current BIM 360 platform and the prototype based on the BEC framework. Because the BEC framework employs a workflow like current practice, the time investment in the initial model change is the same (30 mins). The model adjustment required the design team to review previous data. The retrieval of a CAD drawing's change history took 11 minutes due to inadequate traceability in traditional solutions. The BIM team only spent 3 minutes identifying all BEC framework traceable blockchain ledger records thanks to the HQ smart contract. Both solutions required P2P collaboration and took 8 minutes. The team leader had to sign a design sheet before it could be pre-revised. The current method required 10 minutes to obtain a physical signature (including the waiting time). In contrast, calling the PE smart contract in BEC took 6 minutes. The BIM team also had to do extra work since they missed a supplier update because they were working on a different system; as a result, they had to spend an additional 10 minutes using existing solutions to fix the problem. Finally, by utilizing BEC and smart contracts (72 min in total), 23% of the time was reduced compared to the current solution (94 mins in total)

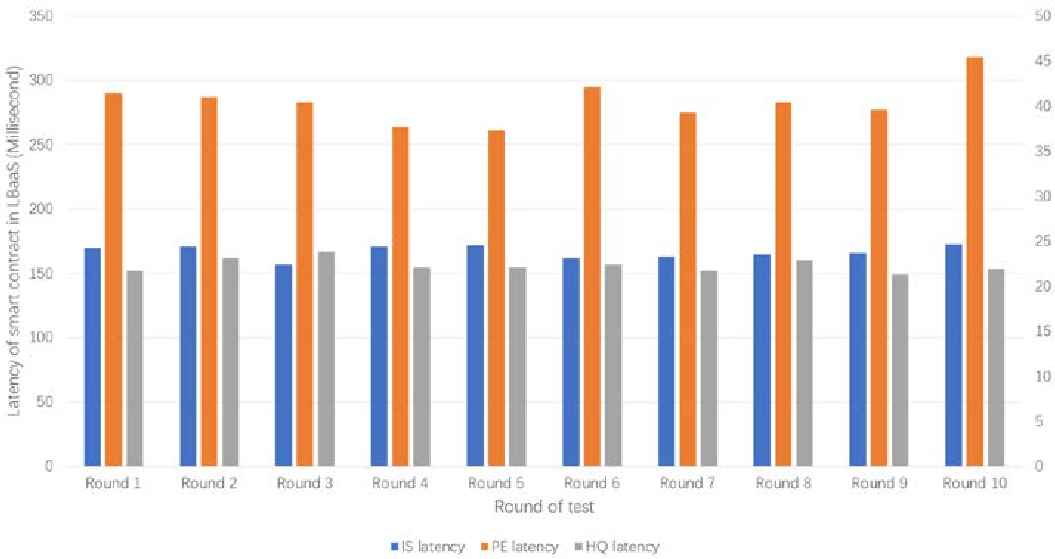

Fig. 6: Latency of BEC framework

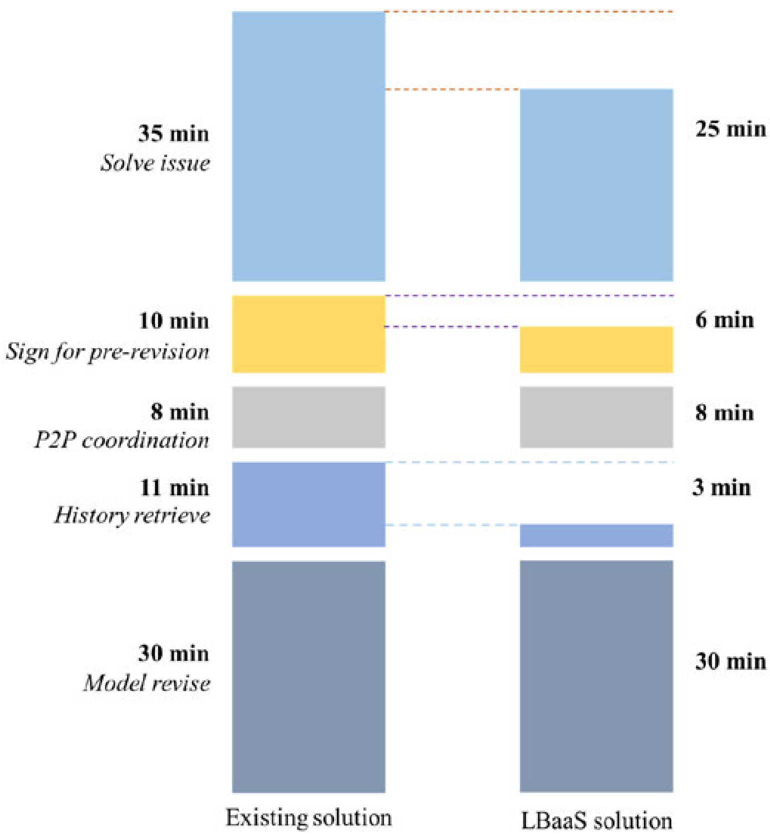

Fig. 7: Comparison results of a BIM coordination scenario

4. CONCLUSION

BIM-based design in MHs risks data security issues that will impair job productivity due to stringent time constraints and complex design processes. Therefore, this study proposes a BEC framework to increase the design efficiency of ECPs while lowering the obstacles to accessing blockchain benefits. Three objectives have been achieved. Firstly, through interviewing BIM participants from an MH project, three risks, namely, lacking transparency, lacking traceability, and lacking permission automation, that will harm the design process are identified. Secondly, a BEC framework is presented to show the technical architecture to guide the data exchange and BEC prototype development. Third, three smart contracts are developed for secure information sharing, permission execution, and historical data query. Due to time and technological limits, there are still restrictions on this early exploration. Non-automatic data verification comes first. The blockchain ledger generates and records data fingerprints. The verification procedure is still manual, though. Further research is still required on automatically comparing a file with its fingerprint.

INTEGRATING ESG FACTORS INTO CONSTRUCTION PROJECTS: A BLOCKCHAIN-BASED DATA MANAGEMENT APPROACH

Xingbo Gong, Xingyu Tao, Moumita Das, Helen H.L. Kwok & Jack C.P. Cheng*
Department of Civil and Environmental Engineering, The Hong Kong University of Science and Technology, Hong Kong SAR.

ABSTRACT: *Environmental, Social, and Governance (ESG) investing has become increasingly significant in the Architecture, Engineering, and Construction (AEC) industry. However, the AEC industry faces challenges such as non-uniform standards, complex information sources, and data security concerns when collecting and verifying ESG data. At the same time, as one of the key points of carbon emission in AEC projects, the ESG management of construction projects is still lacking. This paper proposed a blockchain-based ESG data management framework, which designed to address these challenges in the AEC industry. The framework and the smart contract and transaction data model applied in it realize data collection and information verification in construction projects. By leveraging blockchain technology's key features of transparency, immutability, and traceability, the framework ensures secure and efficient ESG data management. Additionally, the InterPlanetary File System (IPFS) technology enables access to original files for data verification and comparison, further enhancing authenticity. By integrating blockchain and IPFS technologies, our proposed solution enhances the reliability and traceability of ESG data in the construction projects, paving the way for more sustainable and transparent practices.*

KEYWORDS: *AEC, Blockchain, Construction Project, ESG, IPFS, Smart contract*

1. INTRODUCTION

Environmental, social, and governance (ESG) investing refers to a set of standards for a company's behavior, which socially conscious investors use to screen potential investments. In the Architecture, Engineering, and Construction (AEC) industry, ESG reporting serves as a method for evaluating a company's contributions to environmental protection, corporate governance, and financial capability. Investors and government management agencies often jointly assess a company's green development prospects based on ESG reports and other indicators. Concurrently, some investment institutions and market participants may establish ESG funds and investment expectations according to the company's ESG score. These behaviors directly influence the company's capital and stock market conditions. However, collecting and verifying ESG-related information is challenging due to various parallel standards, unclear evaluation criteria, and data security concerns. Ensuring that collected data can be safely verified by a third-party organization is also an essential issue since data tampering may render the company's ESG report and score unreliable if all data is controlled by a single department.

Blockchain technology, characterized by high transparency, immutability, traceability, and non-repudiation, is a potential solution for recording transactions and tracking business operations. From cryptocurrencies to smart contracts, blockchain technology demonstrates its potential applications in the construction industry (Turk and Klinc 2017). In the current research, the intelligent construction platform or technology based on blockchain has shown a high degree of usability and advantages. During the construction phase of a building, a large amount of data is exchanged between various departments and personnel. Effective management of these data can improve work efficiency and reduce unnecessary data and economic losses. Features of Blockchain make it conducive to storing and tracing ESG-related data for AEC projects. The construction industry, in particular, plays an important part in global carbon emissions management.

Regarding ESG-related research, the relationship between ESG and corporate performance highlights importance of ESG for business (Zhao, Guo et al. 2018). However, there is currently no available solution for AEC companies with complex information sources and data formats in construction projects. This paper aims to (1) propose a Blockchain-Based ESG Data Management framework, (2) design and apply technical components within the framework, and (3) verify the framework's feasibility through illustrative example. In order to provide a usable ESG data management method in the construction stage.

framework is to measure the ability of enterprises to achieve sustainable development. Since the signing of a series of environmental protection and sustainability-focused documents and conventions, such as the Kyoto Protocol (Protocol 1997) and the Paris Agreement (Agreement 2015), sustainable development has become an increasingly important topic from national to corporate levels. The ESG framework focuses on a company's environmental, social, and governance performance rather than financial performance, helping global investors identify genuinely sustainable businesses.

As climate and environmental issues become more severe, ESG assessment for companies has become a growing trend. The development of ESG-related management has become a focal point for research and disclosure. In 2021, the construction industry emitted approximately 10 billion tons of carbon dioxide, accounting for about 37% of global emissions (Programme 2022). Analysis of carbon emissions management or ESG in the construction industry is important. Related research on ESG and carbon emissions of engineering projects is also in progress, such as carbon emission estimation methods for highway project construction (Liu, Wang et al. 2017), and carbon emission analysis based on BIM in construction stage (Li, Fu et al. 2012).

Popular ESG evaluation frameworks include GRI, ISO and SASB, each with its own set of analytical indicators and disclosure requirements. Certified assessment indicators are accepted by various stock exchanges and can impact the position of a listed company's stock. Research on the impact of ESG on the economic environment and corporate finance (Broadstock, Chan et al. 2021) has proved that ESG has a positive impact on corporate investment and market value. In the practices of ESG integration in AEC projects, some large listed companies have already attempted and explored this approach. For example, companies such as Gensler, China State Corporation, and JLL have carried out ESG analysis and planning. At the same time, industry research also conducted an analysis of the impact of ESG on the construction industry (Daszyńska-Żygadło, Fijałkowska et al. 2022).

However, there are still some challenges for implementing ESG in the AEC industry. The current ESG standards are not uniform, and the information during the construction phase is abundant and complex, making it difficult to apply directly. During the ESG-related management of enterprises, a large amount of business data needs to be submitted to the review unit. Management methods for sensitive data including materials, supplier data, etc. are also not securely secured (Oltsik, J. 2014). Moreover, available statistical standards still need to be constructed. As ESG reporting and rating directly affect the stocks and economic situation of companies, ensuring the reliability of related data has become a difficult issue that needs to be addressed. The ability to ensure the traceability of ESG data still needs further exploration.

2.2 Blockchain in AEC Industry

Blockchain technology is a distributed information system proposed by Satoshi Nakamoto. From its initial development of cryptocurrencies to the current adoption of smart contracts, blockchain technology has been rapidly researched and applied in various fields. Unlike centralized databases, blockchain technology has high transparency, cannot be modified, and is traceable. Its structure is shown in Figure 1. Therefore, while ensuring the characteristics of information security, the application of blockchain technology can provide benefits such as the application of blockchain and Industry 4.0 (Bodkhe, Tanwar et al. 2020), the attempt in the financial system (Treleaven, Brown et al. 2017), etc

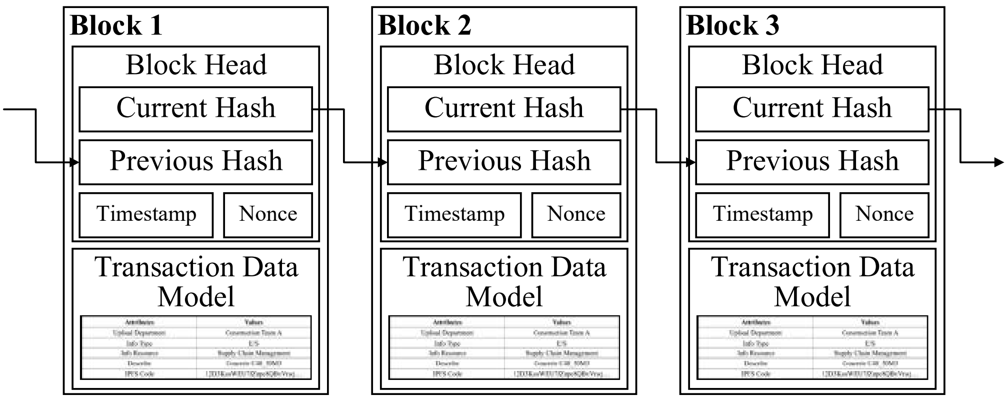

Fig. 1: Structure of Blockchain

In the AEC industry, researchers are exploring the applications of blockchain technology. Examples include a blockchain-based architectural design collaboration framework (Tao, Liu et al. 2022), a blockchain-enhanced BIM (Building Information Modeling) design process integrated with IPFS (Tao, Das et al. 2021), construction project supply chain systems that combine blockchain with IoT (Li, Lu et al. 2022), and a blockchain-based construction quality management platform (Zhong, Wu et al. 2020). These blockchain-based frameworks demonstrate the potential of blockchain technology to enhance the security and interactivity of construction project information, and they contribute to the industry's development of information management capabilities across various domains.

Blockchain systems offer efficient and trustworthy features for smart construction in the AEC industry. In the area of ESG, the requirements for data verification and credibility are high. Due to its high transparency, traceability, and undeniable nature, blockchain technology is a good means of recording ESG data. The potential of blockchain technology in promoting ESG integration, monitoring, and reporting in the AEC industry is worth exploring. In this context, some attempts are already underway, such as research on ESG performance in sustainable supply chains (Liu, Wu et al. 2021), the use of blockchain token designs for ESG reputation to create a more comprehensive carbon trading market (Golding, Yu et al. 2022), and blockchain-based assessment systems using Life Cycle Assessment (Jiang, Gu et al. 2022). However, because the blockchain system cannot store large data. And as a new technology, the technical components and workflow applied in the blockchain system are still lacking. The current research on blockchain technology in ESG management is limited.

3. METHOHOLOGY

3.1 Blockchain-based ESG Data Management Framework

Based on the analysis of the construction process and the sources of ESG data, this paper proposes a blockchain-based ESG data management framework for the construction process, as shown in Figure 2. The framework divides the construction process into three parts: project beginning, construction stage, and project delivery. The information required for ESG collection is placed in the data layer, with specific information sources and types (environmental data or social data) also labeled.

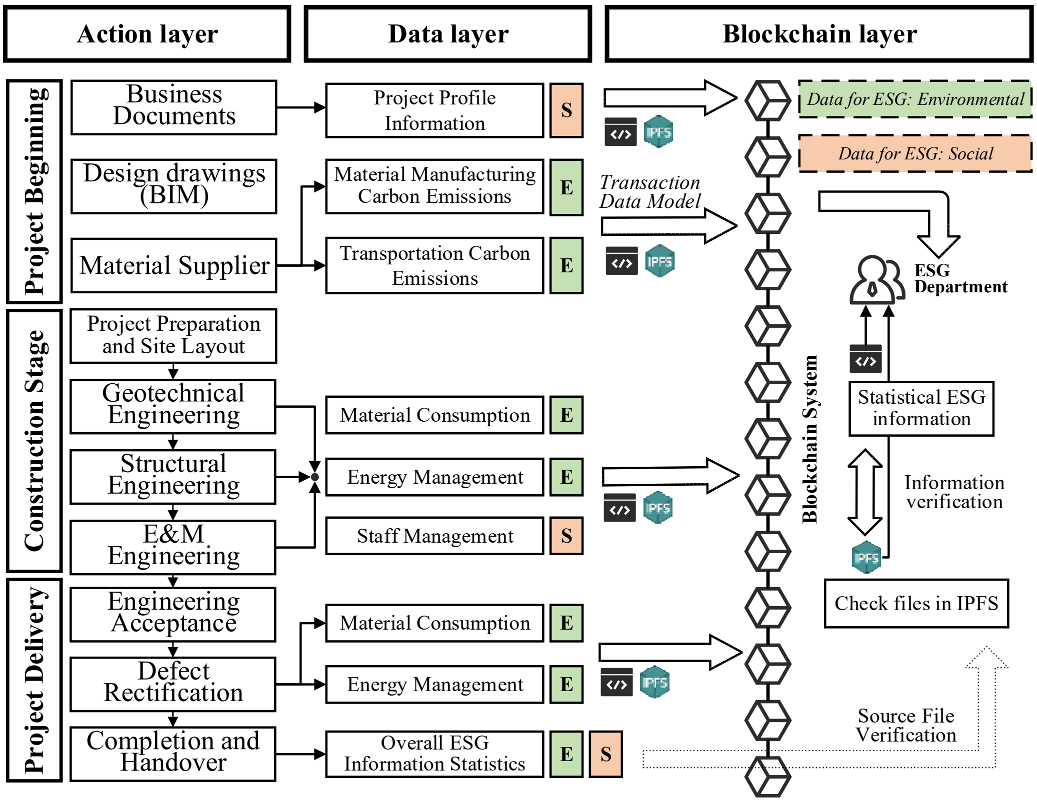

Fig. 2: Blockchain-Based ESG Data Management Framework

The collected information will be uploaded to the blockchain system through the transaction data model. This information includes the identity of the uploader and ESG-related information, and the source files' hash values obtained through the IPFS system are also recorded within the blockchain. When the construction project is completed or the ESG department needs to compile these data, they can access the information within the blockchain system. At the same time, ESG department reviewers can obtain source files through the IPFS system and compare the data in the files with the information in the blockchain to verify the information. Due to the transparency and immutability of the blockchain, all information uploaded to the blockchain system can be properly preserved and traceability is ensured.

3.2 Transaction Data Model for ESG Management

The assessment standards for ESG performance are not uniform, and some exchanges accept ESG assessment scores from multiple institutions for companies. Therefore, this paper has researched several widely recognized ESG assessment standards, compiling their assessment scope and target companies and user groups. Four representative standards include GRI, SASB, ISO, and CDP, as shown in Table 1. Among them, ISO's ESG performance assessment is dispersed across multiple standards, and some NGOs have adopted these standards.

Table 1: ESG Standards and Objects.

Standard	Abbreviation	Scope	Industry	Target	Detailed Name
Global Reporting Initiative	GRI	ESG	Universal	All parties involved	GRI200 GRI300, GRI400
Sustainability Accounting Standards Board	SASB	ESG, Business model	Industry assessment	Investor	SASB Standards
Organization for Standardization	ISO	ESG	Universal	All parties involved	ISO 9001, ISO 26000, ISO 14001, ISO 50001
Carbon Disclosure Project	CDP	Environment	Universal	All parties involved	CDP Standards

Based on the definitions of environmental and social-related information within the collected standards mentioned above, this paper gathers indicators and data sources related to these types of information in construction projects within the AEC industry, as shown in Figure 3. The primary information sources include business documents, BIM (which includes design drawings), supply chain information, and construction site management information. After filtering and processing, this information will affect the ESG reporting and scoring of the construction project.

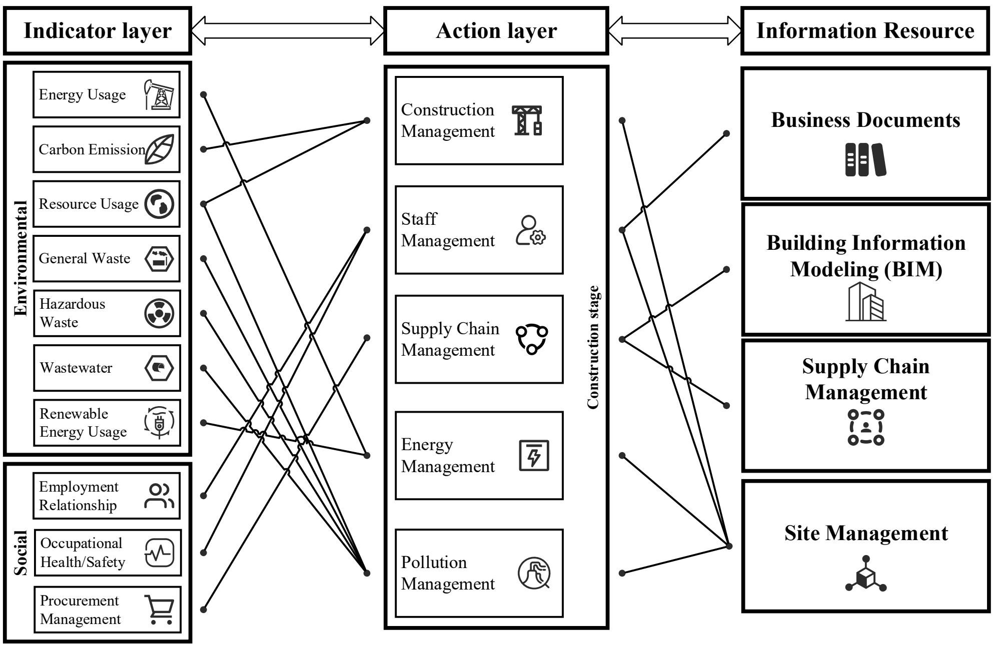

Fig. 3: Sources of ESG Information in Construction Projects

In the blockchain system, both data upload and query need to go through the transaction data model, with the information stored within blocks. A well-designed transaction data model is shown in Table 2. It includes the information uploading department, information type, information source, data description, and IPFS hash code. For instance, when different construction teams upload ESG information, they are required to provide their team identity and specify whether the information is environmental data or social data. For energy usage, the type of energy and consumption can be described; for materials usage, the type and number of materials can be noted; and for personnel management information, descriptions can be provided according to the requirements of the governing department. Once stored in the blockchain system, this information can be provided to the ESG department for analysis and further processing. When needed, the source files can be found in the IPFS system for verification and comparison.

Table 2: Transaction Data Model

Attributes	Values
Upload Department	Construction Team A
Info Type	E/S
Info Resource	Supply Chain Management
Describe	Concrete C40_50M3
Date	20230401
IPFS Code	12D3KooWEU7fZnpc8QBvVrscj…

3.3 ESG-Construction Stage Smart Contract

The blockchain system developed in this paper is based on Hyperledger Fabric. In accordance with the designed transaction data model, this paper presents a smart contract written in the Go programming language, as shown in Figure 4. The smart contract's functions include uploading current information, querying the latest information, and querying all information stored on the blockchain.

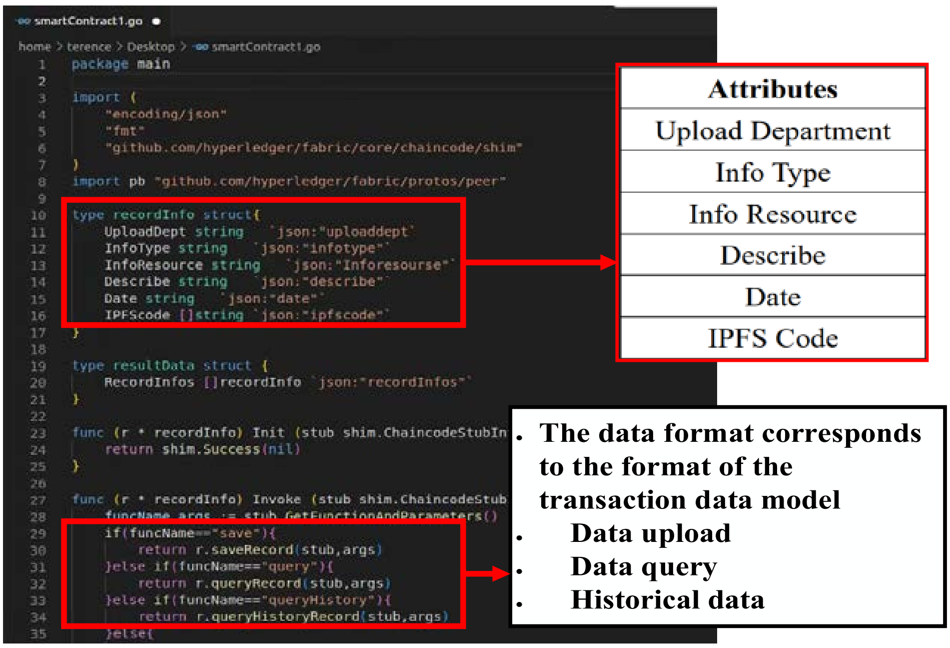

Fig. 4: ESG-Construction Stage Smart Contract

In practical scenarios, the data upload function will be frequently used to ensure real-time updates of ESG data. The other functions of smart contract mainly serve the ESG assessment department. The blockchain-based ESG data management framework consists of two developed technical components: the transaction data model and the smart contract. These two parts support the usage of the framework.

4. ILLUSTRATIVE EXAMPLE

This paper designs two scenarios to test the usability of the blockchain-based ESG data management framework. The first scenario involves data uploading and querying, as this process often needs to be repeated. For example, in actual construction projects, large amounts of materials and energy are used by multiple teams at the same time, and these records are essential in ESG analysis and score. The second scenario involves the ESG analysis department verifying the authenticity of past data. The team can verify the information based on the time information in transaction data model, the timestamps of the blockchain system, and the original files in the IPFS system. These two scenarios serve to validate the usability and traceability, which are characteristics needed by ESG analysis.

4.1 ESG Data Upload and Query

In this paper, the framework is built based on Hyperledger Fabric 2.2. For the first scenario, ESG data is fully stored within the blockchain. The data structure is consistent with the transaction data model settings, and the data query function is also implemented, as shown in Figure 5.

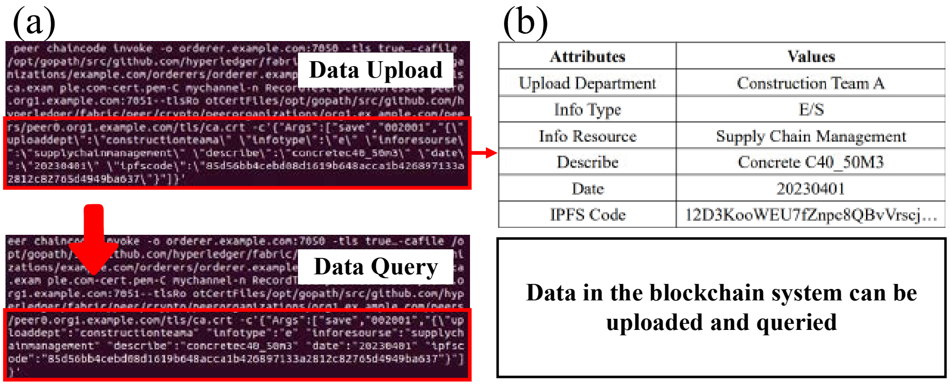

Fig. 5: (a) ESG Data Shows in Blockchain System; (b) Correspondence Between Blockchain System Data and Transaction Data Model;

In this scenario, Construction Team A received 50 cubic meters of C40 concrete from the supply chain management system. Relevant participants were recorded, including the time of the reception event and the IPFS code for the source file (receipt document). The verification results for the upload and query functions of this framework were successful.

4.2 ESG Data Verify

For the second scenario, the verification in this paper utilizes the historical information query function in the smart contract. The results show all submitted ESG-related information. Additionally, by restoring the IPFS code stored in the blockchain and accessing the IPFS system, the experiment retrieves the material receipt document for Construction Site 001 that was stored in the IPFS system during the upload process. The information in the document is consistent with the information stored in the blockchain, as shown in Figure 6.

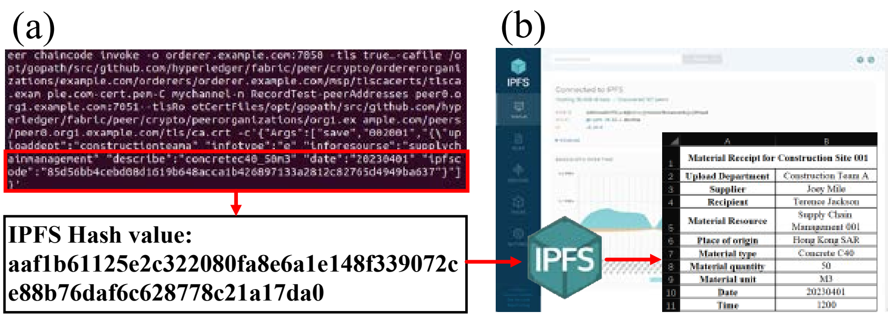

Fig. 6: (a) IPFS Hash Value in Blockchain System; (b) Verification of source files obtained through IPFS;

This experiment demonstrates the successful implementation of the historical information query function in the Blockchain-Based ESG Data Management Framework and its integration with the IPFS system. By providing access to the original files through IPFS, the framework meets the traceability requirements in ESG data management.

5. CONCLUSIONS

In conclusion, the blockchain-based ESG data management framework proposed in this paper effectively addresses the challenges of ESG data collection and verification in the construction project. By leveraging blockchain technology's advantages, such as transparency, immutability, and traceability, the framework ensures the credibility of ESG data while maintaining data security. The integration with IPFS further enhances the data traceability and availability. The verification result of the experiment was also successful.

However, there are still limitations in the research: (1) The framework has only been verified in limited scenarios, and its stability and information throughput capacity have not been tested in actual engineering projects. (2) This design only considers the construction process, and other stages requiring ESG assessment have not been taken into account. In future research, the ESG management process in construction projects should be further considered, while further reducing the cost and efficiency of ESG assessment through secure information technology. As carbon neutrality goals are established and the demand for low carbon solutions becomes increasingly urgent within the AEC industry, further exploration of ESG analysis and technological applications is still needed.

A BLOCKCHAIN-BASED SECURE SUBMISSION MANAGEMENT FRAMEWORK FOR DESIGN AND CONSTRUCTION PHASES

Das Moumita, Tao Xingyu, Xu Yuqing & Jack Cheng
The Hong Kong University of Science and Technology, Hong Kong S.A.R. (China)

ABSTRACT: *AEC projects generate numerous versions of BIM models during the design and construction phases. This process is complicated by the sheer number of domains in large projects and the interlinkage of BIM deliverables (for example the structural BIM model follows the corresponding architectural BIM model). However, due to the generation of multiple versions and parallel design progress in different domains (especially in large projects), multi-domain delivery teams often fail to access and comply with the latest/required/approved design requirements during the progression of the design phase and complete issue addressing during the construction phase, which creates confusion, may lead to disputes. Moreover, due to the contractual nature of the parties involved data and process security is also very important. Therefore, this research presents blockchain-based secure coordination workflows for effective collaboration, parallel design progress, and issue management among BIM developers from multiple domains. Smart contract logic for facilitating dynamic dependency logic for coordinating linked multi-domain submission over the project timeline is presented. A method to ensure that issues are completely, and timely addressed, and related parties are held accountable for their actions or non-response is presented by integrating a BIM change identifier and blockchain in typical issue management workflows. The method considers collaborative design and issue management workflows for the secure, efficient, and complete design of BIM models. The method is validated using an ongoing large construction project in Hong Kong.*

KEYWORDS: *Version Management, Issue Management, Security, Blockchain.*

1. INTRODUCTION

Construction projects generate huge amounts of digital information that requires sharing among stakeholders from different construction domains during the design, construction, and operation phases. It is well established that effective building data management strategies (including rules, programs, and practices) integrated with a Common Data Environment (CDE) is recommended to streamline coordination among project partners to ensure project success. However, the existing CDEs are faced with several error-inducing methods/gaps that cannot prevent incomplete BIM model delivery during the design and construction phases or hold the responsible stakeholders accountable for their actions. In particular, the first problem in existing CDEs is the lack of secure (in terms of accountability) and automated coordination methods in multi-domain delivery teams – Construction projects especially during the design phase generate a large number of BIM model versions. This process is complicated by a large number of domains in large projects and their interlinkage in submission management. For example, it is a regular practice to design structural models (the dependent model in this case) based on the latest or approved architectural model (the leading model in this case). Similarly, MEP (Mechanical, Electrical, and Plumbing) models are designed based on both architectural and structural models. However, due to parallel design progress that creates multiple versions in each domain, multi-domain delivery teams often fail to access and comply with the latest/required/approved design requirements during the progression of the design phase which creates confusion, causing incomplete deliveries and resulting in disputes between the delivery teams. Therefore, methods to facilitate automated coordination of multi-domain submission management and ensure accountability of delivery teams are necessary. The second problem in existing CDEs is the lack of methods to automatically check the completeness of BIM deliverables and to ensure accountability of stakeholder actions during the construction phase. The construction phase is more complex in comparison to the design phase due to the involvement of real-time data, time-bound tasks, and the addition of new stakeholders such as sub-contractors from multiple domains. In big projects, a large number of issues may be generated for reviewing, resolution, and approval by multiple stakeholders. Hence integrating automatic delivery completeness checker and stakeholder accountability in the traditional issue management workflow is desirable. Some existing CDEs facilitate issue resolution workflows with options for manual coordination. However, this may not be efficient in large projects involving hundreds of issues and stakeholders. In addition, the existing CDEs lack robust and secure methods to ensure stakeholder accountability.

A BIM-based issue management approach that incorporates the integration of issue management with other BIM processes such as design coordination was proposed (Wang & Wang, 2020). Jaly-Zada et al. (2015) extended the IFC schema to record a history of changes. A graph-based approach (Moayeri et al., 2017) was investigated to

Moumita Das, Xingyu Tao, Yuxing Xu, Jack C. P. Cheng, *A Blockchain-Based Secure Submission Management Framework for Design and Construction Phases,* pp. 335-342, DOI 10.36253/979-12-215-0289-3.32

capture the ripple effects of BIM version change. Jiao et al. (2013) developed a version update identifier at a BIM-object level to track changes and assign accountability for version change. Commercial and open-source applications such as Autodesk BIM 360 (Autodesk), Newforma BIM Track (Newforma, 2021), and Kubus IFC viewer (Kubus, 2022) have also deployed version and issue management for BIM deliverables. However, the existing approaches lack methods to accommodate submission dependency and completeness-related requirements in the traditional version management and issue management workflows.

Therefore, a "Blockchain-based Secure Submission Management Framework" is presented that captures information from Open BIM models using the IFC format, documents, stakeholder actions, and automated methods and integrates them with blockchain to facilitate stakeholder accountability. The framework includes – (1) a Blockchain-based Dynamic Dependency Workflow to facilitate coordination and stakeholder accountability in large projects with dynamic interlinkage among submissions from different domains and (2) a Blockchain-based Completeness Checking Issue Management Workflow to facilitate automatic checking for faster/efficient issue resolution. To realize this framework, the existing IFC schema was extended to include version and issue-related information. An entity to store blockchain transactions was also created in the extended IFC schema to integrate IFC models with block-chained information. Blockchain smart contracts and ledger data models were developed to irreversibly record stakeholder actions during the version management and issue management phases. An efficient BIM change identifier method was developed using the BIM-segmentation and hashing method to efficiently parse and identify changes between two BIM models. This method was integrated into the traditional issue management workflow to automatically check whether all the issues related to a BIM deliverable were addressed or not. A prototype for the proposed framework was developed using the Hyperledger Blockchain Platform (Hyperledger, 2020) and was tested in an ongoing project in Hong Kong.

The remainder of this paper is organized as follows: Section 2 presents the methodology of the proposed framework. The framework validation scenario and results are discussed in Section 3. The paper is concluded in Section 4.

2. METHODOLOGY

This section describes the methodology used to facilitate secure versioning and issue management in construction projects. As shown in Figure 1, the framework consists of three modules – (1) version management module and (2) issue management module that connects to a blockchain layer. These modules are discussed as follows:

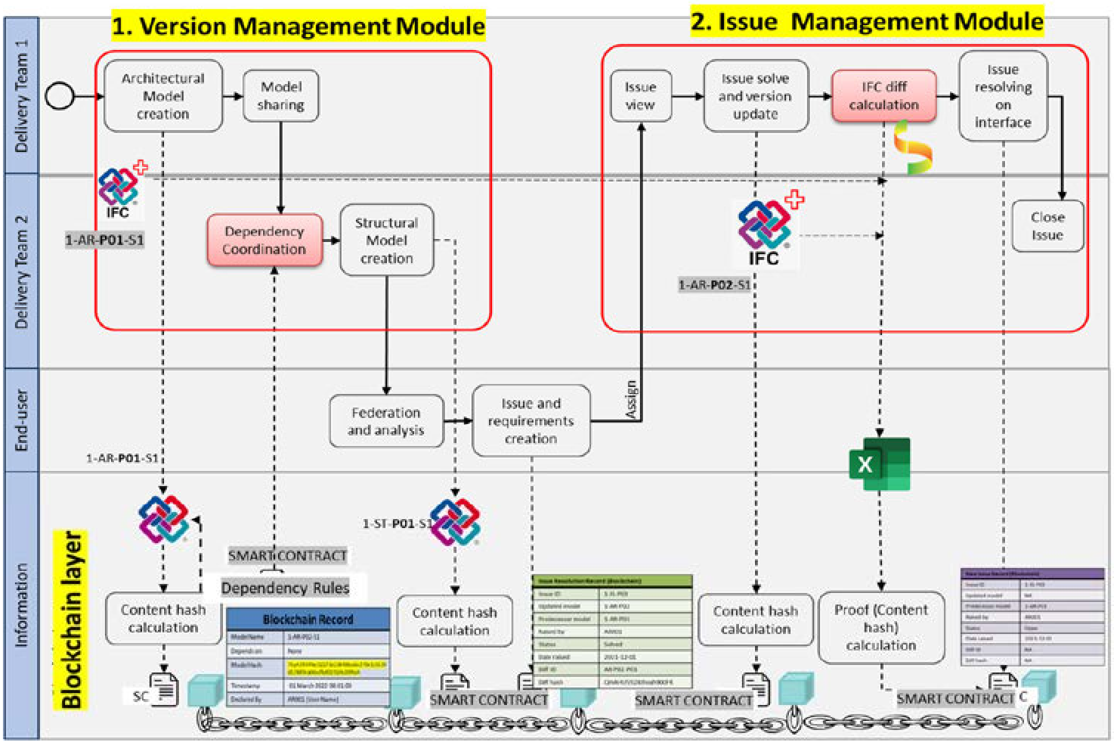

Figure 1 Methodology using Open BIM (IFC) for secure, complete, and coordinated Submission Management

2.1 Blockchain-based Version Management Module

This module manages and coordinates submission management considering versions and dependencies from different domains in an AEC project. AEC project submissions have dependencies on each other. For example, the submissions from the MEP (Mechanical, Electrical, and Plumbing) domain are dependent on the structural and architectural model of a building in general. This means the delivery team of the MEP model should ensure that they are using the latest/approved version of the architectural and structural models. Figure 2 shows some examples of dependency rules identified from a large ongoing project in Hong Kong. However, due to many versions generated during the design phase in each domain, the project stakeholders often fail to follow the latest/approved/assigned versions of the leading models. In this case, a dispute may happen between the leading and the dependent delivery teams causing a delay to the entire project schedule. Therefore, a method including IFC extension and smart contract logic was created to ensure that the dependent parties download the latest/approved/assigned leading model before they can submit their own models. Along with this checking, this action is also recorded in the blockchain to facilitate accountability of the leading and dependent parties at a later stage. Figure 3 shows the extended IFC schema which stores information such as Model name (includes domain name) and version number. An entity to store a blockchain transaction is also added in the extended IFC, called "TnxID" as shown in Figure 3, to link IFC models with blockchain ledgers.

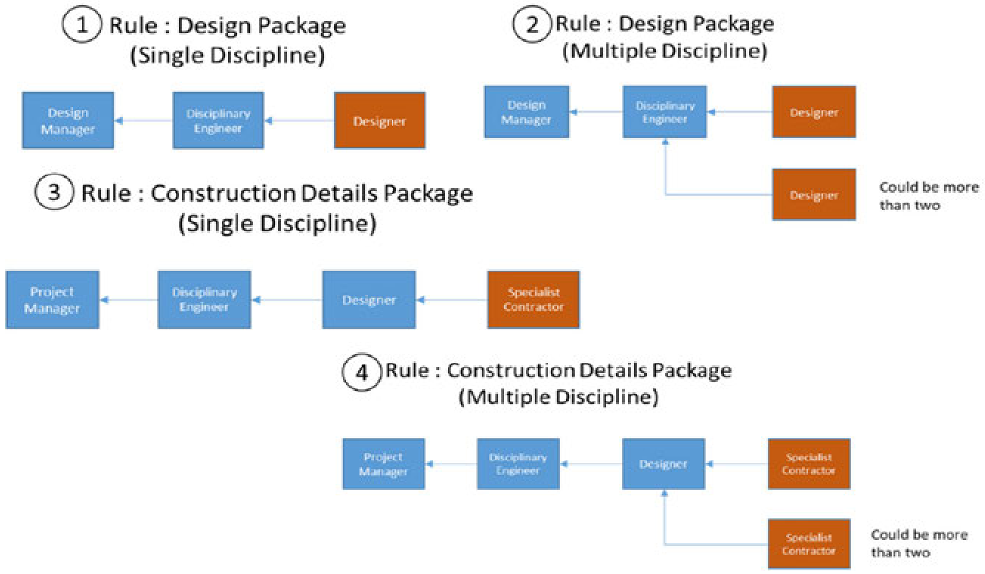

Figure 2 Example of submission dependency rules in AEC projects

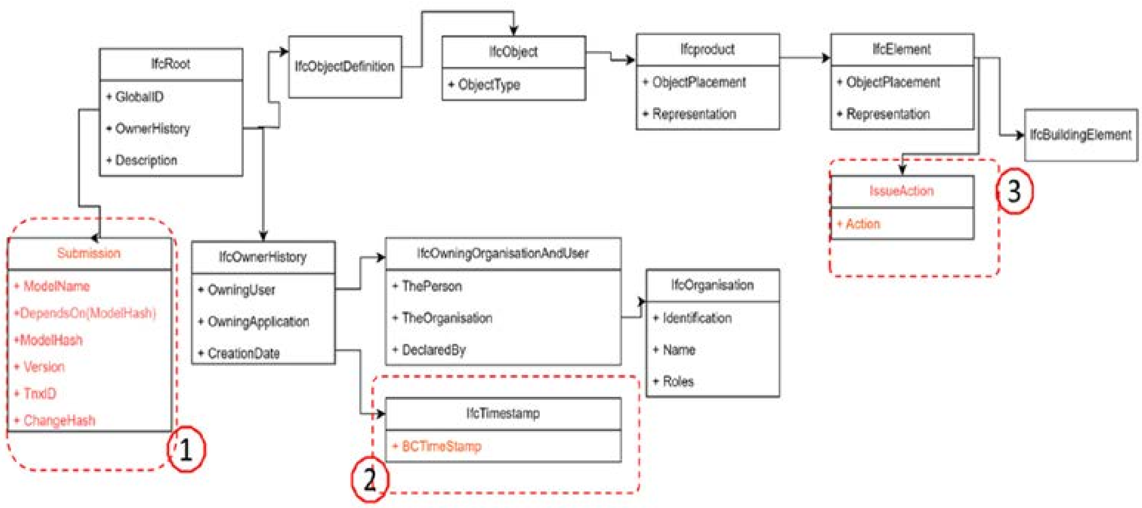

Figure 3 Extended IFC Schema for submission Management

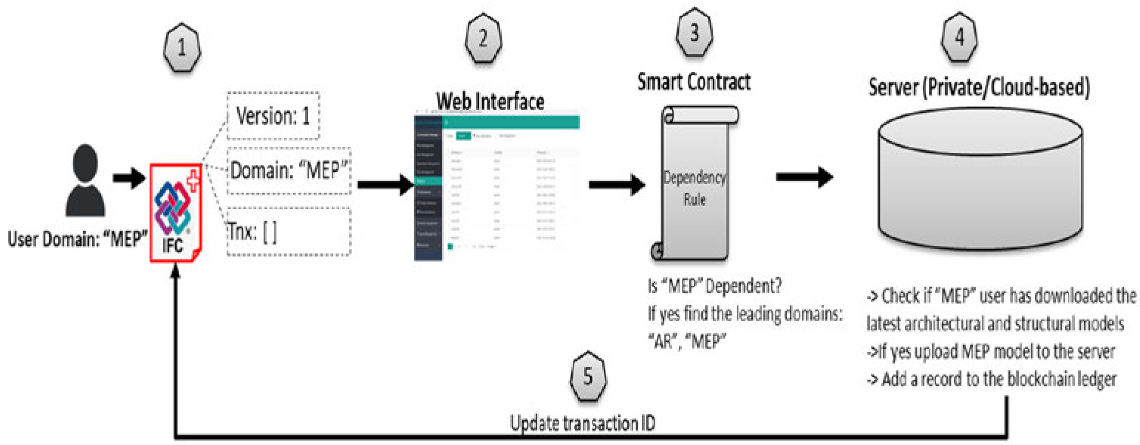

Figure 4 Methodology for Dependency Checking by the Version Management Module

As shown in Figure 4, dependency checking is performed by the version management module in four steps – (1) populating the IFC to be submitted with information such as version number and domain name, (2) submitting via a web interface, (3) invoking blockchain smart contract containing the dependency rule, (4) checking if the corresponding leading models were downloaded, (5) adding a record to blockchain ledger (Figure 5 (a)) and updating the uploaded model with a transaction ID.

Figure 5 Blockchain Data Models for Version Management and Issue Management

2.2 Blockchain-based Issue Management Module

As shown in Figure 1, a workflow was developed to integrate issue management logic with OpenBIM and Blockchain to ensure issue resolution completeness and accountability. This workflow links project issues, stakeholders (Responsible, Accountable, Consulted, and Informed Parties), IFC-based change identifiers in BIM models, and blockchain.

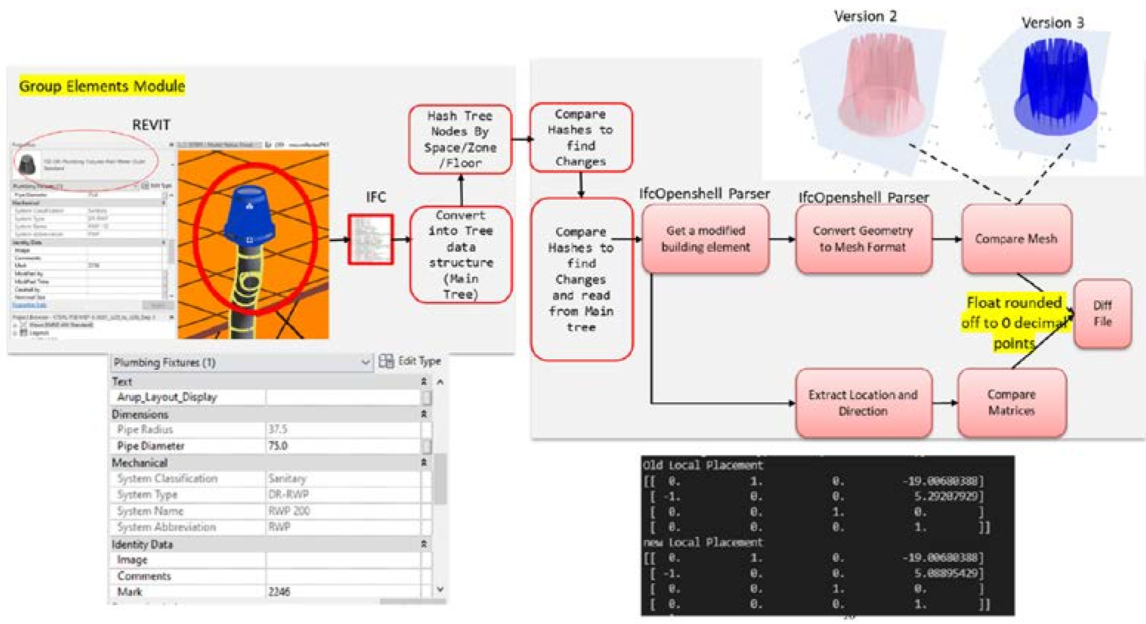

Figure 6 Methodology of the BIM Change Identifier (Diff) Module using OpenBIM and Hash-based Segmenting.

As shown in Figure 1, a BIM change identifier (called Ifcdiff module) is developed and integrated in the issue management workflow, OpenBIM has been used to integrate (interoperability properties) a BIM model change identifier (Diff) and blockchain with a traditional issue management workflow. Figure 4 shows the methodology of the diff which involves – (a) parsing the IFC models, (b) converting it into a tree-like data structure (using OpenShell)-called the main tree, (c) compressing the tree element-wise, space-wise, and zone-wise (as per user input) into a hash-based tree data structure, (d) comparing between BIM versions using the hash-based tree and identifying differences between hashes, (e) extracting the details of the changed elements for fine-grained comparison for geometry, location, and properties, (f) converting element shapes into a mesh data structure and perform mesh comparison to identify the change in geometry, (g) compare location and direction matrices to identify changes in the position of elements, (h) excel-based report generation recording the changes (addition, deletion, and modification based on IFC guides) for manual and automated review, and (i) recording of proof the diff file and issue status on the blockchain (as shown in Figure 5(b)).

The workflow facilitates automated checking of issue resolution using the openBIM-based Diff logic. End users such as issue creators can mark the building elements (using IFC *Global IDs*) (using the IFC extension as shown in Figure 3), which are to be added/modified/deleted as per the issue resolution process. The workflow automatically updates the issue status as incomplete if all the issues are not resolved and send a notification to the issue creator for manual review and override if desired. As shown in Figure 1, the issue creation and resolution are recorded on the blockchain for accountability.

3. VALIDATION

For validation a prototype was A prototype was developed and tested. Python and Openshell (IfcOpenShell, 2022) are used to develop the diff algorithm, which is used to detect model changes that should be tracked and blockchained. Hyperledger Fabric serves as the blockchain platform to immutably and traceably record BIM coordination, delivery, and operation actions. This platform provides a secure and scalable way to manage BIM data, enabling efficient collaboration between different stakeholders. It also provides a transparent and secure way to manage BIM data, ensuring that project progress is monitored and tracked effectively.

The dynamic dependency logic and the blockchain interface and tested for versioning in the Kai Tak Sports Park (KTSP) Project. The project has over 40 domains up to March 2023 which created at an average of 200-300 versions per fortnight from the entire project. This required complex dynamic rule generation for linking submissions and managing their versioning. The prototype was tested and found to be effective in the management of multi-domain submission management for the KTSP project. The end users found the platform to have the following value additions – (a) team members are sure about the model status (because of blockchained single source of truth), (b) team members are sure if the submissions have followed the correct dependency and version for model delivery for a milestone/review, (c) accountability of delivery teams to prepare deliverable with the correct information is added.

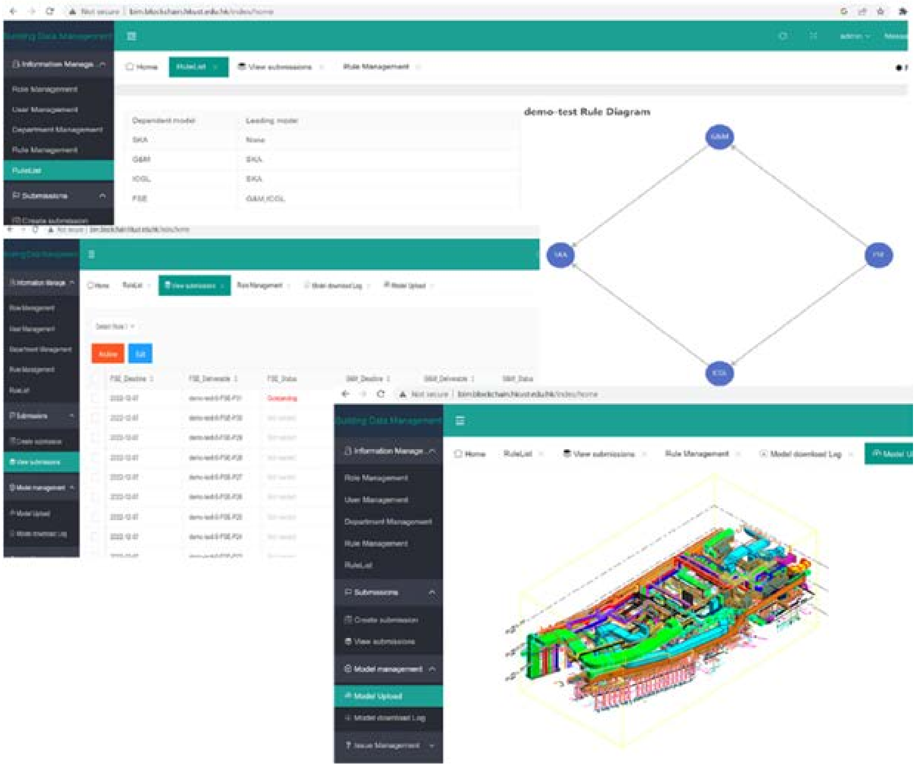

Figure 7 Prototype Web-interface Showing Dynamic Rule Creation and BIM Visualisation

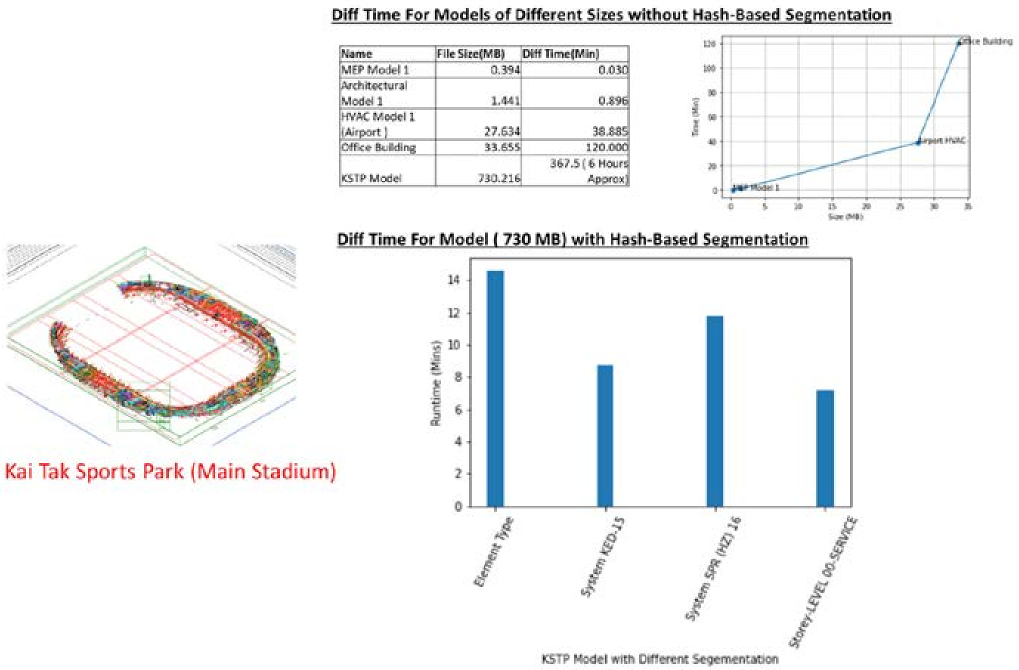
Figure 8 shows that the BIM change identifier was evaluated on models ranging from sizes 0.3 MB to 730 MB. It can be seen that there is a linear rise in the computation time of the diff program with increasing file size. As described in the methodology section, the diff logic uses a hash-tree-based data structure that segments the BIM model and facilitates comparison for a faster computation time. Figure 8 shows the results of hash-tree based segmentation on a model sized 730 GB. This method is particularly efficient in identifying small changes (such as a few modifications on a particular element type or floor) in large BIM models. The prototype is also being tested on the ongoing KTSP project. The end users have so far evaluated the platform as – the actions of all parties are blockchained which will be useful to hold parties accountable if the need arises. They have also stated that a confident audit trail record will be created, that will help resolution of future disputes or remeasurement of works upon quantifying and monetizing additional works variations.



Name	File Size(MB)	Diff Time(Min)
MEP Model 1	0.394	0.030
Architectural Model 1	1.441	0.896
HVAC Model 1 (Airport)	27.634	38.885
Office Building	33.655	120.000
KSTP Model	730.216	367.5 (6 Hours Approx)

Figure 8 Validation of the Diff Module of the Issue Management Workflow

4. CONCLUSION

A blockchain-based framework for version and issue management was presented in this paper. With the advent of digitization and the inherent contractual organizational structure in the construction industry, data security, integration, and stakeholder accountability has become very important. This is more important, especially in BIM projects which contain sensitive information and are difficult to manage in a multi-data owner environment. Therefore, the proposed framework includes - (1) Blockchain-based Dynamic Dependency Workflow and (2) Blockchain-based Completeness Checking Issue Management Workflow to facilitate integration and accountability in large-scale construction projects. For validation, a prototype was developed and implemented on an ongoing Hong Kong based project with real end users. The framework was found useful in terms of security and functionality by the end users including representing a single source of truth, maintaining version dependency, and completing outstanding issues.

ZERO-KNOWLEDGE PROOF FOR TRUSTED CONSTRUCTION MANAGEMENT: A PRELIMINARY STUDY OF ADAPTIVE BLOCKCHAIN BIM IDENTITY AUTHENTICATION

Lingming Kong*, Rui Zhao & Fan Xue

*The University of Hong Kong, Hong Kong SAR, China. *: Corresponding author*

ABSTRACT: *Blockchain technology emphasizes trust and collaboration through distributed networks and is deemed to contribute to building information modeling (BIM) based construction collaboration and management. However, the open nature of blockchain introduces severe cybersecurity attacks that undermine the trustworthiness of construction management. One salient point is identity authentication for security BIM data access in the blockchain environment. The traditional public-private key or password authenticate methods are vulnerable to malicious theft. Zero-Knowledge Proof (ZKP) is an emerging, password-free method for authenticating identities. It allows one party to prove the truth or falsity of a statement to another party without revealing any meaningful information to the counterpart. Therefore, this study proposes a preliminary user authentication protocol based on the non-interactive ZKP protocol, specifically the zk-SNARK protocol, for adaptive authentication of blockchain BIM. The adaptive authentication recognizes a random subset of on-chain historical BIM operation records to prove the identity according to the protocol. Without revealing any meaningful knowledge to the authentication system, this adaptive data access control prevents password attacks using the BIM records on-chain. Finally, the proposed protocol is deployed on the test blockchain and implemented in a preliminary case study to illustrate the feasibility and effectiveness of the proposed method. The main contribution of this paper is twofold. Firstly, the theoretical contribution is proposing a novel zk-SARKs-based identity authentication protocol that utilizes the on-chain BIM operation records. Secondly, the practical contribution relies on presenting a ZoKrates-based workflow of generating proofs, creating smart contracts, and deploying on the blockchain for verification.*

KEYWORDS: *Zero-knowledge proof, Blockchain, BIM, Construction Management, Identity Authentication.*

1. INTRODUCTION

In multi-party construction activities, collaboration and trust emerge as significant yet intricate issues. Building Information Modeling (BIM) stands as a trending and burgeoning technology within the construction industry, facilitating efficient cross-disciplinary collaboration among stakeholders. However, given the inherent characteristics of construction activities—encompassing multiple data contributors, consumers, and geographically dispersed stakeholders—the centralized, file-based BIM collaboration necessitates stringent data access control. This measure is crucial to prevent deliberate cybersecurity attacks, such as login attacks.

Ensuring that the right individuals access the appropriate BIM content – in essence, addressing authentication concerns – has emerged as one of the most critical issues in BIM-based collaboration. For example, Skandhakumar et al. (2018) proposed a BIM-based security model presented by BIM-XACML language to facilitate conditional access to BIM, and Zheng et al. (2019) offered a new context-aware access control model for the decentralized cloud BIM system. These studies cannot avoid password attacks, which represent intentional attacks to steal the authentication credentials such as passwords and private keys.

Blockchain technology brings a transformative alteration from centralized BIM to distributed BIM that is deemed to achieve transparent, traceable, and consensus-based trusted collaboration with better encryption and security (Subangan & Senthooran 2019; Nawari & Ravindran 2019). Blockchain is a distributed ledger network first proposed in 2008 and implemented in 2009 (Zheng et al. 2018). In recent years, the integration of BIM and blockchain has been studied extensively, especially in the data security aspects. Inappropriate distribution and excessive BIM transparency may lead to a loss of reputation and trust.

Considerable literature on trust has grown up around the theme of blockchain BIM in different project aspects (Wu, et al., 2022; Zhao, Chen, & Xue, 2023). For example, Das et al. (2021) categorized BIM data security into five types and emphasized the confidentiality and authenticity of distributed BIM. The confidentiality of BIM represents the necessity of safe data access by authorized people or organizations, and authenticity involves user-related and data-related regions. The Hyperledger community presented a "privacy data" mechanism that only stores the sensitive data as hash code in ledgers and source data such as BIM files off-chain (Androulaki et al. 2018). Accordingly, Tao et al. proposed an access control model based on asymmetric encryption and sensitive BIM model components decomposition (Tao et al. 2022). Much previous research utilized traditional encryption

or access control policy to guarantee secure data access in the distributed blockchain environment, which encountered the same challenge as the centralized BIM, password attacks.

Adaptive authentication stands as a potential solution for circumventing password attacks. Zero-knowledge proof (ZKP) constitutes a cryptographic technique that empowers the prover to persuade the verifier without divulging further meaningful information regarding statements. ZKP has three significant properties: (1) completeness. If the statement or witness is true, the verifier can be convinced by the honest prover. (2) reliability. The prover can deceive the verifier with a negligible probability if they do not know the statement. (3) zero knowledge. The verifier only obtains the information "the prover has this knowledge" without extra meaningful information (Goldreich & Oren 1994). These three main properties of ZKP are deemed to contribute to multi-party identity authentication for blockchain BIM. Typically, ZKP can be classified into two types, interactive ZKP and non-interactive ZKP (Hu et al. 2018). The non-interactive ZKP is widely used in the blockchain environment due to its one-way communication between the prover and the verifier, specifically the zero-knowledge Succinct Non-interactive ARguments of Knowledge (zk-SNARKs) protocol (Parno et al. 2016; Groth 2016). Anonymous currencies such as Zerocash (Sasson et al. 2014) and SERO use zk-SNARK in the blockchain domain for implementing privacy transactions. A large volume of published studies describes the role of ZKP in solving identity authentication problems of blockchain. Wang et al. (2020) summarized the existing solutions to privacy protection issues in blockchain and emphasized the effectiveness of ZKP. Yang et al. (2020) formulated an identity management scheme by leveraging smart contract and ZKP algorithms; Sun et al. (2021) proposed a two-part framework of ZKP in blockchain as on-chain and off-chain parts respectively, aiming to provide a solution of security private data access in the blockchain environment. However, due to the high cost of computation and storage of ZKP, the lack of using historical data stored in the blockchain, and the primitive application of blockchain BIM, research on ZKP-based identity authentication for BIM collaboration in the blockchain environment is still preliminary.

For a construction project, both BIM files and BIM-related operation records are stored in the blockchain system. Due to the limited storage capability of blockchain and the massive-volume nature of BIM files, a typical blockchain BIM system is composed of two parts: on-chain and off-chain parts. The on-chain part stores the metadata of BIM files, including the file name, size, owners, creating time, version information, operation records, and other file-related descriptive data. The off-chain part keeps large-size BIM data such as BIM model files and documents of the project. A representative two-part structure blockchain BIM system is proposed by Tao et al. (2021), and Xue and Lu (2020) introduced a semantic differential approach to capture changes in the local BIM model as transactions on chain. The storage methods of BIM data in the blockchain are out of the scope of this paper, but the BIM data itself is possible to facilitate the ZKP-backed identity authentication of the construction blockchain.

This study proposes a Zk-SNARKs-based identity authentication protocol for blockchain-backed BIM collaboration. By utilizing the random subset of historical data records in the blockchain, stakeholders involved in the construction projects with distinct roles and responsibilities access the blockchain channel through an adaptive authentication process. By leveraging ZKP, a dynamic login function is achieved that avoids password attacks and provides a trusted identity authentication function. The proposed Zk-SNARKs-based BIM user authentication protocol is described in part 2, and a case pilot is illustrated to prove the possible feasibility of the protocol in part 3. Then, the pros and cons of the protocol are discussed in part 4, and part 5 shows the limitations and future works.

2. A ZKP-BASED AUTHENTICATION PROTOCOL FOR BLOCKCHAIN BIM

The two-step authentication processes between BIM stakeholders and the blockchain network is shown in Fig. 1. Firstly, the BIM stakeholders act as provers to prove their authority to the blockchain by providing statements, which are the knowledge of BIM in their mind. Then, the blockchain verifies the correctness of the statement automatically by the deployed smart contract and responds to the BIM stakeholder.

2.1 The zk-SNARKs-based authentication protocol

The structure of the proposed zero-knowledge Succinct Non-interactive ARguments of Knowledge (zk-SNARKs) based authentication protocol is depicted in Fig. 2. The first layer is the blockchain layer which is composed of a block network to store the BIM editing records. On top of the blockchain layer, various smart contracts deployed on the blockchain constitute the second layer. Three types of smart contracts for data storage, data querying, and proof verification are involved. With these smart contracts, BIM stakeholders can interact with the blockchain network, such as uploading the BIM editing records by the data storage smart contract and verifying their identities by the verifying smart contract. The uppermost layer is the application layer, which provides functions for users to interact with the blockchain. Two services, namely identity provider (IdP) and BIM server provider (BIMSP), are designed in this layer. The IdP are various identities, including project manager, civil engineer, designer, BIM engineer, and their combinations. IdP is designed to provide multiple options for users' identification. The BIMSP provides adding, modifying, deleting, and querying operating authorities of BIM models. Authorized users can get editing rights corresponding to their identity in the BIM model.

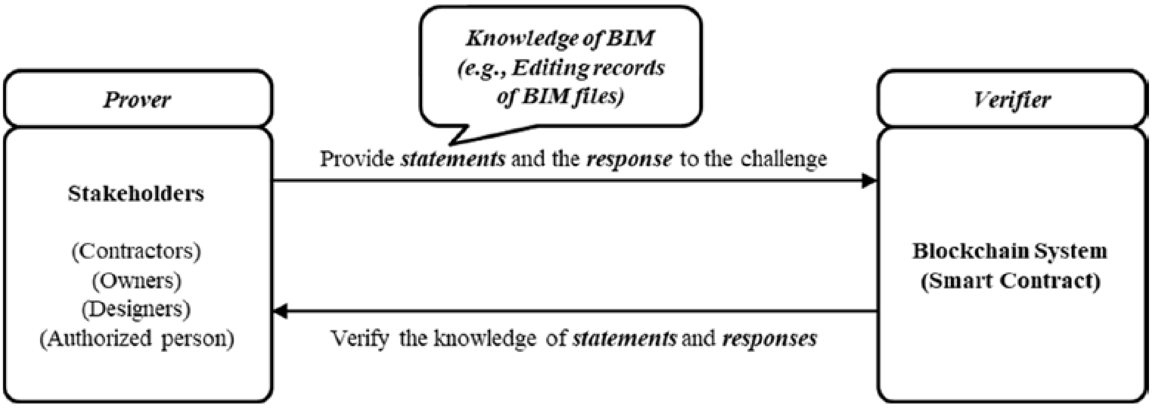

Fig. 1: Possible facilitation of BIM in the structure of ZKP for construction blockchain

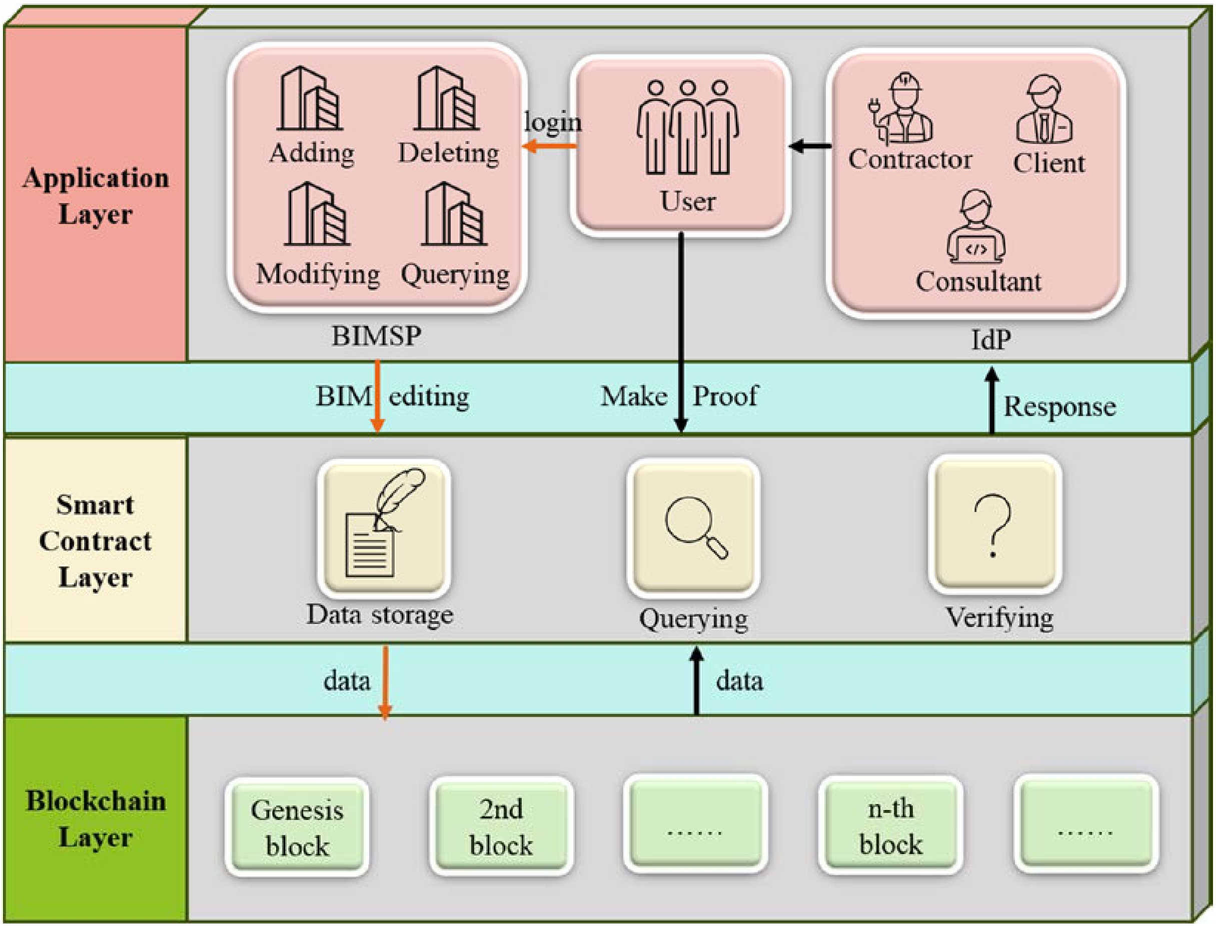

Fig. 2: Structure of the proposed zk-SNARKs-based identity authentication protocol

This paper focuses on the smart contract for proof verification, which implements an automatic authentication model based on the zk-SNARKs protocol. The zk-SNARKs protocol supports succinct proof verification by the one-way message communication between the prover and verifier. Its development processes involve five main steps:

1) Define the domain-specific data model to describe the BIM-related knowledge for identity authentication. For instance, to describe the editing history records of a door, the data of “editing_month”, “door_level”, and “editing_action” should be involved. The “editing_action” is further categorized into four subtypes: add, delete, modify, and query.

2) Describe the logic of the domain-specific data model to be proved using the NP statement such as Rank-1 Constraint Satisfaction (R1CS). An NP statement means that if you have a solution, it is computationally easy to prove it, but it is not computationally to find the solution. In this way, the ZKP protocol is completeness and soundness.

3) The proof circuit accepts some common parameters as input and generates a Common Reference String (CRS).

4) Generate proof about the proposition.

5) Verify the proof.

The core step is generating the NP statement of the domain-specific data model, namely the logic proof circuit. Many tools are developed to do this work, such as Zokrates, libsnark, snarkjs, etc. In this paper, the Zokrates toolbox, which is developed by Ethereum, is implemented to convert the BIM-related data model to the logic-proof circuit. A detailed example is presented in Part 3.

2.2 Workflow

The workflow of proving the identity to the blockchain system is depicted in Fig. 3. A user defined by IdP first requests a login to the blockchain system with a role confirmation process. Then, BIM stakeholders generate proof of the BIM-related knowledge, such as the editing of a BIM version at a specific time, to the blockchain. The smart contract for verifying the proofs is pre-deployed on the blockchain and verified automatically. If the proof is verified as true, a one-time password authenticates the user to log in. The login event will be recorded on the chain, too.

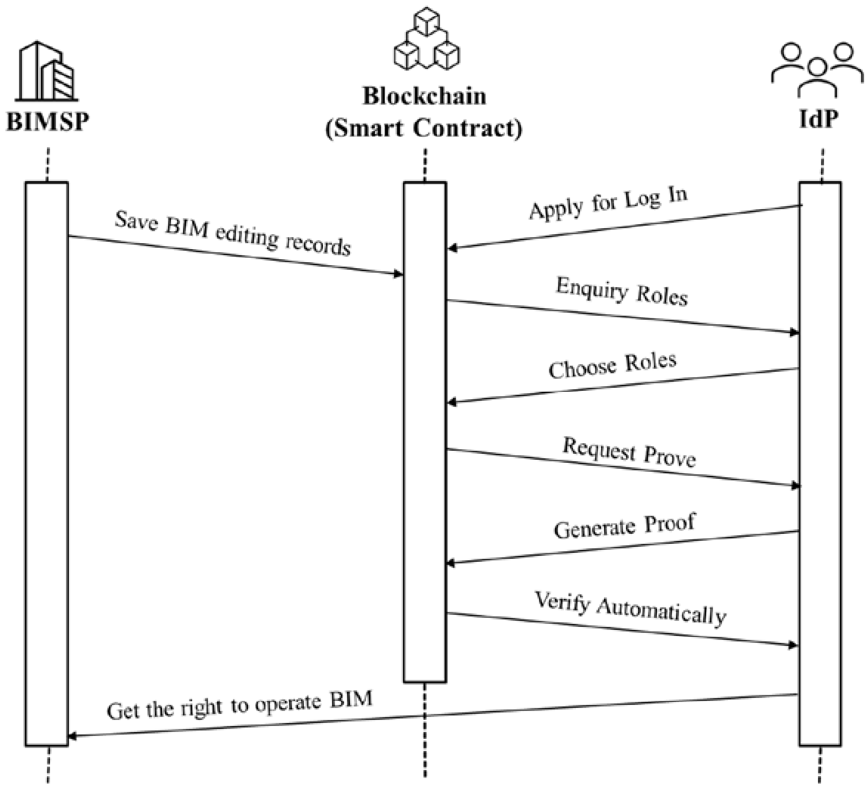

Fig. 3. The workflow of the proposed protocol

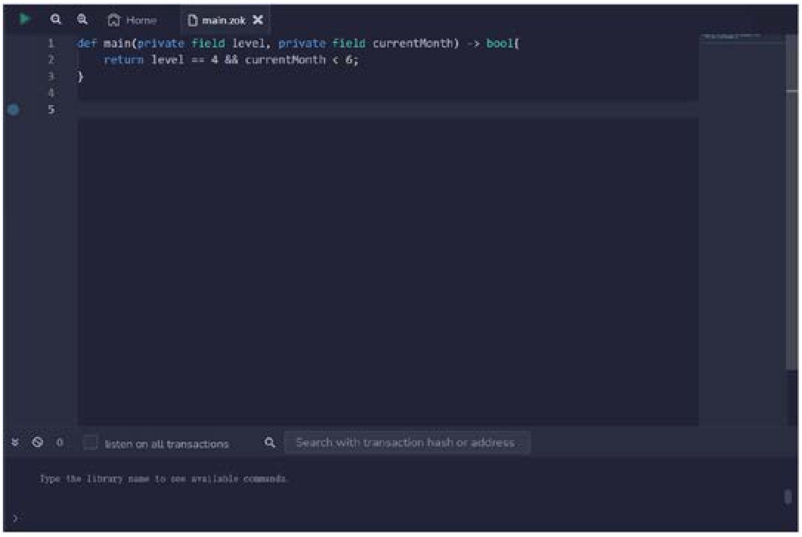
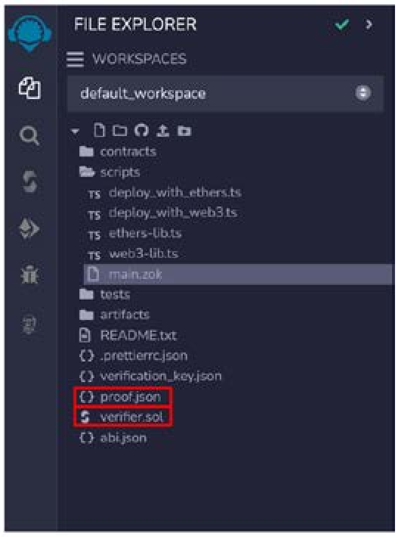
2.3 Software implementation

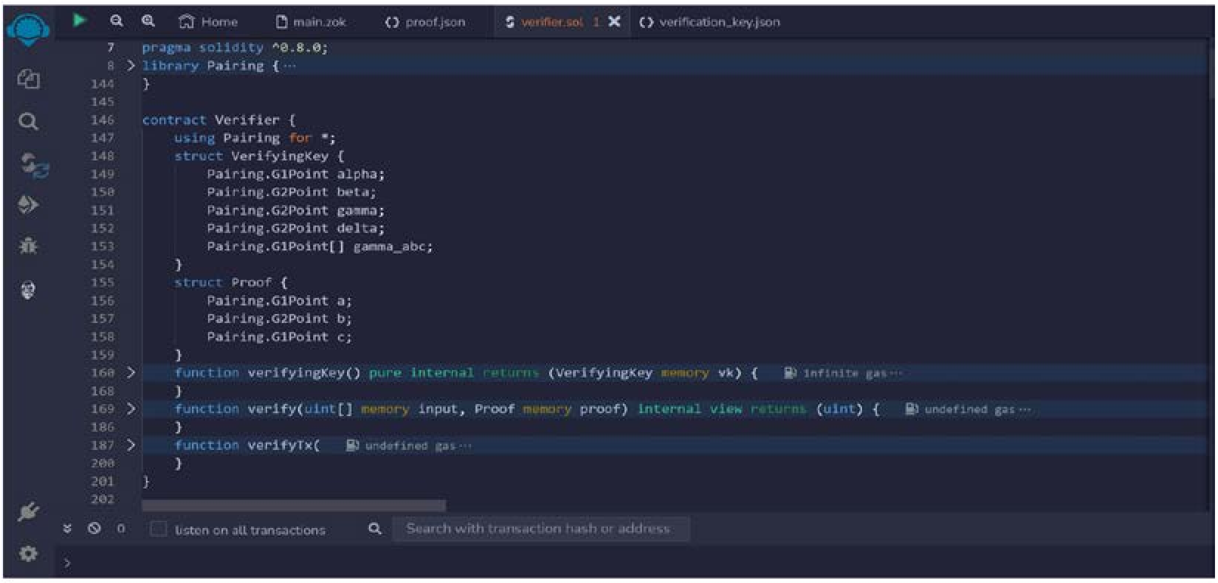
An identity authentication smart contract (IASC) is deployed on the test blockchain network by ZoKrates (Version 0.8, available at https://github.com/Zokrates/ZoKrates). ZoKrates (2023) is a toolbox for implementing zk-SNARKs on Ethereum, which provides functions such as trusted setup, libraries, and proving schemes et al. The Remix IDE is an open-source web-based IDE that creates, compile, tests and deploy Ethereum-based smart contracts on the blockchain network (Jain , 2022). Fig. 4 illustrates the interface of generating an IASC and deploying it on the test blockchain network by the Remix IDE.



(a) Definition of the logic circuit



(b) Generated proof and IASC



(C) An example of IASC

Fig. 4: Interfaces of Remix IDE. (a) define a logic circuit; (b) Generation of proof and identity authentication smart contract; (c) an example of IASC

As Fig. 4(a) shows, the circuit is declared in the ".zok" file alliance with the ZoKrates schema, the private filed type represents the secrete input that will not be revealed in the proof process and return a bool value that represents the verification result. A BIM user is able to generate a proof file, namely the "proof.json" file in Fig. 4(b), which will be sent to the blockchain for verification. The generated IASC is shown in Fig. 4(c), including five parts: (1) two data structures that describe the verification key and proof data; (2) three verification functions.

3. CASE PILOT

3.1 Case selection

A project at the University of Hong Kong (HKU) was selected in this section to demonstrate the proposed zk-SNARKs identity authentication protocol. The project was a modular construction project of a student residential apartment located at Wong Chuk Hong (WCH), involving 1,224 modules. Each module involves three main phases. Each module involves three main phases:

1) Manufacturing phase that the module is manufactured in the factory in Mainland China;

2) Logistics phase that transports the module from Mainland to Hong Kong through maritime transportation and land transport; and

3) On-site installation of modules.

3.2 Mapping of project workflow to zk-SNARKs

The fragmented construction phases and multi-disciplinary participants require high-level access control to the blockchain BIM collaboration platform. The IdP of this project defines three main stakeholders:

1) The main contractor. Paul Y. Engineering is the main contractor, and is responsible for module manufacturing and inspections, module transportation, and on-site installation. Paul Y. utilizes BIM for the on-site instructions and proposes potential changes to the consultant and client.

2) The lead consultant. Architecture Design and Research Group Ltd. (AD+RG) is the lead consultant for design and the key author and data contributor of BIM. Architecture, structure, water/drainage, and HVAC designers collaborate on the comprehensive BIM.

3) The client. HKU is the client of this project can access the whole BIM collaboration system.

According to the category of roles and responsibilities, the statements of the Zk-SNARKs-based authentication protocol of each group should be as follows:

1) Paul Y. Engineering: Browsing history of BIM. For example, "is the statement 'User A browse the architecture BIM Ver. 1.2 on 29th September' *True or False*?

2) AD+RG Ltd: Browsing and authoring history of BIM, including components' changes and revisions. For example, "Is the statement 'the *DELETE* operation of sliding windows/doors at level 4 was done before June' *True* or *False*?"

3) HKU: Browsing records of BIM models or related project information in the blockchain transactions. For example, "Is the statement 'so far, there have been 4 approved BIM changes in the structure domain' *True* or *False*?"

To map the project workflow to the proposed zk-SNARKs-based identity authentication protocol, a statement of BIM-related knowledge should first be converted to a computational problem. For instance, the statement "User A browse the architecture BIM Ver. 1.2 on 29Th September" should be converted as "if version == 1.2 and date == 29th Sep then result == True else result == False". Then, an NP statement such as R1CS should be developed. Specifically, R1CS is a sequence of three vector sets (*A, B, C*) that satisfy the equation $s \cdot A * s \cdot B = s \cdot C$, where s is the solution vector and $A,\ B,\ C$ are coefficient vectors. The simple "·" represents the inner product operation of vectors. The computational statement is converted into several simple expressions to represent the computation logic, such as $x \oplus y = z$ where "$\oplus$" represents the "$+$" or "$\times$" operations in the proof circuit. For the example computation statement, the operation is "$+$". In this way, the project workflow statement is converted to R1CS circuits for further computation.

3.3 Preliminary results

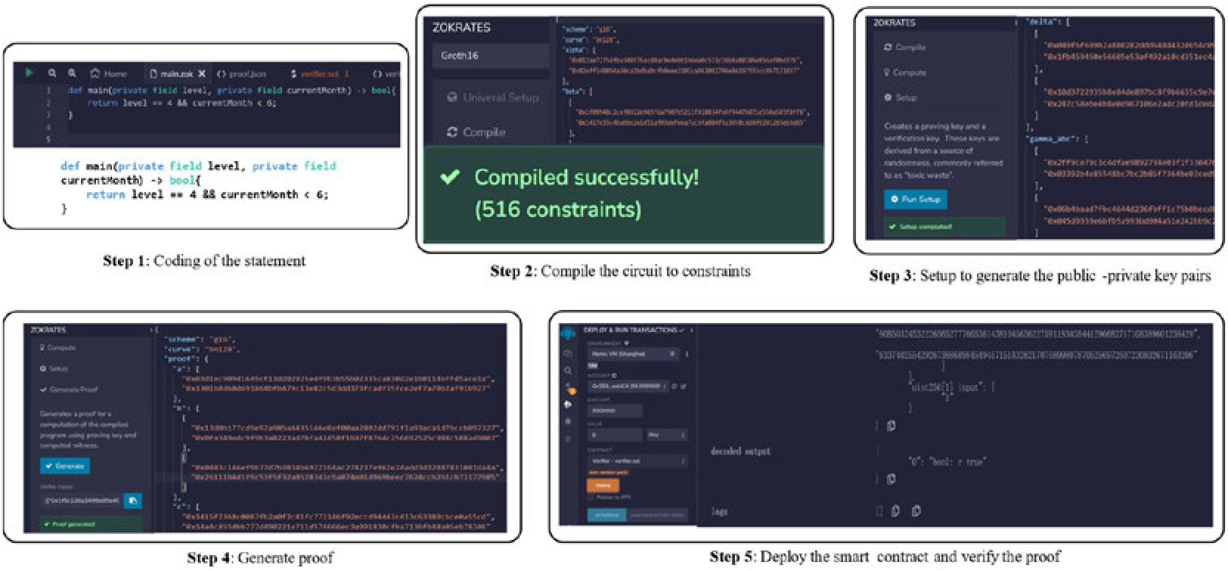


Fig. 5: An example of the identity authentication process of the project consultant.

Fig. 5 gives an example of the zk-SNARKs-backed identity authentication process of the project consultant. The Remix IDE (Ethereum 2023) is utilized to deploy the smart contract. The statement "the DELETE operation of sliding windows/doors at level 4 was done before June" is coded as a computation function firstly according to Sec. 3.2. Then, users can compile the function as a logic circuit with 561 constraints by the compile function provided by Remix IDE. The zk-SNARKs require setup to generate a public-private key pair for further proof generating, which is done in Step 3. After the setup process, BIM stakeholders generate proof through their private input, namely their secret knowledge. As Step 4 shows, the generated proof file is a JSON file that involves data of prove schema (elliptic curves) and a hash of proofs. After that, a smart contract with the suffix ".sol" is extracted and deployed on the test blockchain network in Step 5. Finally, the proof file is sent to the smart contract and verified. As **Errore. L'origine riferimento non è stata trovata.** shows, the verification of the consultant is true in Step 5.

4. DISCUSSION

The potential influences of the proposed Zk-SNARKs-based BIM user authentication protocol can be analyzed and discussed from different perspectives, including technology, business, and user.

From a technological standpoint, Zero-Knowledge Proof (ZKP) aligns effectively with on-chain knowledge. Through the synergy of Building Information Modeling (BIM) and blockchain, construction knowledge attains inherent transparency and becomes readily accessible via the distributed ledger. The blockchain records historical BIM operation activities, preserving collaboration traceability. Meanwhile, off-chain BIM files can be securely accessed via on-chain indexes. The amalgamation of on-chain and off-chain BIM-related data presents itself as suitable knowledge for user identity authentication. Consequently, the integration of ZKP and blockchain BIM emerges as a rational and achievable endeavor.

From a business standpoint, the identity authentication protocol based on Zk-SNARKs fosters a higher degree of reliability and trust in BIM-centered collaborations within the blockchain ecosystem. The adaptive access control, rooted in BIM knowledge, safeguards user identity privacy while accommodating an array of application scenarios, including bidding qualifications. Moreover, this identity authentication solution empowers traditional organizations and data providers to securely generate sensitive data.

From a user perspective, the utilization of ZKP empowers BIM stakeholders to efficiently create a suite of identity authentication smart contracts based on their project-specific knowledge. Nonetheless, the adoption of the zk-SNARKs-based identity authentication protocol demands a fundamental grasp of 'computation representation of knowledge.' In essence, users must formulate the logical representation of project-related knowledge. Regrettably, this prerequisite presents a barrier to the widespread adoption of ZKP.

5. CONCLUSION

The advent of blockchain introduces new prospects for transparent, immutable, and secure distributed BIM collaboration. Yet, owing to the inherently open nature of blockchain, the integrity of construction management faces significant threats from severe cybersecurity attacks, particularly password attacks. Establishing secure identity authentication mechanisms for data access within the realm of blockchain BIM becomes the cornerstone of trustworthy collaboration. However, conventional methods of identity authentication, such as the traditional public-private key pair or password, are susceptible to malicious exploitation. Enter zero-knowledge proofs (ZKP), a cryptographic technique empowering the prover to persuade the verifier without disclosing additional meaningful information about their claims. Consequently, ZKP is positioned to endorse password-free identity authentication, basing approvals on users' knowledge, thus effectively sidestepping the risk of malicious password theft.

This paper introduces a ZKP protocol, specifically zk-SNARKs, designed for identity authentication within the context of the blockchain BIM environment. Through the utilization of the zk-SNARKs protocol and on-chain historical BIM editing data, this study establishes an adaptive identity authentication process for collaborative efforts based on blockchain BIM. In contrast to conventional password or public-private key authentication methods, this study employs the knowledge of BIM and construction projects as the primary means of identity verification. ZKP ensures the privacy and security of this knowledge, effectively functioning as the safeguard to authenticate identities.

A pilot case implements the proposed protocol by deploying a smart contract on the test blockchain network. The results vividly illustrate the feasibility of the proposed method. Subsequently, we delve into the potential impact of ZKP from technological, business, and user perspectives. The theoretical contribution of this research hinges on the development of a zk-SNARKs-based identity authentication protocol. This protocol efficiently leverages a subset of on-chain BIM editing records. In practical terms, the workflow of the proposed identity authentication protocol guides BIM users through tasks such as creating domain-specific circuit descriptions of BIM knowledge, developing the smart contract, and deploying it on-chain using tools like ZoKrates and Remix IDE.

This research is subject to several limitations. Firstly, the zk-SNARKs protocol necessitates a trusted setup before generating proofs and theoretically could produce false proofs that appear valid to the verifier. Furthermore, the intricate domain-specific knowledge associated with blockchain-BIM-based construction management remains unexplored, warranting further investigation to formulate a specialized domain-specific language. Lastly, the case pilot's scope is confined to laboratory testing, necessitating more extensive trials in complex real-world project scenarios. As a recommendation for future studies, we propose the exploration of more advanced ZKP protocols, such as zk-STARK, to effectively address the aforementioned limitations.

LEVERAGING SMART CONTRACTS IN BUILDING INFORMATION MODELING (BIM) FOR UNIFIED PROJECT EXECUTION: A THEORITICAL FRAMEWORK.

Oluwatoyin O. Lawal & Nawari O. Nawari

School of Architecture, University of Florida, Gainesville, FL, USA

ABSTRACT: *Over time, several procurement methods have been adopted to facilitate the successful delivery of construction projects with minimal financial losses in order to offer maximum value to clients. In recent years, the Integrated Project Delivery (IPD) procurement model has been introduced for better overall financial performance. In this model, every member of the project team has a stake in overall profit or risk irrespective of the extent of their roles and change orders and correction of errors and omissions are managed effectively with minimal contractual disruptions. This paper aims to address some of the previously cited barriers in earlier scholarly work, and it proposes a conceptual framework that integrates two novel concepts towards tackling technological and financial barriers in adopting IPD namely, BIM and Smart Contracts (SC). A framework is developed for a BIM-blockchain-IPD whereby the BIM model is integrated with blockchain technology, thereby acting as an immutable and transparent information repository and a platform for interdisciplinary collaboration in Architecture, Engineering and Construction (AEC) projects. The smart contract feature of blockchain technology offers an automated equitable distribution of risk and reward amongst project stakeholders based on agreements at project inception. Thus, the research contributes to a more efficient project delivery method by avoiding information asymmetry amongst stakeholders through a tamper-proof, BIM-enabled Common Data Environment (CDE). The proposed framework is validated with qualitative analysis of information obtained based on AEC industry procurement workflows.*

KEYWORDS: *Integrated Project Delivery, Smart Contract, Blockchain, BIM, AEC, Common Data Environment.*

1. INTRODUCTION

The American Institute of Architecture defined Integrated Project Delivery (IPD) as “a project delivery approach that integrates people, systems, business structures and practices into a process that collaboratively harnesses the talents and insights of all participants to optimize project results, increase value to the owner, reduce waste, and maximize efficiency through all phases of design, fabrication, and construction” (AIA California Council, 2007).

Integrated Project Delivery can be broadly categorized as a type of relational project delivery arrangement (RPDA), developed to generate a cooperative and trustful climate for project implementation that requires an honest and open communication for establishment of a trustful relationship (Lahdenpera, 2012). One key element in this form of procurement process is an early integration of the project team at inception. The early integration of different project participants has a main influence on the optimization of the design and therefore also on the construction as processes become more consistent with less rework (Heidemann & Gehbauer, 2010).

This paper conceptualizes a scenario where blockchain technology, through smart contracts can be integrated with BIM to facilitate integrated project delivery, towards an improved procurement process. It begins with a terse review of relevant literature under a few thematic headings. Then, diagrammatic workflows are used to illustrate a theoretical framework and the interconnected networking of project stakeholders. After which, a use case scenario of a procurement workflow using smart-contract enabled BIM for IPD is used to describe the framework.

2. LITERATURE REVIEW

Project delivery methods continuously evolve to address the specific needs and concerns at the times and each method has implications on the cost, schedule and quality performance, albeit how much performance is typically affected is still unclear. (Sullivan, Asmar, Chalhoub, & Obeid, 2017). Various project delivery types have been used in the AEC industry globally such as Design Bid Build (DBB), Design-Build, Design Build Operate and 4) Construction Manager at Risk (Roy, Malsane, & Samanta, 2018). Lahdenpera (2012) highlighted six (6) key features of RPDA or a cooperative delivery approach namely; a cooperative culture, team formation, administrative consistency, commercial unity, planning emphasis and operational procedures (Lahdenpera, 2012). In collaborative projects, stakeholders must have a high level if shared understanding with respect to cooperation, control and coordination to achieve mutually desired outcomes. (Ali & Haapasalo, 2023). However, the complexity

of construction and the multiplicity of stakeholders and their interests raises the probability for disputes and conflicts. Alaloul et al (2019) described construction as a fertile seedbed for disputes. (Alaloul, Hasaniyah, & Tayeh, 2019). Kumar et al (2020) highlighted 14 factors which lead to dispute in construction in order of hierarchy, stating that ambiguous language of contract was the most influential factor, which may also lead to opportunistic behavior, delayed response to decisions and unrealistic expectations, which may in turn lead to poor communication between project partners, culminating together with other factors to cause payment delays and eventually project cost overrun (Kumar Viswanathan, Panwar, Kar, Lavingiya, & Jha, 2020).

2.1 Challenges and Limitations of Integrated Project Delivery

Construction supply chains have remained contested, fragmented and highly adversarial because of the conflicting nature of demand and supply (Cox & Ireland, 2002). Kahvandi et al (2019) highlighted for limitation categories for the use of IPD on projects namely; contractual, environmental, managerial, and technical ones and resolving contractual challenges is very effective in resolving environmental, managerial, and technical challenges. (Kahvandi, Saghatforoush, ZareRavasan, & Preece, 2019). In less developed construction sectors like Nigeria, practitioners are aware of IPD but not as proactive towards its application, of which technological, legal, financial and cultural issues are hindering its widespread adoption (Ebekozien, Aigbavboa, Aigbedion, Ogbaini, & Aginah, 2023). Similarly, lack of interest amongst stakeholders involved in the construction supply chain and negative perceptions about the efforts, risk and expenses required in implementing IPD are observed limitations to its use (Durdyev, Hosseini, Martek, Ismail, & Arashpour, 2020).

2.2 Smart Contract Solutions for Construction

Smart contracts (SC) are contract clauses written in computer programs that will automatically self-execute when predefined conditions are met. They consist of transactions essentially stored, replicated and updated in distributed blockchains (Zheng, et al., 2020). The construction industry worldwide is known for its adversarial working relationships which exist between the stakeholders (Phua & Rowlinson, 2003). Young-Ybarra & Weirsema (1999) found trust to be the only component of social exchange theory that had a positive effect on flexibility of strategies (Young-Ybarra & Wiersema, 1999) Pishdad-Bozorgi (2017) explored trust dynamics on real world IPD projects and both case studies used in the research confirmed that IPD was more effective in building trust than traditional delivery method (Pishdad-Bozorgi, 2017).

2.3 Blockchain and BIM in Construction

The AECO industry began to actively deploy BIM on projects in the early and mid-2000s (Jung & Lee, 2016). In a scientometric review, Liu et al (2019) mentioned that research in the field of BIM has been developing continuously and has completely subverted the traditional operation mode of AEC industry, while attracting more researchers' attention at the same time (Liu, Lu, & Peh, 2019). Lawal & Nawari (2022) proposed a BIM-blockchain unified ledger to provide traceability for building components for a more auditable real estate valuation. (Lawal & Nawari, 2022). One of the most commonly researched blockchain applications in AEC is its integration with BIM for improved workflows and processes amongst construction stakeholders, thereby fostering improved collaboration. (Nawari & Ravindran, 2019) (Zhang, Doan, & Kang, 2023). BIM adds one or more additional dimensions to traditional design approaches which is the information layer that describes physical properties of building components. Innovations to the blockchain-BIM integration has made it possible for a shared platform like BIM to provide security of sensitive data either through a confidentiality minded framework (Tao, et al., 2022) or by using lightweight blockchain-as-a-service prototypes in the case of emergency construction projects (Tao, et al., 2023). Applications of blockchain-BIM are prevalent in pre-construction stage for secure and traceable control of design documentation, however, as the maturity level of both technologies increase, this integration will cut across project lifecycles.

3. THEORETICAL FRAMEWORK

The use of Building Information Models (BIM) for generation of information has become widespread in the Architectural, Engineering and Construction (AEC) industry in the past decade. BIM also refers to the virtual process and workflow that encapsulates all aspects, disciplines and systems of a facility or asset within a unified virtual model to facilitate a more accurate and efficient real-time collaboration (Azhar, Khalfan, & Maqsood, 2012). BIM is a revolutionary technological development that is rapidly reshaping the AEC industry and transforming the way we build, and the AEC industry have pushed stakeholders to use BIM extensively in a streamlined and integrated manner over the building lifecycle (Liu, Lu, & Peh, 2019). BIM helps to discover collisions which usually occur during construction in a high number and therefore, the team is able to resolve those already during the design phase. A huge amount of time, rework and redesign can be eliminated (Heidemann & Gehbauer, 2010).

The image in figure 1 shows an interconnected loop between all project stakeholders and between stakeholders and the BIM model, which is housed in a cloud-based Common Data Environment. Earlier studies have proposed a Common Data Environment (CDE) for secure data storage of digital assets, interdisciplinary coordination, management, and versioning of information containers (Sreckovic, et al., 2021) (Wang, Wu, Wang, & Shou, 2017) (Pishdad-Bozorgi, Yoon, & Dass, 2020). Figure 1 below is a diagram of interrelationship between all project stakeholders. A cloud-hosted blockchain CDE which is the agreed information repository that records all additions and alterations to the contained information, is used to house a shared BIM model. Blockchain provides a decentralized, automated and secured financial platform which enables multiple parties to control and track financial transactions (Elghaish, Abrishami, & Hosseini, Integrated project delivery with blockchain: An automated financial system, 2020).

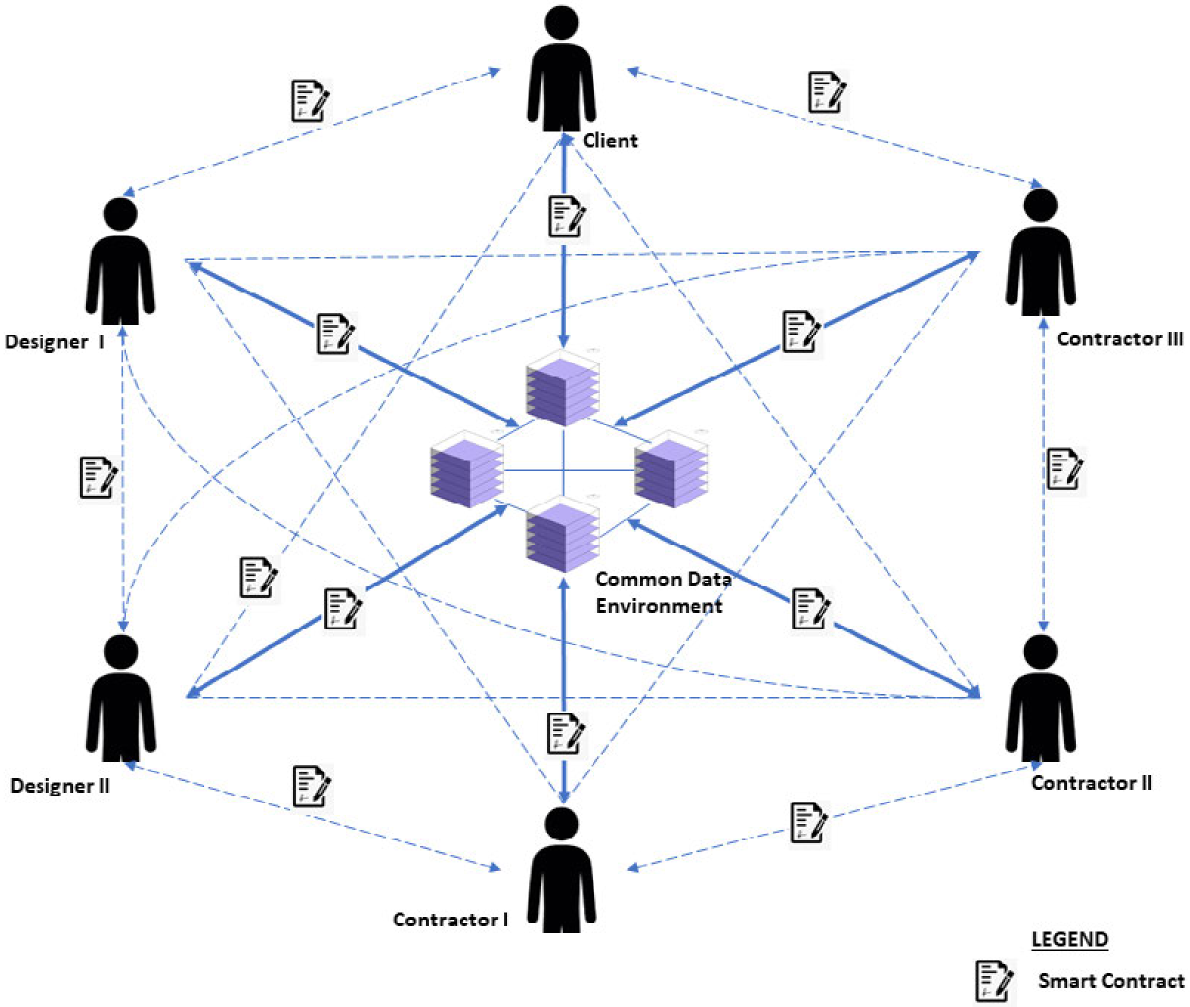

Figure 1: Network of project team and BIM model, with smart contracts managing the interrelationships

The CDE connects to a front-end interface wherein all participants are visibly interconnected and smarts contracts embedded between every interconnection act as triggers to automate and record the transition to a new phase of engagement once certain conditions / project milestones are reached, as confirmed by the BIM and a physical model twin contained in the CDE. The physical twin is derived through the use of IoT and BIM. The emergence of IoT has transformed the way data is shared across various sources (Barricelli, Casiraghi, & Fogli, 2019). Digital Twins refer to the process of merging the virtual world and real world, and has become a widely accepted tool in the Architecture, Engineering, and Construction (AEC) industry due to its ability to enhance cross-disciplinary collaboration (Sahal, Alsamhi, Brown, O'Shea, & Alouffi, 2022). The linear flow of information and smart contract deployment referred to in Figure 1 is shown below in Figure 2.

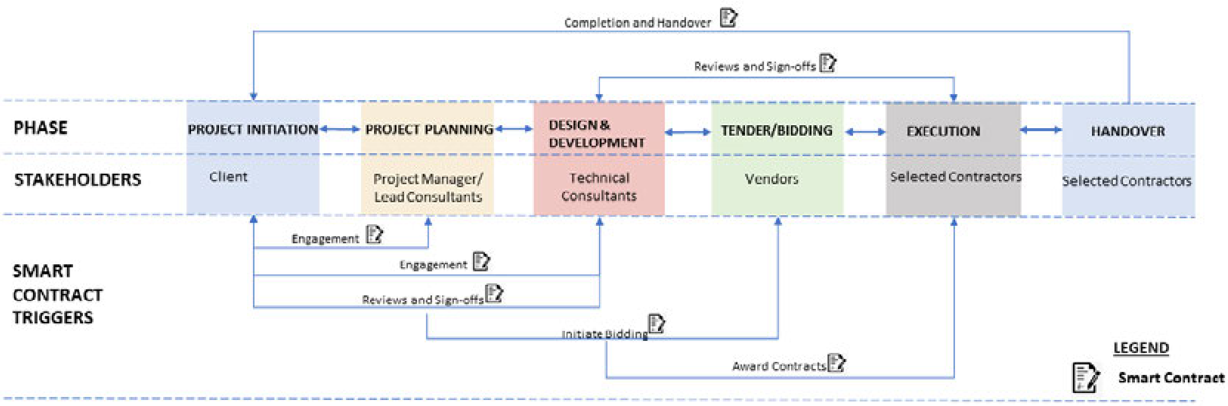

Figure 2: Linear Information Flow in Integrated Project Delivery

Smart contracts are deployed at instances where a client 1) engages a new service provider, 2) reviews and signs off on information, 3) initiates a bidding process, 4) appoints a contractor and also when consultants 1) review and sign-off on documents and procedures submitted by contractors and 2) signs off on construction at project completion.

4. USE CASES

The use case scenario will be discussed under to main headings; 1) BIM-enabled Integrated Project Delivery and 2) Smart Contract Payment Method through BIM Monitoring.

4.1 BIM-Enabled Integrated Project Delivery

The ability of BIM to replicate physical scenarios throughout the building lifecycle makes it suitable for collaborative workflows. BIM and IPD are process innovations that are driven by technology and reconfigure social relationships (Rowlinson, 2017). Existing literature suggests that BIM and/or IPD can dramatically enhance project performance from conceptualization through building management, and ongoing operations. (Ilozor & Kelly, 2012). This scenario leverages the abundance of research in BIM and IPD. The Project Manager (PM) or Lead Consultant (LC) creates the initial BIM model and shares it with the client, other consultants and all the contractors as they join the project. The PM/LC acts as the network administrator throughout the project. All changes as well as milestones are securely recorded in the back-end interface using the smart contracts and these milestones are visible to all members of the project team, so every party knows what stage every aspect of work is. Contract administration is enumerated under section 4.2 using the principle of Common Pool Resource (CPR). BIM-based solutions for IPD have also been proposed to enable accurate cost estimation at project inception when little information is available on the front end (Elghaish, Abrishami, Hosseini, & Abu-Samra, 2021)

4.2 Smart Contract Payment Method Through BIM Monitoring

Common-pool resources are systems that generate finite quantities of resource units so that one person's use subtracts from the quantity of resource units available to others (Ostrom, Gardner, & Walker, 1994). Hunhevics et al (2020) suggested that the governance of a Common Pool Resource (CPR) scenario was a useful guide to future research and applications of blockchain in construction. (Hunhevicz, Brasey, Bonanomi, & Hall, 2020). This phase of the use case deploys the combination of the BIM model, the model's physical twin on site using IoT technology to implement Digital Twins as discussed earlier, and the CPR as illustrated in Figure 3 below. The diagram below is a blow-up of the CDE shown in Figure 1.

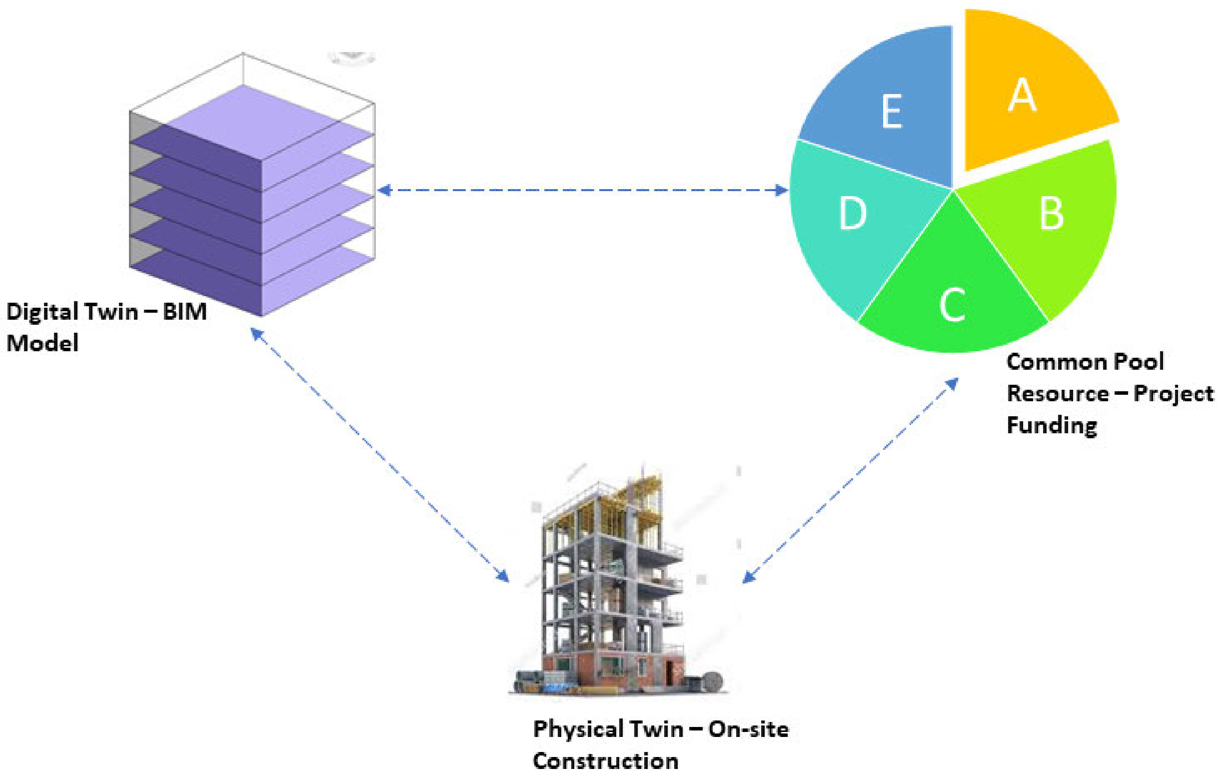

Figure 3: Components of the Common Data Environment

Earlier sections have shown how workflows of several project stakeholders can be integrated. However, contract administration, clarity of contract language and timely payment disbursement are some of the factors which make traditional procurement methods cumbersome. In this instance, the human component of contract administration and payment disbursement are eliminated by depositing project funds in an escrow account, otherwise referred to as the CPR. The CPR acts as a third-party agent except that it is not triggered by any one individual. Once a contract milestone is reached by any of the project stakeholders, the digital twin pair of the BIM model and the IoT powered construction communicate with the CPR to trigger a smart contract between the client and the corresponding project stakeholder. Payment is automated to such stakeholder based solely on the attainment of an earlier agreed milestone.

5. CONCLUSION

This research has built upon a preponderance of academic endeavors in the field of BIM, Integrated Project Delivery, Blockchain, and Smart Contracts within the AEC industry. With recent academic interests in the use of BIM at the forefront of some of the most cutting-edge innovations in construction and deployment of smart contracts to facilitate payment in construction projects. Beginning with a terse literature review which discussed general scholarly efforts around Smart Contracts and IPD, the literature review was broken down into thematic areas like challenges and limitations of IPD, Smart Contract (SC) solutions for construction and blockchain-BIM integration in construction. A theoretical framework was proposed which situates all stakeholders in an interconnected loop and in connection with the blockchain-enabled BIM simultaneously. The BIM is shared through a Common Data Environment (CDE). The linear flow of information/instruction in this form of IPD is also illustrated. Two use case scenarios helped to visualize the applicability of this framework. The first uses a BIM-emabled IPD where the shared BIM model facilitates the construction-phase collaboration amongst the project team whereby the Project Manager or Lead Consultant acts as a network administrator and changes are recorded using Smart Contracts. The second use case deploys SC payment method through BIM monitoring. In this case, a Common Pool Resource (CPR) warehouses the funds required for the project and BIM monitoring such as IoT-enabled Digital Twin can be synchronized with CPR and SC to trigger payment instructions once physical progress corresponds with the pre-coded digital milestone on the BIM model. Although this concept offers a solution to streamline construction workflows, further research is required to elucidate on the algorithmic workings of smart contract deployment in a BIM-enabled IPD.

ISAFEINCENTIVE: TRANSFORMING CONSTRUCTION SAFETY CULTURE THROUGH BLOCKCHAIN INCENTIVES

Mehrtash Soltani, Dohyeong Kim, Akeem Pedro, Jaehun Yang, Si Van-Tien Tran, Doyeop Lee & Chansik Park
Department of Architectural Engineering, Chung-Ang University, South Korea

ABSTRACT: *A significant challenge has long persisted in the construction industry: the lack of a robust incentive system to encourage and motivate workers to prioritize safety. While safety culture has been recognized as crucial, traditional approaches to incentivizing safe behaviours often encounter roadblocks, such as heavy documentation processes, recognition delays, and resource allocation difficulties. This paper addresses this problem by introducing an innovative approach to incentivize and cultivate a safety culture in the construction industry. iSafeincentive integrates blockchain technology and computer vision to develop a novel solution revolutionizing safety monitoring and incentive distribution. Computer vision technology is employed for real-time analysis of safety conditions based on on-site images, ensuring the immediate identification of safe practices. Simultaneously, blockchain technology safeguards the incentive distribution process's integrity and transparency, addressing traditional methods' shortcomings. The findings suggest that iSafeincentive offers an efficient and secure method for rewarding safe activities among workers. Furthermore, the integrated platform offers a promising pathway to enhance job site safety practices, ultimately reducing accidents and incidents within the construction sector.*

KEYWORDS*:* *Safety Culture, Incentive Programs, Blockchain Technology, Computer Vision, Construction Industry, Workplace Safety*

1. INTRODUCTION

The construction industry presents a dynamic workplace where the constant spectre of accidents and injuries casts a shadow over operations (Lim et al., 2021; Won and Soo, 2021). A robust safety culture within this sector is imperative, where safety transcends mere compliance and becomes an integral core value deeply entrenched in the organizational ethos. Such a culture is characterized by a collective commitment to hazard identification, risk mitigation, and the seamless integration of safety into all facets of work ((Zou, 2011); (Barg *et al.*, 2014); (Aksorn and Hadikusumo, 2008)). However, several critical challenges impede the development of this vital safety culture. First and foremost, construction sites often lack effective data management systems and reliable inspection and monitoring mechanisms. This deficit hinders the timely identification and rectification of potential hazards(Alexander Laufer and G. Jenkins, 1982). Secondly, there exists a dearth of incentive programs designed to motivate construction workers to prioritize safety ((Biggs, Sheahan and Dingsdag, 2005)). These programs have the potential to significantly reduce accidents and incidents on construction sites, fostering a resilient safety culture.

It is essential to emphasize the role of management in motivating construction workers to prioritize safety. Management must actively incentivize safe practices, linking desired outcomes to performance ((Alexander Laufer and G. Jenkins, 1982)). Furthermore, cultivating the right safety knowledge interpersonal skills, and fostering appropriate attitudes and beliefs are pivotal in nurturing a positive safety culture within the workforce ((Biggs, Sheahan and Dingsdag, 2005)). (Mohammadi, Tavakolan and Khosravi, 2018) provides insights into the multifaceted factors influencing safety performance in construction projects. (Helander, 1991) underscores the importance of monetary incentives as a catalyst for investing in construction safety. These findings collectively emphasize the significance of providing incentives, improving management practices, and shaping workers' beliefs and attitudes toward safety.

Incentives within the construction industry have shown a demonstrably positive impact on safety practices among workers ((Zulkefli, Ulang and Baharum, 2014)). They serve as structured mechanisms for recognizing and reinforcing safe practices, thereby contributing to amplifying and consolidating safety standards within the construction workforce. (Tang *et al.*, 2008) emphasizes the need for incentives in the Chinese construction industry, advocating for alignment with project features to enhance project delivery efficiency. (Huang and Sun, 2009) delves into various incentive smart contracts and their design principles, while Tinus (2014) highlights concerns regarding their impact on work productivity. (Nurul Fieqah and Ahmad Kazimi, no date) shed light on the challenges of implementing Occupational Safety and Health Act (OSHA) requirements, which can exacerbate administrative burdens and delay incentive distribution. It is crucial to address these issues and develop more efficient and streamlined incentive methodologies in construction. These methodologies should alleviate documentation burdens and enhance project performance, ensuring a harmonious balance between safety and economic sustainability.

Mehrtash Soltani, Dohyeong Kim, Akeem Pedro, Jaehun Yang, Si Tran, Doyeop Lee, Chansik Park, *iSafeIncentive: Transforming Construction Safety Culture through Blockchain Incentives,* pp. 360-367, © 2023 Author(s), CC BY NC 4.0, DOI 10.36253/979-12-215-0289-3.35

In summary, while incentive programs in construction can significantly enhance safety performance, their long-term effectiveness requires continuous evaluation and strategic resource allocation. Addressing challenges associated with traditional incentive methods is essential to boost safety and productivity in the industry. Streamlining the monitoring process is critical, as current safety inspections suffer from issues like infrequent and inadequate assessments, exacerbated by limited resources and human errors. Moreover, a shortage of safety professionals leads to less thorough evaluations. A significant limitation is the absence of a comprehensive incentive system aligning with inspections and rewarding safe behavior.

To effectively address these challenges, this study aims to develop and implement an innovative incentive system that harnesses blockchain technology and computer vision. This system is designed to enable real-time monitoring and recognition of safe behaviors exhibited by construction workers to comprehensively enhance safety practices across various construction sites.

2. LITERATURE REVIEW

In recent years, blockchain technology has gained substantial traction within the construction industry, presenting novel solutions to address enduring challenges. These studies investigate blockchain technology's adoption and potential applications, specifically focusing on its capacity to enhance efficiency, transparency, and safety in construction operations. For example, several studies have adopted blockchain for enhancing information management in Modular Integrated Construction. (Pan Zhang, 2023) employs game theory to delve into this subject, highlighting the pivotal role of diffusion rates influenced by benefits, costs, and government subsidies. The study advocates for implementing pilot projects and governmental incentives to facilitate adoption. In another study, (Minju Kim, 2023) introduces a blockchain-based system to optimize off-site construction supply chains. Using Bayesian updating and incentives, the study aligns contractor and supplier decisions, ultimately improving transparency and reliability.

Another investigation by (Pan Zhang H. W., 2023) employs game theory to analyze the adoption decisions surrounding blockchain technology in Modular Integrated Construction. This study echoes the importance of pilot projects and government incentives as drivers of adoption. (Hossein Naderi, 2023) introduces a decentralized application utilizing blockchain and computer vision to incentivize construction safety through token rewards. The application autonomously evaluates safety performance and issues unique Non-Fungible Tokens (NFTs) as rewards while maintaining user confidentiality. It presents promising prospects for various domains; however, scalability issues and challenges related to individual incentivization must be addressed through further development to expand its practical applications. In addition, (Namya Sharma, 2022) provides an exhaustive review of 33 global strategies for managing Construction and Demolition waste, focusing on integrating Circular Economy principles and lifecycle thinking, particularly in the Indian construction sector.

In another application, (Wenli Yang, 2022) proposes a master-slave chain model and a hybrid consensus algorithm to enhance the efficiency and security of multidomain conversational interactions on a blockchain. It effectively manages various scenarios concurrently while maintaining fault tolerance. However, it faces challenges related to high capacity demands due to diverse data types, necessitating further exploration of big data verification and consistent storage management. Finally, (Liupengfei Wu, 2022) introduces a blockchain-based supervision (BBS) model to improve supervision and security in cross-border logistics within modular construction. The model employs incentives to encourage data sharing, resulting in enhanced product accountability and data traceability compared to centralized platforms. Nevertheless, it encounters limitations, such as the potential for opportunistic behavior in data entry and a static incentive mechanism.

In conclusion, while these studies contribute significantly to our understanding of blockchain adoption and its applications in construction and related domains, they collectively share limitations such as theoretical orientation, lack of empirical evidence, oversimplified stakeholder models, and the need for further practical validation. Addressing these limitations is crucial for advancing the field and ensuring the real-world viability of these concepts.

3. RESEARCH METHOD

3.1 Process

To address the objective of this study, the approach is to integrate computer vision technology, which allows for the automated analysis of safety conditions from site images. Computer vision eliminates the need for extensive manual inspections and enables more accurate and efficient safety assessments. With reduced human intervention, safety assessments become consistent and unbiased, greatly enhancing the reliability of inspection results.

The integration of blockchain technology, in conjunction with computer vision (Figure 1), presents a groundbreaking shift in the construction industry's management of safety inspection data. Blockchain's immutability is pivotal in upholding the integrity and permanence of safety inspection records. Once safety data is securely recorded on the blockchain, it becomes impervious to alteration or tampering, instilling a high level of confidence in the precision and authenticity of the information. This characteristic is paramount in safety inspections, as it safeguards historical safety assessment records, reinforcing their credibility for compliance verification, auditing, and accountability purposes. Furthermore, the symbiotic fusion of blockchain and computer vision technologies fosters enhanced collaboration among various stakeholders involved in construction projects. Digital platforms, underpinned by these innovative technologies, enable real-time data sharing and communication. This digital transformation empowers project managers, safety officers, construction workers, and regulatory authorities to access and comprehensively review crucial safety inspection data promptly.

Consequently, stakeholders can respond swiftly to emerging safety concerns, coordinate preemptive measures, and effectively address potential hazards, ultimately cultivating a safer work environment. This technological convergence signifies a pivotal departure from traditional paper-based data collection methods, significantly enhancing the efficiency of safety inspection processes. Eliminating manual data entry and paperwork markedly reduces the likelihood of errors and omissions, elevating the precision of safety assessments. Furthermore, digital platforms support automated data analysis, providing real-time insights and reports. This data-driven approach empowers safety officers and managers to make well-informed decisions expeditiously, proactively mitigating risks and amplifying overall safety performance.

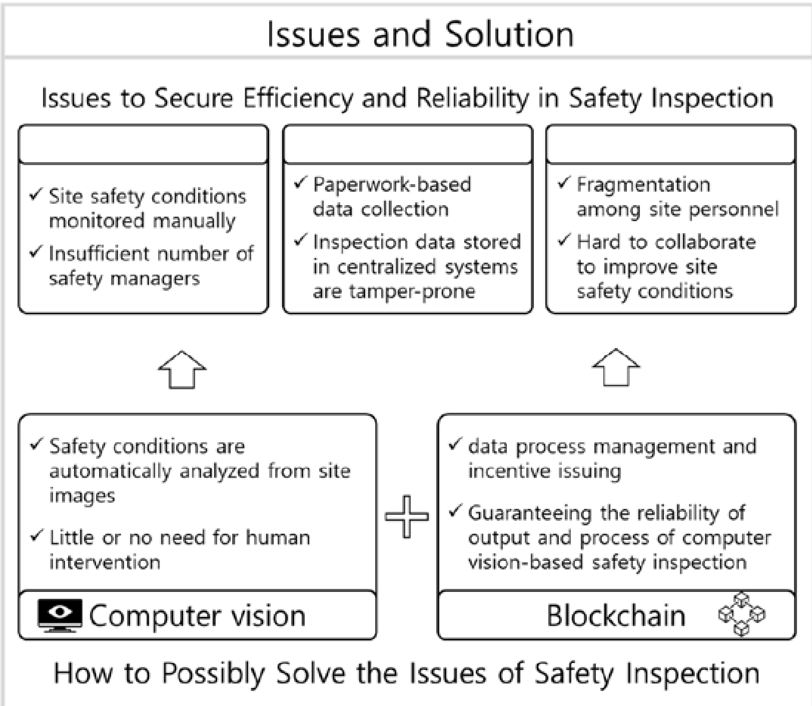

Fig. 1: The existing condition of safety inspections and suggested technological solutions to mitigate their challenges.

In the contemporary construction industry, a conspicuous challenge resides in inadequate motivation and incentives to stimulate safety performance and regulatory compliance among its workforce. This deficiency results in a series of interconnected issues that reverberate throughout the construction ecosystem. Site managers, at times overwhelmed by their responsibilities and bereft of tangible incentives for meticulous oversight, may inadvertently neglect safety protocols or make critical errors. Furthermore, the scarcity of qualified site managers compounds these challenges, leading to lapses in enforcing safety measures. Concurrently, the reliability of management records concerning safety compliance becomes questionable, diminishing the effectiveness of oversight mechanisms. This confluence of factors not only jeopardizes the well-being of construction personnel but also raises concerns about the quality and safety of the final built environment.

In response to these pressing concerns, as depicted in Figure 2, a multifaceted approach is emerging within the construction industry, driven by the amalgamation of technological innovation and incentive systems. This approach extends from project bidding, wherein contractors can accrue additional points or insurance rate discounts for committing to stringent safety and quality standards, to insurance and guarantee providers offering reduced premiums as rewards for safety adherence. Notably, the proposal of a token-based incentive system underpins this transformation, leveraging blockchain and verification technologies to bolster the adequacy and reliability of information generated within the construction milieu. This incentive-driven paradigm fosters voluntary safety activities among all stakeholders, from equipment and material suppliers to structural consultants and safety inspection agencies. By incorporating bottom-up perspectives, this holistic shift aspires to invigorate safety culture within construction, ensuring that every participant is vested in the collective goal of elevating safety standards and mitigating risks across the industry.

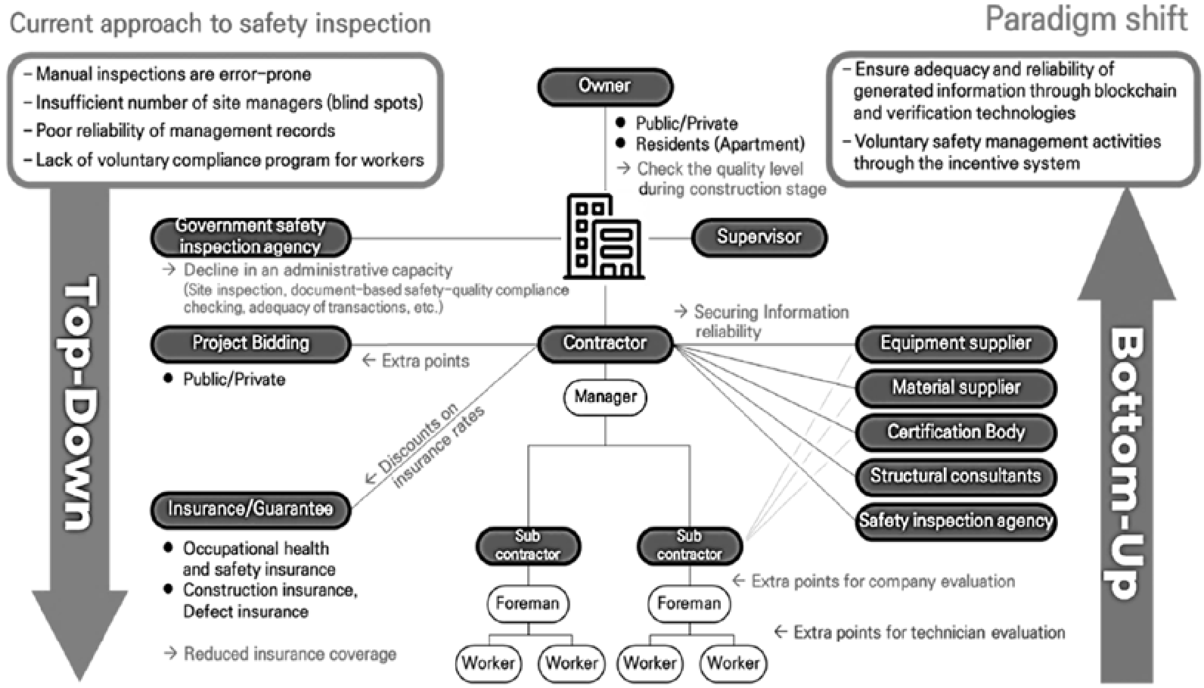

Fig. 2: Token-based incentive system

Furthermore, utilizing blockchain-based evaluations introduces a novel incentive structure that encourages the voluntary participation of managers and workers in safety activities. Rewards are distributed following the evaluation results, directly linking safety performance and tangible incentives. This incentivization model can significantly enhance safety awareness and engagement among construction personnel. In addition to rewards, the system can incorporate mechanisms such as additional bidding points, safety ratings, and reductions in insurance fees, all contingent upon the evaluation scores of the workforce held by companies. This multifaceted approach promotes safety at individual and organizational levels. It aligns safety objectives with broader project and financial considerations, making it a comprehensive and effective strategy for improving safety conditions in the construction industry.

3.2 Applications

3.2.1 Data management

The process of safety condition analysis from on-site images is a multifaceted procedure that seamlessly integrates automated image analysis through computer vision and robust data management, all while leveraging the security of blockchain technology. This comprehensive process involves regular and irregular inspections facilitated by deep learning-based models and cloud-based computing resources. In the first step, regular safety inspections are conducted as scheduled assessments of construction sites. Various devices, such as smartphones or cameras, capture images during these inspections. Subsequently, the captured images are uploaded to a cloud-based system for further analysis, combining the power of computer vision for real-time safety assessment. As shown in Figure

3, once images are uploaded, the inspection process is initiated through user queries and system management. Users interact with the system to initiate inspections based on predetermined intervals or specific triggers, ensuring that safety conditions are consistently monitored using computer vision technology. The system, in turn, effectively manages the entire inspection process, overseeing data collection, analysis, and database management, all while benefiting from the transparency and security of blockchain integration. This systematic approach ensures that inspections are conducted regularly and streamlines the overall process, reducing delays and improving safety outcomes. A key aspect of this procedure lies in data management, further enhanced by blockchain technology. Within the cloud-based system, various types of data are meticulously handled. This includes system management data to maintain the integrity and functionality of the inspection system, project data to manage project-specific details, and user data to regulate access rights and profiles. Inspection data remains at the core of this process, involving records of all inspections and associated metadata such as timestamps, geospatial information, media types, and automatic extraction of relevant metadata from the images. Blockchain technology ensures the immutability and transparency of these critical data records, providing a secure and tamper-proof foundation for the entire safety analysis and incentive distribution process.

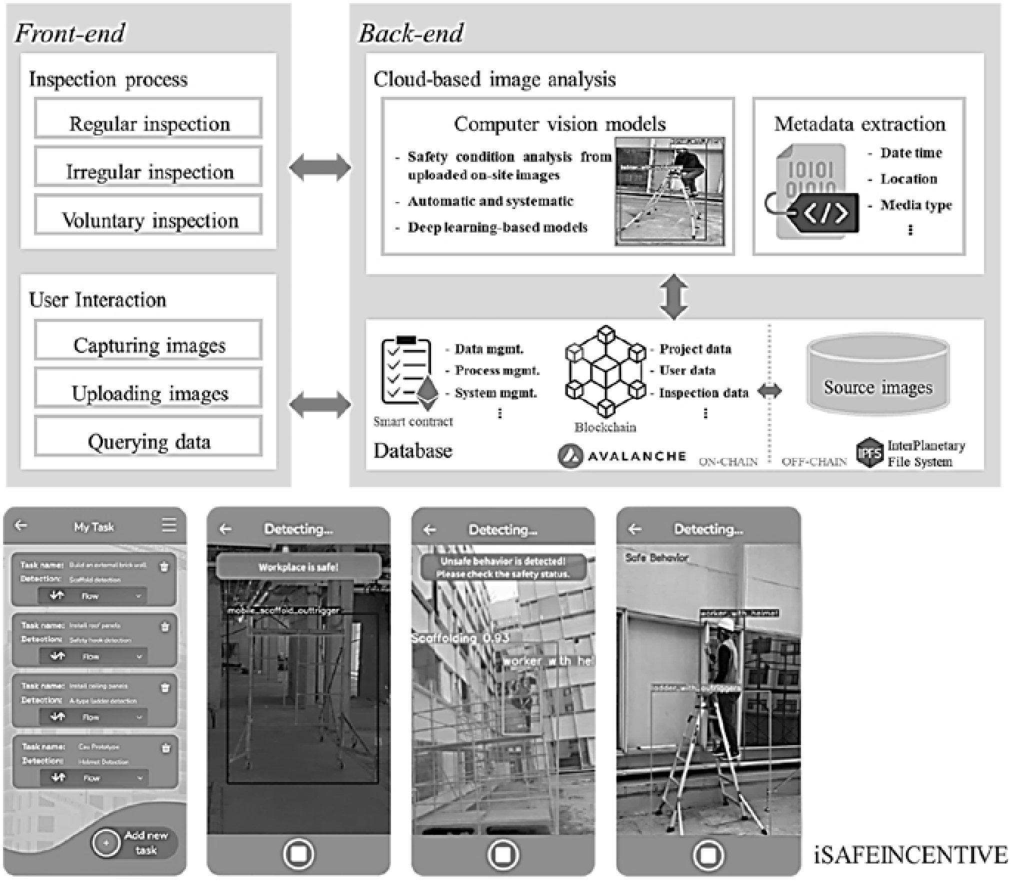

Fig. 3: Blockchain & Computer Vision Integration

3.2.2 Incentive mechanism

The token distribution process within the iSafeincentive platform, facilitated by blockchain technology, is characterized by a systematic sequence of actions. Commencing with continuous monitoring by the platform's AI detectors, the focus is assessing job site activities, including adherence to Personal Protective Equipment (PPE) regulations and safe conduct. Subsequently, vetted data undergoes scrutiny and validation to ensure accuracy and reliability. At the core of this process are smart contracts, meticulously crafted with predefined criteria and rules. These smart contracts serve as the automation engine, enabling the precise allocation of tokens in response to identified safe activities. Tokens are directed to the workers' digital wallets, tightly linked to their unique blockchain identities. Simultaneously, each transaction is recorded within the blockchain ledger, a fundamental feature that underpins transparency and traceability.

Worker notification follows promptly, serving dual purposes: acknowledging the safe behaviors observed and motivating continued adherence to safety protocols. Furthermore, this approach establishes an efficient and transparent record-keeping system. Figure 4 represents the utilization of blockchain technology to streamline the token distribution process. This systematic and secure procedure inspires trust among all stakeholders, enabling workers to employ their tokens in various capacities while cultivating a resilient safety culture within the construction industry.

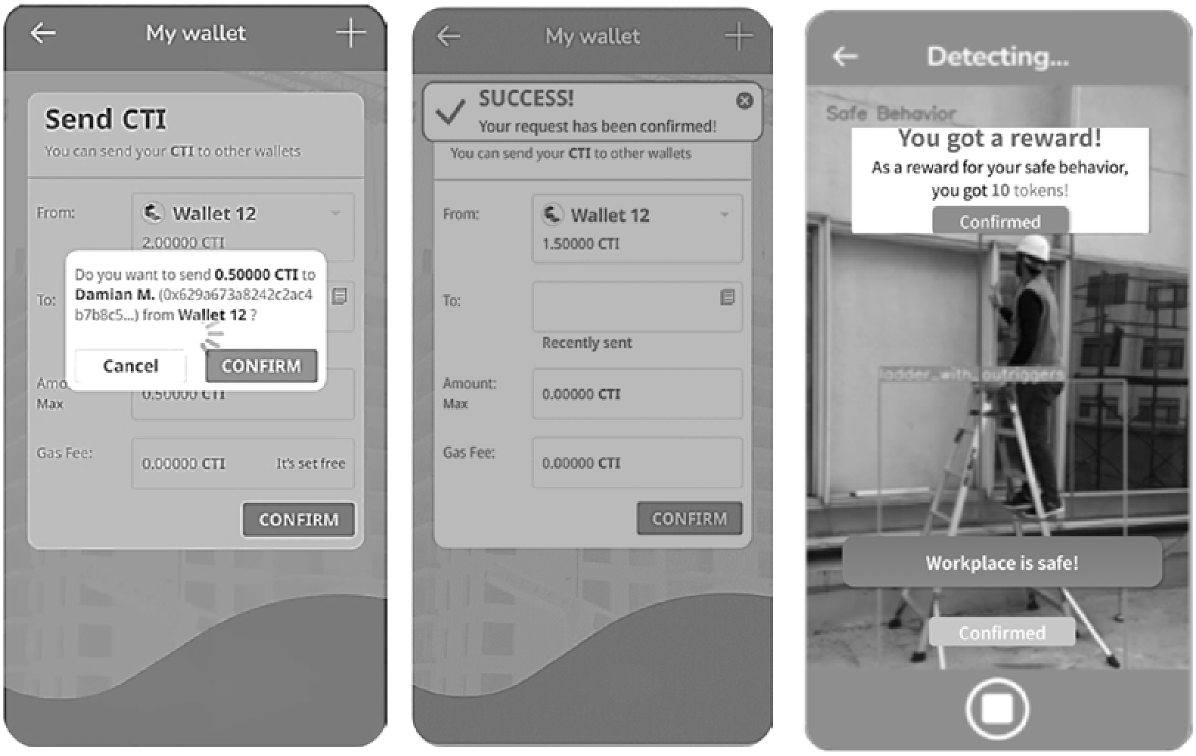

Fig. 4: The procedure for transmitting tokens once the safety measures have been verified through blockchain technology.

4. CONCLUSION

In conclusion, safety culture is vital in the construction industry, significantly influencing safety performance and outcomes. Empirical evidence supports the importance of a safety culture in reducing accidents and incidents within construction organizations. Motivating construction workers to prioritize safety through incentive programs has been crucial. Incentives encouraged safe behaviors, recognized individual efforts, and fostered a collective sense of responsibility for safety. However, as discussed earlier, current incentive methodologies face challenges, including burdensome documentation requirements, delays in distribution, and resource allocation issues. Streamlining documentation processes, reducing distribution delays, and optimizing resource allocation have been essential steps to enhance the effectiveness of incentive programs.

In this study, iSafeincentive has been developed by integrating computer vision and blockchain to automate safety assessments, improving accuracy and efficiency and ensuring the integrity and immutability of safety records and incentives. Blockchain-based incentives have linked safety performance to tangible rewards, enhancing safety awareness and engagement among construction personnel. This multifaceted approach has aligned safety objectives with broader project and financial considerations, demonstrating its potential as a comprehensive strategy for improving safety conditions in the construction industry.

The safety condition analysis process from on-site images combined automated image analysis with systematic inspection strategies, ensuring regular and reliable safety assessments. Token distribution through blockchain technology followed a systematic sequence, promoting safe behaviors and cultivating a resilient safety culture within the construction industry. Overall, these innovations held great potential for enhancing safety and productivity in construction.

MULTI-ASPECTUAL KNOWLEDGE ELICITATION FOR PROCUREMENT OPTIMIZATION IN A WAREHOUSE COMPANY

Franck Romuald Fotso Mtope, Sina Joneidy, Diptangshu Pandit & Farzad Rah

School of Computing, Engineering & Digital Technologies, Teesside University, Middlesbrough, UK

ABSTRACT: *Efficient optimization of business processes required a profound understanding of expertise provided by domain specialists. However, extracting such insights can indeed be a laborious and time-consuming endeavour. This paper introduces the Multi-Aspectual Knowledge Elicitation framework (MAKE4ML) — a novel approach designed to effortlessly and effectively extract valuable information from domain experts. This framework inherently facilitates the development of machine-learning models capable of optimizing business processes, thereby diminishing reliance on experts. The framework's application within a food warehouse company is showcased, specifically targeting the enhancement of the procurement process. The employed methodology revolves around conducting comprehensive interviews with procurement experts, thereby enabling a meticulous exploration of diverse facets inherent to a business process. Subsequently, the gathered insights are employed to conceive and calibrate a machine learning model (time series forecasting). This model effectively emulates the domain experts' proficiency, offering invaluable decision-oriented insights. The outcomes of this study show that our framework allows efficient knowledge elicitation, which is a pivotal factor in formulating and deploying a bespoke machine-learning model. The proposed approach can be extended into various other business processes, thereby paving the way for operational refinement, cost reduction, and amplified efficiency.*

Keywords*: domain experts, knowledge elicitation, multi-aspects, machine learning, procurement optimization, warehouse, technology acceptance.*

1. INTRODUCTION

The growing demand for digitalization and process optimization has led to the integration of machine learning (ML) models across industries. This integration often requires insights from domain experts, necessitating the extraction of pertinent information to design tailored ML models. Researchers and ML engineers have employed various techniques, such as feature selection and knowledge elicitation, to enhance model accuracy while ensuring successful technology adoption. Studies have highlighted the challenges of knowledge elicitation, which significantly affect ML performance across disciplines. Researchers are increasingly exploring human involvement in ML workflows (D'Angelo & Palmieri, 2020; Park et al., 2023; Sundin et al., 2022; Wang et al., 2021), combining expert knowledge with data from diverse sources (Ademujimi & Prabhu, 2021; Ben Brahim et al., 2022; Hu et al., 2019; Huang et al., 2019; Lee et al., 2020; Seymoens et al., 2019), and innovative ways to extract insights (Afrabandpey et al., 2019; Campos et al., 2018; Cheung et al., 2011; Crerie et al., 2009; El-Assady et al., 2020; El-Assady et al., 2019; Mantik et al., 2022; Možina et al., 2018; Park et al., 2021; Yazici et al., 2022; Young et al., 2022).

First, human involvement in ML workflows referred to as "Human-in-the-loop", aims to create cost-effective prediction models by incorporating human knowledge during data preparation and refinement stages. Secondly, the integration of expert-derived knowledge with data from sources like sensors refines training objectives and contextual alignment, as standard sensor data might lack external factors' consideration. Finally, Intuitive techniques (e.g., decision-mining, process mining) bridge gaps between ML engineers and multi-disciplinary experts, translating meaningful insights into ML model specifications.

The central research question is: "How can we extract meaningful knowledge from domain experts for designing ML models while ensuring user acceptance?" To address this, a comprehensive framework is proposed, involving multi-aspectual knowledge extraction, translation into ML specifications, visualizing business workflows, and capturing decision-making rules and constraints. Key contributions include a multi-disciplinary knowledge extraction framework, translating knowledge into ML and software specifications, and visualizing business workflows and decision rules. The framework's efficacy is demonstrated in a warehouse setting, focusing on procurement. Experimental results reveal the successful extraction of diverse expert knowledge.

2. RELATED WORK

2.1. Human Involvement in Machine Learning Workflow

In recent years, there has been a growing interest in human involvement in the machine-learning workflow. The use of human-in-the-loop techniques has been proposed to improve the performance and reliability of machine learning models. Several studies have investigated how human expertise can be used to improve the performance of machine learning models.

In the field of data science, (Wang et al., 2021) introduced AutoDS, an automated machine learning system that aims to support data science projects by automating tasks such as data exploration, model training, and model selection. This system proposes suggestions (ML configuration, pre-process data, etc.) to the users via a web-based graphical interface where they can interact and make amendments. They showed that the proposed system improved the productivity of ML workflow while delivering better models.

In the field of aerospace systems, (D'Angelo & Palmieri, 2020) proposed the use of genetic programming to extract knowledge from aerospace structural defects by providing a mathematical model of the defects, which can be used for recognizing other similar ones. They found that their approach was effective in building reliable models of the defects and can be considered a successful option for building the knowledge needed by tools for controlling the quality of critical aerospace systems.

(Sundin et al., 2022) proposed a principled approach to use human-in-the-loop machine learning to help chemists adapt the multi-parameter optimization (MPO) scoring function to better match their goal. They proposed a method that uses a probabilistic model that captures the user's idea and uncertainty about the scoring function and uses active learning to interact with the user. They showed the effectiveness of their approach in two simulated examples achieving significant improvement in less than 200 feedback queries.

Overall, these studies demonstrate the potential of a human involved in the ML workflow to improve the performance and reliability of machine learning models. However, further research is needed to understand the best ways to incorporate human expertise into the machine-learning process, and how to effectively balance the trade-offs between automation and human involvement.

2.2. Fusion-driven learning

The fusion-driven learning consists of the fusion of knowledge experts with data collected from other sources to improve the performance of machine learning models. Indeed, several works have been introduced to leverage the strengths of both human expertise and data-driven methods to create more accurate and reliable models. The most representative works are discussed hereafter (Ademujimi & Prabhu, 2021; Ben Brahim et al., 2022; Hu et al., 2019; Huang et al., 2019; Lee et al., 2020; Seymoens et al., 2019).

(Huang et al., 2019) propose a hybrid approach for identifying the structure of the Bayesian network (BN) for the threat assessment of mass protests. They demonstrate that traditional methods for discovering BN structure from data or experts were inadequate, and instead proposed a hybrid approach (ISM-K2) which enhanced the BN structure learning methods via a knowledge elicitation method called ISM (Interpretive Structural Model).

(Ademujimi & Prabhu, 2021) introduced a method for fusion-learning of Bayesian network (BN) models for fault diagnostics. They proposed an approach for expert knowledge elicitation of the BN structure aided by logged natural language data and sensor data. They found that the resulting fused BN model improved diagnostics as it had a wider fault coverage than the individual BNs.

(Hu et al., 2019) developed a methodology that combines sensor data with domain expert knowledge to improve energy fault detection. The proposed methodology includes an engagement process with experts in the energy system field to identify relevant data, an integration of domain knowledge with sensor data, an automatic selection of potential input data, and the use of machine learning to automatically build a data-driven fault detection model.

(Lee et al., 2020) presented an interactive machine-learning approach to improve the assessment of rehabilitation exercises by integrating a data-driven model with expert knowledge. This approach uses reinforcement learning to identify the most salient features of the exercise motions and generates a user-specific analysis to elicit feature relevance from a therapist for a personalized rehabilitation assessment. This study improves the performance of predicting assessment and demonstrates how machine-learning models can improve with expert knowledge for personalized rehabilitation assessment.

Overall, these studies demonstrate the potential of fusing knowledge from experts with data collected from other sources to improve the performance of machine learning models. However, further studies are needed to find techniques and methods to easily and efficiently fuse data used to train ML models while achieving the best performance.

2.3. Knowledge Elicitation Methods

There have been several studies in the past that have aimed to improve the efficiency and effectiveness of machine learning models through the incorporation of expert knowledge. These studies (Afrabandpey et al., 2019; Campos et al., 2018; Cheung et al., 2011; Crerie et al., 2009; El-Assady et al., 2020; El-Assady et al., 2019; Mantik et al., 2022; Možina et al., 2018; Park et al., 2021; Yazici et al., 2022; Young et al., 2022) have proposed various methods for extracting and utilizing expert knowledge: active learning, process mining and decision mining, and human-in-the-loop approaches.

One widely used approach is active learning, where a model is trained on a small initial labelled dataset and then iteratively queries the expert for labels on the most uncertain samples. (Možina et al., 2018) propose a data-driven tool for the semi-automatic identification of typical approaches and errors in student solutions for a programming course. They used the argument-based machine learning (ABML) method, which interactively exchanges arguments with an expert until the model is good enough. Similarly, (El-Assady et al., 2019) present a framework that integrates speculative execution, allowing users to preview the potential consequences of their actions with the model and make more efficient decisions.

Another approach uses process mining and decision mining to identify operational processes, viz., business rules. Indeed, (Campos et al., 2018) applies a decision-mining technique in an event log of a real company to discover tacit decisions that could be translated as business rules. In the same way, (Crerie et al., 2009) relies on process mining and data mining techniques to extract two sub-types of business rules: condition action assertions and authorization action assertions. Likewise, (Alkofahi et al., 2022) introduces a method to elicit business rules from real-world web applications; these rules are defined as one-to-one and one-to-many implicit dependency relations, thus minimizing the negative effect of substitute relations in decision-making.

A third approach relies on the concept of human-in-the-loop, (Afrabandpey et al., 2019; El-Assady et al., 2020; Park et al., 2021) whereby human experts are added into machine learning pipelines, allowing them to provide feedback or guidance at various stages of the model development process. For instance, (Park et al., 2021) describe a framework called "Ziva" that guides domain experts in sharing their knowledge with data scientists for building natural language processing (NLP) models. (Afrabandpey et al., 2019) introduce a method to elicit expert knowledge about pairwise feature similarities and use sequential decision-making techniques to minimize the effort of the expert while improving the prediction performance on a small dataset. (El-Assady et al., 2020) has developed a framework allowing users to provide semantics of their knowledge, which will contribute to topic model refinement.

Finally, (Yazici et al., 2022) performs knowledge prioritization after the elicitation from domain experts. The authors use knowledge elicitation and feature selection techniques to identify the most prevalent tacit knowledge variables, which are then prioritized using machine learning methods and the fuzzy Analytic Hierarchy Process (AHP).

Overall, various studies have proposed methods that allow the intuitive extraction of knowledge from experts and train optimized machine learning models. Although these methods allow knowledge elicitation, there are several areas and aspects that have not been (or have been poorly) considered so far. In this work, we aim to introduce a framework that considers the multi-aspect of concepts defining the context, their interdependence and translation into tailored specifications.

3. METHODOLOGY

3.1. Multi-aspectual Knowledge Elicitation (MAKE)

MAKE, multi-aspectual knowledge elicitation, developed by Winfield (Winfield, 2000) for planning and building knowledge-intensive systems, is based on Dooyeweerd's aspects (Table 1). By guiding and stimulating the participants to identify aspects that are important to their situation and opening up their constituents, MAKE begins with the most obvious aspects and gradually uncovers the relevance of each. As Winfield (Winfield, 2000) found, MAKE stimulated the participants to consider broader issues, lay participants were able to grasp the meaning of aspects and work with them during analysis, and some tacit knowledge was explicated through MAKE.

(Winfield, 2000) developed two visual tools to help multi-aspectual analysis. One employs a flexible mind map to build up an understanding of inter-aspectual relationships. The second method employs the Christmas Tree, designed to provide an overall picture of areas of concern that emerge during discussions. Any significant positive or negative repercussion that emerges can be 'hung on' the tree at the aspect in which it is meaningful, with the positive on one side and the negative on the other. As the picture develops, patterns emerge showing areas of significant benefit or problems, which can be clarified and tackled during the design and development process.

3.2. Proposed Framework

The framework in (*Fig. 1*) relies on the 15 aspects of Dooyeweerd (Basden, 2011) (*Table 1*) used in MAKE (Winfield, 2000) to elicit knowledge from domain experts through interactions, which allows an understanding of what is meaningful to them. Indeed, it uncovers the elements that are often not immediately apparent but contribute significantly to overall technology acceptance and success while avoiding unintended consequences. Our proposed framework consists of five key steps.

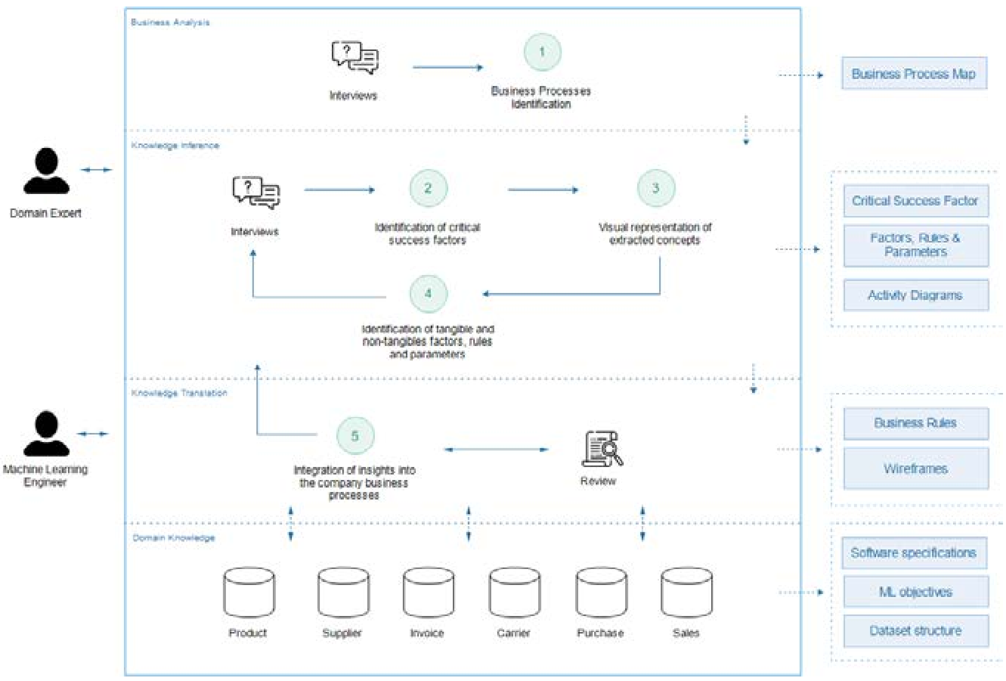

Fig. 1: Overview of the proposed Multi-Aspectual Knowledge Elicitation framework.

Table 1: fifteen aspects of Dooyeweerd (Basden, 2011) and their meaning

Aspect	Meaning
Quantitative	Discrete amount
Spatial	Continuous space
Kinematic	Movement
Physical	Energy + mass, forces
Biotic/Organic	Life functions + organisms

Sensitive/Psychic	Sense, feeling, emotion
Analytical	Distinction, conceptualization
Formative	Achievement, construction, history, technology
Lingual	Meaning carried by symbols
Social	'We': relationships, roles, convention
Economic	Frugal management of resources
Aesthetic	Harmony, play, enjoyment
Juridical	Due: responsibilities + rights
Ethical/Attitudinal	Self-giving love, generosity
Pistic/Faith	Vision, aspiration, commitment, belief

(1) Identification of business processes: analyse the company's internal/external processes to identify multiple cross-functional processes, data points, systems, and non-value-added operations. This step is essential to the identification of key data feeds (internal/external) favourable to the collection of intelligence to guide decision-making.

(2) Identification of critical success factors: gather insight from senior members and staff users of the company to understand the business and contextual issues. This step relies on a series of interviews where the discussion could turn around topics like system usefulness, job security, the impact of the technology on users and their work, user's attitudes to technology, skill levels and other factors that are meaningful to users.

(3) Visual representation of extracted concepts: take concepts from step (2) and map them against Dooyeweerd's aspects (e.g., technical, social, economic, ethical, etc.) to identify any gap or missing concept that will require further investigations (or interviews). The visual representation of extracted concepts highlights any laws, axioms, data, definitions and constraints that apply to the domain of the project.

(4) Identification of tangible and non-tangible factors, extra meta-level rules and parameters: provide a domain conceptualisation and presentation to an expert including different aspectual views to select the aspectual view(s) in which experts see their domain expertise lying. This step goes through the loop of detailed knowledge acquisition to identify business process workflows and decisions making scenarios.

(5) Integration of insights into the company business processes: propose a specification and design of the software solution to be integrated in the company information system to improve and overcome the existing limitations or challenges.

3.3. Knowledge Elicitation: application

The proposed framework relies on a series of interviews with domain experts or managers who have strong knowledge and understand the business processes. The application of this framework to a business starts with "Tutorial" interviews (Winfield, 2000), where the expert is asked to prepare a talk outlining the whole domain. , This helps provide an orientation to a domain and the identification of relevant concepts. The interviews are carried out with senior managers or team leaders who can explain the daily activities to a non-expert interviewer. As a result of these interviews, the interviewer should come up with internal/external processes which can impact the company's objectives.

The next step of the framework aims to identify critical factors which contribute to the success of the business processes. To achieve this, a "Focused" interview (Winfield, 2000) is carried out between an interviewer (ML Engineer) and domain experts to extract more detailed knowledge. This interview consists of three parts. First, there is an introduction where goals are explained to encourage the expert to take part in the discussion. Secondly, a set of topics is carefully chosen regarding previously identified concepts. These topics guide the interviewer to identify what is meaningful for experts (future users). Finally, the interviewer needs to evaluate and summarise the elicited knowledge before the interview ends.

The concepts, collected during the Tutorial interviews and Focused interviews, are mapped against the fifteen aspects of Dooyeweerd (Basden, 2011). Indeed, it consists of the analysis of each concept to determine if it can be defined or interpreted by these aspects. A set of keywords can be considered as references when analysing each concept. A keyword can represent an entity, a process, a task, or a system. As a result, the elicited knowledge can be visually illustrated and structured with the following parameters: laws, axioms, data, definitions, and constraints.

After the extraction of knowledge, the latter needs to be conceptualised to the domain and presented to an expert for validation. This step helps narrow down the knowledge and identify tangible & non-tangible factors, rules and constraints involved in the decision-making process. If the validation failed, the ML engineer needs to organize new interviews to clarify the misalignment or collect what is missing from the expert's knowledge.

Finally, the ML engineer relies on elicited knowledge to propose an ML design: dataset structure (features and observations) and the training objectives. Indeed, it helps in the creation of a multi-variant dataset that was used to train a time series model for stock forecasting purposes. Moreover, the collected knowledge guides the definitions of specifications for the software development part of the project. Indeed, it shaped the definition of models, database tables, workflows and wireframes (UX/UI).

4. RESULTS & EVALUATION

4.1. Case study

In this study, we worked with a wholesale company specializing in food export and distribution across the North UK. It operates in a multi-disciplinary environment, where teams from different disciplines work together to achieve the company's objectives. The company has several business processes, such as sales, procurement, logistics, accounting, warehouse, e-commerce, etc. that guide its daily activities and contribute to its success.

In a warehouse context, a procurement is a business process that involves identifying and selecting suppliers, negotiating contracts, and managing the purchase of food items to maintain inventory levels, meet customer demand and optimize costs. We applied our proposed method to the procurement business process, where we extracted knowledge from the team members and design machine learning models. The data and knowledge collected from the company's operations were used to train ML models, which were then deployed to support the procurement process.

Moreover, the company owns a bespoke resource management platform that supports various operations such as raising and amending purchase orders, stock management, goods-ins and quality control. The trained ML models were integrated into this platform to support the procurement process while offering a technology acceptance by the staff and final users.

4.2. Procurement: Elicited Knowledge

(1) Identification of business processes: the company's business model involves several processes, from ordering to delivery, which aims to meet the supply-demand needs. Interviews have been conducted with the company staff to better understand the existing processes and come up with a supply chain map (Fig. 2).

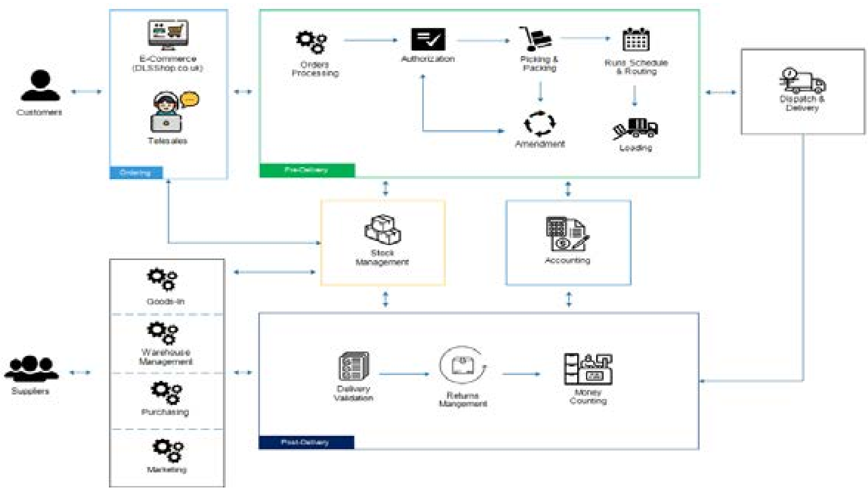

Fig. 2: Supply Chain Map

(2) Identification of critical success factors: we selected the characteristics/factors that will contribute to the technology acceptance of the new artificial intelligence (AI) platform with regards to the procurement business process.

(3) Visual representation of extracted concepts: several concepts have been identified during the interviews with the domain experts. From the procurement concept, we investigated and captured knowledge in terms of laws, axioms, data, definitions, and constraints. The following keywords have been selected as reference for our investigation: product, supplier, purchase manager, carrier, reference for quotation (RFQ), purchase order, manufacturing, delivery, return, and credit note. Table 2 illustrates the knowledge elicited from the entity "Product" and mapped against the 15 aspects of Dooyeweerd.

(4) Identification of tangible and non-tangible factors, extra meta-level rules and parameters: following the mapping of the key business processes against the Dooyeweerd's aspects, we identified data attributes and workflows required to design a ML solution. Indeed, the work sessions with experts from the procurement domain allow us to come up with tacit knowledge that is illustrated in an activity diagram (Fig. 3)

(5) Integration of insights into the company business processes: the knowledge elicited from previous steps allowed us to gather all specifications required to properly design databases of micro-services that will be part of a new software architecture in the company. Moreover, the extracted knowledge allows us to create interface insights (wireframes) illustrating each activity of the business process. Indeed, these wireframes (Figure 4) allows us to quickly validate our understanding of the business processes and ensure the technology acceptance of the future users.

Table 2: Multi-aspectual knowledge elicited from an entity "Product"

Laws	Axioms	Data	Definitions	Constraints	Aspects
Weights and Measures Act 1985	A product must have a measurable quantity	Product quantity, size, weight, cost price, sales price, online price, online offer price, collection price	A product has properties which can take a discrete amount: quantity, size, weight, price	A product should fit with the warehouse shelves dimensions/capacity	(1) Quantitative
Food Safety Act 1990 (Food Safety Act 1990)	A product must have a physical presence in a specific location	Product dimensions, location	A product has a shape, position,		(2) Spatial
Organic Products Regulations 2009 (*The Organic Products Regulations 2009*), Food Safety Act 1990 (Food Safety Act 1990)	A product must be kept in a suitable environment with respect of the shelf life	Product expiration date + Shelf life	A product has a life function	A product needs to be sold before the expiration date. A product expiration date needs to fit with the shelf life	(5) Biotic/Organic
General Food Law Regulation	A product must be stored and transported under conditions that	Product temperature, humidity and light	Product can be touched, smelled & tasted		(6) Sensitive/ Psychic

(EC) No 178/2002	maintain its sensory quality				
Food Safety Act 1990 (Food Safety Act 1990)	A product must be analysed and evaluated for its chemical and physical properties	pH, nutritional content, shelf life	Product can be distinguished	A product must have a set of chemical and physical properties	(7) Analytical
Food Standards Act 1999	A product must be capable of undergoing processing or transformation	Product Package	Some product packages are designed to meet customer expectations	Product rebranding designing should fit with each market segment	(8) Formative
Food Safety Act 1990 (Food Safety Act 1990)	A product must meet industry standards and regulatory requirements for labelling	Product name, description, code	Product labelling using symbols	Product name & code need to follow standards (length, symbols, languages)	(9) Lingual
Sale of Goods Act 1979 (Food Safety Act 1990)	A product must be priced in a manner that reflects its value	Product margin benefits, profitability and growth	Product has a limited value	Product has to be managed with frugality	(11) Economic
Food Standards Act 1999	A product must be consistent with customer preferences	Customers reviews, feedbacks	Product has to bring joy, fun, and harmony to customers	A product needs to satisfy the customers so that they get values for what they pay for	(12) Aesthetic
Food Safety Act 1990	A product must comply with relevant laws	Product reward, recompense	Product has to bring justice	A product needs to be sold in a fair ways	(13) Juridical
Food Safety Act 1990	A product must be produced and marketed with respect of ethical principles	Product advantages, benefits	Product can be beyond the imperatives	A product can be delivered earlier, discounted	(14) Ethical/Attitudinal
Food Safety Act 1990	A product must be produced and distributed with respect of spiritual and cultural beliefs	Dietary restrictions, consumer preferences	A product follows a commitment and trust	A product needs to be trustworthy	(15) Pistic/Faith

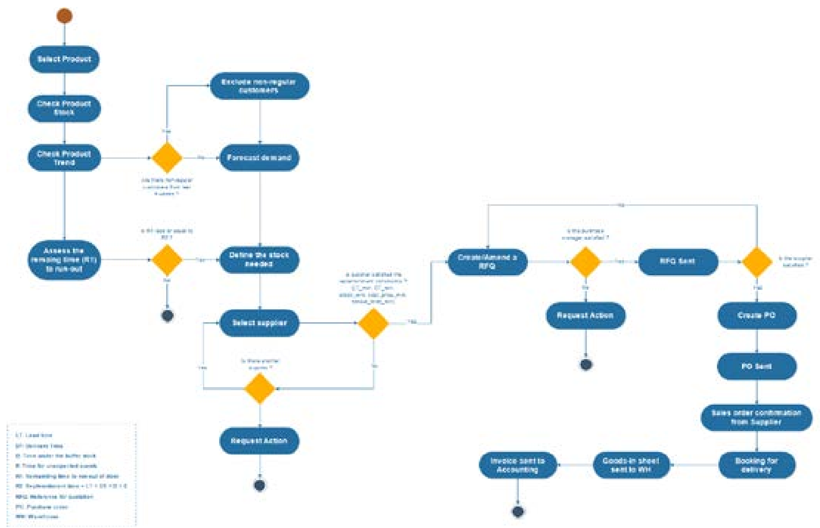

Fig. 3: Activity Diagram – Make a purchase order

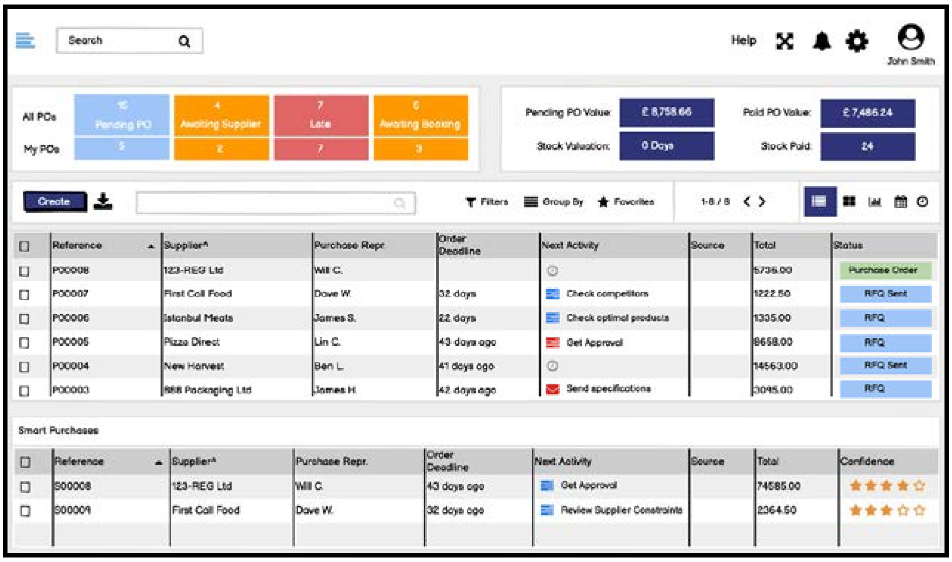

Fig 4: Procurement (Purchasing) module: this wireframe shows a quick representation of the overview page.

4.3. Evaluation of the results

The proposed framework was evaluated in a real-life warehouse environment where knowledge have been extracted from procurement experts and used to build historical sales datasets. These datasets were used to train time series forecasting models that optimize the procurement business process. We conducted the evaluation in two ways: a quantitative analysis and a qualitative analysis.

Quantitative analysis: to quantify the performance of the proposed method, we conducted a series of experiments which consists of training stock forecasting models using the datasets generated from historical sales data. These datasets were also enriched with knowledge elicited from procurement experts using our framework. These methods helped to identify the learning objectives and the representation of the dataset (features, observations, etc). We used two time series forecasting methods like ARIMA (Harvey, 1990) & TFT (Lim et al., 2020) from the literature to illustrate how our framework contribute in improving the performance of the models. To evaluate the performance of our models we used the following metric: Quantile loss (Wen et al., 2018). Table 3 shows the performance of the models trained on a dataset without elicited data (D1) and a dataset with elicited data (D2).

Table 3: Comparison of models trained on two datasets, without (D1) and with elicited features (D2), w.r.t a 0.5 percentile quantile loss (p50 loss) and 0.9 percentile quantile loss (p90 loss)

Datasets	Elicited Features	Model	p50 loss	P90 loss
D1	-	ARIMA	1.9929	1.9451
D1	-	TFT	0.6138	0.4266
D2	**Yes**	**TFT**	**0.5825**	**0.3780**

Each dataset has the following settings: 513484 time points (about 2 years of sales data), 30 days' horizon, and the stock quantity as the target feature.

Moreover, we did a comparison of models trained on datasets, which involved features extracted with knowledge elicitation techniques considered as baselines (ABML, IHTM, Ziva). We used the same time series-forecasting model (TFT) to ensure a fair comparison (Table 4).

Table 4: Comparison models trained on datasets generated with our proposed knowledge elicitation framework against baselines.

Datasets	Elicited Methods	Model	p50 loss	P90 loss
D2	IHTM	TFT	0.6827	0.4702
D2	Ziva	TFT	0.6764	0.4629
D2	**Ours**	**TFT**	**0.5825**	**0.3780**

Qualitative analysis: In order to evaluate the technology acceptance of solutions developed using our knowledge elicitation framework, we selected seven participants. This group included three individuals without prior knowledge in procurement and four members of the procurement team. The main objective was to determine whether the trained models effectively optimized business processes while considering the needs of the end user. Each participant was tasked with creating a purchase order on the system while adhering to two key constraints: avoiding stock shortages and preventing overstocking. The participants were instructed to evaluate the system based on several criteria, including user experience (UX), user interface (UI), workflow simplicity, and knowledge awareness. They rated the system on a scale of 0-5 (bad to good) for each criterion.

In terms of user experience (UX), feedback from seven participants revealed a generally positive response to the system for creating or modifying purchase orders. Five participants rated the experience with a score of 5 out of 5, indicating satisfaction, while two gave a score of 4, suggesting a desire for added features like shortcuts. Regarding the user interface (UI), six participants praised the new design with a score of 5, although one participant gave a score of 3 due to colour preferences. Evaluating workflow simplicity, three participants without procurement expertise rated it 4 for ease of following step-by-step instructions. In contrast, four procurement team members rated it 5 for consistency and accuracy. In terms of knowledge awareness, four participants rated it 5 for facilitating decisions on quantity, delivery, pricing, and supplier selection, while three desired more empirical data to bolster the system's recommendations.

5. CONCLUSION

In this paper, we proposed a multi-aspectual knowledge elicitation framework (MAKE4ML) for optimizing business processes through the design of machine-learning models. Our approach involves conducting interviews with domain experts and parameterize machine-learning models that can reproduce the expertise of the experts and provide insights for decision making. We applied the proposed framework in a food warehouse company to optimize the procurement process, resulting in a significant improvement in the accuracy of forecasting.

This framework allows us to extract concepts that were relevant to the business and useful to optimize the learning objectives of the machine learning models. Our approach can be extended to other business processes, enabling efficient knowledge elicitation, and contributing to the design of machine-learning models that can optimize operations, reduce costs, and increase efficiency.

Furthermore, we plan to investigate the combination of multi-aspectual knowledge elicitation techniques with the active learning. Active learning has been shown to be effective in reducing the amount of labelled data required for training machine learning models. We believe that combining active learning and the multi-aspectual knowledge elicitation technique MAKE4ML can lead to even more efficient and effective optimization of machine learning models.

Overall, our multi-aspectual knowledge elicitation framework can be a valuable tool for optimizing business processes through the design of machine-learning models. By leveraging the knowledge and expertise of domain experts, we can develop more effective machine learning models that can lead to cost savings, improved efficiency, and better decision-making. We hope that this paper provides a valuable contribution to the field and inspires further research in this area.

A SYSTEMATIC LITERATURE REVIEW TO IDENTIFY A METHODOLOGICAL APPROACH FOR USE IN THE MODELLING AND FORECASTING OF CAPITAL EXPENDITURE OF HYPERSCALE DATA CENTRES

David King, Dr Nadeeshani Wanigarathna, Prof. Keith Jones & Dr Joseph Ofori-Kuragu
Anglia Ruskin University, Bishops Hall Lane, Chelmsford CM1 1SQ, United Kingdom

ABSTRACT: *The theme of 'Managing the digital transformation of the construction industry' emphasises the importance of considering various dimensions of digitalisation and optimising the built environment. This review aims to present methodological approaches from existing literature that elucidate location-related factors impacting the capital cost of data centres. These findings facilitate adjustments to historical cost data when estimating total costs for new data centres. A systematic literature review method was employed to ensure an objective and comprehensive synthesis. In conjunction with Bayes's theory, this review identifies that a Delphi methodology is the most suitable methodological approach for forecasting and modelling capital expenditure for hyper-scale data centres. The methodology enables collective decision-making and consensus building, recognising the stakeholder's pivotal role in shaping the future of data centres. These findings offer valuable insights for researchers and practitioners in forming a methodological approach for further investigations into the location-related factors impacting the capital cost of data centres. Embracing this knowledge allows us to align research and practice, ensuring that these practices become integral to shaping the future of data centres and the digitalisation and optimisation of the built environment.*

KEYWORDS: *cost; decision analysis; forecasting, data centres*

1. INTRODUCTION

The rapid expansion of digital technologies requires buildings (called Data centres) to house information technology (IT) equipment to store and process data and services required by digital transformation, including the internet. Due to the advantages such as advanced technological progress in the sector and the cold climate conditions, certain regions of the world, such as the Nordic regions, are preferred by investors to build Data centres. This presents unprecedented challenges to construction cost consulting professionals in providing reliable capital cost estimates as early as a potential (international) location is identified. In the very early stage of a project opportunity, cost consultants provide capital expenditure input to support development appraisal exercises which estimate the residual land value and input to the Order of Cost estimate involved 'in determining the possible cost of a building(s) in relation to the employer's fundamental requirements' (RICS, 2013).

As these activities occur before preparing a complete set of working drawings (RICS, 2013), capital expenditure is estimated by benchmarking cost data from previously completed similar projects. This involves comparing and contrasting the difference between historical and proposed projects concerning the cost-significant variables such as location, building size, market conditions and their impact on capital expenditure. Existing literature reveals generic cost modelling approaches that could be used in early cost estimates and details of cost-significant variables that need to be considered during cost modelling (Parameswaran et al., 2019; Hashemi et al., 2020).

However, as data centres are relatively new to the construction sector and their design and construction significantly depend on the location (King et al., 2023), the suitability of the generic cost modelling approaches has yet to be widely investigated. Therefore, particularly regarding the conference theme and the growth of the internet, more research is required to establish the impact of site location on the capital expenditure of hyper-scale data centres; this will assist in selecting the correct location to make informed decisions and reduce the financial risk and contingency estimate to ensure a more accurate construction cost. This paper aims to present findings of a systematic literature review to determine the theoretical and methodological approaches in existing literature concerning the location-related factors affecting the capital cost of data centres that could be used to adjust historical cost data during their use in estimating the total cost for new data centre projects.

David King, Nadeeshani Wanigarathna, Keith Jones, Joseph Ofori-Kuragu, *A Systematic Literature Review to Identify a Methodological Approach for Use in the Modelling and Forecasting of Capital Expenditure of Hyperscale Data Centres,* pp. 380-387, © 2023 Author(s), CC BY NC 4.0, DOI 10.36253/979-12-215-0289-3.37

2. MATERIALS AND METHODS

2.1 Approach

A systematic approach has been used to identify and synthesise the literature results to ensure an accurate, unbiased synthesis. It is an approach where literature on a complex topic has been conceptualised and studied differently among researchers (Greenhalgh et al., 2005). This review identifies methodological approaches, geographies, historical development, quality, and literature validity.

2.2 Scoping Strategy

The literature search strategy utilised a scoping review based on that as derived from PRISMA (Tricco et al., 2018) and to provide rigour to justify further research (McInnes et al., 2018). The search strategy used the advanced search tool with Boolean keyword operators. In total, 1,375 studies were identified. After an initial review of the abstract of the papers, 508 were identified as being focused on construction, data centres and cost variables. From those identified as suitable, 87 were identified as duplicated, reducing the number of papers for review to 421. As Suarez-Almazor et al., (2000) suggested, it is vital to utilise a second database to identify potential inconsistencies. In addition, it may further enhance and support the literature review with newly identified literature. Using the same search criteria as the stage 1 search, a further 1,623 studies were identified; after an initial review of the abstract of the papers, 402 were identified as being focused on construction, data centres and cost variables. From those identified as suitable, 251 were identified as duplicated from the initial stage 1 search, further reducing the number of papers for an abstract review to 151, bringing the total for abstract review to 572. Following an abstract and full text review a total of 161 studies were selected for final review, as Figure 1.

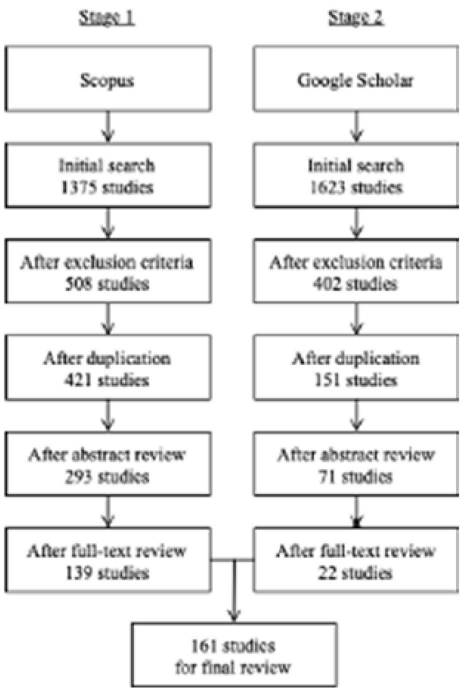

Fig 1. Systematic approach for literature

2.3 Validity and quality of literature

To assess validity and quality, the papers have been analysed and identified against peer-reviewed literature and grey literature, as it is recognised that the inclusion of grey literature in systematic reviews provides rigour and balance of recognised sources of information (McAuley et al., 2000; Blackhall, 2007). Whilst grey literature means many things to many people (Mahood et al., 2014), this review identifies grey literature as being book chapters, conference proceedings and trade publications. According to McAuley et al., (2000), the review process for a meta-analysis should strive to locate and incorporate various reports, including both published and grey literature, that satisfy pre-established criteria for inclusion. In our systematic literature review, we comprehensively searched literature and identified 161 papers for final review. The review process assessed the literature's validity and quality, including both peer-reviewed and grey literature sources such as book chapters, conference proceedings, and trade publications as identified in Table 1. We found that 84% of the selected literature was peer-reviewed journals, while the remaining 16% comprised other sources.

Table 1. Sources of literature

Source	Frequency	% of total
Book Chapters	9	6%
Conference proceedings	10	6%
Peer reviewed journals	136	84%
Trade publications	6	4%
Totals	161	100%

3. RESULTS AND DISCUSSION

3.1 Methodological Approaches to Cost Modelling

To fully understand the methodological approaches utilised in research, provide data on their use by researchers in previous studies; this identifies the approach taken in each study for synthesising the data that may be useful for future studies. Analysing the abstracts identified methodological approaches in the selected literature from the scoping strategy; this meta-narrative has shown that the prediction method has the highest count across all sectors. The prediction method has been used significantly in modelling data centre costs. The other vital approaches include machine learning, heuristic, stochastic method, parametric modelling, AHP, Regression Analysis and Monte Carlo simulation. It is worth noting that some papers identified Machine Learning, and some artificial neural network techniques, whilst others used neural network techniques. Due to the similarity of the techniques and neural networks forming a subset of machine learning, we have grouped these in the Machine Learning category. Likewise, several papers identified similar techniques whilst others identified heuristic techniques; again, we have grouped these in the heuristic category due to the similarity of these techniques.

When analysing what methodological approaches are specific to the data centre sector by eliminating other construction sectors resulting from the scoping search, the results identified 59 different approaches related to data centres. These results demonstrate that prediction methodology holds the highest vote count. This methodological approach aligns with the vote count trend for the prediction method. It is acknowledged that prediction theory is not an absolute exact science and 'can be compared to weather forecasting, stock market predictions or 'betting on how fast a 100-meter foot race will be run' (Line, 2008). Prediction theory also requires a substantial quantity of data to enable prediction. Advanced modelling techniques are extensively used in cost modelling to improve accuracy. One of the most recent advancements in Machine Learning-based approaches. According to a recent systematic review (Hashemi et al., 2020), ANN and Regression Analysis were identified as the most widely used ML-based cost modelling techniques, followed by hybrid models such as ANN with fuzzy logic, CBR and GA (Genetic Algorithm). Machine Learning involves developing a machine-based system that can learn from data. A large volume of historical data is paramount for a machine-learning model.

As data centres are relatively new, developing a machine learning-based model is not feasible at this early stage when historical cost data is limited. Fazil et al., (2021) demonstrate that obtaining a reasonably accurate neural network prediction is possible even when insufficient information is available during the initial design. However, Gunaydin and Dogan (2004) argue that the accuracy that a cost estimation neural network model strongly relies on the quality and quantity of data samples used. They claim that more data samples lead to less prediction error. Therefore, to create an accurate cost prediction model for building projects, it is necessary to have reliable and high-quality cost data for various types and conditions of buildings. Case-based reasoning is another potential method for cost prediction, which involves retrieving information from historical data on similar or identical cases. However, there are challenges associated with the retrieval process, such as computing similarity measures. According to Rashid's research (2017), case-based reasoning is an effective method for predicting costs as it involves analysing past cases' attributes, thereby enhancing cost prediction accuracy. However, these models mainly rely on historical cost data. In the UK, the Building Cost Information Service (RICS, 2018) offers information on construction projects and their corresponding tender prices, and cost managers use this data to estimate the cost of a building based on the cost of a similar project with adjustments to reflect any differences. However, it does not enable generalisations about the relationships between cost and significant predictors. Lowe et al. (2016) conducted a research study, creating a dependable regression cost model that can be used to estimate the construction expenses associated with a building's final account. They highlight that, aside from its practical usefulness, creating such a model serves two other purposes. First, it provides a benchmark for evaluating the effectiveness of neural network models, and second, it helps identify the variables that display a significant linear correlation with cost. However, the effectiveness of these prediction methods has its limitations.

Regression techniques require a substantial quantity of statistical information, and their precision is affected by the supposition that the independent variables are both independent of each other and normally distributed (Son et al., 2012). In contrast, according to Zhang (2003), neural networks possess a crucial benefit over regression models because they can model nonlinear connections without relying on assumptions. Regression methods demand a significant amount of statistical data, and their accuracy is influenced by the assumption that the independent variables are independent and normally distributed (Son et al., 2012). In contrast, the primary advantage of neural networks over regression models is their capacity to model nonlinear relationships without relying on any assumptions (Zhang, 2003). However, building a neural network model also requires data, and designing an optimal network structure involves a costly trial-and-error process. Therefore, according to Son et al. (2012), there is a notable need for prediction techniques that are more robust and reliable. Likewise, acquiring input data for preparing estimates can be challenging. According to Hashemi et al., (2020), in cases where the extent of the work could be better understood, it could result in inaccurate and approximate cost estimates. Whilst it is acknowledged that few studies focus specifically on selecting suitable sites for data centres (Kheybari et al., 2020), the search identified one Delphi study for data centre projects in China as a method for selecting data centres for several cities. However, the main findings identified proximity and geographical locations as having the only impact (Yang & Ye, 2011). According to King et al. (2023), in the absence of data for assessing the impact of location variables for hyperscale data centres, a consensus will need to be obtained from industry experts to obtain the data.

Whilst Delphi has the lowest vote count, as an approach to forming a consensus, Delphi is an appropriate route. This literature review has identified that utilising voting as the ameliorated nominal group technique could be an alternative use of Delphi. According to Brauers (2018), the nominal group technique may help generate ideas about objectives that could be included in an initial version of the Delphi method. This could facilitate convergence towards a final list of objectives. Whilst other top-voted methodological approaches require a substantial amount of data to establish and make predictions for capital expenditure, a Delphi study is well suited to establish consensus to identify the impact of location variables in the case of Data centres where available published data is limited. Some scholars argue that the Delphi method lacks a well-established framework (Crisp et al., 1997; Sharkey & Sharples, 2001; Broomfield & Humphris, 2001; Turoff & Linstone, 2002; Campbell et al., 2004; Hsu & Sandford, 2007).

However, Delphi could be used only to identify location-related variables impacting the capital costs of data centres. In addition, the Delphi technique can also be integrated with Bayes theory to update established opinions through the probability of arriving at different outcomes, as expert opinions are collected through a structured sample collection technique to estimate these probable outcomes. Bayesian statistics is based on the theory produced by Thomas Bayes (1763); it is characterised by a joint treatment of all quantities of interest in a statistical model as random variables. In particular, Bayesian statistics naturally incorporate the uncertainty analysis surrounding the estimates or forecasts described in terms of probability distributions, As Figure 2.

$$P(A|B) = \frac{P(A) \cdot P(B|A)}{P(B)}$$

Figure 2. Bayes theory

- P(B) denotes the prior belief (for example, the probability of occurrence of the variable, such as the probability of encountering ground conditions)
- P(B|A) denotes the level of impact should that variable occur
- P(B) denotes the new evidence

The information obtained by the Delphi study can be fed into the Bayes formula to render current outcomes based on the updated information as provided by a qualitative assessment of the perceived impact of location variables. The combination of Bayes theory and the Delphi method enhances the accuracy and decisiveness of the mathematical model when compared directly with Prediction Theory. It is worth noting that whilst most literature identifies the Delphi method as a tool for knowledge elicitation, it is in the author's opinion that Delphi is a methodological approach in its own right due to its systematic nature, potential for quantitative analysis, iterative feedback process, incorporation of expert judgment, and consideration of uncertainty make it comparable to other methodological approaches, this is also supported by the seminal work of Hasson et al., (2000). For example, while primarily used for knowledge elicitation from experts, the Delphi method is a systematic and structured approach to gathering and aggregating opinions and judgments. It involves multiple iterations of anonymous surveys or questionnaires to collect insights from a panel of experts. While other methods might use probabilistic models, statistical analysis, or simulation techniques to quantify uncertainty, the Delphi method focuses on expert consensus and convergence to address uncertainty. These different approaches to uncertainty management can be compared and evaluated based on their effectiveness and suitability for a particular cost modelling context.

To assess the validity of the findings, we analysed book chapters, conference proceedings, peer-reviewed journals and trade publications against the data centre sector and the relationship between the various methodological approaches. This indicates that 77% of the findings were from peer-reviewed journals, with 23% being from grey literature. As a further analysis, we reviewed the country of research to establish if there were any other research gaps in specific regions or countries; this highlighted that there needs to be an identified approach in the UK. Whilst the list of methodological approaches identified is informative, it is essential to highlight our study's significant contributions and novel aspects compared to previous research in the broader field of cost modelling. Unlike previous studies, our research specifically focuses on the context of data centres, a relatively new domain within the construction sector. Data centres present unique challenges due to their dependency on location factors. Therefore, our study investigates the impact of site location on capital expenditure, addressing a crucial knowledge gap in the literature and aligning itself accordingly with constructing for the future. By exploring this specific context, we provide valuable insights that can assist decision-makers in making informed choices, mitigating financial risks, and enhancing the accuracy of construction cost estimates for data centres.

3.2 Location Specific Factors

We have examined whether there is a relationship between location-specific factors and location-specific factors influencing cost models, or do cost models influence location choices? This relationship is a crucial matter of concern in the decision-making process, as it involves understanding whether location-specific factors influence cost models or if cost models influence location choices. There are two key influences, 1) The influence of location-specific factors on cost models and 2) the influence of cost models on location choices. For example, high land prices in certain areas may increase site acquisition costs, affecting the overall project budget. Similarly, regions with high labour costs may result in higher construction expenses. Additionally, proximity to reliable power sources or fibre optic networks can impact energy costs and connectivity expenses.

Understanding the influence of these location-specific factors on cost models is crucial for accurate budget estimation and financial planning during the decision-making process. By incorporating this knowledge into the cost models, stakeholders can make informed choices regarding the site location, considering the potential impact on capital expenditure. Secondly, cost models can also influence location choices for data centre projects. These cost models allow stakeholders to evaluate potential site locations' financial viability and profitability based on projected construction costs, operational expenses, and expected returns on investment. Cost models typically consider political influences, land and construction costs, energy expenses, maintenance and operational costs, taxes, and potential revenue streams (Baloi & Price, 2003). By analysing cost models, stakeholders can compare different location options and assess the financial implications associated with each choice. This analysis enables them to prioritise locations that align with their budgetary constraints and desired profitability targets. They can provide insights into the cost-effectiveness of various site locations and guide decision-makers in selecting the most favourable option. The relationship between location-specific factors and cost models in data centre construction is bidirectional. Location-specific factors influence cost models by directly impacting various cost components. Simultaneously, cost models play a crucial role in guiding location choices by providing financial insights and evaluating the viability and profitability of potential sites.

In addition, we have compared the data centre sector to other sectors, demonstrating that other sectors also consider location and location-specific factors when cost modelling. For instance, in the retail industry, location plays a crucial role in determining the viability and profitability of a store, as researchers have found that factors such as population density, income levels, competition, and proximity to transportation hubs significantly influence the cost modelling approach for retail establishments (Kerin & Harvey, 1975; Brown, 1993). Similarly, in the real estate sector, location-specific factors are vital for estimating property values and rental rates, with research suggesting that variables such as neighbourhood quality, accessibility to amenities, proximity to schools, and crime rates directly affect residential and commercial properties (Klimczak, 2010). Furthermore, in the transportation sector, location-related factors impact cost modelling approaches, such as when estimating the costs of constructing highways or rail networks, factors such as topography, soil conditions, presence of natural obstacles, and proximity to existing infrastructure play a significant role (Daniels & Mulley, 2012). These examples demonstrate that various sectors, including retail, real estate, and transportation, recognise the influence of location and location-specific factors when cost modelling.

4. CONCLUSIONS

By analysing the methodological approaches through the systematic review, we have established trends in the literature and identified what methods are being utilised together. For example, we have identified the Delphi method as a structured and iterative approach that involves collecting and synthesising expert opinions to make informed decisions. In investigating the impact of site location on capital expenditure, the Delphi method can help gather insights from a panel of experts regarding the relationship between location factors and construction costs. By utilising the Delphi method, we can tap into the collective wisdom of experts in the field and gain insights into the impact of site location on capital expenditure. The Delphi method helps to mitigate biases and provides a more comprehensive understanding of the relationships between location factors and construction costs. Likewise, Bayes's theory is a statistical approach that allows for incorporating prior knowledge and updating probabilities based on new evidence. It provides a framework to quantify uncertainty and make probabilistic inferences. Applying Bayesian theory to investigate the impact of site location on capital expenditure involves formulating and updating probability distributions based on available data and expert opinions. By applying Bayesian theory, we can incorporate prior knowledge and new evidence to quantify the impact of site location on capital expenditure. This approach allows for a more nuanced and probabilistic assessment, considering the inherent uncertainties in the relationship between location factors and construction costs. The Delphi method and Bayesian theory provide valuable tools to investigate the impact of site location on capital expenditure for hyperscale data centres.

The Delphi method leverages expert opinions and consensus-building, while Bayesian theory incorporates statistical analysis and the integration of prior knowledge and data. Combining these approaches can provide a comprehensive understanding of the relationship between site location and construction costs in data centre projects. To conclude, it has been identified through this meta-narrative analysis that the synthesis of both Delphi Methodology and Bayes Theory is a robust methodological approach to identifying the location-related factors for hyperscale Data centres where variables are not fully known. The development and growth of data centres and the result of this research are essential to how we manage the construction industry's digital transformation.

ABSTRACT: *Off-site construction (OSC), including prefabrication and Modular-integrated Construction (MiC), is gaining popularity as a school of sustainable construction methods that can improve productivity, quality, and waste reduction. However, OSC projects face challenges related to technical integration, collaboration among stakeholders, and dynamic uncertainties. As a result, high-quality standards throughout the manufacturing process of OSC products are difficult to ensure, leading to costly rework, delays, and safety issues. This paper applies a value stream mapping (VSM) approach based on lean principles to OSC production for identifying lean management opportunities for off-site construction production. The case studied in this paper is reinforced concrete slabs. First, we employed a combination of field investigations and interviews to formalize the flow of materials and information for the case. Then, VSM processed the flow for the current state map, which highlights twelve opportunities to prioritize for slab production, e.g., the adoption of digital technology (VR, BIM) in information flows. The findings in value-added activities improvement of the opportunities demonstrate the potential of lean management in the slab production case. Furthermore, the VSM approach in this paper can identify the 'wastes' in lean theory, which are the control points of OSC production, for enhancing quality, efficiency, and resource utilization. The findings contribute to the existing body of knowledge by providing empirical evidence of the VSM approach to the identification of lean management opportunities for OSC production.*

1. INTRODUCTION

Off-site construction (OSC) generally involves standardizing design, manufacturing components in the factories and assembling during construction (Hosseini et al., 2018). With the upgrades of industrialization (Mitolo et al., 2021), examples of OSC are Bricks, 2D slabs, 3D volumetric, and Modular-integrated Construction (MiC). OSC is recognized as a promising school of sustainable construction methods that integrates design, production, and construction to save energy, eliminate environmental wastes and maximize the value of the whole life cycle of construction products (Li et al., 2021). In the literature, OSC is confirmed capable of improving labour productivity and product quality, enhancing energy conservation and emission reduction, thus solving prominent problems such as strengthened resource constraints and labour shortages. On the other hand, OSC also faces challenges, such as complex technical integration, collaboration of multiple stakeholders, and dynamic uncertainties (Zhao et al., 2023). Thus, OSC requires the coordination and integrated application of a wide range of multidisciplinary and inter-organizational skills.

OSC production refers to manufacturing precast construction elements in the factory, which is the most important stage for the quality assurance of products, as the construction site could be responsible for limited rework and repairs (Wu et al., 2019). Unlike traditional manufacturing factories, OSC production is a complex system involving different stakeholders and various information interactions (Khalili & Chua, 2014). Therefore, the complexity also leads to quality risks frequently occurring throughout the entire OSC products production processes, including production planning, engineering design, mould production, components manufacturing, quality inspection, storage, and loading for logistics (Lee et al., 2016). Furthermore, the connections between the stages may amplify the risks from one stage to another, e.g., deformation occurs in the moulds at the beginning of

the production will lead to defective components, but components may meet inspection requirements in the following product stage, and such mistakes can not be identified until the inspection of the finished products (Heravi & Firoozi, 2016). Therefore, systematic quality management is vital to OSC production.

Current approaches adopted in OSC production management are limited (Lu et al., 2018). For example, in the inspection process, the inspectors conducted manual spot inspection and made subjective decisions stemming from their prior knowledge in identifying products' flaws early in the production process, which inevitably suffers from labour-intensive consumption and subjectivity of opinions rather than precisely matching the substantial conditions (Xue et al., 2018). Consequently, defects are not perceived until the later stage of logistics or even the on-site installation stage (Park et al., 2013). Defects that arise during the production stage are costly for owners, contractors, and prospective clients because they are nearly impossible to chain significantly during the assembly stage.

Lean management concepts have the potential to increase quality, efficiency, and resource utilization for OSC production (Sacks et al., 2010). In lean principles, value is created by a sequence of value-adding activities. A value stream is the sequence of activities by which a company provides a product or service that delivers a specific product or service to a specific customer (Koskela, 1993). Value Stream Mapping (VSM) is an approach for illustrating the flow of materials and information in a lean manufacturing system (Ko & Kuo, 2015). It utilizes the tools and techniques of lean manufacturing to help organizations identify where waste is and, in turn, streamline the flow of production. The purpose of value stream mapping is to identify and reduce waste in the production process (Rahani & Al-Ashraf, 2012). Waste in this context is defined as any activity that does not provide added value to the end product and is often used to illustrate the total amount of waste reduced in the production process. Managers, engineers, process planners, suppliers, workers in the manufacturing industry, and customers can all benefit from value stream mapping by identifying waste and determining where to start looking for its main causes. In this way, value process mapping can also be a communication tool in linking with stakeholders of the factories (Chen et al., 2008). In general, the adoption of VSM based on lean concepts can enable the effective utilization of resources, e.g., in the automotive industry, supply chain analysis, and manufacturing industries (Rahani & Al-Ashraf, 2012).

This paper aims to apply the VSM approach based on the identification of lean management opportunities in OSC production. The objectives of the paper are: 1) To map the OSC production process; 2) To apply VSM to the map for locating the 'wastes' in the existing process; 3) To identify corresponding management opportunities for OSC production.

2. LEAN PRINCIPLES AND VALUE STREAM MAPPING

Lean manufacturing principles have been used for a long time in the manufacturing sector to boost output, productivity, remove waste, and deliver value (Sacks et al., 2020). The term "lean principle" describes the ongoing process of raising the value of a product by removing waste without sacrificing output, productivity, or quality (Koskela, 1993). Reducing non-value-added activities and achieving value-added delivery in the construction domains are the major areas of concentration for OSC. To address resource difficulties, lean principles' practices pledge to offer solutions that are lasting. Once the lean techniques were applied to the project scenarios, it became clear that significant amounts of materials were saved.

VSM is the whole of the actions—both value-added and non-value-added—currently required to move a product through the primary flows that are fundamental to every product. It is the production flow, from the raw material to the end customer, as well as the design flow, from conception to realization (Grewal, 2008). Firstly, it is a tool to identify waste and problems. It reviews operations and processes from a macro perspective, from the input-output process, and allows managers to easily identify sources of waste (excess inventory, heavy work, time wastage, handling, inspection, etc.), thus providing a scientific basis for continuous, systematic improvement. Secondly, it provides a common language. Value streams can be used as a common language for process and process improvement, making it easy to communicate between different departments. It is a method of determining and differentiating priorities for improvement, avoiding "picking the easy ones" for improvement and maximizing the return on investment. The VSM is the basis for the preparation of improvement plans and their implementation.

The integration of lean principles and OSC has been beneficial in optimizing its production processes and has recognized great potential in effectively tackling resource waste and unsatisfactory quality. As a result, numerous researchers have used VSM in conjunction with lean concepts to increase productivity and efficiency in the OSC manufacturing process as well as other areas. According to Wu and Pheng (2011), value stream mapping of precast manufacturing is essential to achieving sustainability goals. In the case of Yu et al. (2009), by applying the value streaming on a consistent work/product flow rather than on individual tasks, the delay brought on by a conflict between the predetermined schedule and the actual schedule of the complicated process of building a house can be decreased. To identify waste during the construction of concrete slabs in residential constructions, Fontanini et al. (2013) employed value spectrum mapping with lean concepts, increasing efficiency and effectiveness. However, lean principles have their roots in the manufacturing sector, where they have a mature theoretical and research base (Grewal, 2008). There is a lack of an organized framework that can be used to promote the implementation of lean manufacturing principles in the production of OSC products.

In summary, VSM indicates the key operating procedures that adds value to the targeted product. Instead of depending solely on the currently established conventional working hours, the use of VSM is combined with field study, information gathering, and interviews, capturing the flow of material and information. Cycle times, line change times, operator counts, size of batches, and quantities of semi-finished products in a process are a few of the forms of data that are capable of being exploited to analyse the lead time and added value time of the entire process. So, in addition to the VSM approach, both field research and interviews are employed in this paper.

3. RESEARCH METHODS

3.1 Case selection

The case selected in this paper is the reinforced concrete (RC) slab in the prefabricated construction. The selection was based on the product family matrix defined in the VSM approach (Fontanini et al., 2013). Usually, RC slab production accounts for >80% in both prefabricated construction and RC MiC (Loss et al., 2016), which fulfil the requirements of the product family matrix. The case factory is in Shenzhen, which has major products including various types of precast elements such as facades, partition walls, floor slabs, staircases, columns, integrated kitchens and washrooms. The involved projects include residential, commercial buildings, roads, and tunnels.

3.2 Production process mapping

The scope of activities includes added-value activities at each level, from the raw materials to the finished products, which includes conceptual design, product design, and process designs (Sacks et al., 2020). In OSC production, it is the in-factory value stream, i.e., the manufacturing stream from design to ready-to-transport stage.

In the site investigation, observations were made regarding the plant layout, the machinery used, the sequence of activities and the time taken for each activity by visiting the site and also interacting with the staff working there. The typical activities are (A) mould assembly and preparation, (B) fixing of rebars, (C) concreting and curing, (D) de-moulding and (E) transferring for storage.

Mould assembly and preparation. Casting begins with the assembling of the mould. The front-work used to pour and cast concrete is called a mould. Using overhead cranes, the mould plates are removed from the inventory area and set down on the fixed table. Using bolt and weld connections, mould assembly and preparation entails assembling the mould plates. Based on the shop drawings that the design team produced, the assembly is carried out. The timeline of the activities taking place at the mould assembly is shown in Fig.1.

Fixing of rebars. The rebars are then fixed into the mould as the following step. Cutting, bending, and forming the reinforced cage in accordance with shop drawings are all steps in the fabrication of the rebar cage. A separate reinforcing cage is created, and then it is added to the mould. The Fig. 2 is the order of activities that take place as the rebar cage is transferred to the mould.

Concreting and curing. Concreting is the following step. Before the concreting process begins, the raw materials are fed into the mixer. Both the mixing and transporting of concrete are automated and simple to use. The system of the flying bucket is employed. The Fig. 3 is a listing of activities that take place during concreting and curing.

Demoulding and transferring to storage yard. Demoulding is followed by moving the precast concrete component with a crane to the storage location. At the storage location, curing is carried out using a sprinkler system that operates for three days. The storage location keeps the finished components for further transportation. Before delivering the components to the construction site for assembly, it is important to (i) inspect the physical state of the final product, (ii) verify the important parameters, (iii)apply the proper identification markings to the elements that indicate position, individual category, weight, size, and placement in accordance with the shop drawing, and (iv) check whether the components have reached 75% of their design strength in concrete.

Fig. 2: Fixing of rebars of a prefabricated RC slab.

Fig. 3: Concreting and curing of a prefabricated RC slab.

3.3 Non-value-added activities located using VSM

This step aims to apply VSM to locate the non-value-added activities. Non-value-added activities, referred to as waste, are activities that do not directly contribute to the product's value or the customer's perception of value. These activities consume resources (time, materials, labour) but do not enhance the product or service in any meaningful way. As a result, by identifying the non-value-added activities and location of waste, the potential improvement could be a promising action. The categories and identification of non-value-added activities are listed below (table 1).

Table 1: Categories and identification of non-value-added activities.

Categories of non-value-added activities	Identification
Transportation	Unnecessary movement or transportation of materials or products between different process steps, leading to delays, damage, and increased lead times.
Inventory	Excess inventory or work in progress that is waiting to be processed, increasing capital and space without providing immediate value.
Waiting	Idle time for products, materials, or employees waiting for the next step in the process, reducing efficiency
Over-production	Producing more than what is currently needed, which leads to excess inventory and waste.
Over-processing	Performing more work than necessary, such as using high-precision processes for tasks that don't require it.
Defects	Activities required to fix mistakes, rework, or correct defects, increasing costs and schedule delays.

3.4 Identification of corresponding management opportunities

The goal of this step is to adopt VSM analysis to identify opportunities for improvement. The identifying process is based on two basic processes: the information flow and the material flow. The information flow is the process that starts when the marketing department receives an order or has already forecasted the customer's needs and makes it into a purchasing plan and a production plan. The material flow refers to the physical process, i.e., the process that starts with the supply of raw materials into the warehouse from the supplier, followed by the outbound manufacturing, the finished products into the warehouse, until the product reaches the customer. In addition, the material flow includes the inspection and storage of products. Furthermore, there are eight waste principles on which judgement is based, including waste of repair, waste of over-processing, waste of movement, waste of handling, waste of inventory, waste of making too many/too early actions, waste of waiting and waste of management. Therefore, in the analysis of this paper, any part of a product that exceeds the minimum amount of resources necessary to add value to the product is considered waste – a waste is not only an activity by definition that does not add value but also a process that overuses resources.

4. RESULTS

Fig. 4 shows the results of process mapping, the adoption of the VSM analysis for locating wastes in the current process map, and the current state map with information flow, material flow and lead time ladder. The information flow depicts the communication between the management team, the production team, the supplier, and the client. The material flow displays the movement of materials through different steps from supplier to finished product. Cycle time denotes the duration of each step, whereas lead time indicates the length of time it takes to produce precast components from an order to their completion. While cycle time solely includes time for value-added activities, lead time contains time for both value-added and non-value-added activities. The sequence of activities is named from A to E. Evidences of the current waste locating. 1) Waiting. A curing period of 12 hours is required when employing the water pond method, thereby extending the waiting duration for subsequent procedures. 2) Defects. Damage to mold plates occurred when the welded connection was disrupted during the demolding process. 3) Overprocessing. Remediation of damaged finished components was carried out through epoxy injection, thereby elongating the lead time. 4) Motion. The Reinforcement cage production area is situated 200 meters away from the molding table, resulting in an increased travel time for the crane during the transfer to the table platform. 5) Transport. The storage area for mold assembly parts is situated at a distance of 400 meters, leading to an extended travel time for the EOT crane during the transfer to the table platform.

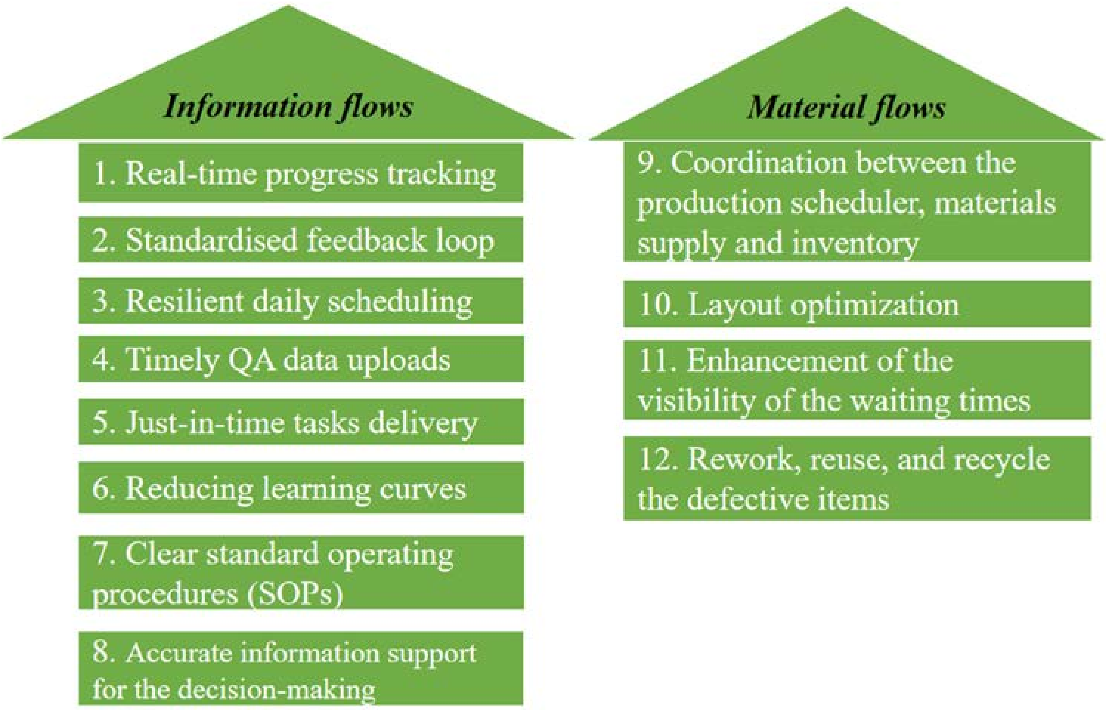

Fig. 5: 12 opportunities for potential improvement

Twelve opportunities are highlighted, as shown in Fig. 5, in information flows and material flows based on the VSM of the RC slab production. In the information flows, eight opportunities are concluded. **Opportunity 1**: real-time progress tracking, such as the adoption of Virtual Reality (VR) (Rahimian & Ibrahim, 2011) and Building Information Modeling (BIM) (Xue et al., 2021), enables the off-site production team to monitor every step of the production process as it happens. This visibility facilitates quick identification of bottlenecks, inefficiencies, or delays. With the assistance of a real-time view of progress, the stakeholders can take proactive measures to optimize workflow, allocate resources more effectively, and prevent unnecessary downtime. **Opportunity 2**: implementing a standardized feedback loop creates a systematic process for collecting insights and suggestions from various stakeholders involved in the factory. The information loop contributes to continuous improvement, as the feedback is used to identify areas for refinement and innovation. By incorporating valuable input from workers, the production process becomes more streamlined, and waste is reduced through collaborative problem-solving and optimized processes. **Opportunity 3**: a resilient daily scheduling approach acknowledges the dynamic nature of off-site construction and prepares for potential disruptions. By building flexibility into the schedule, the stakeholders can better adapt to unexpected changes without causing significant interruptions. **Opportunity 4**: timely quality assurance data uploads play a crucial role in maintaining high-quality production standards. By promptly uploading quality assurance data, any deviations or defects are identified early in the process, allowing for timely corrective actions. This reduces rework, minimizes waste associated with defects, and ensures that the final product meets or exceeds quality expectations. **Opportunity 5**: adopting a just-in-time task delivery approach optimizes the timing of task completion to match actual production needs, preventing the accumulation of excess inventory or work in progress. **Opportunity 6**: emphasizing the reduction of learning curves through proper training and skill development enhances the expertise and efficiency of the production workforce. Skilled workers are less likely to make errors or require additional time to complete tasks. **Opportunity 7**: establishing clear and well-documented standard operating procedures (SOPs) provides a structured framework for the entire off-site production team to follow. These SOPs guide consistent and standardized practices, reducing variations that can lead to errors or inefficiencies. Clarity in procedures minimizes waste associated with defects, misunderstandings, and unnecessary deviations from the optimal workflow. **Opportunity 8**: access to accurate and timely information forms the foundation of effective decision-making in off-site production execution. The reliable data leads to quicker and more confident decisions, aligning with lean principles by reducing delays and uncertainties that can lead to waste.

Four opportunities are summarized in the material flows. **Opportunity 9**: effective coordination between the production scheduler, materials supply, and inventory management is vital for lean management in off-site construction. By synchronizing production schedules with the availability of materials and maintaining an optimized inventory level, the production process could embrace increased efficiency. **Opportunity 10**: optimizing the layout of the factory is a strategic improvement opportunity that can significantly enhance lean management. By arranging workstations, storage areas, and production lines logically and efficiently, material flow is streamlined. This optimization reduces unnecessary movement, transportation, and waiting times, leading to improved overall efficiency and resource utilization. A well-organized layout also supports just-in-time delivery and minimizes the chances of defects or errors. **Opportunity 11**: increasing the visibility of waiting times is crucial for waste reduction and process improvement. By close monitoring and making waiting times transparent to all stakeholders, bottlenecks and delays are quickly identified. This visibility prompts immediate action to address issues, prevent idle time, and maintain a consistent production flow. **Opportunity 12**: the practice of reworking, reusing, and recycling defective items is a sustainable and lean-approach. Efforts are made to salvage and repurpose them where possible, leading production management to the more resource-efficient and environmentally responsible.

5. DISCUSSION AND CONCLUSION

The OSC production is that the dynamic nature of the production requires a rapid response. However, OSC production, unlike a generic manufacturing facility, has long order lead times, relies on several tiers of subcontractors and casual labours, and requires close coordination. This paper maps OSC production processes in the factory and applies the VSM approach from lean manufacturing to lean OSC management opportunities. The findings from the RC slab case demonstrate the identification of the existing wastes, non-value-adding activities, and potential lean management opportunities. Examples of the opportunities include eight opportunities in information flows and 4 opportunities in material flows.

The contribution of this paper mainly lies in advancing lean management practices in the field of off-site construction. By offering practical, and customized solutions, it is promising to drive positive changes, optimize production processes, and foster continuous improvement within the OSC production.

There are several limitations in this paper as well. First, this paper involves one typical case of RC slab without detailed analysis on the generalizability to other products. Further, VSM is a dynamic tool, and the process should be revisited periodically to ensure ongoing improvements. Future research could focus on how to apply a more scientific and rational approach to further improve the quality and management efficiency of OSC products in the identified management phases.

BAYES THEORY AS A METHODOLOGICAL APPROACH TO ASSESS THE IMPACT OF LOCATION VARIABLES OF HYPERSCALE DATA CENTRES: TESTING A CONCEPT

David King, Dr Nadeeshani Wanigarathna, Prof. Keith Jones & Dr Joseph Ofori-Kuragu
Anglia Ruskin University, Bishops Hall Lane, Chelmsford CM1 1SQ, United Kingdom

ABSTRACT: *The theme of 'The Impact of Engineering Practices on a Sustainable Built Environment' emphasises the importance of considering various dimensions of resilient infrastructure. Selecting the location for a Hyperscale Data Centre is a crucial process that involves assessing the impact of various location variables. To determine the viability of a location, it is essential to identify the potential risks associated with each variable. This paper presents a proprietary methodological approach that includes a Delphi study to identify risks, a Likert scoring system to assess prior probabilities, and a Bayesian theory-based decision tree to assess the impact through risk prediction. The paper's contributions are significant, and the proposed methodology makes it possible to predict the risk level of each location variable by identifying the appropriate contingency percentage. The study's findings indicate that the paper's proposed approach is an effective way to mitigate the risks associated with selecting a location for a Hyperscale Data Centre. Embracing this knowledge allows us to align research and practise with the conference's call to studying the resilience of buildings and infrastructure to natural disasters and climate change, and developing strategies for adaptation and mitigation, ensuring that these practises become integral to shaping the future of Data Centres.*

KEYWORDS: *Bayes Theorem, Delphi, Data Centre, Location Variables*

1 BACKGROUND

Investments in Data Centres in the Nordic region have been on the rise, with significant contributions from cloud and hyperscale investors such as Facebook, Google, AWS and Apple, due to advanced technological progress and favourable cold climate conditions, significantly reduce the cooling energy demands of the facilities (Christensen et al.,2018; Avgerinou et al., 2017). However, the location of Data Centres outside of the UK presents a significant challenge for cost consultants during the capital cost estimation and modelling stages, which can impact investment decisions. At the feasibility stage, cost planning involves determining the possible cost of a building early in the design stage in relation to the employer's fundamental requirements before preparing a complete set of working drawings or quantities bills (RICS, 2011) Historical cost data is often used as base cases for cost consulting professionals, who adjust their costs to suit the circumstances of new projects. Although specific characteristics such as shape, inflation, and specifications are relatively easy to adjust based on case-based reasoning, predicting the impact of location is challenging for construction professionals, who rely on location cost indices for this purpose. Various location cost indices, such as Spon's Architects and Builders Price Book (AECOM, 2017) and the Building Cost Information Service (RICS, 2018) are available for cost consultants. However, such indices are less relevant for Data Centres as there are often no precedents set to use as a baseline for cost comparisons, and there are many variables ranging from macroeconomic, construction methodology, geographical, and geological categories. For example, regulations for noise attenuation for hyper-size generators for Data Centres did not exist in Sweden and had to be modelled on regulations from other countries (Vonderau, 2017), International location cost indices, such as those provided by Eurostat (EC, 2019), World Bank (2022) and the OECD (2022) are broad and mainly model variations at the country level, making them less effective during cost planning for individual projects specific to a particular region. Therefore, construction professionals must consider multiple factors and rely on a combination of indices and expert judgment to provide accurate cost estimates for Data Centres.

2 RESEARCH AIM

Whilst a wide range of variables impacts construction project costs and cost modelling, there is no evidence to suggest whether and how these variables would affect site location in cost planning for the capital expenditure of Hyperscale Data Centres. Although there is published data on traditional construction costs and location indices in the UK, they do not provide enough information to assess the impact of location variables, especially considering the specific design requirements of Data Centres (King et al., 2023). This highlights a significant knowledge gap in the existing body of research. This paper aims to validate a methodological concept using Delphi

and Bayesian theory to assess the probability and impact of location variables. This approach aims to aid in selecting the appropriate methodological approaches for the research topic of "the impact of location variables on the modelling and forecasting of Hyperscale Data Centres". By utilising this method, the study seeks to identify the potential risks and impacts of various location variables, contributing to a more comprehensive understanding of the relationship between site location and capital expenditure in the Hyperscale Data Centre industry.

3 METHODOLOGY

3.1 Risk

Risk refers to situations that involve uncertainties that may occur, risk mitigation refers to actions taken to optimise the impact of risk. By selecting a comprehensive risk management strategy that considers all types of risk, one can ensure the implementation of a planned Data Centre investment within the specified time and budget. Various organisations have developed several approaches to risk. Notable among these are the Project Management Institute (PMI., 2001) and PRINCE2 (Bentley., 2012). This paper aims to introduce a concept that can quantify the impact of risk through a Delphi and Bayesian approach. A risk is defined as the probability of an event occurring and the subsequent consequence, as expressed in Equation (1). Here, R represents a risk, P is the probability of the event occurring, and C is the impact or consequence of the event.

$$R = (P, C). \quad (1)$$

Various methodologies exist for identifying risk including identification, assessment, response, and monitoring. Risk identification is identifying potential risks that may impact the project. Risk assessment involves analysing and evaluating the likelihood of occurrence, impact, and consequences of the identified risks. The risk response involves developing a plan to manage or mitigate the identified risks. Lastly, risk monitoring and control. Quantifying the impact of risk, especially with location variables, can provide invaluable information to decision makers and stakeholders and can be used to make informed decisions, develop contingency plans, and allocate resources appropriately. Therefore, developing a method to assess the impact of location variables on project risk can significantly improve the success of a project. Risk decisions involve assessing the factors that contribute to the emergence of risk and the likelihood and potential impact of the event.

3.2 Delphi Study

A pilot Delphi study (King et al., 2023) has been conducted to obtain expert opinions on the key themes that affect the location variables of Hyperscale Data Centres and their impact on the modelling and forecasting of capital expenditure. The analysis of the pilot study data has provided rigour and validity to the questionnaire for the main forthcoming Delphi study. This has allowed for identifying and assessing potential risks associated with the location variables of Hyperscale Data Centres. The pilot study results indicate the current understanding of the variables that impact the modelling and forecasting of capital expenditure for Hyperscale Data Centres. These variables have been identified as potential risks and are an essential consideration in the risk management strategy for the planning and implementing Hyperscale Data Centres. Previous research found that pilot Delphi studies are rarely reported in academic literature, making it difficult to establish best practices (Clibbens., 2012). For this pilot study, industry expert knowledge was obtained through several expert participants (n=5). The response rate was 100%. Through an open-ended questionnaire, experts could respond freely and without restriction. Having completed the thematic analysis of the data arising from the questionnaire, the pilot study identified categories and themes that are considered risk items; the following items were among those rated by the participants as having an impact on capital expenditure when locating a data centre:

- Requirement for cooling towers due to sub-zero climate
- Requirement to import generators due to in-country shortages.
- Acoustic screens to generators due to proximity of residential neighbours
- In-country technical labour shortages require backfilling with imported, experienced technical labour.

The themes arising from the Delphi study provide the data that will be used to provide the data that will be used for the assessment of the impact of location variables within a Bayesian framework.

3.3 Bayes Theory

Bayesian theory is based on the probability theory given by Thomas Bayes in 1763 (Bayes., 1763). Bayes's theory relates the conditional probabilities of random variables to each other. It provides a framework that allows for the integration of a prior belief about the distribution of a quantity of interest (the prior distribution) and the observed data (through the likelihood term). as shown in Equation (2).

$$P(A|B) = \frac{P(A) \cdot P(B|A)}{P(B)} \qquad (2)$$

To clarify, in this instance:

- P(B) denotes the prior belief (for example, the probability of occurrence of the variable, such as the probability of encountering ground conditions)
- P(B|A) denotes the level of impact should that variable occur.
- P(B) denotes the new site-specific evidence (for example, when new information arises, i.e., a higher probability of occurrence of encountering ground conditions)

Bayes theory can be applied to numerous components by using the product rule (Pearl., 2022) and, therefore, Bayes theory is applied for calculating the probability of occurrence of a phenomenon or hypothesis using multiple factors or variables. It is also considered a powerful method for hypothesis testing (Wetzels et al., 2012) making assumptions and having wide-ranging decision-making applications related to artificial intelligence, machine learning, and bio-statistics approaches. Prediction theory is a sub-field of statistics and machine learning that involves the development of mathematical models and algorithms for predicting future outcomes or events (Sarker., 2021). It uses data from past observations to create models that can be used to forecast future outcomes. Prediction theory employs various data analysis techniques like regression, clustering, and classification. It also involves identifying essential variables and patterns within the data, calculating the probability of specific outcomes, and selecting desirable outcomes based on the model generated. Although prediction theory and Bayes theory are related, they differ in terms of their fundamental principles. Bayes's theory concerns conditional probability and allows for the revision of probabilities based on new information or evidence (Ajzen et al., 1975). On the other hand, prediction theory is focused on building models and computing algorithms to predict outcomes from complex data sets. While prediction theory may incorporate probabilities, it does not involve the revision of probabilities like Bayes's theory. Using Bayesian theory and correlation analysis is a common practice for predicting future outcomes and events. In addition, integrating prediction theory with the Delphi method is a recognised technique used to forecast future outcomes based on expert opinions (Turoff et al., 2002). The Delphi method involves obtaining consensus opinions from subject matter experts through a series of planned interviews or surveys, which can then be used to forecast future outcomes. Furthermore, the Delphi method can be combined with Bayesian theory to revise established opinions based on the likelihood of different outcomes. This study highlights that expert opinions gathered through a structured sampling technique such as the Delphi method can be utilised to estimate probable outcomes, which can then be inputted into the Bayesian formula to provide current outcomes based on updated information gathered through qualitative risk assessments. The combination of the Delphi method and Bayesian theory enhances the accuracy and decisiveness of the mathematical model compared to using prediction theory alone. Previous research supported this approach, including Bijak (2011), who identified Bayesian theory as a natural methodology for combining expertise and data with expert judgments. Additionally, Bernardo (2003) suggests that Bayes's formula allows for expert opinions to be incorporated into projections in the form of prior distributions. However, a limitation of Bayesian forecasts is that they may contain subjective elements due to their dependence on expert opinions and history obtained from the data series (Abel et al., 2013). In conclusion, the combination of Bayesian theory and the Delphi method can provide a robust methodology to model and forecast the impact of location variables on Hyperscale data centres.

4 DATA COLLECTION

4.1 Likert

Psychologist Rensis Likert invented the Likert scale (Likert., 1932). It is a rating scale used to measure attitudes, opinions, or perceptions. The scale can have anywhere from 5 to 11 points, with the most common being a 5-point scale. It is widely used in social sciences, especially in survey research, as it allows researchers to gather information about people's attitudes, opinions, or perceptions systematically and standardised. The scale is also commonly used in market research, customer satisfaction, and employee engagement surveys. The Likert scale has several advantages, including ease of use, simplicity, and flexibility. It is easily understood by respondents, which can improve the accuracy and reliability of the data collected. However, it is important to remember that the Likert scale also has limitations, such as possible response bias, limited ability to capture complex attitudes, and the potential for data to be misinterpreted if it is not used appropriately. It is important to carefully consider the wording and format of the questions in the Likert scale to minimise these limitations and ensure accurate data collection. Additionally, it is essential to use appropriate statistical techniques when analysing the data obtained through the Likert scale to avoid misinterpretation of the results.

4.2 Probability

To establish the likelihood of events, a Likert ranking has been proposed with two extremes at either end of the scale. A score of 1 denotes an event highly unlikely to occur, whereas a score of 5 represents a highly likely scenario, as shown in Table 1. For instance, when assessing power availability, one might score it as one because the likelihood of that event occurring is low. On the other hand, if there is a substation on-site and the site is situated in the centre of a seismic zone, a score of 5 may be assigned since the probability of a seismic event causing damage is very high. These scoring descriptions outline the scoring criteria and help prevent ambiguity when experts score as part of the Delphi study.

Table 1: Likert ranking for probability.

Likert scale	Probability
1	Very unlikely
2	Unlikely
3	Neutral
4	Likely
5	Very likely

The variables identified and presented in Table 2 are derived from a previous Delphi study by King et al (2023).

Table 2: Likert scoring results for the probability of the event occurring.

Variable	Very unlikely	Unlikely	Neutral	Likely	Very Likely
Cooling towers	4	1	4	41	16
Imported generators	4	4	32	23	3
Acoustic screens	4	1	4	39	18
Technical labour shortage	4	28	27	5	2

These Likert scoring values are intended to illustrate the proof of concept. They are based on the authors' professional judgment regarding the probability of each item occurring in the real world. However, it is essential to note that these scores are hypothetical for illustration only to demonstrate the proof of concept. They will be subject to revision based on new available information, resulting in updated posterior probabilities that may differ significantly from the initial estimates.

5 RESULTS AND DISCUSSION

5.1 Establishing Nodes

The scoring rankings for probability are derived from the Likert scoring results in Table 2 and weighted to generate the probability distribution required for the Bayesian analysis. A weighing method has been used to assess these conditional probabilities, as shown in Equation (3).

$$\frac{Occurance}{Total\ respondants} \qquad (3)$$

The variables and the conditional probability of these events occurring are shown in Table 3. The results subsequently creating the nodes for the Bayesian network.

Table 3: Conditional probability of the event occurring.

Item	Very Unlikely	Unlikely	Neutral	Likely	Very Likely
Cooling towers	6%	2%	6%	62%	24%
Imported generators	6%	6%	48%	35%	5%
Acoustic screens	6%	2%	6%	59%	27%
Technical labour shortage	6%	42%	41%	8%	3%

Therefore, the node describing the event of Cooling Towers together with possible scenarios of this likelihood together with possible assessment factors is as Figure 1

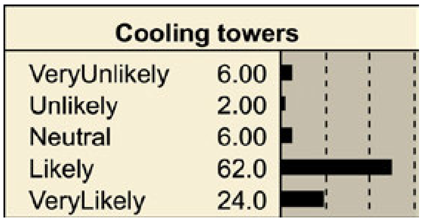

Figure 1: Conditional probability node of Cooling Towers being required.

5.2 Assigning event probabilities

A process of identifying possible events for each of the variables was established. The basis of the Bayesian network is related to determining the relationship of each individual node in the network. For this proof of concept, the relationship of individual node was based on the authors' own experience and assessed using a low, medium, and high ranking. For example, the impact of cooling towers is identified in Figure 2.

Cooling towers	Low	Medium	High
VeryUnlikely	100	0	0
Unlikely	50	50	0
Neutral	0	50	50
Likely	0	0	100
VeryLikely	33.3	33.4	33.3

Figure 2: Conditional probability node of Cooling Towers impact

These relationships have been used to identify scenarios that could occur because of events in the process of assessing the impact of location variables through four ranges for contingency between 0% and 20%, as shown in Figure 3. These contingency values have been presented based on the author's experience as proof of concept. Further research will be required to refine these contingency values.

Cooling towers	Technical labour sh...	0 to 5 percent	5 to 10 percent	10 to 15 percent	15 to 20 percent
Low	Low	100	0	0	0
Low	Medium	50	50	0	0
Low	High	0	0	100	0
Medium	Low	50	50	0	0
Medium	Medium	0	50	50	0
Medium	High	0	0	50	50
High	Low	0	50	50	0
High	Medium	0	0	50	50
High	High	0	0	0	100

Figure 3: Conditional probability node of Contingency for Mechanical

5.3 Performing calculations

The Bayesian network conditional probabilities were calculated using Netica software (Ni et al., 2011). This resulted in a functional and working network being developed to assess the impact of location variables. After calculations, the results of the conditional probabilities were established, as shown in Figure 4.

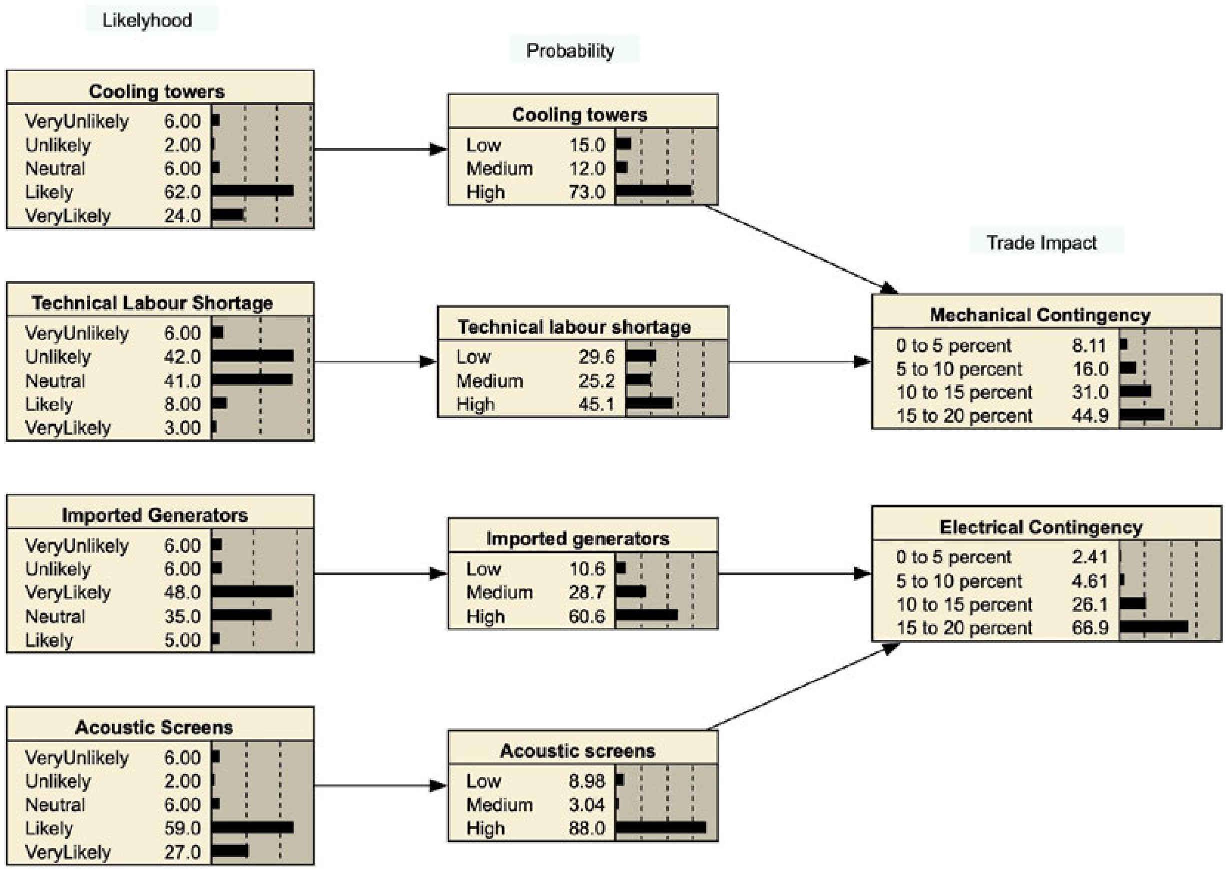

Figure 4: Bayesian network identifying trade Contingencies based on conditional probabilities.

5.4 Event scenario analysis

An example of the updated impact of Cooling towers is shown in Figure 5. This event has been modelled on the node ’Cooling towers’. A 100% likelihood of this event occurring has been assumed as ’Unlikely’ in this hypothetical scenario.

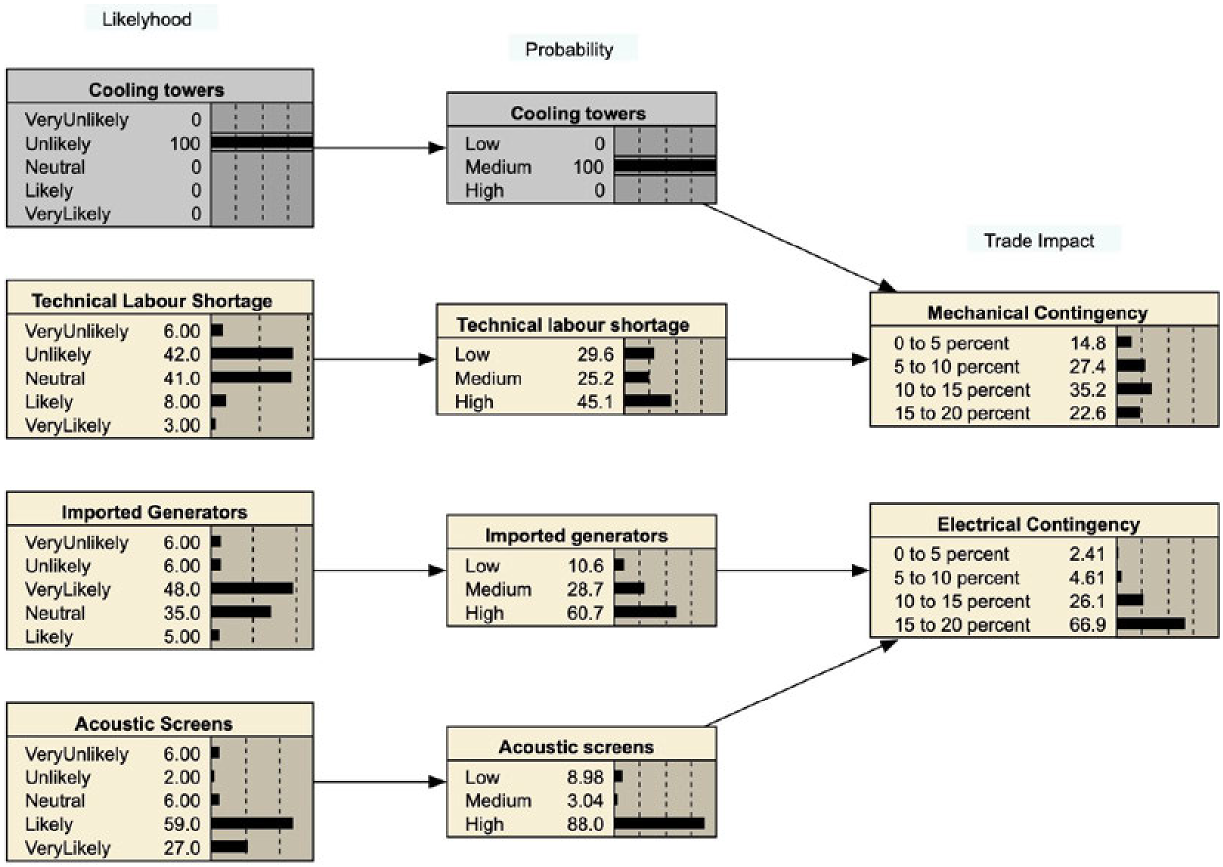

Figure 5: Bayesian network updated with new probabilities impacting Mechanical contingency.

In this scenario, we have also selected the node for a probability of an increase in cost to 'Medium.' Using this Bayesian network, this updated information has impacted the node for Mechanical Contingency, changing from 15%-20%, as identified in Figure 4, to 10%-15%, as shown in Figure 5. Therefore, in this example, the impact of location variables has, using the Bayesian theory, identified an improved risk and reduced contingency for the Mechanical Works.

6 CONCLUSION

Using a combination of the Delphi study, Likert scale, risk, and Bayesian theory to evaluate the impact of site location on capital expenditure for Hyperscale Data Centres has been demonstrated to be a feasible approach. The study findings indicate that it is possible to identify the likelihood of specific location variables impacting capital expenditure by conducting a Delphi study to obtain expert opinions and utilising a Likert scale to acquire subjective information about the probability and perceived risk of occurrence. These probabilities can be integrated into Bayesian analysis as prior knowledge, and as new information becomes available, they can be updated to calculate the posterior probability. The resulting percentage impact can then be applied to assess individual or multiple items and incorporated into the total capital expenditure, providing a method for determining the percentage impact, cost increase, or contingency. The findings of this study have significant implications for evaluating the impact of location variables for Hyperscale Data Centres, where variables can be identified and quantified as a percentage variance to capital expenditure. By utilising a Delphi study, the method can gather expert opinions, increasing the reliability and validity of the data obtained.

Furthermore, using a Likert scale allows for quantifying subjective information, which can be challenging to measure using other methods. Finally, by incorporating the probability and risk of occurrence, the Bayesian analysis provides a more accurate assessment of the impact of location variables on capital expenditure. The methodology described in this study can be applied to various industries, providing a comprehensive framework for determining the impact of various factors on capital expenditure and informing decision-making processes.

UNIVERSITY ASSET DIGITALIZATION GUIDELINES: THE PILOT CASE OF POLITECNICO DI MILANO REAL ESTATE

Giuseppe M. Di Giuda
Department of Management, University of Turin, Turin, Italy

Elisa Cacciaguerra, Francesco Paleari, Marco Schievano, Stefano Campi & Alessandro Tucci
Department of Architecture, Built environment and Construction engineering, Polytechnic of Milan, Milan, Italy

ABSTRACT: *This study describes a multi-year project aimed at digitizing the real estate assets of an Italian university, specifically the Politecnico di Milano. The objective is to enhance and streamline university asset management through the implementation of Building Information Modelling (BIM) methodology. BIM fosters a collaborative environment among stakeholders, facilitating the digitalization of asset management processes. The project focuses on modeling the university's assets in a BIM environment, for the creation of a repository of structured information that will streamline and optimize the processes related to the buildings' life cycle. This initiative aims to enhance real estate management services, optimize space utilization, and ultimately elevate user satisfaction within the university community. The project commenced with an in-depth analysis of the technical areas within the university responsible for design, construction, redevelopment, and overall real estate asset management. Each of these areas was evaluated for strengths, constraints, and critical points. Various approaches to BIM integration were explored to enhance digitalization processes. Based on these initial assessments, a comprehensive set of methodological and operational guidelines was formulated, encompassing modelling, management, and data-sharing aspects of digitalization. This paper provides an overview of the initial phases of the project, highlights its strengths, and identifies areas for improvement and testing in future project development. Emphasis is placed on standardizing information to ensure consistency throughout the asset's entire life cycle.*

KEYWORDS: *Building Information Modelling, Real estate management, University asset digitalization guidelines*

1. INTRODUCTION

The digital transition in the Architectural, Engineering, Construction, and Operation (AECO) industry has emerged as a priority in national policies, thereby garnering attention from administrative bodies. The AECO industry, however, remains relatively under-digitized, leading to diminished productivity. This is exacerbated by the fragmented processes within the industry, resulting in information loss throughout project lifecycles (Succar, 2010).

Frequently, the absence of accessible and up-to-date information underlies inadequate resource control in real estate asset management (Lauria et al., 2015; Meschini et al., 2022; Vivi et al., 2019). Incorporating operational strategies and digital tools like BIM into administrative procedures holds the potential to enhance data quality in decision-making processes, thereby fostering better-informed choices (Cacciaguerra et al., 2022; Derakhshan et al., 2019; Munir et al., 2019).

BIM's capability to construct digital building models incorporating information from various project stages provides valuable data for operations and maintenance across the building's lifecycle. Moreover, it transforms the relational dynamics among stakeholders involved in the construction process (Eastman, C., Teicholz, P., Sacks, R., Liston, 2008).

This research marks the initial phase of an extensive project undertaken by the Politecnico di Milano for asset digitalization, which started in 2021. The objective is to establish a BIM management system that enhances and streamlines real estate asset management through a digital transition process.

The project standardizes procedures and processes through the introduction of BIM methodology, aligning with the Polytechnic's endeavour to digitize building documents stipulated in the University Strategic Plan. This is achieved through proprietary guidelines and operational protocols. The development of these documents emanates from an analysis of the current organizational model's state, task and workflow assessments, and interdepartmental interactions. Consequently, the project identifies needs and revamps the organizational model to cultivate a collaborative environment among contributors to real estate development and management, integrating procedures.

Giuseppe Martino Di Giuda, Elisa Cacciaguerra, Francesco Paleari, Marco Schievano, Stefano Campi, Alessandro Tucci, *University Asset Digitalization Guidelines: The Pilot Case of Politecnico di Milano Real Estate,* pp. 407-418, DOI 10.36253/979-12-215-0289-3.40

This project holds replicable potential: Politecnico di Milano's digital transition process could serve as a pilot case for other university campuses, given the shared requirements and challenges of similar Italian institutions.

2. REFERENCE CONTEXT

2.1 Government BIM implementation and Guidelines

The role of governments in the successful implementation of BIM is crucial. Numerous studies have sought to evaluate implementation initiatives across various scales, investigating both limitations and drivers for adoption (Jiang et al., 2022). Challenges such as institutions unprepared for the market, high associated costs, and lengthy training periods have been identified as significant obstacles. Additionally, difficulties arise from a lack of clear standards and a structured approach to change management (Elmualim & Gilder, 2014). The adoption of BIM within construction processes remained sluggish until government institutions mandated its usage in public works projects. To achieve effective implementation, the legislative bodies must strategically plan and structure interventions to facilitate adoption. Many governments have championed initiatives aimed at advancing construction industry digitalization through BIM (Abdirad, 2017; Liu et al., 2015; Marocco et al., 2023).

Recognizing the increasingly acknowledged benefits of the BIM methodology, a growing number of nations have adopted comprehensive implementation strategies. In the United States, a leading figure in this domain, the General Services Administration (GSA) has mandated the utilization of BIM in all projects since 2007, with guidelines and standards developed by the National Institute of Building Science (NIBS) (National Insitute of Building Sciences US, 2023). The formulation of tailored guidelines, aligning with client needs, facilitates the generation of coherent information-rich models, essential for effective BIM implementation within organizations (Di Giuda et al., 2017). This underscores the importance of both public and private institutions establishing customized guidelines during the initial stages of transitioning to BIM, ensuring clear objectives and actions throughout all project phases.

Organizations equipped with well-defined guidelines can translate their requirements into precise information, thus ensuring the desired outcomes. Simultaneously, professionals and manufacturers can follow a structured work plan, fostering seamless collaboration and cooperation, and supported by standardized practices.

2.2 Regulatory background

The global and Italian legal and technical regulations governing BIM methodology draw upon references from both mandatory and voluntary standards. In the European context, Directive 2004/18/EC marked the initial directive, subsequently replaced by European Directive 2014/24/EU in 2014. Article 22 comma 4 of this directive emphasizes Member States' authority to "require the use of specific electronic tools, such as electronic simulation tools for building information or similar tools." This directive compels member states to incentivize, specify, or mandate digital tool adoption through dedicated legislative measures. In Italian law, this directive was adopted by Delegated Law n. 11 of January 28th, 2016, and subsequently confirmed by D.Lgs 50/2016, followed by its implementing decree (DM 560/2017), and the recent D.lgs 36/2023, which reinforces the significance of digitalization across the entire procurement lifecycle. This decree outlines the incremental, mandatory introduction of BIM in public procurement. Organizations are obligated to establish a comprehensive plan for staff training, hardware and software acquisition and maintenance for digital decision-making and information management processes. The decree underscores the importance of an organizational framework that articulates the control and management of information and related aspects. DM 312/2021 incorporates elements from the preceding decree, explicitly stipulating that models should be accompanied by decision-support workflows. Furthermore, this decree references the use of technical specifications in accordance with voluntary European technical standards (EN or EN ISO), international technical standards (ISO), and national technical standards (UNI). Notably, in the construction industry, relevant standards encompass the ISO 19650 Series on BIM-based information management, the UNI 11337 Series on digital construction information process management, the ISO 21500 Series on project, program, and portfolio management, the 55000 Series on asset management, and the ISO 9000 Series on quality management.

3. DIGITALIZATION ROADMAP METHODOLOGY

One of the principal challenges of a digital transition process is related to the need to implement a new working logic within practices that are not always regulated but are well-rooted and difficult to change (Ahmed et al., 2017; Barbosa et al., 2017) Moreover, the necessity to maintain information at the core of the construction process throughout its different phases is a key aspect of BIM methodology and necessitates the practical application of concepts such as information sharing and standardization. This often becomes critical as the individuals responsible for managing information during the various stages of the building's life cycle are diverse and handle an array of disparate or non-uniform information.

This research introduces the initial stages of the digital transition process within a public university, which began in 2021 and anticipated to be completed over approximately six years. It is segmented into three strategic work phases. The project's long-term objective is to execute the digital transition process for the digitalization of the university's real estate and its management procedures through BIM (Fig.1). The proposed methodology can be readily replicated for other university real estate assets.

The project addresses the need to integrate the new digital work methodology into an organization with established processes while striving to strike a balance between coexisting established practices and implementation of new ones. To achieve this, a framework was established across three consecutive and interconnected phases, progressively integrating novel methods. Emphasis was placed on optimizing work processes and resolving critical issues primarily stemming from information loss during the transition from building design to management phases. Maintaining the structuring and management of information vital for the building management phase remained the focal point of the project.

The first phase represents a strategic stage, during which strategic macro-objectives of the digitalization project were defined. The research context was examined, organizational processes were analyzed, and project-specific objectives were formulated, aligned with regulations for optimization purposes. This phase culminates in the creation of the Methodological Guideline, a strategic document that elucidates project objectives and the application context, outlines the document structure comprising the Guideline, and delineates the roles of involved stakeholders.

The following phase, the application phase, focuses on delineating the information content of digital models through the development of operational documents. These documents outline modeling specifications, element hierarchies, information granularity, and asset attributes. The phase concludes with the initial implementation of case studies to validate guideline content.

The ongoing third phase involves the practical integration of BIM into facility management, enabling comprehensive utilization. This phase necessitates comprehensive staff training to ensure the adoption of guidelines and their gradual integration into strategic projects, ultimately leading to their universal application.

The described workflow, reflected in the hierarchical structure of the Guideline's documents, is characterized by three levels:

- Methodological Guideline: The primary document defining the foundational principles underpinning the application of BIM methodology within the university's processes.
- Operational Documents: These executive documents address specific concerns.
- Project Operational Documents: templates for specialized documents mandated by regulations in contracts.

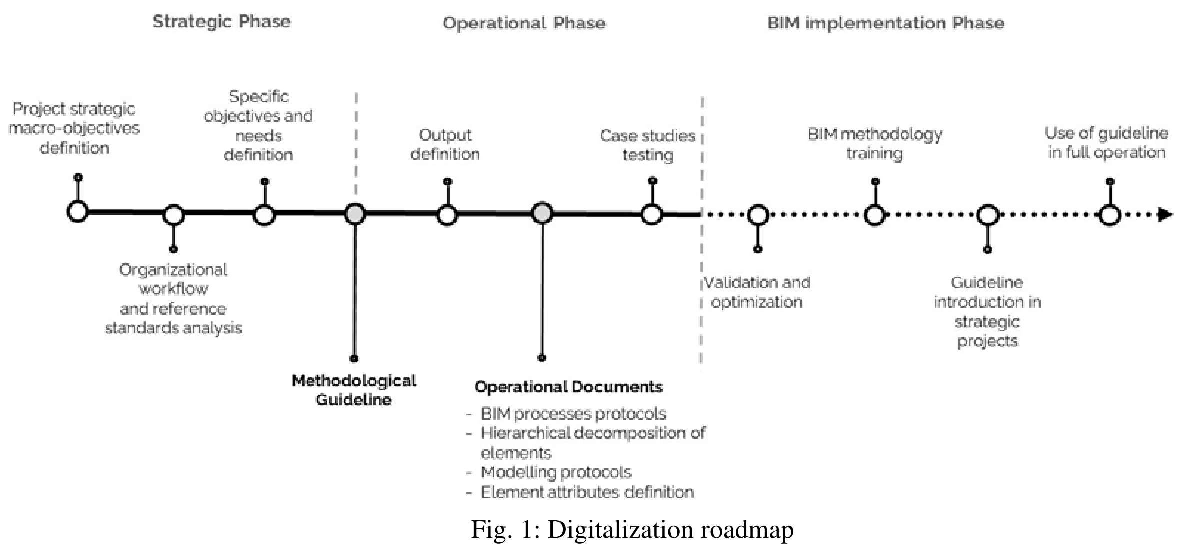

Fig. 1: Digitalization roadmap

4. POLYTHECNIC OF MILAN CASE STUDY

The Polytechnic's real estate holdings are spread across six campuses situated in different cities, comprising a total of 117 buildings and covering an extensive area of 467,000 square meters. The university community comprises approximately 53,264 individuals who engage with and utilize these facilities in various capacities. These include students, researchers (including research fellows and PhD students), professors and technical and administrative staff (Fig. 2).

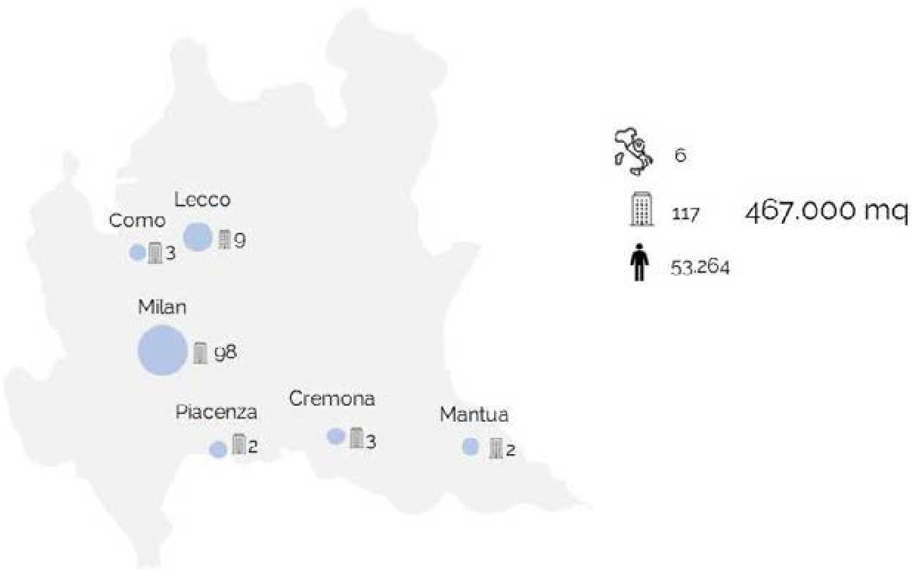

Fig. 2: Consistency of the real estate assets of the Politecnico di Milano

The Politecnico di Milano is a large, complex organization and its management is quite challenging. To address this complexity, the institution has undertaken the development of the BIM Management System Standards. These standards have been devised while considering the regulations pertaining to quality, asset, and project management, as well as information management. While the adoption of these regulations remains partial within the technical domains and their associated activities, the overarching goal is to achieve comprehensive integration into all operational processes. Such integration is anticipated to yield intricate synergies, fostering streamlined operations while concurrently minimizing both effort and expenses.

The following sections provide an overview of the stages completed to date in this ongoing process.

4.1 Strategic and organizational Phase

4.1.1 Organization chart and existing processes analysis

Achieving a successful digital transition process requires integrating change with existing processes. Therefore, the initial phase of the process was dedicated to comprehending the organization and its operational logic, achieved through an in-depth examination of the departments involved in the university's building processes.

At the organizational level, a dedicated BIM Task Force was established at the central university level to oversee the project. This Task Force, comprised of technical and research personnel, was specifically constituted for this purpose.

By examining the organizational structure, the primary departments engaged across all stages of the building process were identified (Fig.3):

- Technical Building Area: This office assumes responsibility for the strategic planning and coordination of real estate development, encompassing activities such as extraordinary maintenance, restoration, rehabilitation, building renovations, and new construction.

- Infrastructure and Services Management Area: This office tasked with maintaining university spaces, ensuring their livability, security, cleanliness, and the provision of services and resources essential for administrative operations.
- ICT Services Area: This office manages the provisioning and administration of ICT services, facilitating the cohesive management of information in support of governance, administration, and all stakeholders. Its primary role within the process is to facilitate information management.

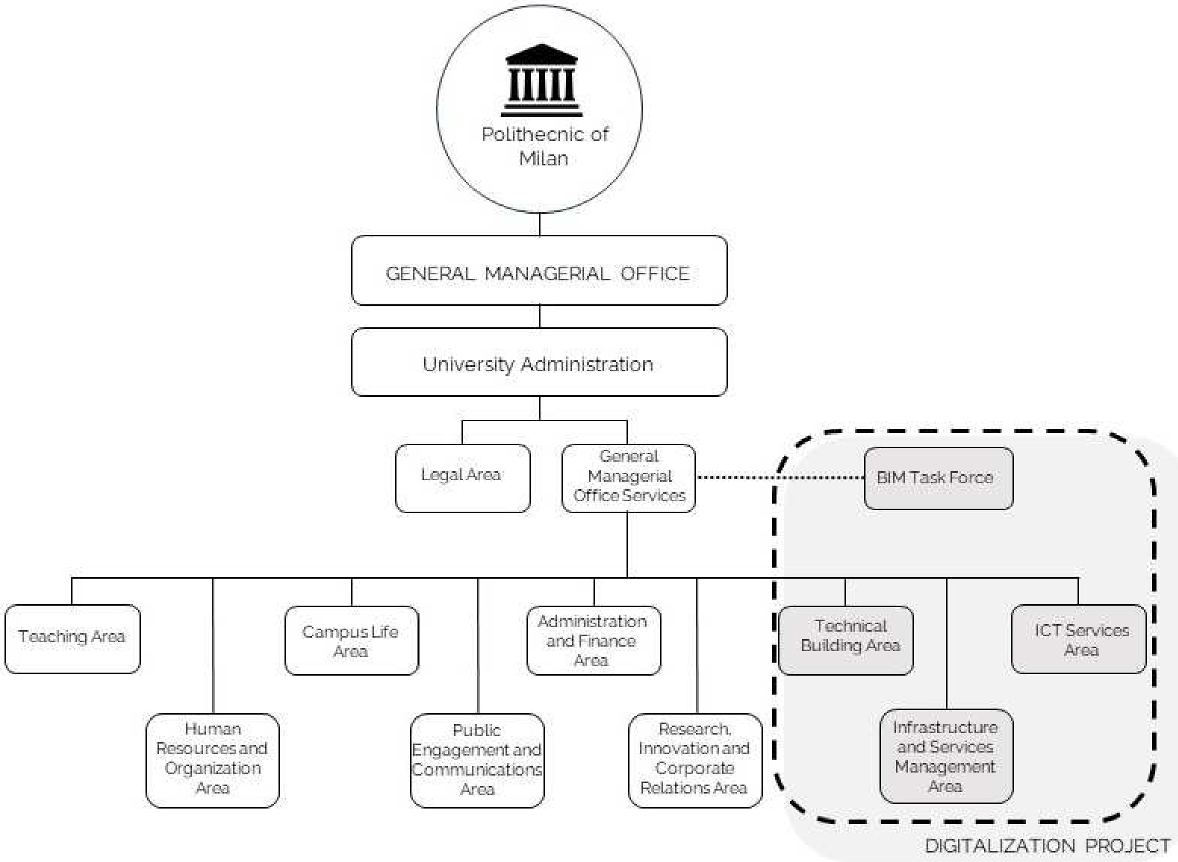

Fig. 3: Examination of the University Organizational Structure and Identification of Involved Departments

The workflows of these offices were studied through the analysis of the documentation provided and a survey campaign, with the aim of learning about the procedures and interactions between internal and external parties and assessing possible problems.

This phase of the offices analysis occurred in two cycles:

- The first cycle involved conducting standardized interviews across all offices to identify characteristics, responsibilities, tasks, and structural facets. It further sought to analyse the means of communication, document exchange, and interactions among individuals, both within offices and across different departments and external entities.
- The second cycle encompassed tailored interviews for each office, delving into specific inquiries pertaining to the adoption of information modeling, particularly during the design and management phases.

The main critical issues highlighted by this analysis were:

- Difficulties in collaboration between offices.
- Inadequate management of the document exchange from construction to building management phases.
- Unclear delineation of roles and responsibilities throughout distinct stages of the construction process.
- Absence of standardized storage systems.

- Inaccurate or incomplete building information.
- Lack of uniform and shared coding across offices of spatial and technological-functional elements.
- Absence of protocols and technical specifications for the transition from the design phase to the management phase.
- Lack of a definitive list detailing elements to be maintained and their associated attributes.

All existing processes were then mapped and diagrammed through Business Process Model and Notation (BPMN), an internationally recognized open standard that provides a graphical notation for specifying an organization's processes. This graphical notation system has gained prominence within the AECO industry due to its capacity to simplify comprehension between individuals with diverse backgrounds enhance interoperability. The schematic representation of processes promotes clearer apprehension of tasks, roles, and information exchanges, and consequently, information requirements (ISO 19560) are defined. In that way, processes are translated into a computing language, making possible future automation (Fleischmann et al., 2012; Meschini et al., 2023)

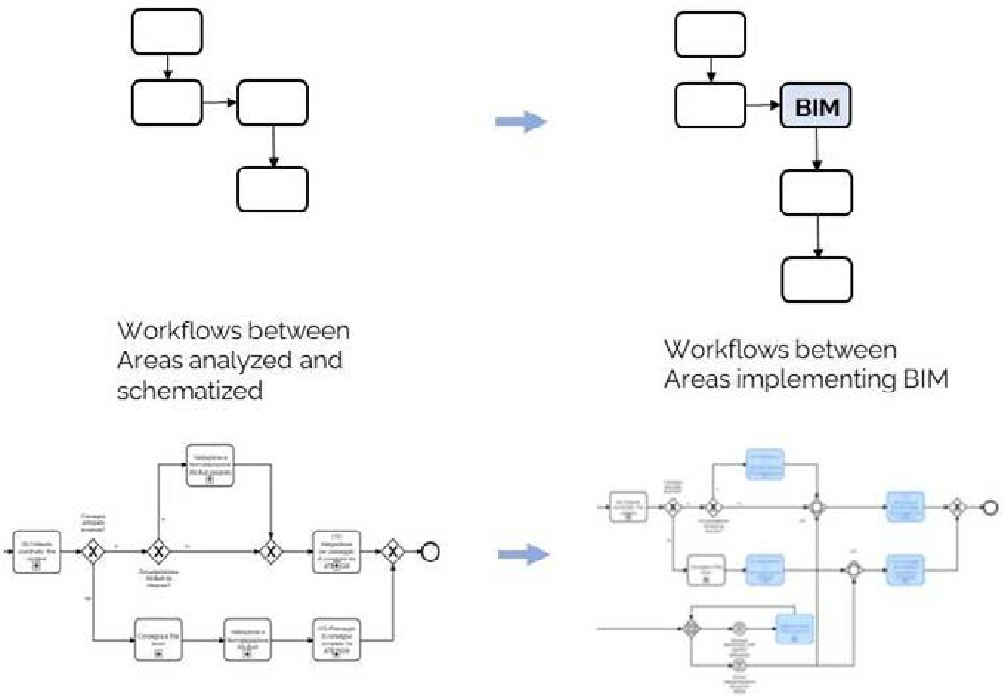

Fig. 4: Exemplification of a BPMN extrapolation illustrating an analyzed process and its redesign proposal through BIM.

Processes have been classified into three categories:

- Main processes: These encompass workflows that involve activities spanning multiple departments. They relate to tasks such as designing and constructing new buildings, revitalizing existing structures, and initiating property management.

  These can be represented in:

  - Process models: sequence or flow of activities with the goal of accomplish a task;
  - Collaboration models: a set of processes that work together for a purpose and are individually referred to as actors involved in exchanging information.

  Main processes may contain sub-processes and recursive sub-processes, which may be process or collaboration models:
- Sub-processes: These represent processes identified within main processes.
- Recursive sub-processes: These further delineate processes within main processes, outlining a series of activities conducted between departments. These sub-processes can be invoked within various higher-order processes.

After sistematically analyzing existing processes, a proposal to reimagine these processes using a BIM-based approach was formalized. This proposal underwent subsequent rounds of review, revisions, and validation by the offices that had been previously investigated (Fig.4).

Furthermore, an updated organizational chart was devised, introducing new roles within each department. These additions catered to the responsibilities of individuals resulting from the integration of BIM into processes, as mandated by technical regulations.

4.1.2 Defining the specific goals and Organizational needs

The specific objectives of the project were established by deriving insights from the strategic objectives defined within the transition process framework. This process was further informed by an analysis of the structure and evidence of critical issues uncovered during the process study.

This was supported by the BPMN flows study, which examined the path and importance of each piece of information throughout the building process, from the design phase (Technical Building Area) to the management phase (Infrastructure and Services Management Area).

The needs of the new building asset management system were identified with respect to the needs of each of the previously identified offices, with the aim to solve the highlighted critical issues. In particular, the new building asset management system must ensure collaboration among the subjects by optimizing building management through coordination among various project disciplines. The need to collect information consistently despite different data collection occasions must be considered to ensure reliable and up-to-date information in a single BIM repository of as-built BIM models (Fig.5).

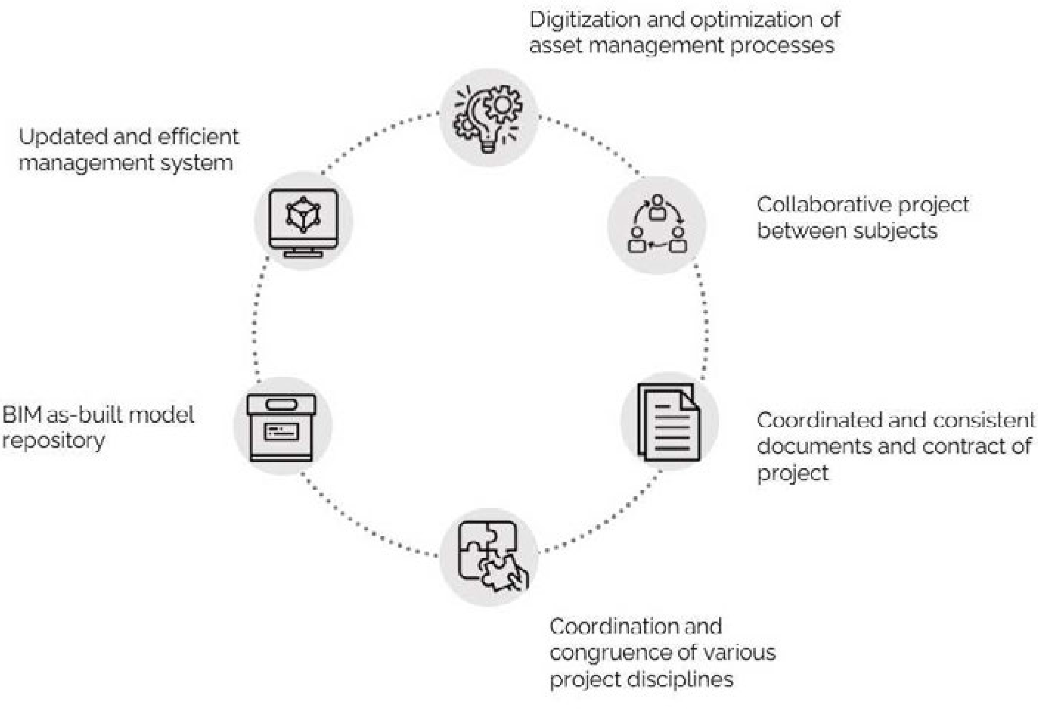

Fig.5 Goals of the New Building Management System

This new system is characterized by its focus on shaping a dataset of information tailored to enhance real estate management. Through this strategic emphasis, the project aims to forge a comprehensive and coherent solution to the challenges identified within the organization's building processes.

4.2 Operational Phase

4.2.1 Define the information requirement

Defining information content is essential for proper asset management through BIM methodology. Within the Politecnico di Milano Guideline was based on the guidance provided by the UNI EN ISO 19650 and UNI 11337 series of standards.

Central to this initiative is the concept that information should be produced and retained with a distinct purpose. The process of defining information requirement revolves around outlining the specifics of the information to be generated and preserved, all with the overarching goal of ensuring that whatever the stakeholder's role, the subsequent objective is achieved seamlessly. Organizations able to govern the management of information during the processes allow the progress of both internally and externally coordinated operations to be made fast and uninterrupted, obtaining only the products they need, avoiding unhelpful material, and guaranteeing the quality of the information obtained.

Therefore, it is essential to establish a structure capable of managing requirements to ensure the effectiveness of data production, collection, and exchange throughout the process. Client awareness regarding the value of information content also clarifies client requirements for various aspects, such as production and sharing methods, delivery times, and formats. Furthermore, this awareness supports the development of verification and control methods.

The approach to defining information content for the Polytechnic is based on three concepts:

- Information needs level: detail with respect to quality, quantity, and granularity of data to be adopted to define information related to a purpose.
  Information that makes explicit the level of information need is divided into:
  - Geometric information
  - Alphanumeric information
  - Documentary information
- Granularity: degree of subdivision and specification of information management levels;
- Data aggregation strategies: ways in which data should be aggregated or disaggregated.

The process of defining information requirements for the real estate assets of the Politecnico di Milano was motivated by the need to address critical issues identified during the study of information flow throughout the processes. Specifically, the investigation focused on the issue of data collection's relevance to the maintenance phase under different circumstances.

One of the issues found was the mismatch of elements from the design phase to the maintenance phase. This problem was leading to a mismatch between the data entered into the archives during the design phase and those entered during the maintenance phase, resulting in the need to re-search the information with a consequent loss of time. This lack of correspondence, combined with the absence of an unambiguous listing of assets to be maintained and the sharing of related management information requirements, led to the inability to record the related operations performed on the items, resulting in the impossibility of timely control their maintenance status and standardization of contracts.

The subsequent focus of the endeavor was on establishing a unified and shared asset list for the As-Built and maintenance phases. To achieve this objective, the technological-functional elements that were previously employed by the Technical Building Area (a Project Breakdown Structure that segments the project into its technological elements used in the design phase) were examinated. Subsequently, we formulated an inventory of homogeneous objects that amalgamate various technical elements related to maintenance contracts. This endeavor culminated in the creation of a new asset list that seamlessly binds these components together (Fig. 6).

Through the establishment of this unified asset listing, bridging the technical aspects of the design phase with maintenance-oriented elements, the attributes requisite for each identified element during both design and maintenance phases were effectively defined. This meticulous approach ensures the determination of the minimum essential information required for each phase.

The level of information detail required will vary during different phases of the building's life and will be managed to streamline the recording of essential data, optimizing the time dedicated to information census and modeling. At the same time, the quality of the information entered into the system must be excellent, with the goal that it will always be completely reliable.

To ensure cohensiveness across all information derived from models, at whatever stage of the asset life cycle these were produced, the operational document "Modeling Protocols" was formalized. This is a document that makes explicit the rules and guidance necessary for the development of information models within the University's BIM Management System. The document aims to ensure a defined and shared BIM model structure.

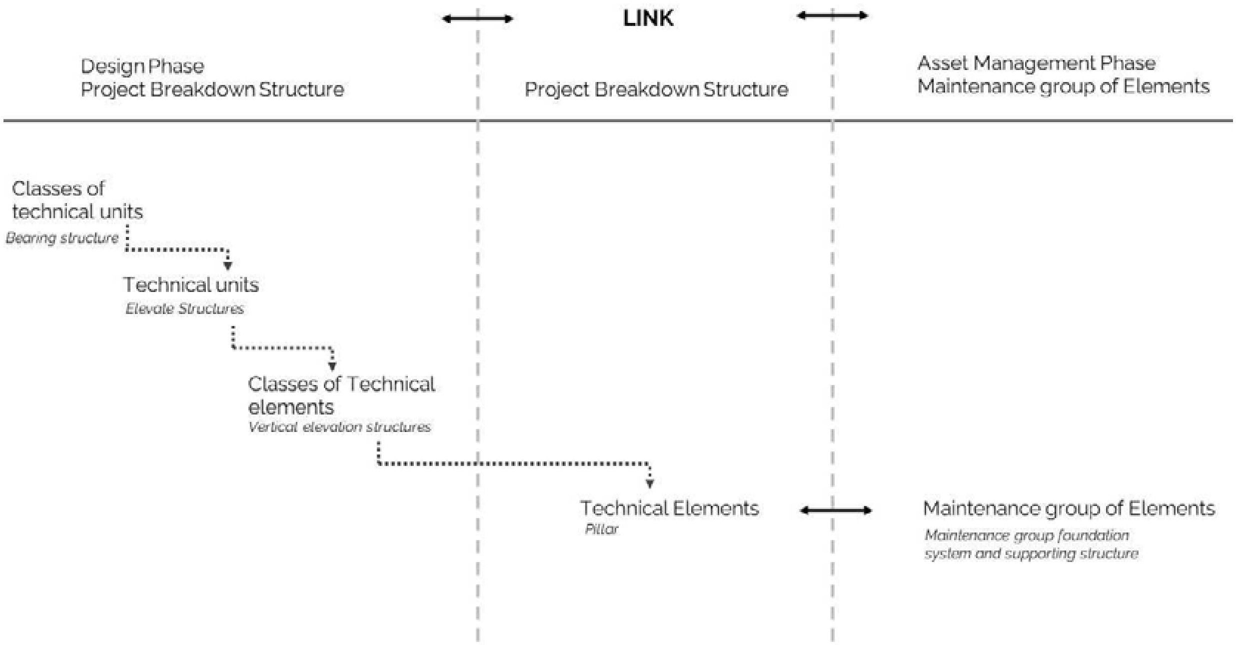

Fig. 6 Relationship between hierarchies of elements in the design and in the maintenance phases

The requirements underpinning the regulation of BIM Modeling in the document, which is based on the relevant legislation, are (i) the definition of a clear and shared structure, (ii) the need for continuity between pre-existing processes in terms of models and software, and (iii) streamlined models that can be used and reworked efficiently while ensuring the exchange of information.

The protocols are structured with consideration of three information modeling scenarios that the Organization may face:

- new construction interventions.
- representation of the existing.
- existing redevelopment interventions.

The paper explicitly outlines the technical characteristics models must possess to ensure consistency within the management system. A particularly important aspect of ensuring consistency between model elements is the mapping process, which relates elements to: (i) the Product Breakdown Structure of the assets previously illustrated, (ii) the categories of the modeling software chosen by the university, (iii) and the related entities for exporting the models in open format IFC (Industries Foundation Classes) ensuring interoperability (Laakso & Kiviniemi, 2012) (Fig. 7).

Throughout the transition project, we identified software to be used for information management based on various purposes. Rearding modeling, information collection, and management in the later phase, a comparative evaluation of FM and CDE software was conduced to determine the most suitable ones at the technical level according to the University’s requirements.

To validate the correctness of protocols and decisions in the operational documents, two pilot buildings were modeled following the guidelines. Pilot cases were selected to test an already existing building and a new construction project, ensuring that each.

Product Breakdown Structure Asset	Proprietary BIM authoring software Category	Non-proprietary software entity
Pillar	Structural Columns	IfcColumn
Stair	Stair	IfcStair
Window	Window	IfcWindow
Boiler	Mechanical Equipment	IfcBoiler

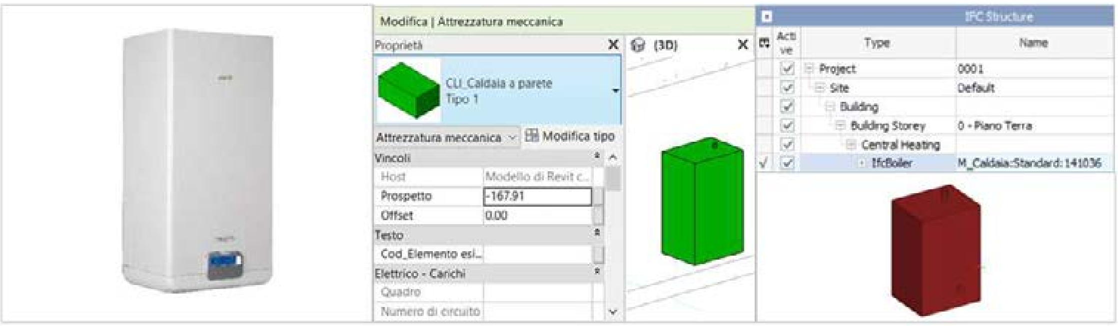

Fig. 7 Example of boiler element mapping

5. FIRST RESULTS DISCUSSION AND FURTHER DEVELOPMENT

To date, the digitalization project of the Politecnico di Milano organization is an ongoing process expected to be completed by 2026. The first two phases of the project have concluded successfully with the approval of the Methodological Guideline and Operational Documents, detailing specific features of information modeling. These documents were validated through the modeling of two case studies to verify the accuracy of the decisions made.

The University Governance intends to base new procurements addressing the university's space needs on these approved Guideline documents. This approach ensures that new construction adheres to defined rules, gradually populating the university's BIM repository with consistent information. The ability of external parties to use the Guideline will enable the research team to validate comprehension and correctness in data reception, addressing and resolving any issues through updated document versions. Therefore, establishing protocols for internal data verification is essential.

The subsequent phase of the digital transition project involves the actual implementation of the BIM methodology within the organization. This phase commences with comprehensive training for the offices on the use of the Proprietary BIM Guidelines and compliance with the new standardized procedures. This training ensures their assimilation and prevents the distortion of client requirements in terms of information content over time, which could render the entire data processing process ineffective.

6. CONCLUSIONS

This work explored the implementation of a digital transition process for the property management of a large university. The application research was structured in three progressive phases, aiming to optimize the management of the information flow through process implementation, resulting in improved management of the entire building process while structuring information essential for the real estate management phase.

The specific focus was on defining a consistent information set derived in part from existing processes. The implementation addressed critical issues related to the loss of useful information during the transition from the design phase to the management phase. The definition and subsequent verification of information requirements by the organization are essential for properly aggregating and disaggregating information as needed.

For this type of process to succeed, the organization must possess proprietary Guidelines aligned with its processes and requirements while internally training its staff to recognize the importance of maintaining consistent information content.

7. ACKNOWLEDGEMENT

The authors express their gratitude to the Politecnico di Milano offices involved in the process for their valuable contribution and collaboration.

ABSTRACT: *The integration of Building Information Modelling (BIM) and Geographic Information System (GIS) with Business Intelligence (BI) is promising for managing vast and diffused assets. It enables valuable insights into asset performance and resource uses, supporting savings, improved efficiency, and sustainability. The research proposes a web-based Asset Management System application (AMS-app) via BIM-GIS-BI integration, providing an updated digital representation of university assets by combining spatial, performance, and operation data with related analytics. The AMS-app was developed in the context of the University of Turin's strategic plan as a pilot case to improve asset management procedures through a data-driven approach. Indeed, campuses are complex assets managed by multiple actors through still document-based and fragmented databases, often leading to ineffective and untimely decision-making processes. The AMS-app represents a valuable decision support system for facility managers aimed at asset monitoring and user experience improving through better and more sustainable decisions concerning space, occupancy, and indoor environmental quality (IEQ). To demonstrate the effectiveness of the BIM-GIS-BI integration through the AMS-app, several case studies were implemented with the following objectives: (i) the digitalization of university building data, (ii) the optimization of courses timetables according to space availability, (iii) the optimal workstations management, and (iv) the analysis, monitoring and optimizing of IEQ and comfort via IoT networks. The paper illustrates the advantages and applicability of the developed methodology through the case studies, and further developments in university asset management.*

KEYWORDS: *Asset Management System, BIM-GIS integration, Business Intelligence, Information management*

1. BACKGROUND AND MOTIVATION

University assets, especially Italian ones, are characterized by strong management complexity due to their diffused buildings, often built in different eras with various construction technologies and high heterogeneity. The management is often based on fragmented, incomplete, and hardly accessible databases, preventing the correct definition and optimization of usage patterns, as well as the normalization of management processes (Qian and Papadonikolaki, 2020). This results in inefficiencies in services and maintenance activities, leading to wasted resources and inefficient decisions concerning the expected performance, user comfort, and economic and environmental sustainability. Thus, university assets represent a crucial opportunity to propose a solution to the information gaps currently found in managing large assets. There is an increasing need for the adoption of information management strategies aimed at shifting from highly document-based and fragmented approaches to digital and collaborative ones (Chen et al., 2015). Digital tools and effective information management strategies enable data integration, ensuring the availability of accurate information with various granularity levels, at the right time, in the required formats, and throughout the asset lifecycle. Despite its application in asset management is still rare (Moretti et al., 2021), BIM-GIS integration provides high potential (Liu et al., 2017; Beck et al., 2020), especially in borrowing the Smart City concept at the Campus scale, improving the management of such complex assets for a better user experience and optimal resource utilization (Lu et al., 2020; Ward et al., 2021; Wang et al., 2019). BIM enables the development of highly detailed building information models, while GIS allows their management and analysis through a global spatial reference system (Zhu et al., 2021). BIM-GIS integration combined with BI tools can be exploited to optimize the management of large assets and to foster the development of AMS tools as concrete decision support systems (Pärn et al., 2017). The further integration of IoT and digital devices can facilitate data collecting, providing a better maintenance and asset management through the monitoring and analysis of real-time data about asset performance and condition, enabling timely interventions (Wong et al., 2018).

DOI 10.36253/979-12-215-0289-3.41

The research project exploits BIM-GIS integration with BI tools to develop an interactive, web-based 3D map (AMS-app) for the management of large and diffused university assets. The main objective consists in facilitating information management and decision-making processes by improving information accessibility and sharing among stakeholders, and normalize management processes. The paper illustrates the replicable methodology developed to define and implement the AMS-app within the management system of the University of Turin (i.e. UniTO), an emblematic case for testing and demonstrating the potential offered by such a decision support system. Then it describes how data are collected from various siloed databases and integrated, providing an easily accessible and implementable knowledge base. Indeed, the AMS-app collects all the data currently handled separately by different administrative offices, providing a still independent but collaborative management system. Thus, the asset can be managed at the system level, rather than at the level of individual isolated buildings. The potential that such an AMS-app can provide to asset and facility managers of large university assets is described through the illustration of several case studies implemented so far, selected based on the management needs encountered within UniTO. Finally, the results are discussed, and the potential future developments and implementations are reported. Further objectives concern the development of information modelling protocols and guidelines to facilitate the adoption and transition to such a digitalized and shared management approach. In this way, the data can be modeled and structured ensuring the availability of accurate information at the right time, in the required format ,throughout the asset lifecycle, and the method can be easily replicated.

2. METHODOLOGY

The main steps of the methodology adopted to develop and implement the AMS-app in the university organizational structure are illustrated in the following paragraphs.

2.1.1 Main objectives and needs definition

The first step concerns the definition of the main objectives and needs that the organization intends to handle via the AMS-app. The organizational structure was analyzed to understand the management issues faced by UniTO and to define the relevant case studies to be implemented and tested through the AMS-app. Consequently, meetings and interviews with the managers of the technical areas in charge of the university asset management, its maintenance, information systems management, as well as teaching and educational services were conducted.

2.1.2 Current database structure and dataflow management strategies investigation

An investigation of the procedure currently adopted by the university to manage the information flow has been conducted to identify which information and data are handled by the different technical areas, as well as the methodology used to produce, store, and exchange them. One of the main aims of the analysis concerned the identification of the tools and formats currently exploited by the areas so that the AMS-app could be developed without disruptively changing current workflows, facilitating its adoption.

2.1.3 Organization information exchange and information requirements formalization

Once identified the organization's current database structure and dataflow management strategies, the analysis and formalization of the information exchange among the technical areas have been performed. The main aim was to ensure the easy integration of modifications occurring over time, providing a constantly updated digital representation of the building asset. The information exchanges were formalized to ensure that the technical areas can continue to rely on current tools and procedures with minor changes in data production and management. Then, the Information Requirements (IRs) have been defined to foster communication and support the creation of a coherent database to feed the AMS-app. Table 1 provides an example of an exchange information requirement schedule.

Table 1: Example of an exchange information requirement in the standardized form for data collection.

Field	Data source	Note	Type
Building code	OpenSIPI, Technical Areas: EDISOS, SILOM, SIPE, Asset Management	Building coding (Settlement_Building: e.g. 029_B)	Text
Building name	OpenSIPI, Technical Areas: EDISOS, SILOM, SIPE, Asset Management	Free field	Text
Main address	OpenSIPI, Technical Areas: EDISOS,	Free field	Text

	SILOM, SIPE, Asset Management		
Municipality	OpenSIPI, Technical Areas: EDISOS, SILOM, SIPE, Asset Management	Extended name, es. Turin	Text
Main use	OpenSIPI, Technical Areas: EDISOS, SILOM, SIPE, Asset Management	Free field	Text
Building Type	OpenSIPI, Technical Areas: EDISOS, SILOM, SIPE, Asset Management	Bound field: Building, Portion of Building, Agglomeration of Buildings, No Type, ND	Text
Status	OpenSIPI, Technical Areas: EDISOS, SILOM, SIPE, Asset Management	Restricted field: Decommissioned, In use, Under construction, No Status, NDo	Text

Furthermore, a possible change in the university's organizational structure was investigated for better supporting the AMS-app adoption.

2.1.4 AMS-app development: approaches, technologies, and tools selection

As stated before, the scientific literature has widely discussed how BIM and GIS integration can bring significant benefits in the field of asset management. BIM enables an overview of a single building and GIS allows the contextualization of each building, enabling analysis at a territorial level. Thus, the two resources optimally lend themselves to the university campus management, which, given its complex infrastructure, the amount of heterogeneous data, and spaces spread over a vast territory, needs systems that can facilitate the management, use, and maintenance of their assets at different levels. The proposed system integrates these resources providing the necessary tools for understanding, visualizing, and analyzing information related to the university building stock, its services, and infrastructure, thanks also to the support of BI tools. Data are core to the system, populating it and being the key to the different components' connections. The platform integrates data of various nature and from multiple sources: geographic data, geometric and functional data, as well as data concerning IEQ derived from sensors (Table 2).

Table 2: Data sources, information and types.

Source	Information	Type
Piedmont Territorial Geoportal	Building location, heights, geometries, restrictions	Text, numbers, coordinates, shape files. Static data.
OpenSIPI	Name, encoding, address, floor numbers, state of use, geometries, area, department assignment	Text, numbers, drawing. Static data.
Department offices	Courses schedule, personnel employed information, buildings construction site	Mainly text. Sheet-form organization. Dynamic data (on long term)
University website	Timetables, organizational units, building property state and expenses	Mainly text. Sheet-form organization. Dynamic data (on long term)
IAQ Platform	Environmental sensors measurement (CO2, humidity, temperature, VOC, PM2.5, etc.)	Numbers. Dynamic data (on brief term)

The different datasets are then collected from various sources, processed, and stored in a cloud repository so that data can be queried by any operator without duplicates, errors, or information loss. Aiming at the optimal integration between the different data, information sheets have been prepared and provided to the technical areas, asking for their fulfillment. Nonetheless, their compilation is not always possible such as in the case of geometric data derived from drawings or models, or geographical data from cartographic services such as the Geoportal of the Piedmont Region. In these cases, the sheets have been compiled manually by the authors.

Once the needed data have been collected, they are interlinked thanks to the semantic association of encoded names. An encoding system was defined for each city, building, and space, which is part of the university asset, starting from the one currently used by the university's administration to promote a smooth integration process. The encoding system was also key for data association in GIS. The entire campus buildings were identified, geolocated, and associated with their encoded names. The map was developed in a 3D view, aiming at offering a better perception of urban space, asset consistency, and distribution. Thanks to the geolocation of the encoded buildings through a 3D environment, and to the association with functional data, various analyses were developed at the territorial level, providing the depth knowledge of the university asset with information on its use and consistency, useful to support decision-making processes.

QGIS was selected for the shape files creation and first population, while Mapbox was exploited for the 3D map development and visualization. It was chosen for its easy integration with Microsoft Power BI, thanks to the opportunity to generate a customized web map based on the created shape files, shareable through URL and carrier of selected information. In addition to the GIS representation of the university asset, BIM was exploited for the analysis and visualization of each single building at different levels. The modeling phase succeeded in exploiting the Autodesk Revit Software for geometrical construction and the Visual Programming Language Application Dynamo for information population. The BIM modeling and the Dynamo nodes were developed with the aim of generating a replicable workflow, adaptable at each building of the asset. So, each BIM model presents three different levels of consistency: the building volume, the building levels, and the building spaces, modeled as mass, floors and rooms, respectively. Each element is firstly associated with the corresponding code, then the encoded name and the Revit Element ID are exported for each geometry modeled. The encoded name association ensures the association between the different datasets, but the connection between the BIM geometries and the information occurs via the Revit Element ID association. It is needed for various reasons, for example, some rooms may temporarily present the same encoded name during a space renovation, or their geometry can change throughout the building lifecycle, as well as their name. Despite the mutability of information such as the name, the Revit Element ID remains unchanged over time.

The BIM model is then associated with information related to the standard use of the building and its characteristics. During parameters' creation, a parameters comparator enables to individuate the shared parameter between masses floors and rooms, avoiding repetition that could lead to association errors or can compromise the final model quality. Both the Revit parameters and the associated values are extrapolated by the same dataset, stored in the cloud repository, and in the future, each building of the university asset will have its own datasets for better management. At this stage, the association of the most dynamic information, such as the real-time collected data, has been avoided. In this way, the model can represent the basis for multiple analyses related not only to environmental quality but also to space occupancy or educational and working spaces management. This choice provided also lighter models, with smaller file sizes and greater smoothness. Finally, with the aim of facilitating BIM and Microsoft Power BI integration, the BIM model was exported with Proving Ground Tracer. This software allows the exportation of both 2D and 3D geometries with related information, all preserved in an SQL database generated by the software itself. At the end of the process, the BIM is then ready to be imported and visualized in Microsoft Power BI. It demonstrated great capacity in data analysis and visualization, allowing information sharing between different stakeholders through analytic dashboards which can involve data, BIM models, and GIS maps. So, it represents the preferential software for web-app structure development.

2.1.5 Data visualization, analytics, and dashboard structure definition

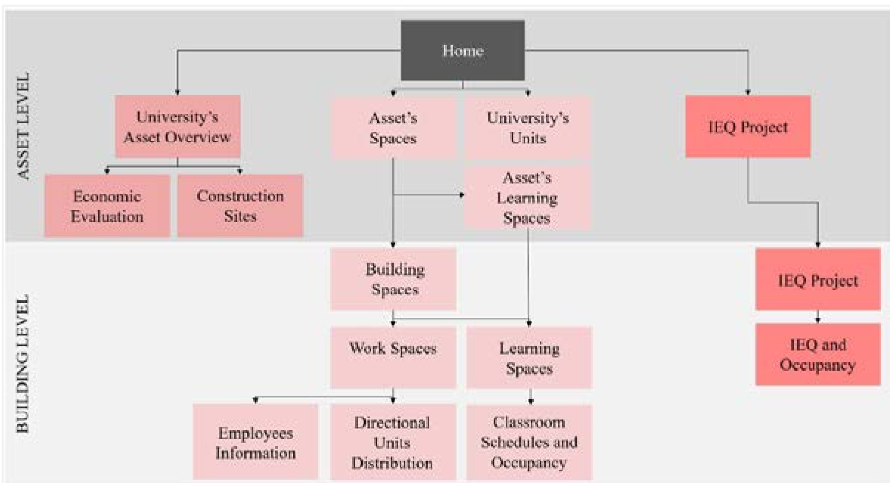

Fig. 1: UniTO's asset management system platform based on BIM-GIS-PBI integration

Power BI was chosen not only for data analysis and visualization but also as the software to generate the AMS-app main structure. The dashboards created are directly connected to datasets stored in the cloud repository and can be integrated with BIM and GIS maps. Thanks to these connections, based on the relationship of the encoded names, it's possible to associate the resources, the data previously excluded, such as the dynamic data related to real-time environmental quality measurement, the course timetables, the occupancy rates, etc. The platform is structured so that the dashboards are gathered in thematic reports (asset consistency, economic evaluation, construction sites, IEQ, spaces' occupancy, etc.), classifiable also into territorial and building reports, depending on the level of information visualizable. Each report is correlated to the others based on a predefined structure (Fig. 1), but still independent, allowing to introduce different accessibility levels according to the requesting user.

3. RESULTS AND DISCUSSION

The proposed methodology and AMS-app are being applied as a pilot study to the UniTO asset management, as described in the following sections.

3.1 UniTO pilot case

3.1.1 Main objectives and needs definition

UniTO aims to create an integrated AMS-app that enables updated data visualization to optimize the management of its diffused asset, providing information about performance and resource utilization, to promote cost reduction and improve efficiency. The main goal consists in improving the management of spaces and resources. The AMS-app enables to identify and monitor the asset over time, leading to better decision-making concerning space, occupancy, and IEQ management. It was applied to digitalize the whole UniTO building stock, providing an overall view with data about its consistence and usage (i.e., geolocation, building asset consistency, geometrical and financial data, building performances, rooms capacity, equipment, and performances, occupancy level, and usage, etc.). The updated visualization of the building portfolio through a 3D map with data and information handled through GIS, BIM, and BI systems aims to support the:

- Management of university facilities at the territorial and building levels allowing to produce data analytics at different layers for improved facility operation;
- Optimization of university teaching timetables based on the actual teaching space availability and capacity;
- Optimization of workstations management by introducing remote working strategies;
- Analysis and optimization of IEQ to improve users' comfort and safety through IoT monitoring.

3.1.2 Current database structure and dataflow management strategies investigation

Currently, the university technical areas handling data and documentation about facilities, spaces and related equipment, performance, capacity, workstations' number, and concerning the teaching timetables' definition, rely on a document-based system characterized by siloed information. Data about spaces and related usage are stored and exchanged via semi-structured formats such as .xls or .csv. Information exchanges take place mainly via traditional communication systems (printed reports, e-mails, calls, in-person or remote meetings, etc.), and data are not shared between stakeholders or administrative offices, resulting in struggling or absent analysis of integrated aspects and information to support the decision-making processes. Thus, a data integration system is proposed with the aim of creating an updated tool collecting data from several sources, shared among the whole UniTO staff. The different data silos are integrated by exploiting BI tools and methods, enabling to collect and integrate data from the various Excel sheets produced by the technical areas. In this way, it is possible to maintain the current processes adopted to manage space, staff, and usage data, avoiding disrupting the management procedures. Furthermore, it is possible to avoid the effort of creating a structured DB (e.g., a relational SQL database) that would have been more disruptive and difficult to integrate within the UniTO management system. This allows for the gradual and low-impact integration of the AMS-app and the system, with a greater likelihood that it will be concretely used by UniTO staff.

3.1.3 Organization information exchange and information requirements formalization

The data integration system has been set up by a cross area within the UniTO organization represented by a research group of seven people which acts as a data analysis area. The authors are part of this research area that collects the different data from UniTO areas integrating them through the proposed system (AMS-app) according to the schema illustrated in Figure 2.

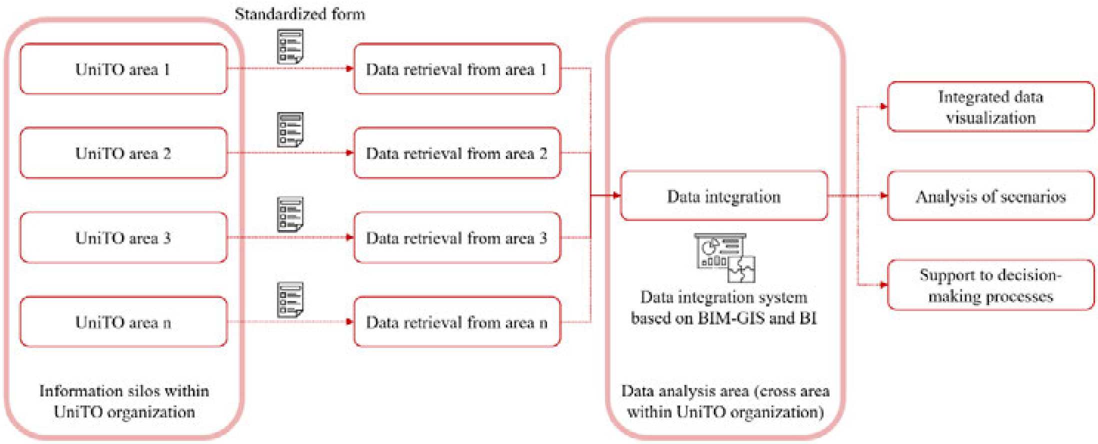

Fig. 2: Information exchanges and data processing schema within UniTO organization.

Data are retrieved from UniTO technical areas via standardized forms (Table 3), and the data analysis area receives information concerning buildings, spaces, capacity, occupancy, people occupying the spaces, etc. through similar forms. This enables quick data management via structured data sheets and avoids the cleaning and processing of data first. The integrated data, the resulting information, and knowledge are made available and displayable via the platform, enabling scenario-based analysis to support the decision-making processes of the UniTO's asset management staff.

Table 3: Example of standardized form for collecting data about some of UniTO facilities, collected in the.

Building code	Building name	Main address	Municipality	Main use	Building type	Status
001_A	Palazzo del Rettorato	Via Verdi 8	Torino	"Uffici a supporto didattica e ricerca	Fabbricato	In uso

021_A	Palazzetto Aldo Moro	Piazzale Aldo Moro	Torino	Uffici a supporto didattica e ricerca / Aule / Dipartimenti	Fabbricato	In uso
029_B	Campus Luigi Einaudi	Lungo Dora Siena 100	Torino	Dipartimenti / Biblioteche / Aule / Uffici a supporto didattica e ricerca	Fabbricato	In uso
032_A-B-C	Centro Pier della Francesca	C.so Svizzera 185/Via Pessinetto 12	Torino	Dipartimenti / Aule / Magazzino / Rimessa / Uffici a supporto	Porzione di fabbricato	In uso
064_A	Torino SUISM	Piazza Lorenzo Bernini, 12	Torino	Aule/Uffici a supporto didattica e ricerca	Fabbricato	Dismesso

Specific applications of the proposed data integration system and AMS-app are described in the following sub-sections, including advantages and limitations. The case study selected as a demonstrator for such applications at the building level is the Campus Luigi Einaudi (CLE). The main facility of CLE is located in the northeast area of Turin, with a total net area of more than 36,000 square meters. The facility hosts the Department of Law, the Department of Political and Social Sciences, and the Department of Economics and Statistics "Cognetti de Martiis", hosting more than 500 research fellows. In addition, there are numerous administrative areas with around 100 administrative employees dealing with the management of spaces, people, contracts, and related bureaucratic matters. Furthermore, the CLE has 47 lecture halls and hosts around 16700 university users, so it represents a significant case study with a large catchment area and many activities within it.

3.2 Real estate asset management at territorial level

Real estate asset management at the territorial level deals with the storing and managing of data concerning the location, the type of building property (e.g. owned, rented from another institution or a private subject, partially owned or partially rented, etc.), the overall occupancy, the presence of listed buildings, and other facility management data. This kind of data regarding UniTO facilities currently are stored in siloed documents or .xls files, preventing the integrated analysis needed to support decision-making processes. Thus, overall dashboards regarding the whole UniTO's real estate property are produced to investigate multiple data at once. The dashboard maps provide an overview of the entire territory over which UniTO buildings are distributed, useful to investigate data at a territorial level. All the views provided on the dashboard pages (e.g., maps, charts, graphs, and cards) are dynamic and interactive. A selection in one view, acts as a filter for all other views of the page or of the entire dashboard report, according to the specific requirements. The dashboards at the territorial level support the decision-making processes regarding the strategies to be pursued at a high level on the whole university facilities.

Figure 3 shows the dashboards at the territorial level with general data regarding UniTO real estate propriety. Other information, such as UniTO facilities under refurbishment and data concerning specific interventions or the listed buildings are visualized in other tailored dynamic dashboards, allowing an integrated analysis of the data and supporting complex decisions of the UniTO's administrative areas.

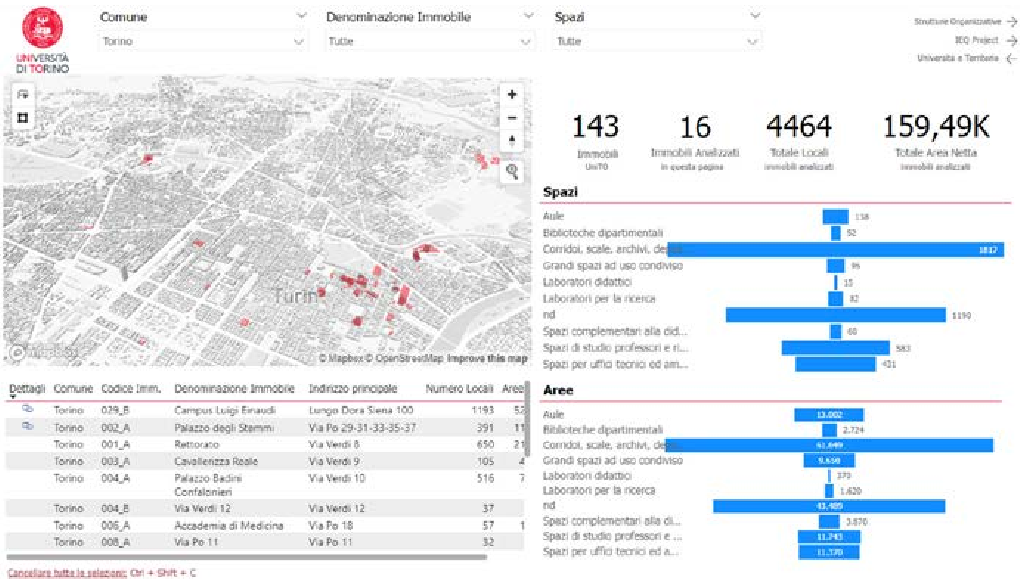

Fig. 3: AMS-app dashboard at territorial level regarding general data of UniTO real estate propriety.

3.3 Lecture hall spaces and teaching timetable management

Managing teaching spaces and, specifically, organizing lesson timetables, poses a multifaceted challenge. The problem is intricate due to the numerous and diverse variables involved, especially concerning CLE. Notably, the presence of various departments and their distinct methods of allocating the timetable adds to the complexity. Additionally, the extensive range of teaching hours dedicated to different subjects and the diverse nature of activities carried out further necessitate a highly varied schedule even within the same building.

The current process for creating class schedules and allocating spaces seems to be structured in stages, with three distinct directorates/offices involved. Firstly, the "*Educational Services Directorate*" supplies information regarding course enrolments, course codes, and academic credits assigned to each course. This data is then passed on to the "*Degree programs office*" which operates under the school's guidance, serving the departments and is tasked with creating the teaching timetable. Finally, a local branch of the "*Building Logistics and Sustainability Directorate*" is responsible for space allocation based on the received teaching timetables.

The entire process is characterized by fragmented data handling and manual switching between different software, which could increase the risk of errors. Thus, the primary objective was to consolidate the data into a single data analysis platform, ensuring more secure management and facilitating the analysis of teaching space utilization. To achieve this goal, a dashboard was developed, providing a comprehensive view of various data that would otherwise require gathering from three different offices. This single dashboard allows users to access information about the teaching spaces, including classroom names, room codes, capacity, classroom equipment, and net area. Moreover, the dashboard also offers insights into space utilization and teaching hours, enabling the estimation of the percentage of hours during which classrooms are booked, optioned, or available for use. This centralized and user-friendly approach streamlines data access and analysis, enhancing overall efficiency and accuracy in managing teaching spaces. Figure 4 illustrates the flexibility of viewing rooms in both 3-dimensional and 2-dimensional formats. Regardless of the chosen view, users have the option to select specific rooms and access detailed data. The interactive line graph enables direct interaction with the data, and users can also apply filters based on the building's floors. At the room level, the scheduled time for each room throughout the week, month, or year can be displayed, as depicted in Figure 5.

Fig. 4: AMS-app dashboard at building level with the analysis of lecture hall spaces and occupancy.

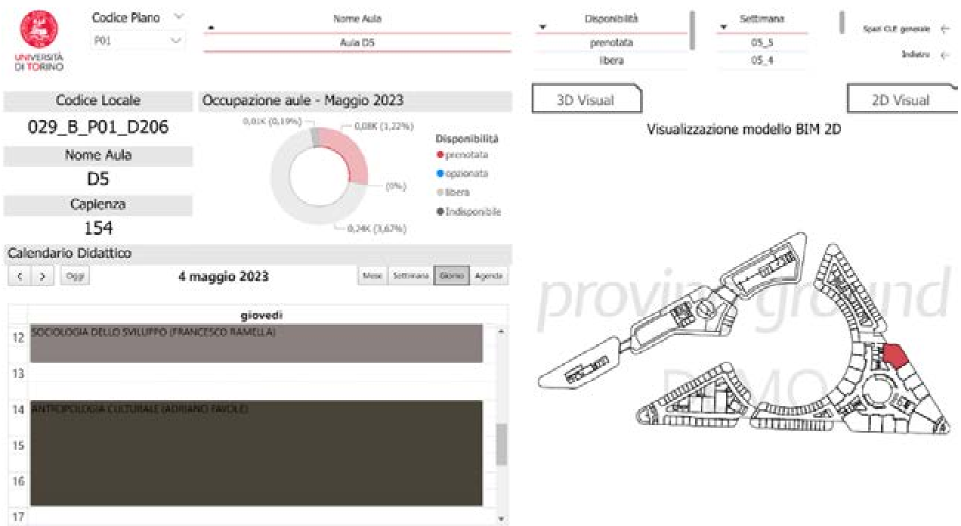

Fig. 5: AMS-app dashboard at room level allowing the analysis of lecture hall spaces, occupancy and timetable.

3.4 Real estate asset management at building level

Real estate asset management at the building level refers to multiple activities necessary to operate a facility and can include the following: people management including contract management, space and equipment allocation; space management including space allocation to the departments and areas hosted in each building. As of now building operation at UniTO is performed by the same departments or administrative staff hosted in each facility.

Except for space codes, the structure of which is common to all UniTO administration, all other space management information is managed locally by each building's space management staff. There is no central structure that manages all UniTO facilities at the space level.

The main objectives of this application are to support the decision-making processes regarding UniTO facilities, collect all the necessary information, and produce dashboards at the building level to investigate space, occupancy, and people management via BIM-GIS integration and BI technology. The data that are treated are the following:

- Space data regarding the location inside the building, area, and space typology;
- Allocation of spaces to the departments or administrative areas;
- Allocation of spaces to specific people and their role inside UniTO, contract typology, affiliation to a department or administrative area.

Figure 6 and Figure 7 show the AMS-app dashboard at the building level regarding all the spaces of CLE and the specific analysis of occupancy and staff allocation in the offices respectively.

Figure 6 allows the analysis via dynamic maps and charts of the spaces in terms of space typology and number of rooms, the allocation of the spaces to the departments or administrative areas, and single data points concerning the space net area and the number of rooms. The page allows the overall analysis of the building and the consultation of the general data regarding spaces, as well as the distribution of the space typologies on each building floor and the summary of the total building net area and number of rooms.

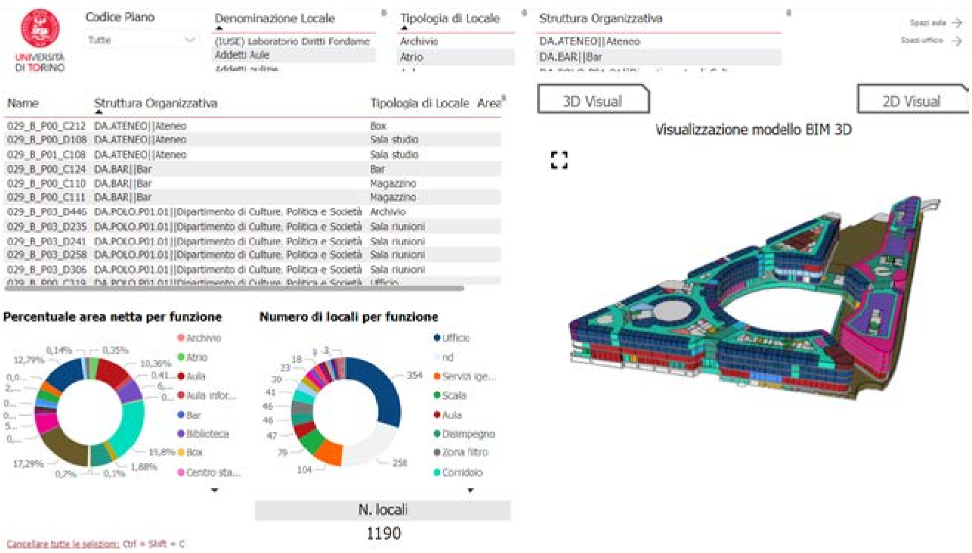

Fig. 6: AMS-app dashboard at building level allowing the analysis of space features and allocation of CLE.

Figure 7 enables a more specific analysis of the offices at CLE, including the percentages of area and staff assigned to each department and administrative area. A graph allows the comparison among the employee and research fellows allocated to the spaces and the maximum number of people that can be hosted according to the net area of each room, supporting the decisions related to the new staff that can or cannot be allocated in a space. In addition, an equal distribution of the spaces among departments and areas can be ensured based on the analyses

Fig. 7: AMS-app dashboard at building level with the detailed analysis of office and staff allocation at CLE

3.5 Space management improvement

Space management improvement in UniTO pilot case refers to the study of strategies to improve space occupancy, allocation, and usage with the introduction of work from home (WFH) practices. The contracts of professors, research fellows and PhD students already include flexibility as regards working hours and location, consequently, WFH is already allowed. On the other hand, concerning administrative employees, WFH practices have been introduced due to the recent COVID-19 pandemic events and then maintained for a total of two days a week. However, as of now, no improvement in space management has been introduced related to flexible work scheduling.

This application of the UniTO AMS-app aims at improving space management by hypothesizing a homogenous distribution of WFH days of the employees/researchers of the same office over the working week. As a consequence, the maximum occupancy of a single office can be increased. All the occupants are never present in the office at the same time, while WFH days are planned so that in each day of the week a certain number of office occupants work at home. As a results, the overall occupancy in a building can be increased. Considering two days a week of WFH for each worker in a five-day working week, the overall occupancy of the building increases by around 60% (Figure 8). This ensures that in the case of recruitment, workstations are already available in the existing facilities, without the need of acquiring or renting new spaces.

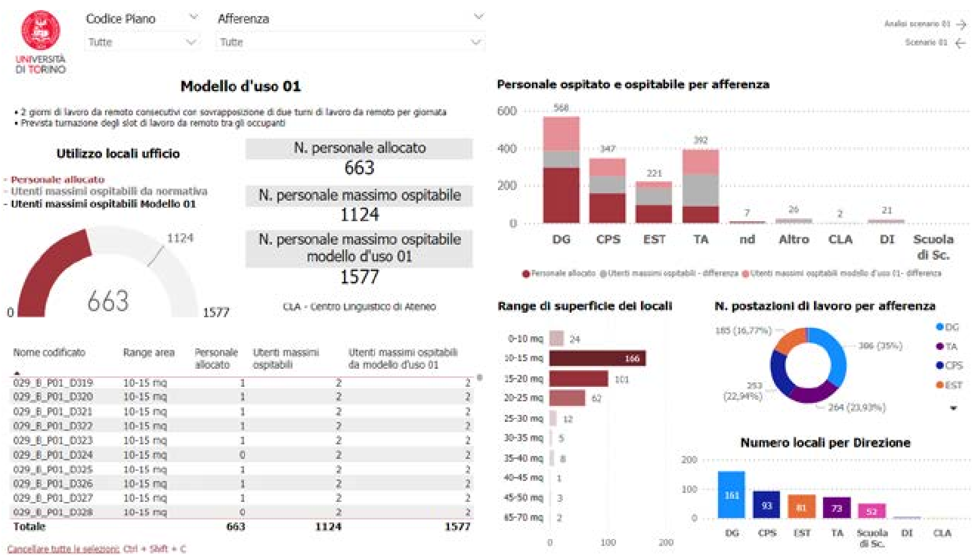

Fig. 8: AMS-app dashboard analyzing space allocation and current number of occupants, the maximum capacity of each space, and the maximum one with WFH and strategies to improve CLE space usage.

3.6 Indoor environmental quality monitoring and optimization

Monitoring data related to environmental quality data monitoring within educational spaces is of utmost importance. It serves two primary purposes: ensuring a healthy learning environment for conducting lessons and detecting any anomalies that may indicate system faults or the need for system remodeling. This approach also contributes to energy conservation and the reduction of heating and cooling systems' emissions. Over the past two years, several UniTO's buildings have been equipped with IEQ sensors. Among these, the CLE buildings serve as an excellent testing ground for evaluating the effectiveness of these systems due to the high number of sensors and the presence of classrooms with different capacities and orientations. UniTO has chosen IoT devices from Aircare® that can capture 15 types of measurements, including air quality, environmental comfort, and electro-smog indicators. Notably, the devices' accuracy and reliability have been scientifically validated by the Italian Society of Environmental Medicine (SIMA) for PM2.5 and CO2 measurements. A total of 39 IoT devices were strategically installed across 37 classrooms within the CLE, focusing on the ground and first floors, dedicated to teaching activities. Once installed, the data generated by these devices was directly streamed to a cloud platform, facilitating data collection. The collected data are accessible through reports, providing valuable information via an experimental platform managed by the ICT directorate, and at this stage data aren't shared publicly or with other directorates.

The objective was to optimize the AMS-app potential by linking the data to specific spaces and creating interactive dashboards to display real-time data from the continuously flowing information from the IoT devices. To maximize the advantages of measuring multiple types of data with a single IoT device, it was decided to associate viewable spaces with data related to CO2, CO2e, VOC, PM10, and PM2.5. A dashboard was developed to integrate the data with floor plans, clearly indicating the locations of installed sensors in the respective classrooms. By selecting a specific classroom, users can readily access and visualize the recorded values throughout the week (Figure 9).

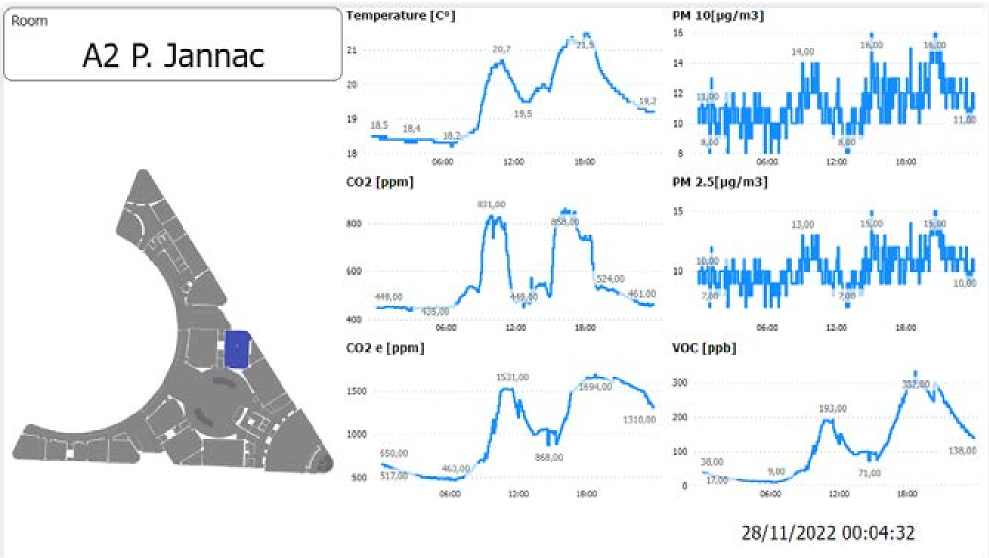

Fig. 9: AMS-app dashboard at room level allowing the visualization of spaces and data acquired from sensors.

To serve as alert indicators, specific limit values were established for the main parameters. During the heating season, temperature values between 20 and 22 degrees Celsius were selected, while for the cooling season, the range was set between 22 and 24 degrees Celsius. The CO_2 concentration threshold was defined at 1000 parts per million (ppm). As for particulate matter, the limit values suggested by the World Health Organization were adopted: below 25 µg/m^3 for PM_{10} and below 50 µg/m3 for $PM_{2.5}$. Furthermore, for volatile organic compounds (VOCs), the limit of 550 parts per billion (ppb) was chosen, following the guidelines of the US Environmental Protection Agency (EPA). This solution offers various advantages: firstly, it allows immediate visualization of the data collected by IoT devices and their correlation with specific spaces; secondly, it facilitates the analysis of recorded anomalies in relation to occupancy and class schedules of those spaces. This comprehensive approach provides valuable insights for maintaining a healthy and optimized teaching environment.

4. CONCLUSIONS AND FURTHER DEVELOPMENTS

The paper illustrated the research conducted under the umbrella of the UniTO's strategic plan, aimed at developing an AMS-app to optimize the management of one of the largest university assets in Italy. The replicable methodology developed for the definition of the app and its implementation in the organizational system was illustrated. The BIM-GIS-BI integration enabled to systemize the various information currently siloed managed, providing an integrated decision-support tool accessible starting from the territorial level to the single building and component. Through the illustration of several case studies implemented so far on selected buildings, the potential of this management system was illustrated, also highlighting the difficulties encountered and the margins for improvement. Such a system is easily replicable and showed true potential in being able to manage the available resources optimally and consciously. Both in terms of space and economics, it also allows for the optimized management of facility services and improved IEQ performance for the end-user experience, leading to effective and sustainable management. In the future, information protocols and guidelines will be developed for the proper adoption of such an AMS and the correct definition of the IRs. Furthermore, it is envisaged that the management processes currently underway will be reviewed in consultation with the heads of the technical-administrative areas aiming at the optimal adoption of the system, as well as the implementation of a data-sharing system exploiting a data lake from which to extrapolate the targeted information, identified based on the management processes and the defined IRs.

ACKNOWLEDGEMENTS

The authors thank the University of Turin for the case study and the availability of both administrative offices and technical areas. A special thank also to the colleagues Mirko Locatelli, Laura Pellegrini, Marta Boscariol and the BIMgroup lab from Politecnico di Milano for the participation and support.

TOWARDS A FRAMEWORK FOR RAILWAY NETWORK ASSETS MANAGEMENT BASED ON BIM/GIS INTEGRATION

Mattia Mangia & Carla Di Biccari
University of Salento, Department of Engineering for Innovation, Italy

Mattias Roupé
Chalmers University of Technology, Gothenburg, Sweden

ABSTRACT: *Complex infrastructures such as railway networks face increasing challenges related to resource allocation, external events, constraints, and demands. Therefore, it is crucial to optimize the Asset Management (AM) phase to ensure the value and functionality of the assets. The integration of Building Information Modelling (BIM) and Geographic Information Systems (GIS) can support this phase, but it can only yield benefits with a comprehensive approach that considers and addresses the specific needs and resources of the assets and their AM organization. The main benefits include improved data management, manipulation, information visualization and optimized resource allocation. This study describes an intermediate step towards developing a BIM/GIS integration framework for AM that can guide both researchers and practitioners. The framework aims to bridge theory and practice by incorporating insights from literature reviews and case studies. Its main objectives are to provide a comprehensive multi-stakeholder view and methods for effectively integrating BIM and GIS in this context. To develop the framework, the study employed focus groups, interviews, and practical BIM/GIS tests, which provided insights reported in this article. Furthermore, the study provides research directions for effective BIM/GIS integration in infrastructure AM.*

KEYWORDS: *Building Information Modeling, BIM, Geographic Information Systems, GIS, BIM/GIS integration, Asset Management, Railway*

1. INTRODUCTION

Railway networks, like other complex infrastructures, are affected by manifold challenges. Given their significance for societal improvement, they must provide increasingly high-quality services (Famurewa et al., 2015) while coping with external factors such as extreme weather and resource management (Garmabaki et al., 2021). Moreover, railway networks function as intricate systems, requiring adoption of complexity-based approaches in order to achieve effective management (Oughton et al., 2018). The improvement of the tools, processes and information management during the Asset Management (AM) phase and the Operation & Maintenance (O&M) phase is a key factor to address these issues and to implement an effective management of railway networks. O&M represents one element of the broader concept of (AM), which is defined as "the coordinated activities of an organization aimed at generating value from assets" (ISO, 2014). The O&M phase, being focused on the operational and maintenance aspects of the asset is commonly considered as a part of the whole AM phase, in which also strategical and tactical decisions about the owned assets are addressed (e.g., investments, risk management etc.). In particular, for infrastructure such as railways, a systematic approach is required in order to properly manage the assets and to avoid resource waste which would affect the benefits provided to society (Almeida et al., 2022). According to the National Institute of Standards and Technology (NIST), approximately 60% of the total life costs of built assets are accounted for in the O&M phase due to inadequate interoperability, leading to considerable wasted resources on information retrieval and poor data management (Gallaher et al., 2004).

As a technical solution, the integration of Building Information Modeling (BIM) and Geographic Information Systems (GIS) has been widely addressed both in literature and in practice. BIM is a widely adopted methodology that encompasses the entire AECO/AM sector (Architecture, Engineering, Construction, Operation, and Asset Management) and the complete life cycle of a built asset. BIM aims to promote collaborative processes and prevent information loss between phases, such as from construction to the AM phase. By means of parametric 3D models and standardized workflows and information exchanges, BIM allows to implement digital built environment asset management (Re Cecconi et al., 2017). BIM aims to address cost reduction and optimize related tools and processes. However, for effective BIM adoption in AM, asset owners and managers (in the role of appointing party as defined by ISO 19650) need to carefully assess which information and BIM uses are required. This process involves the definition of several requirements, as specified in ISO 19650, such as OIR, AIR, EIR, and PIR (Organizational, Asset, Exchange, and Project Information Requirements) (BS EN, 2019). In the context of AM, OIR and AIR serve as the primary sources of requirements for delivering the AIM (Asset Information Model),

derived from the PIM (Project Information Model). For most AM processes, 3D geometries become less relevant, while non-geometric data related to the asset, e.g., warranties, installation dates, etc. are more important. Furthermore, organizations managing infrastructures deal with diverse assets, including both punctual buildings and horizontal infrastructures like railways, roads, and pipelines. Infrastructural AM can benefit especially from BIM/GIS integration, due to the specific need of multi-scale approaches (Breunig et al., 2017). In fact, while BIM may provide detailed data about the asset itself, GIS complements it by representing data at larger scales. The aim of this research is to investigate and address the needs of railway network management through business-oriented BIM/GIS integration for AM. To link literature with practice, the final goal of the entire research is to provide a framework based both on current theories and the findings from case studies. The construction of the framework was guided by the following research questions:

- Which is the current status of BIM and GIS implementation by organizations in charge of AM of the railway network?
- Which are the main benefits and hindrances of BIM/GIS integration for the AM of complex infrastructures such as railway networks?
- How BIM/GIS integration should be implemented according to the business core of the organization in charge of AM of railway networks?

At the current state of the research, results from an Italian case study are presented. The subject of the case study is RFI (Rete Ferroviaria Italiana), a large public company responsible for managing the railway network in Italy. The case study was conducted through Focus Groups and semi-structured interviews. Subsequently, practical tests of both BIM and GIS software have been performed and discussed in order to highlight theoretical and practical implications of BIM/GIS integration for AM in the railway context.

1.1 Background

1.1.1 BIM/GIS integration

BIM/GIS integration is a topic that has been deeply investigated in recent decades due to its acknowledged multi-purpose potential. A key point of the topic is that methodologies for integration may vary significantly, occurring at different levels and with different tools (X. Liu et al., 2017). Moreover, BIM/GIS integration is affected by several issues and challenges at the geometric and semantic levels. Several methods, frameworks, and software prototypes have been proposed for different applications, such as flood damage assessment (Amirebrahimi et al., 2015), web-based bridge management (J Zhu et al., 2020), infrastructure asset management (Garramone et al., 2020), etc. In terms of semantics, a promising approach found in literature is the adoption of semantic web technologies, ontologies, and Building Linked Data (Pauwels et al., 2017). Liu et al. (X. Liu et al., 2017) proposed a ranking of the several BIM/GIS integration methods classified by EEEF criteria, namely Effectiveness, Extensibility, Effort, and Flexibility. Addressing these criteria is crucial because the choice of a BIM/GIS integration path depends on the needs of the specific case and context. According to these criteria, semantic web technologies have been ranked with a “high” score in Effectiveness and Extensibility, but also a “high” amount of effort required for the implementation. These criteria imply a cost/benefit analysis which is necessary for effective BIM/GIS integration. Linked to this matter, another recurrent trend found in literature is the almost forced adoption of commercial software for effective BIM/GIS integration. In fact, the adoption of ArcGIS PRO is recurrent, along with the one-directional approach “BIM to GIS” for data integration (Ma & Ren, 2017). Regarding the complex conversion of BIM to GIS files, FME software is also a solution frequently found in the literature (Junxiang Zhu et al., 2019). However, important efforts found in literature foster open-source approaches and tools (Jiang et al., 2019), because they may provide support to address the increasing complexity of projects, the need for better interoperability and the need to mitigate costs. Among relevant open-source tools, Cesium is an open platform for 3D geospatial data that may implement a 3D BIM/GIS environment (F. Liu et al., 2020), as long as BIM models are converted to other formats such as .gltf or .obj. The literature shows that BIM/GIS integration is a complex and multifaceted topic, which requires an in-depth contextual analysis. For this reason, this research attempts to contribute by providing a framework based on knowledge obtained not only from literature but also from specific case studies. Besides the technical challenges, BIM/GIS integration is also an organizational cultural and competence shift, thus it should be addressed according to the specific needs of companies and involved stakeholders.

1.1.2 Asset Management and BIM/GIS integration for infrastructures

When compared to previous phases such as design and construction, AM and the O&M phase are affected by peculiar theoretical and practical gaps when related to BIM. One of the reasons is that the object-oriented paradigm and the parametric approach provided by BIM authoring software tools are less straightforward to utilize in the context of AM. On the other hand, given that AM is facilitated by IT systems, leveraging BIM for automated information exchanges holds considerable promise and potential benefits. Furthermore, the primary standard for AM, namely the ISO 5500x collection (ISO, 2014), does not directly address BIM methodology. Instead, it relies on ISO 19650-3 (BS EN, 2019) as the main reference source. In comparison to GIS, BIM is relatively recent and lacks shared and well-standardized paths for AM. Several factors contribute to this situation. Firstly, AM suffers a lack of a structured framework of BIM standards and tools (Munir et al., 2019). Secondly, the IFC (Industry Foundation Classes) data model has only recently been updated to consistently represent railways with the IFC 4.3 schema release (buildingSMART, 2022). Lastly, the specification of OIR and AIR poses challenges for asset management companies due to unclear role of BIM in supporting their core activities (Hadjidemetriou et al., 2023). The conjunction of these factors hinders BIM or BIM/GIS adoption, with the risk to implement an ineffective change management from traditional to BIM-based AM (Jupp & Awad, 2017) thus nullifying the benefits of BIM adoption and resources invested (Dixit et al., 2019).

Despite the challenges of BIM/GIS integration, the literature still agrees on its need and expected benefits. For instance, BIM-based information exchange and storage standards may ease information retrieval and management, meanwhile GIS may provide analysis tool for the whole asset portfolio and its relation with environment and surroundings (Wang et al., 2019). However, fully unlocking the potential of integrating BIM/GIS for infrastructure AM requires a more in-depth investigation across strategic, tactical, and operational levels. The entire potential of BIM/GIS integration for infrastructure AM needs to be further explored at these levels (Garramone et al., 2020). Existing literature and available tools illustrate a promising scenario for achieving and effectively implementing BIM/GIS integration. To the best knowledge of the authors, in the current literature, organizations' awareness of possible benefits given by BIM-based AM approaches and solutions is not sufficiently considered, especially in the specific context of railway networks. To address this gap, this research aims to offer insights from an organizational perspective while conducting technical evaluations of both commercial and open-source alternatives.

2. MATERIAL AND METHODS

To answer the aforementioned research questions, a broader research has been undertaken as a multi-step process, of which a brief overview is provided in Figure 1.

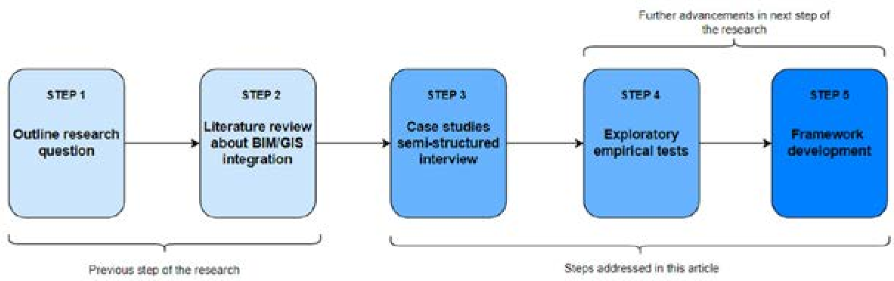

Figure 1 Overview of the multi-step research.

The work presented in this article follows a systematic literature review (SLR) concerning BIM/GIS integration (Mangia et al., 2022). Building upon the findings from this initial step, the focus was subsequently narrowed down to a specific life-cycle phase and asset class, namely the AM phase and transport infrastructures. Following this, two case studies (involving RFI and Trafikverket, respectively) have been conducted to answer the research questions. In this work the RFI case study is presented, and case study methodology is defined as an in-depth investigation of a particular subject, such as a group, organization or phenomenon in a real-life context (Crowe et al., 2011). The case studies have been addressed by means of four main activities:

1. Data collection by means of semi-structured interviews (SSIs) and focus-group;

2. Data processing;
3. Tests and experiments with several BIM and GIS-based software;
4. Evaluations of the key elements of a framework for business-oriented BIM/GIS integration.

Data collected in activity 1 are mainly related to the following two topics:

- Existing AM, GIS and/or BIM systems employed by the company;
- Awareness of benefits obtainable from BIM and BIM/GIS integration for the business core of the company.

Activity 1 was carried out across multiple sessions. The Focus Group method was selected as it facilitated the involvement of RFI departments interested in BIM/GIS integration and allowed confirmation of the authors' hypothesis: "BIM is not yet a well-established tool adopted in the core business and it lacks a standardized integration approach with existing systems." The focus groups engaged personnel from various RFI departments that could potentially be impacted by BIM/GIS integration, such as AM/ERP system users and administrators, GIS users, and others (Table 1). The researchers, acting as focus group facilitators, were able to provide a common and shared understanding of BIM/GIS integration opportunities and limitations and to receive feedbacks from different perspectives.

Table 1 List of participants of focus groups and interviews.

Department	Executive Manager	Maintenance management	InRete.2000 system support	MUIF support	Asset Management
Interviewees	N°1	N°2, N°3, N°4	N°5, N°6	N°8, N°9	N°10, N°11

In addition to this, semi-structured interviews were conducted with each business unit to delve deeper into the investigation and to pose specific technical and organizational inquiries to each interviewee. The "Data processing" activity involved the analysis of the information retrieved from the Focus Groups, interviews and related documentation provided. Knowledge about company-level standards, demonstrations of existing systems and datasets were provided for processing. This led the authors to the "Tests and experiments" activity, in which a series of exploratory experiments with several BIM and GIS software and tools were performed. The objective of these tests was to identify and assess a list of "key-elements" which the framework should address (i.e., the fourth activity of this research). For the tests and experiments, QGIS was employed for inspecting and extracting data from the geodatabase provided by RFI. Autodesk Revit and Bentley OpenRail Designer were used as BIM authoring tools to create simple 3D models of different types of assets (such as buildings, railway tracks, and sidewalks). Autodesk InfraWorks was utilized to present a 3D BIM/GIS environment for Proof of Concept (POC) purposes. The IFCjs and ifcopenshell software libraries are currently under test in order to extract data from IFC BIM models and evaluate web-based BIM/GIS viewers. Taking into consideration the outcomes of focus groups, interviews, and software tests, the final step of the broader research will concentrate on developing the framework for BIM/GIS integration for AM.

3. RESULTS

In this section the results obtained in the scope of the Step 3 and 4 reported in Figure 1 are reported. These results provided the conceptual and practical foundations which drive the ongoing development of the framework (i.e., Step 5) discussed in Section 4.

3.1 BIM potential for existing systems

One of the pivotal results for the development of the framework is the identification and analysis of existing systems. This information is one of the two main results retrieved from the Data Collection and the Data Processing activities. The second main result is addressed ins sub-section 3.2. RFI adopts two primary information systems for AM that have potential for integration with BIM. The authors were presented with comprehensive demonstrations of these systems during the interviews. The examination of the systems currently utilized by RFI supplied essential insights for assessing BIM/GIS integration options and addressing the initial research question.

A schematic overview of the two main systems is provided in Table 2.

Table 2 Overview of the two RFI system investigated.

System	Type	Data involved	Tasks performed
InRete.2000	ERP	SeTe's data model, master data sheets	- Translation of infrastructure projets into a railway network model composed of locations and routes. - Censorship the railway network assets by means of a compiled master data sheet (e.g., train stations, railways). - Management and maintenance tasks of every asset of RFI (e.g., asset is in function or surpressed, failure management etc.).
MUIF	WebGIS	Geodatabase consisting of 2D GIS layers, DTMs photospheres and 3D pointclouds.	- Context and asset visualization at the macro-, meso- and micro-scale. - GIS spatial analysis (e.g., buffer zones). - Bi-directional linkage with other RFI systems for AM and O&M (e.g., route interruption).

The first system is InRete.2000, a customized version of SAP AM software. It is an Enterprise Resource Planning (ERP) software which supports the management and maintenance of the railway network infrastructure. Based on RFI data model, assets managed with InRete.2000 are represented by means of two entities, namely called "Sede Tecnica" (SeTe) and "Equipments". SeTe entities serve to represent spatial structures or components that require maintenance, such as train stations and tracks. "Equipments" refer to physical objects installed within SeTes. Each SeTe and Equipment is assigned an ID within InRete.2000, referred to as the "Code of Sede Tecnica," which establishes semantics and hierarchy among the assets. Information within a SeTe is populated through on-site surveys, manual checks, and operator input. A SeTe is composed of sets of data and metadata, such as its location, working status, maintenance activities etc. In InRete.2000, a SeTe's record acts as a master data sheet for the respective entity. The hierarchical decomposition of SeTes mirrors the network model adopted by RFI. In particular, the railway network (which is a SeTe of first level) is characterized by two main elements: "Località" (Locations, code LO0000) which constitutes the nodes and "Tratte" (Routes TR0000) as the edges of the network.

Presently, InRete.2000 lacks geometrical and geographical visualization for SeTes, which is instead provided by MUIF (Modello Unico dell'Infrastruttura – Unified Infrastructural Model) in the form of a web-GIS application. MUIF is a long-term project initiated to establish a common information system supporting the business logic of each department of RFI. MUIF encompasses information about all assets within the rail network managed by RFI, facilitating the tracking of related data, visual representation of asset physical aspects, and verification of their geographic locations. The geodatabase predominantly comprises shapefiles, Digital Terrain Models (DTM), photogrammetric data sources like point clouds and orthophotos. Both InRete.2000 and MUIF are firmly established as essential tools for RFI, supporting their core business functions. These systems enable activities such as failure management, maintenance orders, route interruptions, and more. The former is employed for the management and maintenance of the railway network, and at the current state it is bi-directionally linked with MUIF by means of the hierarchical ID named "Code of Sede Tecnica". In addition, MUIF users may inspect a part of the railway network by means of photo-spheres and point clouds as shown in Figure 2. However, the 2D maps and the 3D point clouds are displayed in two distinct frames within a browser page, thus a unified 3D web GIS environment is not implemented yet. According to the interviewees, BIM holds potential for integration with existing systems, since it could significantly improve several processes such as context inspection and information retrieval. With BIM, detailed asset-level 3D models and information could be readily accessible, both for large entities as SeTes and for small ones like Equipments, which can be challenging to represent in MUIF despite their presence in InRete.2000. Moreover, the hierarchical data model of assets managed can be reflected in BIM components with dedicated attributes, which needs to be specified by RFI in its AIR. Working as an ID, these attributes may also partly overcome the needs of semantic which will be provided by the release of the new IFC 4.3 version.

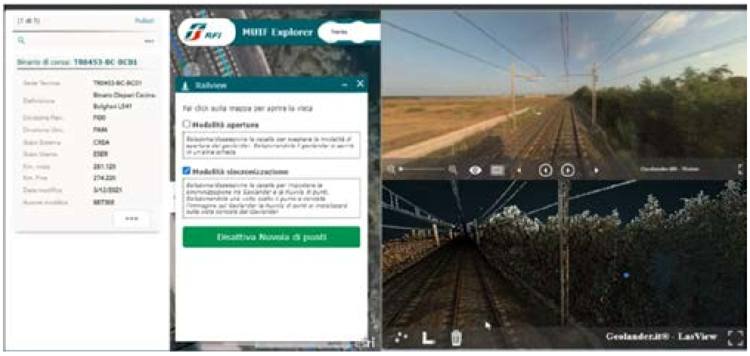

Figure 2 Screenshot of MUIF point clouds and photospheres to integrate the 2D GIS environment.

3.2 BIM and GIS state of the art in the organisation

The interviewees provided a comprehensive and multi-perspective overview of the current status of BIM and GIS within the organization. From the analysis of the Italian case study, as the second main result of the Data Collection and Data Processing activities, the researchers identified key concepts that need to be considered for the development of the framework:

- BIM: While existing systems have not yet fully integrated BIM, the organization actively participates in various BIM pilot case studies and work groups to test and implement BIM led by buildingSMART initiatives;
- The existing systems are undergoing continuous strategic development, making disruptive software changes impractical. Therefore, BIM should be integrated into the existing systems without severe changes to the system architecture;
- Several commercial vendors of AM systems already offer BIM-plugins in the AM environment, including SAP;
- Asset management personnel currently lack autonomous access to relevant data and technical drawings of assets (e.g., plants, sections), where AIM CDE linkage could provide support;
- BIM data and models can enhance several manual processes, such as InRete.2000 datasheet filling and on-site inspections;
- Organizations involved in AM of infrastructures are typically large, and implementing changes and processes can be costly and time-consuming;
- Vendor-agnostic approaches for information exchange, like OpenBIM, are vital since these organizations will mainly receive BIM-based data in open formats such as .ifc or COBie-compliant datasets. It also supports BIM/GIS integration thanks to IFC model conversion to 3D GIS formats;
- The prevailing notion regarding BIM models is that they become static data sources stored in the AIM CDE after project handover. However, there is potential for dynamic BIM utilization in the AM context, involving data management and manipulation tasks.

To support these conceptual foundations, the authors conducted experiments and tests to gather insights on how BIM and GIS data can be effectively managed according to business needs, current system limitations, resources, and requirements.

3.3 Test and experiments on software applications and tools.

Throughout the design and handover phases, specialized tools are employed to facilitate iterative and extensive data manipulation activities for generating BIM models. The authors sought to explore the applicability of these tools for Asset Management (AM) purposes and conducted tests on two software solutions: Autodesk Revit's Dynamo plug-in and the "Asset Manager" tool in Bentley OpenRail Designer CE Edition. Both tools enable users to carry out batch operations, including property set and properties creation, parameter updates, and more. Dynamo adopts a Visual Programming Language (VPL) with a graphical user interface (GUI) to facilitate script development, although some level of programming familiarity is still necessary. Conversely, the "Asset Manager" tool follows an approach more aligned with traditional AM systems and user experience. It employs pre-structured Excel files, allowing users to batch assign property sets and properties to the necessary entities. This tool expedites the rapid incorporation of especially pertinent data for integration with InRete.2000, such as the "Sede Tecnica" ID and the class code. The tests began with the creation of a BIM model of an actual location using data and documentation provided by RFI, which included a geodatabase (.gbd) containing point clouds, 2D shapefiles of the asset, digital terrain models (DTM), and orthophotos. Furthermore, RFI guidelines and the class database of the “Sede Tecnica” classes were made available. These tasks were conducted in the “BIM model creation” step shown in the overall workflow is summarized in Figure 3. Once the BIM models have been developed, the authors wanted to employ them both with commercial software (i.e., Autodesk Infraworks) and open-source tools (ifcopenshell, IfcJS). In this article, we acknowledge that only the workflow “BIM/GIS viewer POC” is introduced and discussed; however, a comprehensive discussion of the “BIM web-based viewer and AM module” workflow is intentionally omitted because it is still in development and to avoid an excessive length of the article.

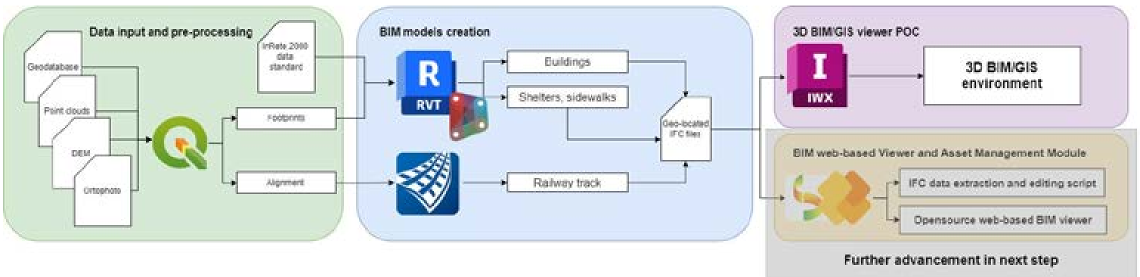

Figure 3 Workflow of the different software and tools tests performed in this study.

Shapefiles provided the asset footprint and alignment, along with coordinates and InRete.2000 data. These data were used to develop the BIM models. Buildings were modeled with Autodesk Revit (2022-2023 version), with simple architectural models linked together to provide an overview idea of a set of contiguous assets. From QGIS, as shown in Figure 4, the “Info Project” pop-up window is shown with the two most important data, namely the ID of the “Sede Tecnica” and the class code of the InRete.2000 data model. To replicate the attributes and values of the data from the shapefile attribute table to the BIM models, several paths can be undertaken after the export of the table in a spreadsheet.

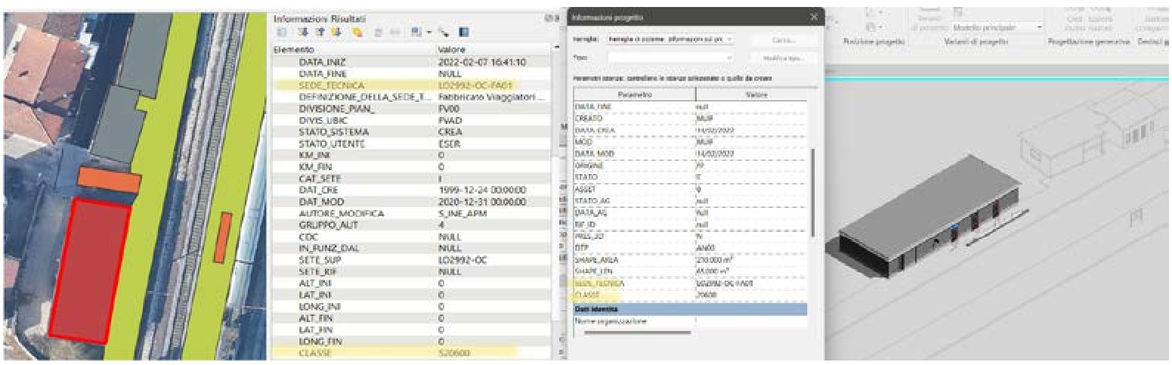

Figure 4 Shapefiles in QGIS (left picture) and derived BIM models (right picture.)

In Figure 4 is also reported a 3D view of the model, with the other developed models attached to check the correctness of geolocation data. Data at “asset-level” has been assigned to the “Info Project” entity in Revit. During the export to IFC files, information about the main SeTes representing the nodes and the edges of the railway network can be associated to the IfcProject or IfcBuilding entity. To handle the large amount of data that should be added to or extracted by BIM elements, batch parameters procedures are an opportunity to save time and reduce errors. Shifting to Bentley OpenrailDesign CE, the same process has been performed for railway tracks using the Asset Manager pre-structured excel files. These two workflows were shown to the interviewees, for feedback collection. Both the aforementioned processes require commercial software, even if an IFC file is used. These kinds of tasks are typically performed by designers (usually not an RFI employee). However, the authors are confident in the idea that companies like RFI may adopt similar tools for the management of data inside their AIM BIM models. In fact, these tools provide semi- or automated procedures for data extraction and manipulation which can ease the link of BIM models with InRete.2000 and MUIF. For this reason, the IfcOpenShell and IfcJS library are also under test to implement sample scripts for extracting, validate and store data in JSON or CSV format for information exchanges with InRete.2000 and MUIF, based on REST API protocols. Compared to commercial software, these libraries allow to develop bespoke script for the extraction and manipulation of data from IFC models. However, this improved flexibility and interoperability requires dedicated team of developers compared to “out of the box” commercial software, and thus companies such as RFI needs to evaluate which alternative best suit their needs and capabilities.

In addition to the criticalities regarding information management and exchanges, interviewees raised an issue regarding the limitations of MUIF for precise measurements and inspections despite its ability to visualize 2D GIS layers, point clouds, and 360° photos. They expressed the need for a more reliable tool, such as BIM models, to facilitate indoor inspections, object data retrieval, and accurate measurements. For this reason, two alternative integration pathways were discussed. The "basic" integration involves BIM models being integrated into MUIF similar to point clouds and 360° photos, connected to the 2D GIS environment via a URL inserted in an attribute field of 2D GIS shapefiles entities. The "basic" integration, therefore, involves a process-level integration where BIM and GIS data are not manipulated or converted into each other's formats. However, according to the interviewees, this integration can already enhance the aforementioned tasks. Conversely, an "advanced" integration would establish a unified environment where 3D BIM and GIS geometries are visualized together. This advanced integration could be achieved through open-source tools like CesiumJS or QGIS, as well as commercial software options like ArcGIS PRO and Autodesk ESRI GEOBIM. For the purpose of this research, Autodesk InfraWorks, as depicted in Figure 5 was selected because it readily provided a proof of concept for a 3D BIM/GIS environment. The interviewees conveyed that such an environment would yield significant benefits to their core business tasks, providing enhanced context visualization, multi-scale dimensioning and data aggregation at larger scales. However, despite recognizing the advantages of the "advanced" approach, the interviewees exhibited a stronger interest in the "basic" integration due to its easier implementation. While the "advanced" approach was seen as a desirable future goal, the interviewees identified complex change management efforts as the main hindrance to its company-wide implementation.

Figure 5 Infraworks 3D BIM/GIS environment for proof of concept.

4. DISCUSSION

Upon the findings of the Focus Group, interviews and experiments, two relevant points of discussion were identified. The first one focuses on the technical aspects of the BIM/GIS integration for infrastructure AM, discussing two alternatives which could be implemented in the short- or mid-term. The second point is about the organizational aspects, which according to the authors should require a deeper investigation in future works.

4.1 Pathways of BIM/GIS integration for AM

For the “Test and experiments” of this study (sub-section 3.3), a limitation is that Semantic Web Technologies have not been tested. This is due to the fact that RFI currently relies on relational databases, and transitioning to more advanced tools like graph databases and ontologies may present a challenging change management effort while a full BIM adoption is still in progress. According to the outcomes of the “Test and experiment” activity, the development of custom scripts and software to link the BIM AIM CDE with existing systems could prove advantageous for AM activities by reducing error-prone manual data management. The interviewees expressed positive feedback regarding several functionalities available within BIM authoring tools, particularly the Visual Programming Language (VPL) features of Dynamo. As a result, the authors suggest that a potential AM-specific BIM solution could incorporate VPL or similar tools as one of the possible modules to enable guided scripting for AM purposes.

Regarding the second research question, it was found out that the answer hinges on the chosen approach and thus it is strongly correlated to the third research questions (i.e., how to integrate BIM and GIS). For these reasons, in this work two approaches are considered, named “basic” and “advanced”, yielding distinct outputs in terms of benefits and hindrances. The "basic" integration primarily involves linking BIM models and shapefile attributes with tailored scripts for data management. This integration allows for converting simple data and geometries from BIM models into the GIS system, such as footprints and project-level information. In the MUIF web-environment, BIM models can be accessed as a separate frame by clicking on the GIS 2D representation. Despite its simplicity, this level of integration already provides benefits for maintenance tasks such as census activities and on-site inspections. For asset management and maintenance tasks, non-geometric data are commonly related to the asset itself and does not require an intensive integration with territorial data. However, efforts and resources must be dedicated to developing solutions for managing non-geometric data and handling sets of properties across multiple systems, using the "SeTe ID" as the matching key. Following an OpenBIM approach, a BIM-viewer inside MUIF web application can be implemented by means of IFCjs or ifcopenshell libraries avoiding intensive rework inside the existing system.

Conversely, the "advanced" integration unlocks the potential for converting conventional 2D spatial analysis into a dynamic 3D realm, seamlessly incorporating attributes like elevations, building stories, BIM components, and more within a comprehensive 3D BIM/GIS environment. The primary advantage of this approach lies in the amalgamation of asset-specific and territorial data within a single interactive environment, enabling querying and management capabilities across diverse assets, such as multiple BIM models of railway bridges. In contrast to the "basic" integration, where each BIM model resides within its individual window frame, the "advanced" approach facilitates asset-specific data analysis on multiple models coherently. Moreover, 3D BIM/GIS visualization contributes to increased awareness of the impact of the asset in the environment compared to its footprint on a 2D GIS map. Thus, the “advanced” approach allows for a comprehensive 3D model of the railway network assets alongside other assets (e.g., from third party sources) and digital terrains. However, its implementation is more complex and costly, especially with open-source approaches, due to the technical pipelines and workflows required to utilize BIM data in a 3D GIS environment. There exists a clear trade-off in benefits between the "basic" and "advanced" integration. While 3D BIM/GIS models enable 3D spatial and data analysis, achieving it demands intensive efforts with open-source solutions or the adoption of commercial software. In perspective of the development of the framework, a “integration layer” should be conceptualized to highlight that the choice of a BIM/GIS integration approach directly influence the “business layer”.

It is also important to consider the recent advancements of the latest version of the IFC schema, i.e., IFC 4.3. Even if crucial for semantic interoperability between BIM-based software, it is worth noting that in the AM context the link with other systems may be driven by specifying an attribute which allows companies to implement its company-level data model or classification systems. In the case study performed with RFI, the “Code of Sede Tecnica” attribute implemented in the BIM model act as a global ID of the asset throughout the other systems such as MUIF and InRete.2000. This approach can ease both the implementation of the “basic” and “advanced” integration, since it enables a certain degree of interoperability even if several elements in the BIM modeles needs to be exported in IFC files as IfcBuildingElementProxy entities.

4.2 BIM/GIS integration insights for framework development

Given the expansive nature of BIM/GIS integration for AM, it is essential to approach it at the organizational level as a systematic, step-by-step process, delineated into "modules" or "key functions". This segmentation allows for the assessment of enabling technologies, prioritization, benefits, challenges, and other pertinent aspects for each module. For instance, one module could pertain to the "BIM/GIS viewer," evaluating its necessity and applications. In this context, the aforementioned "basic" integration would enable swift asset location on GIS, while inspections would be conducted using a BIM-only viewer. On the other hand, assessing how a BIM model of a railway route interacts with train stations necessitates a 3D BIM/GIS viewer, as envisaged in the "advanced" integration. Another illustrative module could be "AM data analysis," aiming to empower BIM/GIS-based business intelligence and data analysis tools. The adoption of this modular approach mandates the formulation of a well-considered change management strategy that aligns with existing information systems, processes, and staff competencies. Without such a strategy, companies might choose counterproductive BIM/GIS integration solutions. While advanced solutions may seem preferable, adopting a modular mindset enables companies to opt for a cost-effective "BIM/GIS viewer" module while concentrating greater resources on other modules. Therefore, concerning the third research question, organizations should strive to associate the benefits of modules with particular tasks, such as utilizing a 3D BIM viewer for asset-wise measurements or employing a 3D BIM/GIS viewer for context-wise measurements. The framework currently in development not only aims to provide a module-based view of the problem, but it is also linked to the primary concerns and needs emerged from the semi-structured interviews and Focus Group outlined in the sub-section 3.2. It's worth noting that both the "basic" and "advanced" does not serve as substitutes for MUIF or InRete.2000. Furthermore, modularity enables changes to be implemented incrementally. For example, if only a BIM-based data exchange for InRete.2000 is required, it can be developed without the need for investment in a BIM/GIS viewer. However, it is important to emphasize that these assumptions hold true if there is a comprehensive understanding of the existing systems employed, as they will inevitably impact the effectiveness and significance of BIM/GIS-based modules and tools in relation to business activities and objectives.

As a future work, the authors aim to embed this concept in the development of the framework, highlighting this "modularity by design" approach for the specific case of RFI as a novel contribution to the current body of knowledge. This approach is intended to provide the framework with a certain degree of generalization, since it is also meant to be a replicable tool for asset owners responsible for other kinds of infrastructures. In the AM phase, BIM is addressed by means of AIM. Since they are considered the backbone of Digital Twins (DT) (Lu et al., 2021), the framework is also intended to be extendable with modules regarding other technologies and tools such as Internet of Things (IoT), Machine Learning (ML) and Virtual/Augmented Reality (VR/AR) (Johansson & Roupé, 2022) which could uplift AM activities. However, these strides necessitate preliminary steps, and BIM/GIS integration is among the most intricate. Compared to previous researches, the ongoing work presented in this article aims to provide a connection point between the advanced proposals found in literature (e.g., semantic web technologies, brand new BIM/GIS systems) and the short- and mid-term needs of organizations involved with AM. Hence, this work addresses the second research question by offering guidance and assessment on implementing changes within existing systems. As a theoretical implication, this research aims to contribute providing two research directions. First, a BIM/GIS integration approach specific for AM should take in consideration the feasibility and the concept of "modularity" and to "innovate with the lowest degree of changes required to the overall existing system architecture". The second research direction is related to the analysis of specific BIM requirements for AM software features and the definition of core skills and needs of a "AM-BIM specialist". Unlike prior phases, the escalating significance of non-geometric data, the pivotal role of open non-proprietary formats, and the dynamic nature of working with AIMs highlight the need for a professional role currently undefined. Furthermore, while BIM authoring tools in earlier phases evolved naturally from preceding tools (e.g., AutoCAD), BIM/GIS-based AIM software poses challenges as it requires integration into existing AM systems. In light of this, the authors recommend investigations into change management for AM-specific BIM/GIS integration, spanning tool prerequisites and professional roles encompassing competencies, core skills, and training.

5. CONCLUSION

The work presented in this paper marks an intermediate stage within an ongoing research endeavour focused on the development of a BIM/GIS integration framework for efficient assets management in the railway context. Starting from this, the framework will be enriched by insights derived from literature, two case studies, and experiments with both open-source and commercial software. Tests involved the creation of simple 3D BIM models from existing data sources, batch data manipulation and BIM/GIS representation alternatives. As a future work, the authors plan to extend the applicability of the framework to complex infrastructures beyond railways. One limitation of this current work is its reliance on the perspective of an Italian case study; thus, a future Swedish case study is being developed to enable a comparison and generalize the framework's applicability. Another limitation lies in the exclusion of widely discussed software like ArcGIS PRO and FME. Instead, Autodesk

Infraworks was selected for the purpose of the proof of concept. Additionally, the company's unfamiliarity with semantic web technologies restricted the inclusion of this technology in the study.

The results of this work are geared towards contributing to two distinct research directions. Firstly, pertaining to the technical facets of BIM/GIS integration for infrastructure asset management, the suggestion is to explore alternatives that can be readily comprehended and implemented by companies. This implies that BIM-based solutions should be approached more as adaptive tools designed to seamlessly integrate with existing GIS and AM systems. This is preferable to introducing disruptive, entirely new systems that would necessitate significant investments and comprehensive system overhauls. The second research direction focuses on organizational aspects. Change management emerges as a pivotal factor in BIM/GIS integration and should be closely aligned with the operational, tactical, and strategic levels of asset management. Several tools and procedures can be tailored from BIM software employed in earlier phases to benefit asset management. However, this adaptation necessitates a profound comprehension of the organization and may warrant the establishment of novel professional roles, such as AM BIM specialists. The final goal of this work is to contribute to the body of knowledge by addressing this multidimensional problem suggesting “modularity” as a key concept for BIM/GIS integration-based AM frameworks. Regarding this, future works in this research will address the complexity of the technical alternatives declined with the capabilities (i.e., resources, staff training, tools etc) of organizations. It is important to note that, without effective change management, companies might encounter counterproductive BIM/GIS integration efforts, which could substantially impede investments intended to enhance the quality and functionality of critical and complex infrastructures, such as railway networks.

ABSTRACT: *Enterprise resource planning (ERP) is an integrated business management system aimed at monitoring and maximizing resources and efficiency; on the other hand, Building Information Modelling (BIM) represents a broad series of approaches to design, based on the development of virtual models that cover the building's whole lifecycle. The integration of ERP systems within the Architecture, Engineering and Construction industry, while promising, has yet to reach the same results that its use has achieved in other fields. Although BIM and ERP are traditionally systems employed in different disciplines, they both deal with data integration and customization, and are designed to reconcile varied and scattered information. A mutual incorporation could allow for a more comprehensive understanding of the project starting from the initial phases, while also granting a more streamlined construction process and a reduction in errors and complications later on. The aim of this paper is to identify the possible connections between the two systems examining a case study, starting from an analysis of the current state of the art regarding this implementation, and by evaluating both the existing limits and the future possibilities of this implementation, for both small and medium enterprises (SMEs) and the industry at large.*

KEYWORDS: *Enterprise Resource Planning (ERP), Building Information Modelling (BIM), Small Medium Enterprises (SMEs), AEC, Construction, Data integration*

1. MANAGEMENT INFORMATION SYSTEM AND ENTERPRISE RESOURCE PLANNING

1.1 Brief history of ERP

Enterprise Resource Planning is a type of business information system meant to manage and monitor all the resources within an organization. Introduced in the 60s within the manufacturing industry as Material Requirement Planning (MRP) (Lee, Arif, & Halpin, 2002), the system mainly focused on the storage and allocation of materials. In 1975 IMB then developed the Manufacturing Management and Account System (MMAS), now considered the true precursor to ERP (Jacobs, 2007): the system was aimed at creating ledger postings, job costings and related forecasting updates based on the inventory status and order transactions, while also generating orders using a standard Bill Of Material (BOM).

The consequent technological growth enabled, during the 80s, the development of the Manufacturing Resource Planning (MRP II) system, which allowed the integration of functions related to human resources and marketing, as well as the management of all financial and accounting information (Kumar, & Van Hillegersberg, 2000). The ability to manage and update orders, inventory and financial transactions in a single system, allowed the companies to replace and centralize multiple typically stand-alone systems with a single software, resulting in easier communication between different areas and the automatization of data sharing.

However, the term ERP wasn't coined until 1990 by Gartner (Katuu, S. 2020), in order to describe a new generation of unified systems that could manage different departments within the same company, and that were based on the standardization and integration of processes within a single, shared database. This new type of management software also dealt with back-office data, financial transaction, marketing, and all the information related to all the different production stages, from planning and procurement to transportation and delivery. A rapidly growing business, ERP sales crossed the $10 billion mark in 1998 (Shi, & Halpin, 2003), with companies like J.D. Edward, Oracle, PeopleSoft, Baan and SAP surpassing IBM and positioning themselves as leaders in the ERP market. A critical factor in the success and spread of the software was also the so called Millennial Bug, or Y2K Problem, which was thought to cause global electronic damage due to how programs used to format year dates; in order to prevent possible informatic problems at the switch of the millennium, many companies took advantage of the

Paola Federici, Daniela Julea, Sara Comai, Kavita Raj, Silvia Mastrolembo Ventura, Giuseppe Rigamonti, Giorgio Paolo Maria Vassena, Angelo Luigi Camillo Ciribini, *Integration Between Enterprise Resource Planning and Building Information Modelling,* pp. 443-453, DOI 10.36253/979-12-215-0289-3.43

necessity to update their own software and implemented ERP systems, cementing the software's consolidation in the industry.

Despite a promising start and initial accounts reporting a Return On Investment ranging from 30 to 300% within a year after installation (Shi, & Halpin, 2003), many failures were also accounted: the main problems were mostly related to the initial costs of purchase and installation - which, at the time, varied from $2 million to $130 million (Ross, 1999), and the time needed for full implementation, as well as the likelihood of a performance dip during the stabilization phase of the software, which was expected to typically lasts for four to 12 months. By 2002 all main ERP distributors faced a significant stock plummet: Baan had fallen off by then, and J.D. Edwards and PeopleSoft opted for a merger between the two companies, since there was very little overlap between what the two software offered and the joint venture was thought to, in this way, manage to exceed SAP and Oracle (Jacobs, 2007); nevertheless, Oracle itself took over the merger after a few days with an hostile takeover, leaving itself and SAP as the main distributors.

In the meantime, a new system was being developed: Extended ERP, or ERP II, not only allowed for real time access to information and immediate data sharing between members of the company, but also had managed to integrate two other software, Supply Chain Management (SCM) and Customer Relationship Manager (CRM), which could manage interactions with suppliers regarding procurement and transportation, while also handling clients' data (Al-Amin, Hossain, Islam, & Biwas, 2023). The advent of the digital era, paired with the difficulty for Small and Medium Enterprises (SMEs) to bear the software's implementation and managing costs, resulted in the development of Cloud-based ERP systems: in this case, the system runs on the provider's cloud platform as opposed to an on-premises hardware that needs to be handled by a IT team employed by the company. Traditional ERP software, developed for an easier but less flexible management than what the market requires today, have been proven to be insufficient in handling the complex internal processes required within an enterprise, as they are not able to grant the same streamlined integration that a cloud system can offer.

Many possibilities are viable today considering the advancements of technologies within the 4.0 Industry, one of which could be the development of ERP Mobile platforms, accessible from smartphones through internet connection, and that could allow for easier and instant access to information and more customization possibilities. The introduction of AI and Machine Learning could also quicken processes, thanks to the prediction of inventory status and the atomization of repetitive processes, as well as error predictability; the integration of IoT solutions, such as smart sensors, could, too, facilitate the monitoring of materials and equipment within the supply chain.

1.2 ERP within the construction industry

1.2.1 State of the art

ERP systems are currently used by construction companies in order to:

- Improve customer response time;
- Improve relationship with suppliers while also strengthening the supply chain all together;
- Increase organizing flexibility;
- Reduce time related to decision making processes, as well as the competition times and related costs.

Considering the great level of customization that this kind of management system can offer, it might seem impossible to define a standard ERP software for an industry like the AEC (Architectural, Engineering and Construction) one, which is incredibly fragmented and characterized by different areas of work, each one of which has its own particular needs, usually related to the specific project currently being worked on. As Helo and Szekely (2005) mention, many are, in fact, the benefits that an ERP system can provide, such as the possibility to immediately develop a Master Production Schedule which allows sales orders and forecasts, the creation of purchasing orders for suppliers and production orders for plants, the constant update of inventory statuses updated depending on procurement and delivery status, and tracking of financial records of both the customers' orders and the company's internal status regarding payroll and suppliers payments. Integrating an ERP system inside the company can help manage all this information within one single centralized software, allowing for a more streamlined sharing of data, which can prevent errors or duplicated records during the various stages. This implies a sort of standardization of processes that, while it can result in more transparency and rapidity during the processes and, all around, a general improvement of performance, clashes with the nature of the construction industry.

Multiple attempts have been made in order to push the industry towards the same levels of efficiency that this kind of implementation brought to other branches, while failing to get the same results (Gavali, & Halder, 2020): the outcomes achieved by sectors that rely on standardized mass production such as the production and manufacturing industry – industries ERP systems where developed by and for (Kumar, & Van Hillegersberg, 2000) – seem to be unrealistic for construction companies, which work instead on a project by project basis and where every case is characterized by specific needs related to not only the requests of the client, but also are dependent on the different and multiple teams working on the project itself, which vary often and might end up working together for the first time. As Yang et al (2007) noted, the Construction Managements packages offered by commercial ERPs cannot provide a once-and-for all model for all industries, much less for construction firms, especially considering how the level of digitalization and use of IT solutions within the industry is still very low and far from the rationalized and mechanical nature of other sectors.

Though, as of today, this type of technology cannot manage a reality so fragmented and unpredictable nor the increment of complexity within projects, the flexibility required by 4.0 Industry, and the recent development of technological advancements, require the establishment of a new type of interoperability between systems and a new way of designing and planning.

1.2.2 Construction Enterprise Resource Planning

According to Augenbroe (2006), an ERP system can be divided in two interfaces, one related to the project and one to the financial aspects: the development of a stable and clear link between the two – granted by a common access to the financial data, project data and customer data - is essential in order to allow a more streamlined planning and decisional process. In the construction industry in particular, the system should be project-oriented, since the project itself is the cornerstone of the financial activities: in order to ensure the handover of the construction within the established timeframe and costs, an efficient organization of the ERP system is needed.

As explained by Dudgikar et al (2012), the software allows the company to manage its own resources, split into:

- Manpower, meaning the definition and planning of the workforce, as well as identifying the teams and the skills required, especially if the work requires the introduction of subcontractors and their crews within the project;
- Materials, which groups all processes aimed at materials planning, programming, and their purchase, inventory control, materials transportation and handling on site;
- Machines, which handles, for example, the acquisition and management of all the equipment, and the identification of the tasks to be undertaken by said mechanical equipment;
- Money, including financial forecasts, project budget and cost control measures.

The company, then, needs to coordinate not only internal resources (workforce, equipment, inventory …) which can be handled directly, but also various external influences (suppliers' transactions, subcontractor relationships, market situation …) from which it depends on. Whoever is tasked with the decision-making process has then to manage a vast quantity of information that belongs to different areas, and that must also be properly recorded and shared.

Shi & Halpin (2003) developed the so called Construction Enterprise Resource Planning (CERP) system, an internet-based framework that develops in three tiers: one related to the User Interface, related to clients' management and data, one related to the Management Servers, which provides administration and the link between the other two levels, and one related to Applications, which includes the database of the system and all the project and materials information. This type of system can offer immediate access to all the data, granting better performance and quickness within the decisional stage; by being a cloud-based system, this system also supports a more transparent and collaborative process, as all information is stored within the system itself and is readily available to everyone, and can be traced to the person tasked with the transaction or the decision made.

The main obstacles of these applications can still be ascribed to the costs and time required for implementation and development of the systems, and the lack of software and modules that can handle the complexity of the processes typical of the construction industry. While the aim of these systems is to standardize and automate the workflow, so that every individual can access and use them easily, the landscape of this industry is still too fragmented and requires a level of specificity often incompatible with these goals.

1.3 ERP-BIM Integration

A potential integration between ERP software and BIM models could be one of the viable solutions aimed at facilitating the implementation of ERP system in construction companies. The status of this integration is, nowadays, still at the embryonal stage: the first pursuits focused on the attempt to connect the manufacturing data to the information related to the construction processes by exploiting 2D CAD files, but failed to define an efficient information-centric approach that could establish a proper integrated work frame (Holzer, 2014).

Within the multiple causes of these undeveloped integrations between the two systems, the main one can be traced to the slowness of the AEC industry in implementing solution related to the digital management of the designing and planning stages: the creation of digital and parametric virtual BIM models is still too underdeveloped in many companies, and rarely this way of modelling also takes into consideration the procurement or the construction process. Particularly, SMEs are especially the ones struggling with the development of these systems, mostly because of the lack of properly developed IT systems, which would allow for a more digitized process. As Ghosh et al (2011) point out, the time and costs implementation and management of these software is, once again, the main cause, as well as the lack of investments in proper staff training. Considering also the typical traditional and conservative outlook still very present within the industry, and the very high rates of change of technology solutions (Andresen et al, 2002), it’s easy to imagine why these kinds of processes are rarely pursued by SMEs.

In light of the potential developing a common platform or a direct integration between ERP and BIM systems, one of the fundamental traits must be full transparency between all the involved parts, and constant and clear communication. Considering the typology and the volume of data and information that would be managed in this scenario, this kind of communication and integration requires a properly defined planning process starting from the initial phases: basically, a preliminary planning stage should take place well before the designing process itself, so that complications and unexpected events can be prevented or properly handled beforehand.

This sort of reengineering process is described by Kahn (2021), who proposes a total reshuffling of the typical designing and planning processes, resulting in a shift of the stress of workload to the initial stages, and a better distribution of efforts all-around. In this case, the Operation Stage, which includes 3D Coordination, design review and site work, is given the most emphasis, allowing for a better organization between the teams, a consequent reduction of designing and construction times. A transparent and well-developed coordination since the initial stages is therefore needed and the solution can be the connection between the ERP system and the BIM model.

2. CASE STUDY

For the purpose of achieving an integration between the ERP system and the BIM model, a real case study was analyzed. The following examination also takes into consideration the management system used by the construction company, in this case SAP, that was in charge of the construction of a building that covers an area of 1400 square meters. As part of this analysis, a first attempt was made to link the ERP software and the information model; ideally, the goal would be to directly integrate the two system so that changes within the model (in terms of 3D objects volumes and quantities, for example) could be automatically recorded by the ERP software, resulting in the update and correction of data and information related to material orders and scheduling.

2.1 Project content within the management and control software

In the initial stages of construction planning, a comprehensive preliminary Bill Of Quantities (BOQ) was compiled, which took into consideration the cost and pricing of materials, the need for equipment and workforce, taking into account not only the market average prices, but also personal agreements settled between the company and the suppliers or subcontractors. The structure used to define the BOQ during these initial exchanges between the construction company and the clients was therefore replicated in the ERP system, in order to consider every material, item and construction task, and their placement within the construction timeframe.

In order to translate and develop the construction timetable within the Project Builder of the software, a dedicated project profile was meticulously created. This project profile has been subdivided into discrete "Work Breakdown

Structure Elements," serving as a crucial classification system to effectively categorize the essential tasks for the comprehensive project plan. By using a top-down approach, the project structure branches out into multiple "networks", which represent the succession of activities that define the construction processes and that are characterized by start-to-end relationships and various interdependencies related to the time schedule of the task itself. These element profiles are used to plan, analyze and monitor time and resources during the whole construction timeframe: in this way, all the items present in the Bill Of Quantities are actually translated into the management system, each one representing a particular task on site and its related information.

These elements, that essentially represent every material used during the construction project and, in this way, its relative activity on site, are sorted with the following data:

- Milestones, which are required to proceed with payments;
- Information regarding the production centers related to the supply chain;
- Standard duration and minimum duration for each task (in terms of days); ideally, this kind of information should be the result of data obtained from the production center, however, it is often necessary to proceed with manual data entry of the durations, according to the schedule defined by the timetable;
- Deadlines: the start/end relationships between activities are determined in this section, as well as which task has the priority over the others within the construction process, and any time buffers that might need to be taken into account due to possible delays;
- Data relating to materials' orders, in the case of outsourced work. This section collects data referred to the identification of the supplier, its prices, cost items and planned delivery times, as well as data related to purchase requisitions managed by the accounting department.

2.2 ERP-BIM link

In order to develop a connection between the BIM model e the ERP system, only a small part of the whole project was taken into consideration. The work mainly concerned two categories of materials: concrete elements (exclusively focusing on the main structures, meaning the pillars and the load bearing walls on the main floor, the foundation slab, and roof) and drywall components. These elements were specifically chosen for a few reasons: firstly, these materials were enriched with the biggest volume of information - especially for the concrete, and therefore were considered ideal examples to test the potential transfer of data between the two system. Secondly, these are very different and partially antipode materials: on one hand, once arrived on site, the concrete cannot be stored, and has to be poured and used within a certain time frame; additionally, the concrete samples must go through a meticulous round of controls and checks, whose resulting documents can be collected and archived in the ERP system by connecting them to their relative object inside the project network. On the other hand, drywall elements, used here for vertical and slanted elements and for the false ceilings both, can be stored and stocked within the perimeter of the construction site for a long period of time, and have to undergo a less strict process of control and verification.

Considering the nature and the purpose of the ERP system, the time aspect and the possibility to whether to store or not the materials are especially crucial: delays in previous works, changes regarding the delivery dates of materials, or eventual changes in the project can influence the progress and continuation of the whole construction phase. Therefore, the possibility to track these changes directly and quickly, whether from variations in the BIM model or notification from the site, is essential in order to coordinate the work time schedule, the procurement and the delivery of materials and resources.

In order to then develop a proper connection, upon gathering all the pertinent data related to the tasks and materials taken into consideration for this analysis, links have been developed in order to establish a direct correlation between the ERP system and the information model. This connection was accomplished through the exportation of URL links related to the materials in each phase: each material is, in fact, within the project system, enriched with all the information collected from the accounting team (e.g. purchase orders, delivery dates, and all information previously mentioned), the project team (e.g. quantities, locations, construction phase…) and from site personnel (lab results and any type of documents collected on site). Once extracted (Fig 2.), the hyperlink can be sent by e-mail. Furthermore, the mail can be sent along with eventual notes or attachments from the operator, to other professionals who may need it (Fig. 3).

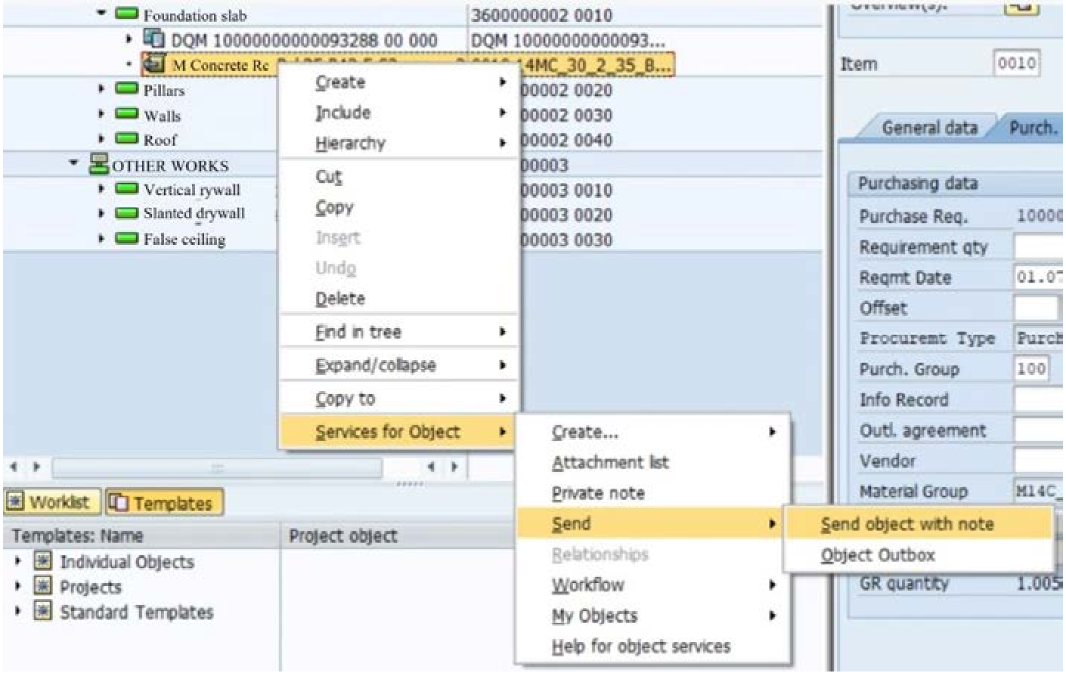

Figure 1. Procedure used to extract URL links related to the material; in this case, the concrete used for the foundation slab.

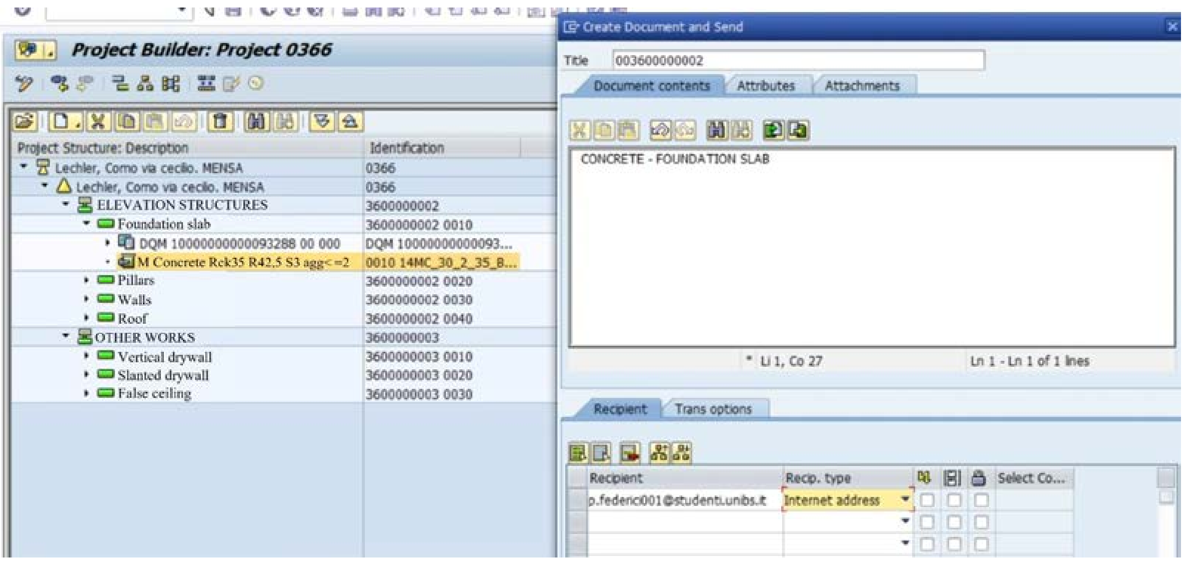

Figure 2. Creation of the URL link, related to the material, that can be sent via e-mail along with eventual notes and attachments.

The URL link provides direct access to the interface of the material, which collects and groups all the information related to the material itself and its construction activity on site, as previously mentioned. The hyperlink was then incorporated into the 3D object properties that belong to every object in the information model in the modelling software; by clicking it, the operator can directly access the ERP interface related to the material taken into account. In order for this connection to be operable, the personnel needs to, of course, have to access to the ERP system and the project at hand, and be familiar with the ERP interface and use. A basic run down of the system then would be needed for all the professionals within the work frame, in order to understand and make use of the connection.

The possibility to export a link that can directly bind an object inside the model to its material in the ERP system enables the association of the material with multiple objects at the same time, as they refer to a specific item rather than a task, effectively increasing the information and data strictly related to the object within the BIM model. For example, rather than extracting a single different link for each pillar built, which would consist realistically into a different activity each on site, a singular link to the specific type of concrete used was extracted: the link then brings up the related item in the ERP system, showcasing prices, deadline, schedules, orders and all the data related to that specific activity. In this way, an effective direct link was created between the BIM model and the ERP.

On the other hand, it is, again, necessary to point out that the access is limited to approved personnel since they are the only ones having the authority and responsibility to develop the project in the ERP system. Moreover, at stage of this case study, the linking system is not only manual, but also static, since it needs to be constantly updated.

3. AUGMENTED REALITY TOOLS AND PROCUREMENT

Another way to establish a link between the 3D BIM model and the ERP, concerns the use of the augmented reality (AR) tools. Through the AR technology it is in fact possible to overlap the BIM model containing the digital information, and the physical space of the construction site; thus, the data contained in the property set of the BIM model will be transposed to the matching objects in real life.

Thanks to this superimposition, AR is conventionally primarily used for project monitoring and control, but it can also be employed to implement the logistical aspects related to the procurement of materials and to their storage within the construction site. Through the use of an AR mobile app, by selecting each 3D BIM object, it is possible to notify its status in real life in terms of procurement information. In this way, every member of the construction and designer team gets to know in real time if a specific object is identified, ordered, delivered, checked, or installed, and the corresponding information can be recorded in the ERP system (Wang and Love, 2012). The planning of the supply and procurement of materials can be easily updated, allowing a more effective planning of subsequent orders. Similarly, it is possible to track the availability of materials by precisely defining the requirement for the consecutive period, guaranteeing an on-time supply approach.

3.1 Definition of status notification for the case study

Each status notification groups a potentially wide amount of information, therefore their selection based upon predefined criteria is fundamental. In the specific case study - in addition to the above-mentioned advisory of identification, order, delivery, check and installation - the information considered most significant to form this type of report (Fig. 4) are:

- Object of the notification and location in the construction site;
- Figure in charge: in order to fill out this field, one or more companies responsible for the procedure of supply and installation of the object must be selected;
- Expected date for delivery and installation of the object attending to the construction schedule;
- Properties of the BIM object: this field, unlike the others, cannot be filled in by the individual completing the status notification. The properties of the object are inherited from the BIM model and automatically entered in the field to avoid errors and to speed up the signaling procedure.

Considering the purpose of the object status notification, the most significant property concerns the Work Breakdown Structure (WBS) code which uniquely identifies the selected objects. These alphanumeric codes are also present in the ERP network and allow the operator to identify the corresponding purchase order and to update it by registering a delay.

Once all the fields have been completed, the final report will be visible on a web platform to which only specific members of the team have access to. The operator who is in charge of updating the orders on the ERP software will be notified via e-mail and will consequently look for the matching WBS code in the ERP network and act consequently.

As for now, the transfer of this kind of information from the construction site to the ERP takes place manually, due to the lack of interoperability between the software involved in the procedure; nevertheless, it is easy to imagine that the automatization of the process is the next achievement that needs to be accomplished in the future developments of the technologies and tools involved (AR, 3D BIM, 4D BIM-ERP).

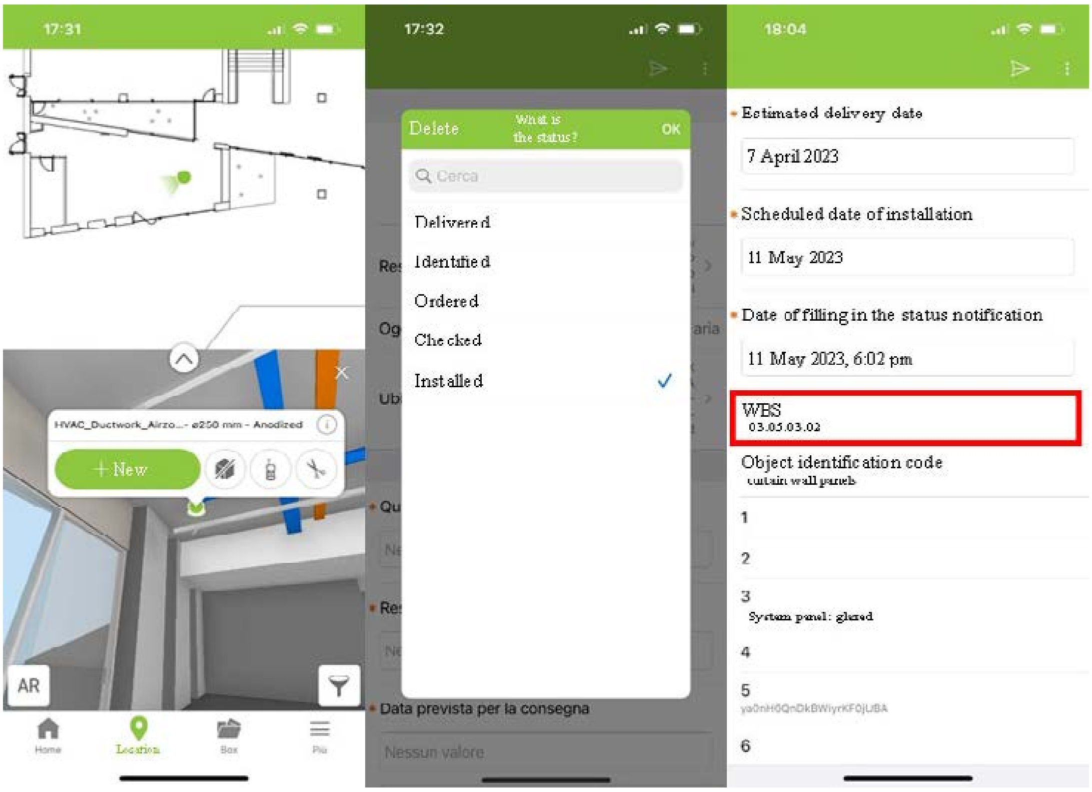

Figure 3. From left to right: (a) Selection of the object the completion of the Status Notification is referred to. (b) Multiple-choice responses to indicate the object's status. (c) Properties of the BIM object, automatically collected from the model: the WBS code is highlighted.

Ultimately, the two types of connections between the BIM model and the ERP system established operate in accordance with the diagram presented in fig.4 and necessitate a continuous update of information following the recording of new data obtained through the surveying of the construction site.

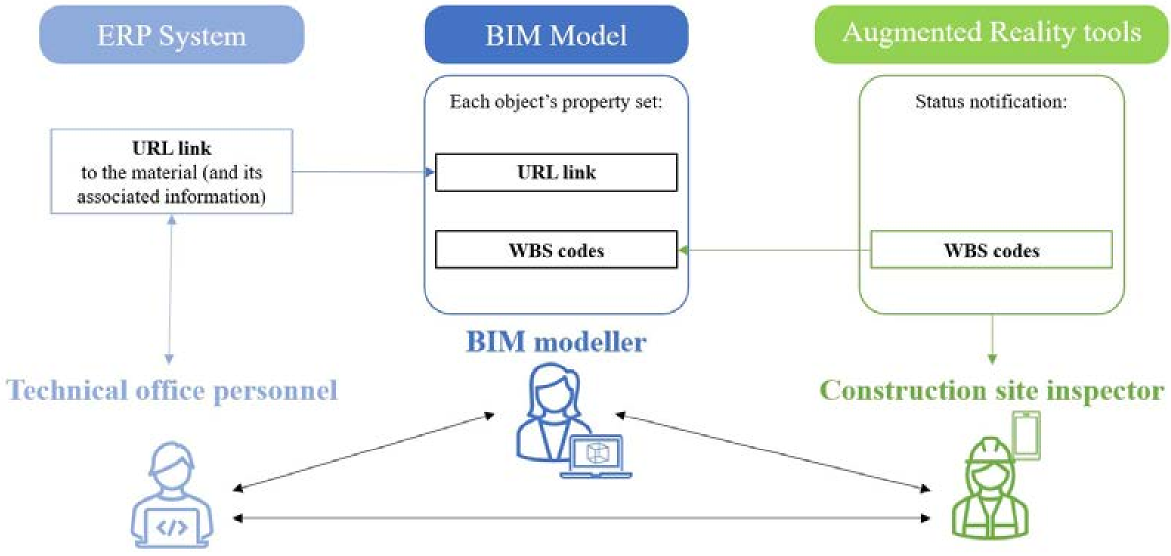

Figure 4. Schematic drawing of the procedure for establishing the ERP-BIM connection. An URL link is extracted from the ERP system and incorporated within the properties of objects in the BIM model, alongside WBS identification codes. Utilizing augmented reality tools, the Construction Site Inspector generates status notifications, which subsequently inform the BIM modelers and the Technical Office personnel of the current progress of the ongoing work. Both the BIM model and the information contained in the ERP system will be updated, and the flow will potentially start over again.

4. CONCLUSIONS

Through the process described, it was possible to develop a connection between the ERP system and the BIM model, both by the development of a hyperlink between the material stored in the management system and its own 3D object, and by the establishment of status notifications sent directly from the construction site to the company's system.

While effectively linking the two systems, the connection created remains, as mentioned, accessible only to those who have access to the company's management system, as the software access credentials are required to be able to view the system interface. Furthermore, the hypothetical idea of connecting the material in the ERP system to the 3D object belonging to the information model currently constitutes a manual and non-automated task, resulting in an exceedingly laborious process, especially considering the number of objects modeled and the materials used. Moreover, the link appears to be static and unidirectional: any change made to the BIM model, such as alterations in volume quantities or material types, are not directly perceived and recorded by the ERP system, and every modification has to be arranged manually. Similarly, item entries updates within the ERP system do not automatically update within the link, which would need to be exported again and consequently replaced in the 3D object properties.

As mentioned, it is still a very preliminary and underdeveloped connection, still manual for the most part, and far from the potential goal of streamlined automatization between the two systems.

To achieve a higher level of integration, the development of a potential plug-in bridging the gap between the modeling software and ERP software would be necessary: since these two systems were designed for different purposes and objectives, mostly due to the different industries they were developed for and by, establishing a direct connection between the two programs would entail the involvement of the respective software distribution companies. Their cooperation and a great amount of resources, both in terms of time and investments, would be required to generate a bidirectional linkage between the systems.

In the eventuality of such a development, it would become crucial to take into consideration the high level of variability that characterizes not only construction projects, but also the coordination and management of these projects by construction firms. The perspective of a full-scale ERP-BIM integration would imply the standardization of the designing, planning and managing processes within the AEC industry, so that the transaction developed within the software can be distributed and used universally. This would result in an adjustment of the management procedures between the companies, further facilitating collaboration and communication.

5. ACKNOWLEDGEMENT

This research was partially funded by the Italian government through the PRIN2017 project entitled “Distributed Digital Collaboration Framework for Small and Medium-Sized Engineering and Construction Enterprises”.

DEVELOPMENT OF AN AUTOMATED WORKFLOW IN THE FIELD OF FIRE PREVENTION USING BUILDING INFORMATION MODELING

Vincenzo Donato & Andrea Bongini

University of Florence (DIDA)

Marco Sparacino

Freelancer

ABSTRACT: *The research focuses on an approach for the development of an automated workflow in the field of fire prevention for the validation of BIM models regarding "Subjected Activities" (according to Italian law - Presidential Decree 151/2011), with reference to the contents of the Horizontal Technical Regulation of the Fire Prevention Code. In fact, since 2019, the Italian Fire Department, through the Fire Digital Check project, is seeking to digitize the Fire Prevention Code in order to allow professionals to integrate their BIM models with the objectives required by the fire regulations. The workflow proposed involves three distinct processes, integrating them within a single workflow: study of the technical regulations and transposition into the digital environment using proven methods such as RASE, Tx3 and TIO, information modelling of a case study and implementation of validation algorithms using Solibri software. One of the main points of the proposed process is to use an open and interoperable format such as that offered by the IFC schema for the information exchange between the different software involved.*

KEYWORDS: *fire prevention, BIM, validation, code checking, digitization*

1. INTRODUCTION

With the Industry 4.0 approach, the construction sector has been involved in the development of systematic digitization processes (Daniotti et al., 2022) and its progressive transformation into a data-driven production sector appears to be irreversibly (Mêda et al., 2021). Furthermore, in recent years the introduction of information management with Building Information Modeling (BIM) tools and methodologies in public supply, service and works contracts has highlighted the need to define structured and planned data flows and information exchange between the various phases of the construction process. This text is intended as an in-depth study on the subject of digitization within the technical-administrative processes concerning public administrations with a thematic focus on fire safety in Italy. In particular, it describes and presents an application of a workflow aimed at checking BIM models to be submitted to algorithms for automatic validation and verification of the contents of the Fire Prevention Code D.M. 03-08-2015.

The following software was selected for the application of the workflow, which met the requirements that emerged in terms of flexibility in model creation, data export and control: Autodesk Revit, as BIM authoring software, and Solibrì Model Checker, as BIM model checking software. The proposed structure, however, want to be more general, in fact it does not require the use of specific software and exchange formats, and for its implementation reference was made to proven methodologies for the translation of normative code such as TIO, Tx3, RASE. The exchange of data between proprietary software was also carried out using the IFC (Industry Foundation Classes) format, which is an open standard, developed by buildingSMART, capable of describing the ontology of the building and the different specialisations related to a generic building process, through the use of entities, properties and relationships. In addition, the use of such data schema has become mandatory for any BIM services in the public sector in Italy.

The application of the workflow presented in this paper refers to "subjected activities" to the controls of the the National Fire and Rescue Service in accordance with D.P.R. 151/2011, without a Vertical Technical Rule, within the project evaluation procedure. This is limited to the automatic validation and verification of the contents of the Fire Prevention Code D.M. 03-08-2015 at *Section S.1 - Reaction to fire*. The starting point and main reference of this work was the Fire Digital Check project, born from the will of the Department of Fire, Public Rescue and Civil Defence to undertake the necessary digitisation process of the fire prevention procedures provided by D.P.R. 151/2011.

2. STATE OF ART

BIM modelling of new or existing buildings guarantees a homogeneous database capable of transmitting

information not only regarding the geometric component of an object but also its informative and documentary characterisation. The model assumes in this context not only the meaning of a geometric representation of building components but rather becomes a database where all the information produced in the different phases of the building process can be collected (C. M. Eastman, 2011). This methodology can be applied for new buildings as well as for existing buildings (Volk et al., 2014), and in particular much research is being developed on HBIM field (Murphy et al., 2013) for the digitisation of historical heritage (Biagini et al., 2022). The digitisation of all this assets must, however, be followed at the same time by a digitisation also of the national and international regulations so that it becomes possible to apply automated or semi-automated methodologies for the verification of these rules and the issuing of authorisations in the design phases of an asset. The concepts of clash detection and code checking, defined in the UNI 11337 standard as 'analysis of possible geometric interferences between objects, models and drawings', and 'information inconsistencies of objects', respectively, become important in this context. The automation of these checks with different tools during the design phases (C. Eastman et al., 2009) has led to many experiments over the years in different areas around the construction process, such as the verification of health and safety requirements in the design of the site layout (Getuli et al., 2017). The Singapore government has been a forerunner in this discipline through the CORENET e-PlanCheck project, developed by a collaboration between the Ministry of National Development and the Construction and Real Estate Network, which proposed the automatic checking of BIM models in the open IFC format. In general, code checking can be set up as a multi-domain framework based on a set of parametric rules (Solihin & Eastman, 2016; Zhang et al., 2013) that can be generated on the basis of quantitative specifications derived from a text.

The objective of this study is to understand which parts of a specific regulation are most easily digitised and how to translate these into verifiable entities or parameters within a BIM model through a combination of different methods (Solihin & Eastman, 2015). A reproducible workflow for the digitisation of a regulation using proven methods, such as TIO, Tx3, RASE, is then proposed for analysis (Hjelseth & Nisbet, 2011).

RASE (*Requirement - Applies - Select - Exception*), is a methodology aimed at identifying key points within the regulatory text. The latter are selected, classified and organised schematically with the aim of simplifying the elaboration of rules that can be implemented through programming languages. These operations are generally carried out by highlighting the text using coloured mark-ups that correspond to precise types of content within it. The portions of text that can be defined as necessary or requested requirements are highlighted In blue (*requirements*), the portions that define the scope of applicability of the requests or necessary requirements are highlighted in green (*applies),* the portions of text that contain the object or reference to the request or necessary prerequisite are highlighted), in red (*select*), and finally the portions of text that refer to an exception or that otherwise restrict the scope of applicability of the requested requirements are highlighted in yellow (*exception*).

Tx3 (*Transcribe - Transform - Transfer*), is a method aimed at expressing the degree of translatability of regulatory text into digital language. This is a very important assessment to make, since this translation process is not always advantageous and it may happen that the result obtained does not justify the time taken to achieve it. Basically, the method involves the classification of standards into three different categories: *transcribe*, i.e. those parts of normative texts that can be easily translated into digital language, usually prescriptive norms fall into this category; *transform*, parts of normative texts that can be rewritten while retaining their implementation purpose, but which often require the introduction of constraints such as qualitatively defined benchmarks but from which it is still possible to translate the requirements quantitatively; *transfer*, instructions that cannot be implemented due to the imprecise way in which they are expressed within the reference text, such as benchmarks that are not defined quantitatively but only qualitatively.

TIO (*Test Indicator Objectives*), has the objective of bridging the gap between qualitative and quantitative requirements in such a way as to be able to increase the degree of digitisation for the former, thus allowing them to be incorporated into the process. This is a very important step as the most difficult requirements to translate are often qualitative ones, because they cannot always be correlated to quantitative parameters or measurable quantities.

In order to verify the applicability of these procedures, it was decided to take as a reference the Fire Prevention Code, for which a discussion table on its possible digitisation has already been started in Italy at the beginning of 2019 as part of the BIM-FDC (Fire Digital Check) project, aimed at automating the validation of Fire Prevention projects drawn up with the code, limited to compliant solutions. A combination of the above methods was then used to digitise the regulatory text, limited to section S.1 of the code.

The TIO method, aimed at translating the requirements expressed in qualitative terms, and at identifying parameters that allow their verification and control, allowed the results of the risk analysis to be parameterised, and to correlate parameters such as R_{Vita}, R_{Beni}, $R_{Ambiente}$ that characterise an activity (or compartment) to specific requirements. The Tx3 method, on the other hand, was used to verify only the compliant solutions foreseen by the Fire Prevention Code. Given the high specificity of the alternative solutions, which do not generally have a prescriptive character, these must eventually be treated in a specific way for each case study and are not suitable for verification within a general automatic validation methodology. Finally, by means of the RASE methodology, the object to which the regulatory prescriptions of Section S.1 refer is identified: in this specific case we refer to the scope of the subjected activities, defined by the code in section G. In addition, a distinction has been made between the areas that constitute "escape routes" of the activity (or compartment) and areas that constitute "other spaces" of the activity, since different levels of performance are generally required of these, depending on the *Life Risk* attributed to the activity (or compartment).

3. METHODOLOGY

The workflow presented within this paper is based on the application of the BIM methodology in the field of fire risk management and the validation of the related regulatory features. Specifically, the objective is the automatic validation of BIM models concerning subjected activities (according to D.P.R. 151/2011), with reference to the contents of the Horizontal Technical Regulation of the Fire Prevention Code. Three distinct areas can therefore be found in the process: technical regulations, BIM modelling and validation algorithms. Each of these areas must relate to the others, and for each of these relationships objectives and criteria for their achievement must be defined.

Technical Standard - BIM Modelling. Technical regulations contribute substantially to determining level of development of BIM models. Operationally, therefore, it determines what is to be modelled.

Technical Standard - Validation Algorithms. Technical standard provides the basic parameters, criteria and logic for the implementation of validation algorithms.

BIM Modelling - Validation Algorithms. The data structures of BIM models must be organised according to predefined criteria, so that the necessary information is available for the application of validation algorithms. At this juncture, a standard must be defined for the databases on which the logic of the algorithms can be developed.

3.1 Preliminary study of legislation and information exchange

Annex I of the Fire Prevention Code 'Technical Regulations for Fire Prevention' consists of the following Sections: G (Generalities), S (Fire Strategy), V (Vertical Technical Rules) and M (Methods). From the study of the relative contents of the Sections, with reference to the scope of application and the objectives set, it was possible to define a workflow for the digitisation of the Code as shown in the figure (fig. 1).

The following methodology is based on the following principles:

1 - validation is performed on BIM models inherent to a specific subject activity (pursuant to D.P.R. 151/2011);

2 - risk analysis, the definition of design goals and safety objectives, and risk assessment, are steps that must necessarily precede the entire workflow from the creation of the BIM model to its validation. These steps need a specific assessment by a fire safety professional. From here, we arrive at the quantitative definition of the R_{Vita}, R_{Beni}, $R_{Ambiente}$ parameters for each compartment of the subject activity, which represent input data for the project;

3 - on the basis of the R_{Vita}, R_{Beni}, $R_{Ambiente}$ parameters, the minimum required performance levels are identified within the chapters of section S of the Fire Prevention Code, and for these, through the digitisation of the regulatory text, the parameters that determine compliance with the relative solutions are identified;

4 - when creating the BIM model inherent to the subject activity, geometric and alphanumeric data are defined by the fire protection professional responsible for the project;

5 - the achievement of these performance levels is verified through the application of the compliant solutions set out in the code, which, in general, are prescriptive in nature. Verification must take place by means of automatic validation procedures, using a library of algorithms specifically created for this purpose, which is applicable to each subject activity without a Vertical Technical Rule. This library of algorithms must also be scalable and reusable for more complex projects;

6 - the workflow does not provide for the application of alternative solutions to achieve the minimum performance levels.

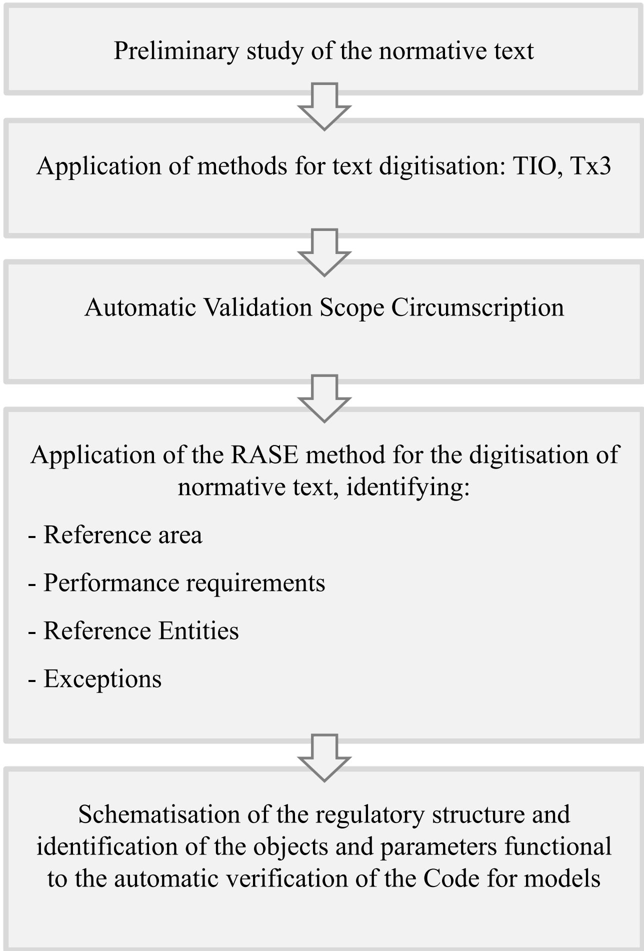

Fig. 1: Workflow for digital translation and parameterisation of normative text.

Based on these assumptions, three main work packages were then set up: the analysis of the regulatory text and its digitisation, the BIM modelling of the activity subject to regulatory control, and the application of algorithms for the validation of the BIM model. The first phase involved the definition of information requirements, in the form of alphanumeric parameters and geometric characteristics, which were to be included in the model and subsequently subjected to verification. The second phase involved the modelling of the considered activity, including not only the geometry, but also the design parameters that need to be. The last phase, on the other hand, led to the application of validation algorithms of the BIM model with reference to the contents of the Fire Prevention Code in order to verify the achievement of the minimum performance levels required for a generic subject activity.

Whereas the objectives and the actors involved in this information exchange process, each with its own tools and software, it is necessary to answer to two needs: to provide BIM authoring and code checking software capable of managing open and interoperable exchange formats, and to define a standard for the data structures to be exchanged, so that the information content within the model can be correctly analysed by the automatic validation algorithms used by the Fire and Rescue Service. Autodesk Revit BIM authoring software was then used to create the geometric model and assign the required parameters, then its information content was exported in IFC format. Once exported in IFC, it is possible to open this model within any model checker software, in our case the Solibri Model Checker software (Office version) was used, and to perform the validation operations on several levels.

The image below (fig. 2) shows the schematisation of which entities were involved in the verification algorithms. In particular, it shows the hierarchy of the spaces within the entire activity subject to inspection and where the areas for which specific performance levels are to be verified are located.

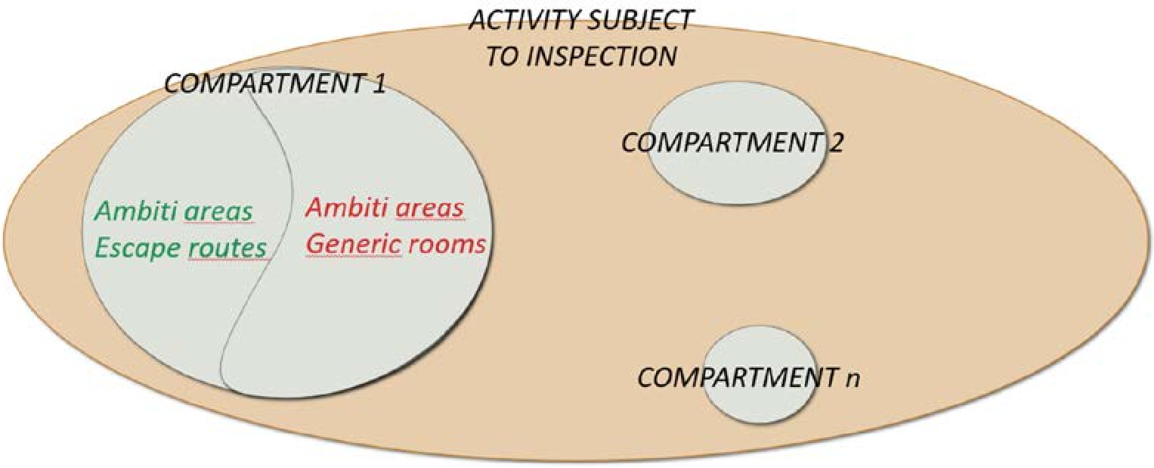

Fig. 2: Outline of the functional structure for digitising the code - Section S.1.

To achieve the required performance levels, some of the objects in the areas will have to have certain fire characteristics. The diagram below (fig. 3) shows what was modelled in the workflow application.

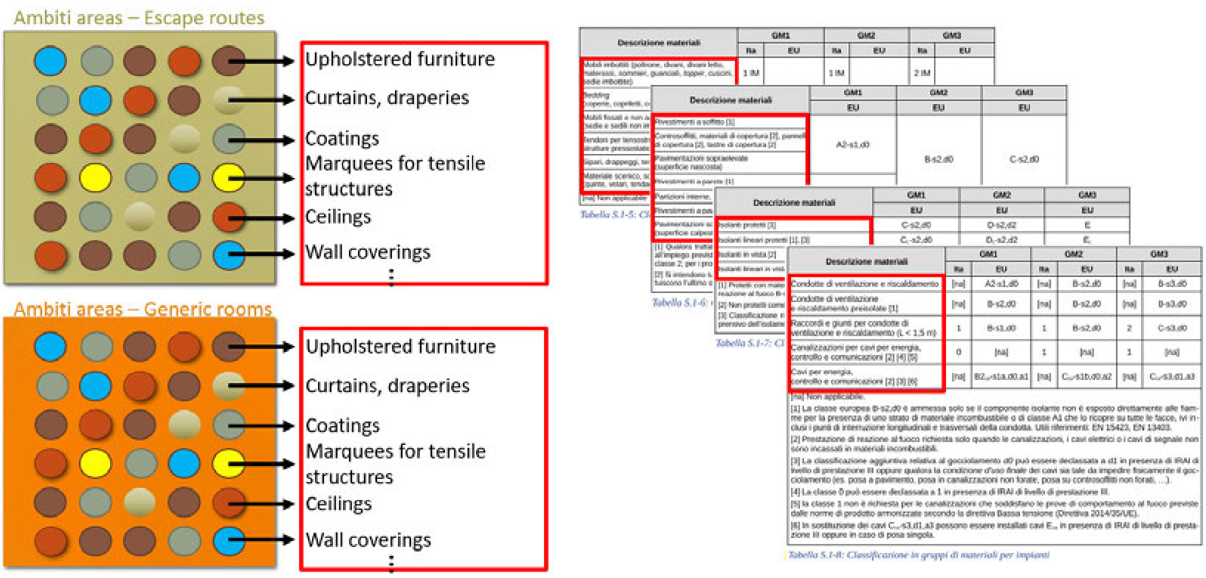

Fig. 3: Identification of the entities subject to verification within the schematic structure for code digitisation purposes.

3.2 P_set definition

The process of rule interpretation and digitisation of the normative reference text necessarily entails the definition of specific parameters that will subsequently be used in the verification process. Furthermore, in order to efficiently organise the data structure contained in the model, it is necessary for parameters to be grouped into specific Property Sets. This will make it easier to retrieve the necessary data to be analysed at a later stage. As part of the digitisation of section S.1 on the achievement of *Fire Reaction Performance Levels*, with reference to the normative structure outlined in the previous chapter, the elements to be modelled and the parameters to be assigned to them are defined.

Two entities were modelled within the BIM authoring software: activity scope and material. The tables below show the parameters associated with these two entities.

Table 1: List of parameters associated with the Ambiti areas of activity.

Property name	Property type	Description
NomeCompartimento	IfcLabel	Its value makes it possible to define to which compartment a given domain belongs, so that all domains belonging to a given compartment can be filtered in the validation processes
RVita	IfcLabel	Its value corresponds to the Life Risk determined during the risk assessment for a given compartment. By assigning the Life-Risk of the relevant compartment to each area, the performance level required for the Fire Reaction characteristics can be easily linked to it.
ViaDiEsodo	IfcBoolean	Its value makes it possible to determine the type of scope, as this contributes to determining the required minimum performance levels.

Table 2: List of parameters associated with materials.

Property name	Property type	Description
ClassificatoReazioneAlFuoco	IfcBoolean	Its value is used to determine whether an object representing the Material entity within the model falls within those listed in Tables S.1-5, S.1-6, S.1-7, S.1-8.
GruppoReazioneAlFuoco	IfcLabel	Its value, assigned with reference to the provisions of Ministerial Decree 26/6/1984 and Ministerial Decree 10/3/2005 by the fire protection designer, frames the fire reaction characteristics of a material, which, as can be seen in the normative text, are closely related to the minimum performance levels indicated by the law.

4. CASE STUDY

Modelling inside the BIM authoring software Autodesk Revit, within the scope of application of this methodology, is carried out for a simplified case study characterised by the structure shown in the table.

Table 3: Pilot model structure.

ACTIVITY SUBJECT TO FIRE BRIGADE INSPECTIONS			
COMPARTMENT 01		COMPARTMENT 02	
R_{vita} = D1 – R_{beni} = 1 Rambiente = NC		R_{vita} = B2 – R_{beni} = 1 Rambiente = NC	
Ambito 01	Escape Route	Ambito 02	Escape Route
		Ambito 03	Generic Room

Each *Ambito* (area of activity) within the Revit software was modelled as space, then exported as IfcSpace class within the IFC scheme. Regarding the modelling of the construction and furnishing elements that are covered in the tables of the Fire Prevention Code (S.1-5, S.1-6, S.1-7, S.1-8), and subject to verification in the validation process, the objects in the table below were modelled.

Table 4: Identification of the entities subject to verification within the pilot model structure.

[Compartment 01]	**Ambito 01**	n.3 Upholstered furniture [Category: Furniture]
		n.1 Floor covering [Category: Floor]
		n.1 Suspended ceiling [Category: Ceiling]
		n.1 Protected insulation [Category: Wall]
	Ambito 02	n.3 Upholstered furniture [Category: Furniture]
		n.1 Floor covering [Category: Floor]]

		n.1 Suspended ceiling [Category: Ceiling]
[Compartment 02]		n.1 Protected insulation [Category: Wall]
		n.3 Upholstered furniture [Category: Furniture]
	Ambito 03	n.1 Floor covering [Category: Floor]]
		n.1 Suspended ceiling [Category: Ceiling]
		n.1 Protected insulation [Category: Wall]

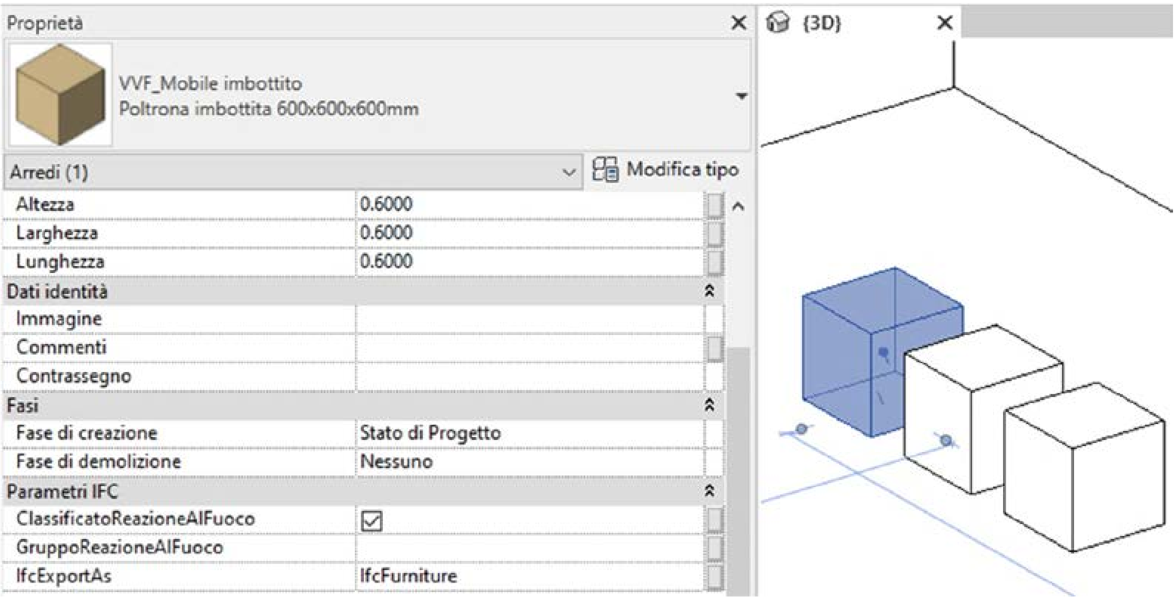

Fig. 4: Functional parameterisation for automatic validation of entities within the model.

To reach the level of information contained in the model and to implement the subsequent automatic validation process, it is necessary to enter the parameters foreseen during the digitisation of the normative text by assigning them to the modelled entities. These parameters were created as shared parameters, organising them in an external text file and therefore reusable in other models. Once the parameters had been assigned to the categories of the modelled objects, the data subject to verification were entered (fig. 4). The data assigned to the parameter GruppoReazioneAlFuoco did not in all cases reflect the requirements of the Code for achieving the minimum performance level required of the area belonging to a particular Compartment. This was an intentional error in order to show any issues that may result from the analysis.

The next step involved exporting the model created in the BIM authoring software in the open IFC format. The operation was carried out by first checking the settings of Revit's IfcExporter, analysing that the correct IFC classes corresponded to the different entity categories present in the model. Should it prove useful to further specify the IFC export class for a single instance, it is possible to exploit the shared parameters collected in the specially provided PSet_IFC_Exporter Property Set. As far as the export of parameters within the IFC format is concerned, these were organised in specific custom P_sets, through the structuring of a special file in .txt format subsequently called up in the Revit software export settings. Once the model was exported in the IFC schema, it was possible to open the latter within the model checking software. The image below shows how the imported model, displayed in the three-dimensional view, is represented by an organised data structure characterised by the hierarchy defined during the model creation phase (fig. 5).

At this point, within the model checking software we proceed to set up the groups of validation algorithms for the BIM model. Referring to what emerged from the study of the structure of the Fire Prevention Code, for the complete realisation of a library of verification algorithms, a library of Rulesets organised as shown in the table 5 is envisaged.

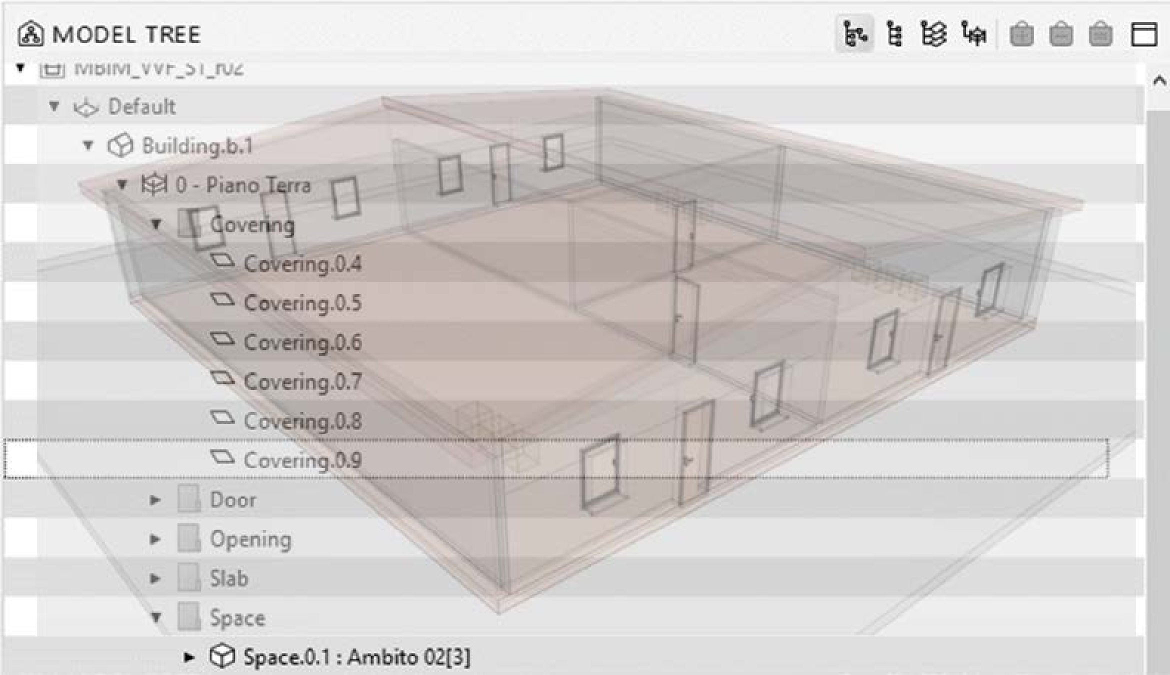

Fig. 5: Representation of the BIM model within the automatic validation software.

Table 5: General ruleset structure for the automatic validation of the fire prevention code

RULESETS	
Ruleset Name	Function
VVF_S.1_ReazioneAlFuoco	Verification of conforming solutions
VVF_S.2_ResistenzaAlFuoco	Verification of conforming solutions
VVF_S.3_Compartimentazione	Verification of conforming solutions
VVF_S.4_Esodo	Verification of conforming solutions
VVF_S.5_GSA	Verification of conforming solutions
VVF_S.6_ControlloIncendio	Verification of conforming solutions
VVF_S.7_RivelazioneAllarme	Verification of conforming solutions
VVF_S.8_ControlloFumiCalore	Verification of conforming solutions
VVF_S.9_OperativitàAntincendio	Verification of conforming solutions
VVF_S.10_SicurezzaImpiantiTecnologiciServizio	Verification of conforming solutions
VVF_G _AnalisiDelRischio	Data compilation check
VVF_Altro	Data compilation check

Each of the rulesets listed above will contain specific validation algorithms for the BIM model built with reference to the Code conforming solutions set out in the ten Chapters of Section S of the Fire Strategy. Two further rulesets are also foreseen: VVF_G _AnalisiDelRischio, dedicated to the control of the correct compilation of the parameters relative to the risk analysis, and VVF_Altro, dedicated to the control of parameters not directly referable to the contents of sections G and S of the regulations, but necessary to define the more complex validation algorithms.

Accordingly, for the purpose of validating the contents of Section S.1 of the Code, the structuring of the internal subgroups of the Ruleset VVF_S.1_ReazioneAlFuoco is given.

Table 6: Ruleset structure for the verification of reaction to fire performance for a compartment characterised by a generic risk profile.

RULESET - VVF_S.1_ReazioneAlFuoco	
Subgroups of validation algorithms	Function
VVF_S.1_ReazioneAlFuoco_Controllo	Verification of correct compilation of validation parameters
VVF_S.1_ReazioneAlFuoco_A1	Verification of Conforming Solutions by Activity or Compartment R_{vita} A1
VVF_S.1_ReazioneAlFuoco_A2	Verification of Conforming Solutions by Activity or Compartment R_{vita} A2
VVF_S.1_ReazioneAlFuoco_A3	Verification of Conforming Solutions by Activity or Compartment R_{vita} A3
VVF_S.1_ReazioneAlFuoco_A4	Verification of Conforming Solutions by Activity or Compartment R_{vita} A4
VVF_S.1_ReazioneAlFuoco_B1	Verification of Conforming Solutions by Activity or Compartment R_{vita} B1
VVF_S.1_ReazioneAlFuoco_B2	Verification of Conforming Solutions by Activity or Compartment R_{vita} B2
VVF_S.1_ReazioneAlFuoco_B3	Verification of Conforming Solutions by Activity or Compartment R_{vita} B3
VVF_S.1_ReazioneAlFuoco_C1	Verification of Conforming Solutions by Activity or Compartment R_{vita} C1
VVF_S.1_ReazioneAlFuoco_C2	Verification of Conforming Solutions by Activity or Compartment R_{vita} C2
VVF_S.1_ReazioneAlFuoco_C3	Verification of Conforming Solutions by Activity or Compartment R_{vita} C3
VVF_S.1_ReazioneAlFuoco_Ci1	Verification of Conforming Solutions by Activity or Compartment R_{vita} Ci1
VVF_S.1_ReazioneAlFuoco_Ci2	Verification of Conforming Solutions by Activity or Compartment R_{vita} Ci2
VVF_S.1_ReazioneAlFuoco_Ci3	Verification of Conforming Solutions by Activity or Compartment R_{vita} Ci3
VVF_S.1_ReazioneAlFuoco_Cii1	Verification of Conforming Solutions by Activity or Compartment R_{vita} Cii1
VVF_S.1_ReazioneAlFuoco_Cii2	Verification of Conforming Solutions by Activity or Compartment R_{vita} Cii2
VVF_S.1_ReazioneAlFuoco_Cii3	Verification of Conforming Solutions by Activity or Compartment R_{vita} Cii3
VVF_S.1_ReazioneAlFuoco_Ciii1	Verification of Conforming Solutions by Activity or Compartment R_{vita} Ciii1
VVF_S.1_ReazioneAlFuoco_Ciii2	Verification of Conforming Solutions by Activity or Compartment R_{vita} Ciii2
VVF_S.1_ReazioneAlFuoco_Ciii3	Verification of Conforming Solutions by Activity or Compartment R_{vita} Ciii3
VVF_S.1_ReazioneAlFuoco_D1	Verification of Conforming Solutions by Activity or Compartment R_{vita} D1
VVF_S.1_ReazioneAlFuoco_D2	Verification of Conforming Solutions by Activity or Compartment R_{vita} D2
VVF_S.1_ReazioneAlFuoco_E1	Verification of Conforming Solutions by Activity or Compartment R_{vita} E1
VVF_S.1_ReazioneAlFuoco_E2	Verification of Conforming Solutions by Activity or Compartment R_{vita} E2
VVF_S.1_ReazioneAlFuoco_E3	Verification of Conforming Solutions by Activity or Compartment R_{vita} E3

As can be seen from the list above, net of the group of rules necessary to control the parameters strictly related to the verification for section S.1, within the Ruleset VVF_S.1_ReazioneAlFuoco there are subgroups of validation algorithms which refer to the specific R_{Vita} attributed to each compartment of the activity, defined in the risk assessment phase. Each subgroup of the ruleset VVF_S.1_ReactionAlFuoco will be the container of validation algorithms necessary to filter the objects to be verified and which in general belong to different types of areas. It may be noted that this type of organisation of the structure for the verification algorithms allows the application of the Ruleset VVF_S.1_ReactionAlFuoco to a BIM model of any activity, even a complex one, and made up of compartments to which different risk assessment parameters are attributed.

It should be noted that the verification algorithms were created from the library contained in the Solibri Model Checker software, which provides a very extensive archive of basic rules, with which even complex validation algorithms can be created. We take the validation algorithms contained in the Ruleset VVF_S.1_ReazioneAlFuoco as an example, highlighting the following subgroups: VVF_S.1_ReazioneAlFuoco_Controllo and

VVF_S.1_ReactionAlFuoco_B2.

The subgroup VVF_S.1_ReazioneAlFuoco_Controllo (fig. 6) provides two control algorithms that verify the presence of the parameters and the correct input of the relative values for the purposes of subsequent Code checks. The first check verifies that all the elements requiring a Fire Reaction classification, and therefore referable to Tables S.1-5 S.1-6 S.1-7 S.1-8 contained in Section S.1 of the Fire Prevention Code, have a plausible value assigned [GM0, GM1, GM2, GM3, GM4] to the GroupFireReaction parameter. The second check verifies the presence of the parameters NomeCompartimento, Rvita, ViaDiEsodo and their compilation with plausible values.

Fig. 6: Structure of the control ruleset for the correct compilation of parameters

The subgroup VVF_S.1_ReazioneAlFuoco_B2 (fig. 7) has been divided into two further subgroups whose function is to check the two types of Ambiti areas identified by the Code in Section S.1, namely Vie d'Esodo [VE] and Altri locali [AL]. The rule Ambiti Vie d'esodo_Rvita=B2 has the purpose of filtering all the entities within the model which must comply with Fire Reaction requirements, and which belong, specifically, to Activity Ambiti areas which are Exit Routes and which belong to compartments to which an Rvita=B2 has been attributed during the risk assessment phase. The Fire Reaction characteristics of all objects belonging to these areas will be specifically verified by the following algorithms. The image below shows by way of example one of the verification algorithms which hierarchically follow the rule Ambiti Vie d'esodo_Rvita=B2.

Fig. 7: Ruleset structure for the identification and verification of performance for the reaction to fire of compartments.

In particular, the tab below refers to the rule GruppoReazioneAlFuoco_Arredi (fig. 8). This takes into account all the elements filtered by the previous algorithm classified as Furniture, for which specific reaction-to-fire characteristics are specified.

Component	Property	Allowed Value
Furniture	PSet_VVF_ReazioneAlFuoco.GruppoReazioneAlFuoco	GM2
Furniture	PSet_VVF_ReazioneAlFuoco.GruppoReazioneAlFuoco	GM1
Furniture	PSet_VVF_ReazioneAlFuoco.GruppoReazioneAlFuoco	GM0

Fig. 8: Definition of possible values for the parameters under verification.

The possible values of the property GruppoReazioneAlFuoco, in this specific case described, are GM2, GM1, GM0. The operation of the remaining rules underlying the rule Ambiti d'esodo_Rvita=B2 is entirely similar and should be defined for each of the materials defined in Tables 5 S.1-6 S.1-7 S.1-8 contained in Section S.1 of the Fire Prevention Code.

Two types of errors found during Code Checking are given as examples:

- Failure to compile the parameters (algorithm for checking the formal correctness of the information model). For some instances, the GruppoReazioneAlFuoco parameter is not filled in, although the objects they represent must necessarily respect precise reaction to fire characteristics to reach the minimum performance level required by the Standard.

- Reaction to fire of materials not suitable for the Rvita value of the compartment (algorithm for checking the technical correctness of the information model). Some instances do not have suitable fire reaction characteristics with respect to the area and compartment in which they are located. The value assigned to the parameter

GruppoReazioneAlFuoco, which are not among those covered by the validation algorithm.

At the end of the validation procedure, the Solibri Model Checking software can generate a report of the issues that emerged during the analysis phase that can be exported in various formats, including the open BCF format, allowing further possibilities for the development of the data flow considered in the methodology presented.

5. CONCLUSION

In the methodology just shown it was possible to observe how automated verification procedures can be implemented for the verification of the Fire Prevention Code, at least regarding the compartment of prescriptive measures given by the conforming solutions reported in the different sections of the RTO of the fire prevention strategy. Although the work presented focuses only on the contents of section S.1, given the RTO's structure and potential, as well as the flexible interoperability between Revit and Solibri software, there appears to be ample scope for the development of Code Checking of the other sections.

In any case, it is necessary to emphasise the importance of developing a standard for BIM modelling, and in particular for the structure of IFC models that, in view of the digitalisation of fire prevention procedures, will have to undergo automatic validation by the Technical Office of the Fire Service. In fact, the same organizaton will implement the code checking phase and it will define the data structure of the IFC model that can then be linked to its set of automatic validation algorithms. Validation algorithms are an information verification tool that needs databases structured according to a declared standard to function properly.

Regarding the necessary characteristics of the BIM authoring software useful for the application of the workflow described in this text, a high degree of flexibility in the export of data in IFC format is considered of fundamental importance, which means having both the possibility of creating user-defined P_sets and the possibility of assigning user-defined properties to the objects in the model. These features will allow the creation of the data structure in IFC format, as required by the validator.

DATA-DRIVEN CONSTRUCTION AND OPERATING COST DECISION SUPPORT THROUGH TECHNO-ECONOMIC ANALYSIS: RESIDENTIAL CASE STUDY

Panos Karaiskos & Tulio Sulbaran, Ph.D.

The University of Texas at San Antonio, TX

ABSTRACT: *Construction and operating costs of residential buildings are important. Because, it can help designers, builders, owners, and renters make informed decisions about where and what to buy or rent. One of the most significant operating costs of residences is energy cost. More specifically, heating, ventilation, and air conditioning account for as much as 35% of the overall energy consumption of buildings in the world. Thus, the problem that this research paper addresses is the decision trade-off of construction costs vs. operating costs. Therefore, this paper aims to perform a techno-economic analysis of exterior residential wall-type alternatives in a warm-humid climate. The research followed a quantitative methodology using a virtual case study with multi-objective analysis. The results of this study show the significant importance of the building's infiltration on the operational savings and the return on investment (ROI) of the different types of exterior residential walls. and emphasizes the importance of a holistic approach to energy conservation regulations. The novelty of this study is the emphasis on the importance of infiltration in pre-construction decision-making. The broader impact of this result is that the International Energy Conservation Code (IECC) and similar standards could be revised to reduce energy consumption and reduce greenhouse gas emissions produced during energy generation.*

KEYWORDS: *Residential, Building Performance, Construction Cost Estimating, Insulation, Infiltration, Return on Investment, Decision Support.*

1. INTRODUCTION/OVERVIEW

Buildings are a major consumer of energy, accounting for approximately 40% of all energy demands for many countries (Farhanieh & Sattari, 2006; Ogulata et al., 2002; Vine & Kazakevicius, 1999). Likewise in the U.S., the building sector accounts for about 40% of all primary energy use, and 76% of electricity use, and is responsible for the significant associated greenhouse gas (GHG) emissions. The major areas of energy consumption in buildings are heating, ventilation, and air conditioning (HVAC) which account for approximately 35% of total building energy. (Department of Energy, 2015)

Various elements affect the energy consumption of buildings. The most important element is the thermal envelope which includes all building components separating conditioned spaces from unconditioned spaces or outside ambient conditions and through which heat is transferred (IECC, 2015). The thermal envelope assembly can have a positive or a detrimental impact on the overall building performance and therefore on the HVAC energy consumption. Although the insulative properties of exterior walls and windows are commonly regulated, with a minimum R-value or maximum U-value, other parameters are not normally considered. A higher insulative value of a wall is not always advantageous, and can also increase the heating or cooling loads, in some cases, despite complying with the legislative requirements for each location (D'Agostino et al., 2019). Another significant parameter that could hurt the performance of buildings is infiltration. Infiltration is airflow into and out of buildings through unintentional leakage in the thermal envelope due to pressure differences induced by wind, indoor-outdoor temperature differences, and the operation of ventilation and other building systems (Persily et al., 2019.). Air infiltration has a significant influence on the energy performance of buildings and can result in excessive energy demand to maintain adequate indoor comfort levels (Ji et al., 2017; Persily et al., 2019.).

The problem that this research paper addresses is the effect that different exterior wall assemblies can have on the operating cost of a building accounting for both the insulative properties and the infiltration level of the building. Furthermore, this study also addresses the initial construction costs to provide insight into the economic viability of these construction updates. The effect of the exterior wall assembly on the building's energy use is a complex issue that depends on many parameters including climate, building use, building design, and materiality (Kaynakli, 2012). Improving the thermal performance of the building envelope can remarkably enhance the whole building's energy efficiency (Abanda & Byers, 2016; Huang et al., 2020). There are various ways of improving the building envelope. As previously mentioned, thermal insulation is one of the most valuable tools in achieving energy conservation in buildings (Ghrab-Morcos, 2005; Kaynakli, 2012; Wang et al., 2007). Furthermore, air infiltration

Panos Karaiskos, Tulio Sulbaran, *Data-Driven Construction and Operating Cost Decision Support Through Techno-Economic Analysis: Residential Case Study,* pp. 466-476, © 2023 Author(s), CC BY NC 4.0, DOI 10.36253/979-12-215-0289-3.45

improvements can potentially lead to HVAC energy savings on the order of 26% (Tian et al., 2019). The objective of this paper is a techno-economic analysis of an exterior residential wall in a warm-humid climate. The analysis focuses on the effects of the insulative properties of the exterior wall (R-value) and the infiltration rate on the HVAC energy consumption. Furthermore, this study includes a cost estimation analysis for the initial construction costs associated with these assemblies, to quantify the economic feasibility of these proposed construction updates.

2. METHODOLOGY

2.1 Overview of the methodology used

A quantitative research methodology was used in this project using a virtual case study. The virtual case study consisted of a residential building with different wall types and infiltration levels. Each of the wall systems was modeled and the construction cost as well as the energy consumption/operating were determined. This was achieved in three stages: 1- Data Collection, 2- Energy Performance Modeling, and 3- Results Analysis as shown in Figure 1.

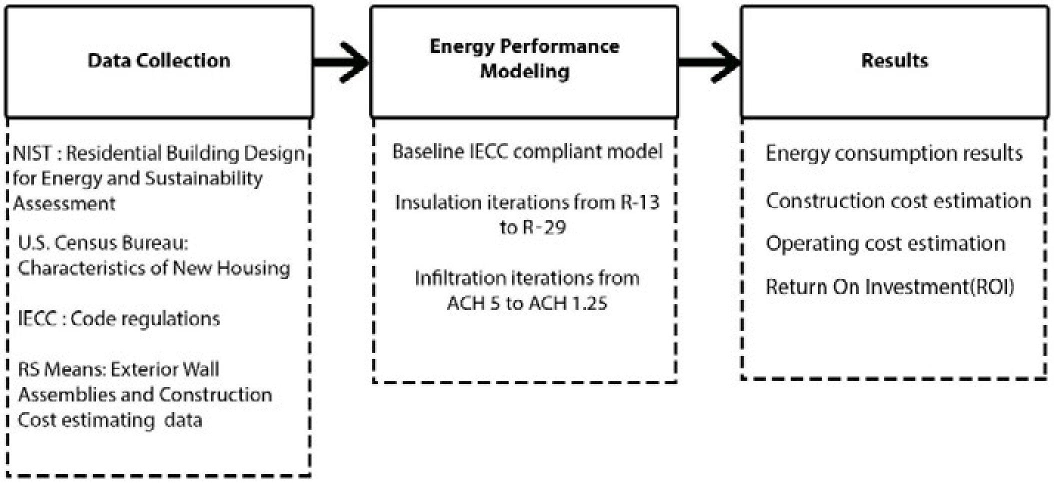

Figure 1: Methodology Diagram

2.2 Data collection process

The data collection was done from multiple sources to design and model the residential building that accurately represented the energy consumption standard and building code in the case study area.

<u>NIST:</u> The general building characteristics were based on the "Prototype Residential Building Design for Energy and Sustainability Assessment" which was published by the National Institute of Standards and Technology (NIST) (Kneifel, 2012).

<u>U.S. Census Bureau:</u> The exterior wall framing type appropriate for this study was selected based on the U.S. Census Bureau's database on residential buildings (*U.S. Census Bureau*, n.d.). As can be seen in Figure 2, for many years wood-frame construction has been the predominant type of exterior wall framing for all residential construction in the U.S. The latest available data shows that out of the 970 thousand new single-family houses built in 2021, 875 thousand were built with a wood-frame method which translates to approximately 90%. For that reason, this study focused on wood-frame-type exterior wall assemblies. Furthermore, because of the nature of wood-frame type wall assemblies, compared to mass-wall type assemblies, this study did not include thermal inertia as a parameter of the performance analysis study.

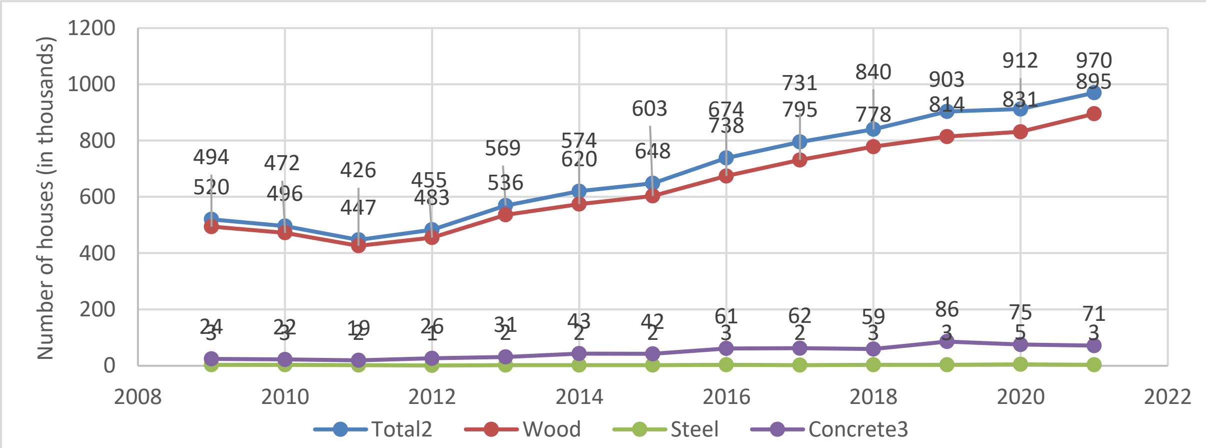

Figure 1: Type of Framing in New Single-Family Houses Completed in the U.S

IECC: The model for this case study was created to be compliant with the IECC codes for climate zone A2 which includes the Bexar County area in Texas, U.S. (See Table 1). To identify the technical characteristics (R-values, U-values) that are necessary for the building to be code-compliant, data was obtained by the International Energy Conservation Code (IECC). Because the case study of this work is placed in San Antonio, Texas, the IECC values for Zone 2 were used to determine a baseline for the energy performance modeling. Specifically, for the baseline model, an R-13 wall was implemented in the Energy+ software. Furthermore, the floor R-value was also R-13, and the ceiling was R-38. The windows used had a U-factor of 0.40 and a Solar Heat Gain Coefficient (SHGC) of 0.25.

Table 1: IECC requirements table for Texas climate zones.

	Windows			Insulation				Foundation		
	Fenestration U-Factor	Skylight U-Factor	Glazed Fenestration SHGC	Ceiling R-Value	Wood Frame Wall R-Value	Mass Wall R-Value	Floor R-Value	Basement Wall R-Value	Slab R-Value and Depth	Crawl Space Wall R-Value
Zone 4	0.32	0.55	0.4	49	20 or 13+5	8/13	19	10/13	10, 2ft	10/13
Zone 3	0.32	0.55	0.25	38	20 or 13+5	8/13	19	5/13	0	5/13
Zone 2	0.4	0.65	0.25	38	13	4/6	13	0	0	0

Regarding infiltration rates, the IECC code requires a maximum of 5 Air Changes per Hour (ACH) when tested at a pressure of 50 pascals for climate zone 2 (See Table 2). Therefore, for this study, the baseline simulations model infiltration rate was set at 5ACH.

Table 2: IECC requirements table for air leakage rates.

Air Leakage Rate	Climate Zone	Test Pressure
≤ 5 ACH	1-2	50 Pascals
≤ 3 ACH	3-8	50 Pascals

RS Means: Data on the specific characteristics of each wall assembly tested in this study and the associated costs of these assemblies were collected from the RS means publications, the industry's leading standard for construction practices, and cost estimates (John Wiley & Sons., 2012). To identify the industry standard of exterior wall assemblies, the RS means database was used. This database of standard construction practices was used to determine the wood-frame assembly design and all the construction costs associated with these wall assemblies. It can be seen in Figure 3, how the standard wood-frame exterior wall has many layers in which it can be designed and constructed. The wall variations, and their associated thermal properties, were used as simulation iterations of this study.

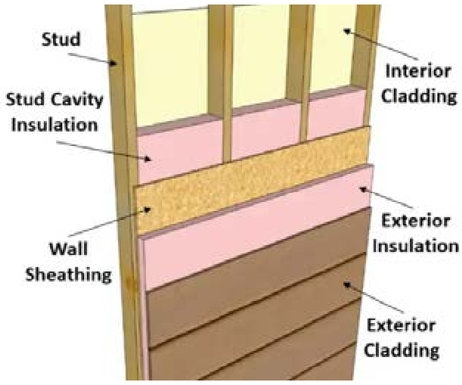

Figure 3: RS means, industry-standard exterior wood frame wall assembly (Builder's C., 2023)

2.3 Energy performance modeling

The energy performance modeling was done using the Design Builder software. Design Builder includes Energy Plus (*Energy Plus*, n.d.) which allows us to quantify the energy consumption and therefore the energy savings of the building. EnergyPlus is funded by the U.S. Department of Energy's (DOE) Building Technologies Office (BTO), and managed by the National Renewable Energy Laboratory (NREL)

The building models were designed to be identical with the exception of the construction of their external walls' insulation (from R-13 to R29) and the infiltration level of the building (From ACH 5 to ACG 1.25). The "baseline" model was designed to be compliant with the IECC code for the climate zone of Bexar County (A2) which includes San Antonio.

In order to perform the EnergyPlus simulation analysis for this study, first a 3D model of a residential house was designed in the DesignBuilder software (Figure 4). The general building design characteristics followed the "Prototype Residential Building Design for Energy and Sustainability Assessment" which was published by the National Institute of Standards and Technology (NIST) (Kneifel, 2012). The weather data required for the EnergyPlus energy simulations were downloaded internally via the DesignBuilder software for the geographical area of San Antonio, Bexar County, Texas.

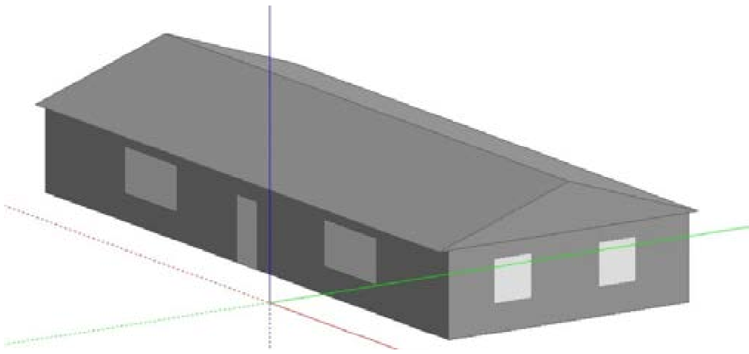

Figure 4: 3D axonometric view of wood frame building, in Design Builder software.

3. ANALYSIS AND RESULTS

3.1 Energy consumption results

Figure 5 depicts the monthly energy consumption for heating and cooling for the baseline model (IECC compliant) of the energy simulation analysis. For the summer months of June, July, and August, energy consumption for heating was minimal. This result was expected for the Warm-humid climate of this case study. Following a similar pattern, the cooling loads for the colder months (December, January, and February) were also minimal.

In the warm-humid climate of this case study, it is expected that the energy consumption for heating during the summer months of June, July, and August would be minimal. This is because warm-humid climates typically experience high temperatures and high humidity levels during the summer, reducing the need for heating. Therefore, the baseline model's energy consumption for heating during these months would be negligible.

Similarly, the cooling loads for the colder months of December, January, and February were also minimal in this case study. This can be attributed to the fact that colder months in warm-humid climates tend to have milder temperatures, reducing the need for cooling. As a result, the energy consumption for cooling in the baseline model during these months would be minimal.

These patterns of minimal energy consumption for heating in summer and cooling in winter align with the expected behavior in warm-humid climates. It indicates that the simulated baseline model's design, in terms of heating and cooling systems, is appropriately responding to climate conditions.

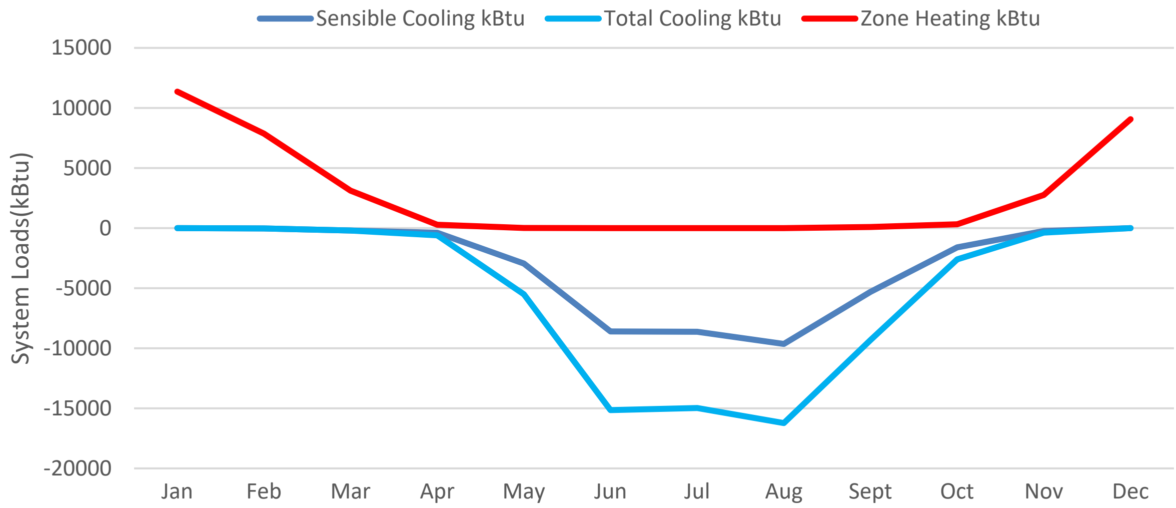

Figure 5: Monthly heating and cooling loads for the modeled house

Figure 6 showcases the effect different exterior wall iterations (R13 to R-29 and ACH 5 to 1.25) have on the cooling (shown in red) and heating (shown in green) of the house. As expected, because of the climate of this study, the cooling energy demands are overall higher than the heating energy demands, following a very similar ratio for all the wall iterations. Furthermore, Infiltration rates show a significant effect on the HVAC energy consumption compared to the Insulation levels.

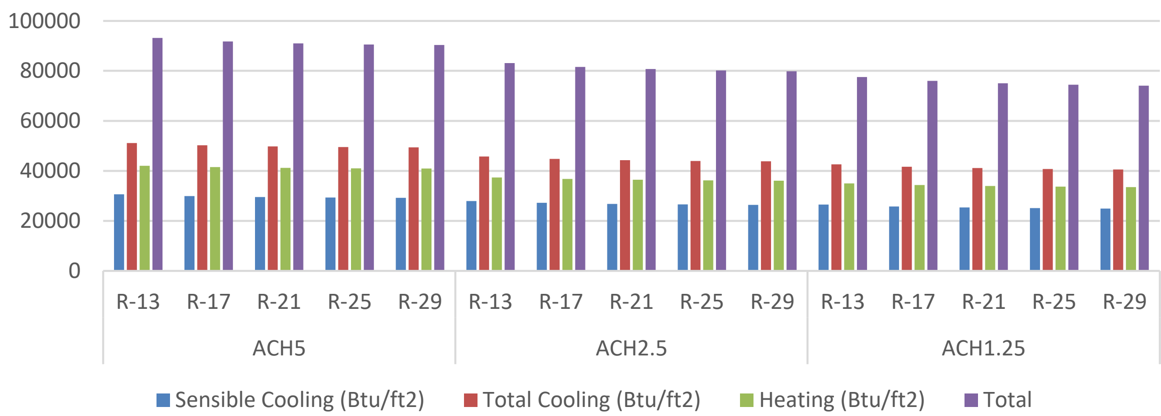

Figure 6: HVAC loads per square foot for different R-Value wall iterations

Figure 7 is a 3-dimensional graph that showcases the relationship between exterior wall R-value, building infiltration (ACH), and the overall energy consumption normalized by square foot (BTU/FT^2). As expected, a higher R-value lowers the energy consumption and a lower infiltration rate lowers the energy consumption. The colored strips of the graph represent energy consumption levels. This type of analysis allows us to easily identify and comment on the relationship between these 3 parameters, insulation, infiltration, and energy consumption. For example, the most effective level of lowering energy consumption is depicted with a light blue color at the bottom of the graph, and it represents a consumption rate of 75-77.5 kBTU/FT^2 for the building of our case study. It is apparent that a lower infiltration rate allows for this higher efficiency, even with the standard, minimum-compliant R-13 insulation. On the opposite spectrum of this graph, the inverse is also true- the building with a high, code-compliant infiltration rate is performing relatively poorly, despite the upgraded R-29 insulation. These findings quantify and validate the anecdotal rule of thumb of the residential building industry that *a good air sealing job with marginal insulation* is *far better than a good insulation job with poor air sealing.*

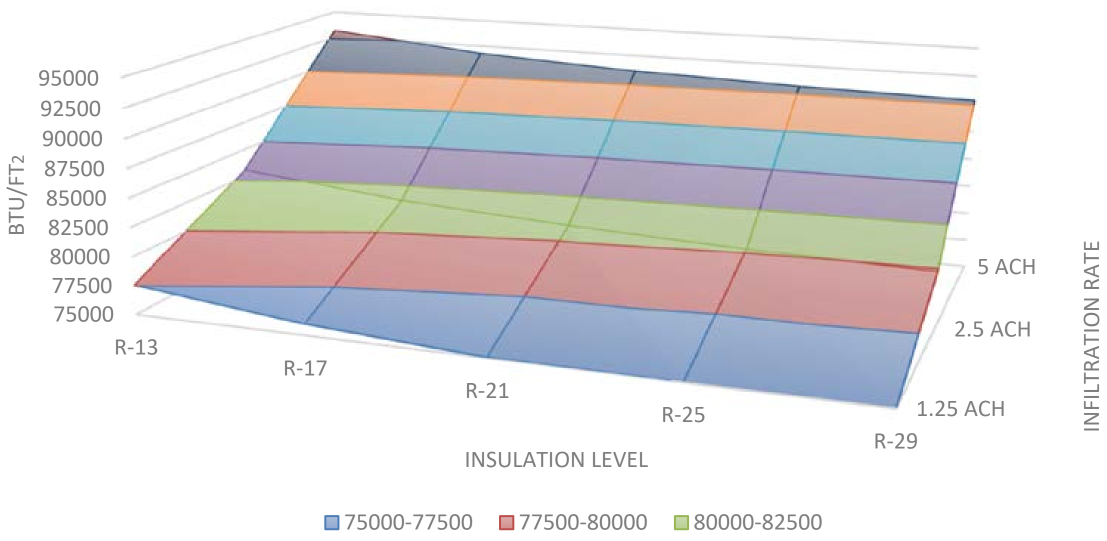

Figure 7: The effects of infiltration and insulation on energy consumption.

3.2 Cost Estimate and Return on Investment Results

The goal of this study is to provide an example of a valuable and applicable decision-making tool for many construction professionals in the pre-construction phase. Therefore, the energy consumption analysis of the previous chapter is supported by a cost analysis to evaluate the financial feasibility of these different wall assemblies. The cost analysis is presented in three parts. The first part of the cost analysis presents the cost estimating data, which includes the material and labor costs for the construction of these wall assemblies. This cost-estimating data was collected by the most recently published RS Means database(RS Means, 2023.). The second part consists in determining the operating cost analysis, where the energy consumption is converted into a monetary amount, based on the current average kWh cost of 0.14c for the area of Texas (electricityplans.com, 2023). The third and final part of the cost estimation analysis compares the initial construction costs with the operating cost savings to calculate the return on investment (ROI) and the payback period for each of these different construction updates.

3.2.1 Construction Cost Estimation

In order to properly quantify the construction cost of the different wall assemblies of this study, RS Means data was used, which includes both the material cost and the labor cost. There are a number of exterior wall construction methods that can be used to reach the R-values considered in this study. However, only the most commonly used methods of insulation practices were used for this analysis. The two most common types of insulation are Batt insulation and rigid board foam insulation. Furthermore, as mentioned before, this study focuses on the most common framing type for the U.S. market, the wood-frame wall. Therefore, the geometric limitations of the wood frame wall also affected the cost estimation analysis. Specifically, the maximum R-value that can "fit" inside a 2x4 framing wall using Batt insulation commonly found in the market is R-13 or R-15. That results in an increase of stud thickness from 2x4 to 2x6 in order to reach the values of R-25 and R-29. The cost associated with the thicker stud wall is taken into account for the cost estimate. Furthermore, a combination of Batt insulation and rigid board insulation is used to reach the specified R-values. This is a common construction practice in the industry. The last two rows of Table 3 show the total cost of insulation as well as the cost differential between the enhanced insulations (R-17 through R-29) with respect to required insulation per IECC Code (R-13).

Table 3: Cost Estimating data for exterior wall framing and insulation.

	R-13	**R-17**	**R-21**	**R-25**	**R-29**
Framing type	2X4,	2X4	2X4	2X6	2X6
Batt Insulation	3.5", R13	3.5", R13	3.5", R13	6", R21	6", R21
Exterior Board Insulation	-	1", R4	2", R8	1", R4	2", R8
Framing type cost (L.F.)	24.5	24.5	24.5	31	31
Batt Insulation cost (S.F.)	1.24	1.24	1.24	1.48	1.48
Board Insulation Cost (S.F.)	-	1.3	1.61	1.3	1.61
Total Cost / Linear foot	34.42	44.82	47.3	53.24	55.72
Total Cost for the house (U.S. $)	**4,268.08**	**5,557.68**	**5,865.2**	**6,601.76**	**6,909.28**
Additional cost from IECC code (U.S $)	**Baseline**	**1,289.60**	**1,597.12**	**2,333.68**	**2,641.20**

In the U.S., the common construction method used to reduce air leakage is the use of sealing tape (Building Energy Codes Program, 2018). Other methods can be used to reduce air leakage, the method used in this research project was Liquid Flash which can be applied in the building envelope (i.e.: bottom and top of the walls, around windows and doors, etc.) It was assumed that to reduce the ACH from 5 to 2.5 the Liquid Flash should be applied at the bottom and top of the walls and that to reduce the ACH from 2.5 to 1.25 the Liquid Flash should also be applied to windows and doors perimeter in addition to the walls. The last row of Table 4 shows the cost differential between the enhanced leakage (ACG 2.5 & 1.25) with respect to the required air leakage requirement per IECC Code (ACH 5) in the climate zone of the study.

Table 4: Cost Estimating data for air leakage sealing

			Cost	
	Length/Perimeters	**ACH 5**	**ACH 2.5**	**ACH 1.25**
Length of Wall on the Bottom (in contact with Slab)	178 FT	--	356.00	356.00
Length of Wall on Top (in contact with Roof)	178 FT	--	356.00	356.00
Windows	8 Windows (4'x'4) = 128 FT	--	--	256.00
Exterior Doors	2 Doors (3 x 6.5') = 38 FT	--	--	76.00
Additional cost from IECC code (U.S $)		**--**	**712.00**	**1,044.00**

3.2.2 Operating Cost Estimation

Figure 8 presents the energy saving result differential for each R-value step increase and for each of the 3 infiltrations (ACH 5, 2.5 & 1.25) categories tested. As expected, a higher R-value leads to more savings and a lower ACH level also leads to more energy savings. Furthermore, the operational savings in the case of poor infiltration rate (ACH5) are marginal. Specifically, for a greatly updated insulation to R-29, the operational savings are only 127 U.S. dollars, yearly, for the entire house of the case study. On the contrary, the improvements in infiltration rate, while maintaining the same R-13 insulation on the walls, lead to $ 453 and $ 702 in annual savings for ACH 2.5 and ACH 1.25 respectively.

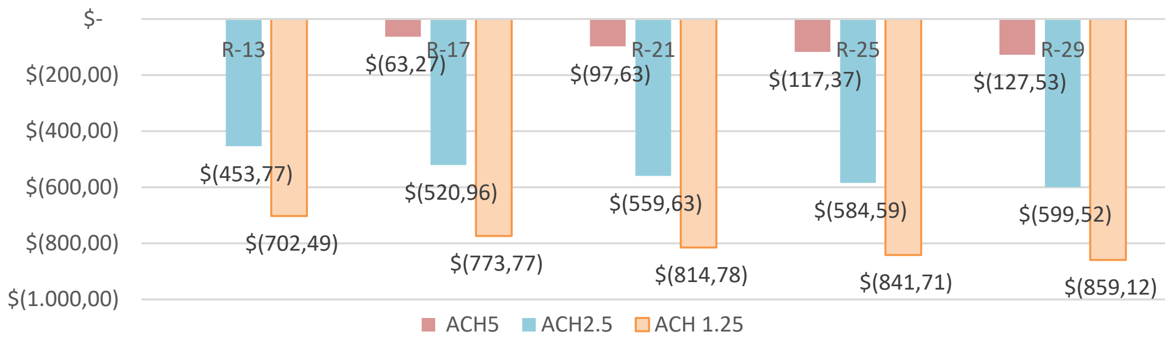

Figure 8: Annual Savings in U.S. dollars for the 1076 square foot house.

3.2.3 Return on Investment and Payback Period

The Return on Investment (ROI) and payback period analysis of this study showcases the importance of this type of methodology as a pre-construction decision tool. Figure 9 shows the ROI in bars and the payback period in lines. As shown in Figure 9, improving the R-value from R-13 to R-17 without improving the ACH results in an ROI of 4.9% and a payback period of 20.4 years (R-17 blue bar and line in Figure 9), while if the R-value from R-13 to R-17 is improved and the ACH is also improved from ACH 5 to ACH 1.25 the ROI is 33.2% and the payback period is 3.0 years (R-17 orange bar and line in the Figure 9). The same pattern showing a significantly better ROI and Payback period with lower ACH appears in all the other tester wall iterations of this study. The highest ROI was estimated to be 67.3% for improving the building's infiltration from ACH5 to ACH 1.25, without altering the insulation (R-13) of the exterior walls.

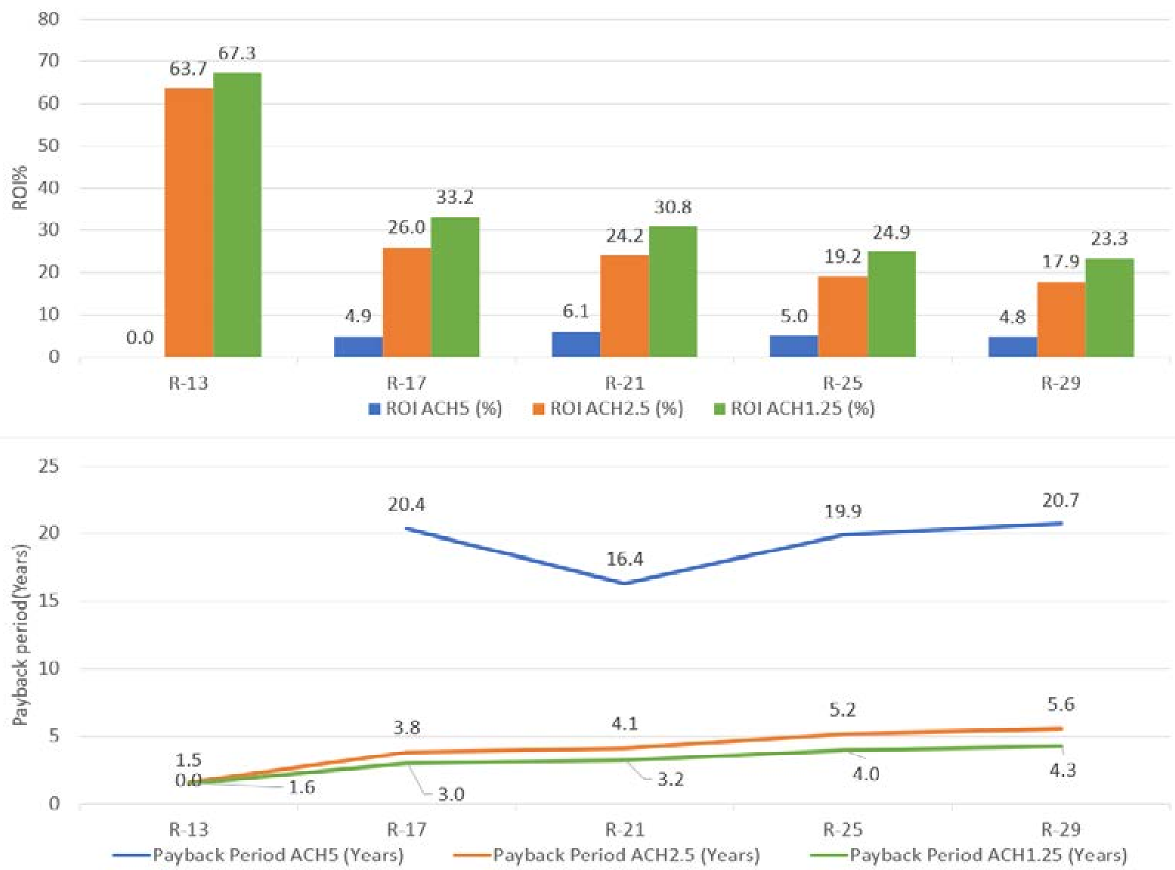

Figure 9: ROI and Payback Period

4. INTELLECTUAL MERIT

The intellectual merit of this work is to provide a greater understanding of the effects of the insulative level and the infiltration level on a residential building's performance. Furthermore, this analysis, combined with the construction characteristics and costs of the different wall assemblies can be used as a valuable decision-making tool during the pre-construction phase of a residential project. This work compared the energy-saving capability of upgraded exterior wall assemblies. Furthermore, the "upgraded" walls were tested under 3 different conditions of infiltration of the envelope of the case study. The results showcase the importance of infiltration levels for the overall performance of the residential case study. Furthermore, the methodology of this study can be replicated and scaled by construction professionals, in order to increase the economic competitiveness of a real project. Last but not least, a better understanding of the energy-saving capabilities of a better-built wall and the financial incentives presented in this study can promote a future of higher-standard construction methods for a myriad of houses across the globe.

5. SUMMARY AND CONCLUSIONS

This study highlights the importance of considering the construction and operating costs of residential buildings, with a focus on energy costs. Heating, ventilation, and air conditioning (HVAC) contribute significantly to a building's energy consumption. The research paper aims to analyze the trade-off between construction costs and operating costs by studying different exterior residential wall types in a warm-humid climate. The study uses quantitative methodology and a virtual case study to assess the impact of insulation and infiltration on energy consumption. The results highlight the importance of building infiltration on operational savings and return on investment (ROI) for different wall types. The study suggests that energy conservation regulations, such as the International Energy Conservation Code (IECC), could be revised to reduce energy consumption and greenhouse gas emissions.

In the study's climate, cooling energy demands are generally higher than heating energy demands, with a consistent ratio across different wall designs. Additionally, the infiltration rates, or the amount of air leakage, have a more significant influence on HVAC energy consumption compared to insulation levels.

Higher R-values and lower infiltration rates result in lower energy consumption. It is evident that a lower infiltration rate contributes to higher efficiency, even with the standard R-13 insulation. On the other hand, a building with a high infiltration rate, despite having upgraded R-29 insulation, performs relatively poorly. These findings support the industry belief that good air sealing with minimal insulation is superior to good insulation with poor air sealing.

The differential energy savings for each step increase in R-value and for each of the three tested infiltration categories. As expected, higher R-values result in greater energy savings, and lower air changes per hour (ACH) levels also lead to more savings. It is noted that the operational savings are minimal when dealing with poor infiltration rates (ACH5). Specifically, for a significant insulation upgrade to R-29, the yearly operational savings for the entire house in the case study amount to only $127. In contrast, improvements in infiltration rates, while maintaining the same R-13 insulation on the walls, result in annual savings of $453 for ACH2.5 and $702 for ACH1.25.

The results of the study highlight the significance of utilizing the ROI (Return on Investment) analysis as a decision-making tool during the pre-construction phase. The data presented in the study demonstrates the impact of different factors on ROI. For instance, with a consistent R-value wall of R-17, the ROI is calculated to be 4.91% for a poorly air-sealed example (ACH5), while it significantly increases to 33.13% for an improved air-sealing example (ACH1.25). This pattern is observed across all the tested wall iterations in the study. The study also identifies the highest ROI, estimated at 186.93%, for enhancing the building's infiltration rate from ACH5 to ACH2.5 without making any changes to the insulation of the exterior walls. These findings emphasize the importance of considering air sealing measures in order to maximize the return on investment, as it can have a substantial impact on energy savings and overall financial benefits. The study's distinctive contribution lies in its exploration of the typically overlooked aspect of infiltration rates in pre-construction building considerations, shedding light on the benefits of including these rates for a more holistic analysis of a building's performance.

Future work to build upon this research includes conducting a comparative study in different climate zones and with multiple building types and geometries to analyze the trade-off between construction and operating costs; conducting long-term monitoring of building performance to assess the actual performance of different wall designs over time; investigating the impact of occupant behavior on energy consumption; conducting a Life Cycle Costing (LCC) to evaluate the economic viability of different wall types; exploring the integration of renewable energy systems into residential buildings; focusing on retrofitting existing buildings to improve energy efficiency; and conducting a sensitivity analysis of parameters to determine their influence on energy consumption and ROI. Additionally, analyzing energy conservation regulations and providing policy recommendations for improving energy efficiency in residential buildings.

ABSTRACT: *The automation and innovation have impacted Architecture, Engineering and Construction Industry, particularly when transitioning from traditional or conventional methods of construction to modular or Industrialized Building System (IBS). Thus, to ameliorate the processes surrounding built environment, researchers have been interested in the BIM's integration into construction industry. To ensure BIM's adoption and integration into construction supply chain, supply chain's management and procurement, we need to have an extensive comprehensive research base regarding global outlook of BIM's relation with supply chain. The purpose of this study is to identify global scientific research patterns and trends related to BIM's role in supply chain, by performing scientometric analysis. The scientometric analysis will help us analyze the work being done in this field and whether a significant literature exists that supports or helps in adoption of this idea. Most of the already existing research on BIM is performed on various other aspects of BIM like infrastructure sustainability, green buildings, design, framework, management of facilities and other BIM related managerial aspects. Thus, it is highly imperative to systematize and analyze the existing global scientific literature research to identify the global trends and frontiers on current BIM's relation with construction supply chain. Not only this would pave the way towards identification of current relevant literature but would also lay down the foundations for digital transformation in construction.*

KEYWORDS: *Building information modelling (BIM), construction, digitalisation, procurement, scientometric, supply chain management*

1. INTRODUCTION

The concept of integration of services is not new, over the past several decades this concept has been applied in various industries. However, integration in construction supply chain is still lagging as opposed to other sectors. There are several reasons behind it, including complexities in construction processes owing to the fragmented procurement processes, multiple project stakeholders and several other challenges. The instability and fragmentation occur when supply chains are temporarily created or setup for each individual one-off construction projects. (Papadonikolaki, et al., 2015). Meanwhile, Building Information Modelling (BIM) is a kind of technology that can collect, create, impart, and share accurate information among different stakeholders of construction supply chain. BIM is equipped and able to tackle operational, organizational, and other technical complexities in the construction supply chain. BIM not only enhances visualisation, design coordination and construction sequencing but also aids in construction processes through its various built-in features. These features include clash detection visualisation, scheduling and controlling capabilities. (Rathnasinghe & Kulatunga, 2019).

However, BIM's impact on challenges, faced by construction supply chain (CSC) at organisational level, is not thoroughly researched. The integration of BIM and CSC are still quite theoretical and conceptual, lagging in substantiated research. Only after extensive research and observing BIM's impact on the construction supply chain and its management, we can be fully assured of its contributions to the CSC. These gaps and voids in research thus need to be further explored. Thus, the following literature review will focus on the BIM's role and contributions so far to the CSC and its management. The literature review will also shed light on the underlying problems and background in the supply chain processes (Le et al., 2022). The research proposal has immense significance in terms of contributing to the theoretical knowledge related to the problem statement. The author believes that the

FUP Best Practice in Scholarly Publishing (DOI 10.36253/fup_best_practice)
Syed Haseeb Ahmad, Melissa Chan, Wei Yang, Hongyu Jin, Amirhossein Heravi, *Building Information Modelling (BIM) for Construction Supply Chain: A Scientometric Analysis,* pp. 477-488, © 2023 Author(s), CC BY NC 4.0, DOI 10.36253/979-12-215-0289-3.46

need for this proposal is highly imperative as it further compliments the existing knowledge in context of BIM's multi-dimensional relations to construction supply chain at large and procurement.

The idea of construction supply chain has been around for a while now but still the constraints and challenges exist in construction supply chain owing to its uniqueness in each individual project. That means, every project being delivered is different in some ways from other projects rendering it difficult for integration to happen. This further tells that the construction supply chain is not strongly tightened interrelated process but a loose system which despite being important to global economy, is somewhat inefficient and untrustworthy. Thus, the research gap exists when it comes to addressing the issues (Papadonikolaki, et al., 2015). Moreover, if we narrow down the supply chain of Architecture, Engineering and Construction industry to mere procurement, again we'll find many unanswered problems. Integrating BIM with project delivery contract methods should ideally give rise to some new contract types specific to BIM usage but that hasn't been done yet and is a largely unexplored area.

2. LITERATURE REVIEW

The late twentieth century saw an evolution in logistics and supply chain management. This evolution had a direct impact and affected the construction supply chain and its management, due to its importance and magnitude. Since then, several problems and shortcomings in the construction supply chain management have been identified by the researchers involved in this field. Many problems were identified such as incoherence, lack of integration and inefficiency of the procurement or supply chain process (Khalfan et. al., 2015). A report on commercial construction industry highlighted that the mega projects take almost 20 percent more time to get completed than their scheduled completion date (McKinsey & Company, 2015). The report proclaimed that the construction industry still lagged in adopting innovative technologies when it came to information sharing about projects.

BIM can play a pivotal role in data collection, integration, and provision. The goal is to obtain or gather data which is accurate enough that it can be channeled to other projects to aid or assist in the building processes including Construction Supply Chain. This includes the gathered data that can link the mega scale projects and can be modelled using Building Information Modelling systems (BIM), and then exploring further ways to link these information and models to the construction supply chain (Wang et. al, 2017). To help everyone involved to have a better understanding and clarity of the overall project, the data that is already gathered in the BIM system can help in driving labour and material requirements hence assisting in a construction supply chain management (Wang et. al, 2017).

The approaches related to BIM and supply chain management revolve around supply chain integration with BIM to enhance and improve construction processes. Hence, it is believed that BIM can act as a catalyst for supply chain management adoption in construction (Wang et. al, 2017). The supply chain's integration is linked with both stakeholders and processes involved who are expected to coordinate and collaborate across various SC levels with long lasting trustworthy relationship. The researchers observed that supply chain stakeholders early risk management/allocation, involvement, participation, information technology investment and long-term procurement could further strengthen SC integration. (Getuli, et al., 2016). BIM can also help to enhance performances of mechanical, engineering, and plumbing aspects of the project. This can be done only with the stakeholder's cooperation, that means, early joint planning, joint decision making and operations. Construction supply chain partnership can be helped by Building Information Modelling through data-information sharing, trust building and enduring long-term commitment (Le et al., 2022).

During the early days of BIM development and while it was undergoing further technological advancement, one of the associated areas of interest was supply chain procurement and legal aspect of BIM. During early 21st century the BIM advocates observed that the two of the major hinderances in potential data sharing through BIM's platform; are legal constraints and varying frameworks of contracts. These two were seen to be obstacles in putting BIM in practice. Some of the key issues that surfaced include roles and responsibilities of individual stake holders being affected by use of BIM, liability and copyright issues associated with the BIM models, sharing of BIM's data and model ownership, and stakeholders focusing more on their individual components of the project rather than giving due consideration to the bigger picture of process (Holzer, 2015).

3. METHODOLOGY

This study aims to identify research patterns and trends about the global BIM research and how it is related to construction supply chain, construction supply chain management, and procurement in AEC industry. The research question focusses on how BIM is related to or being utilized for construction supply chain, supply chain management at large and procurement. The research method revolves around devising a framework of research design that defines and outlines the criteria for scientific databases, rules of search, defining data curtain, retrieving, processing, and analyzing of preliminary and final datasets. Therefore, this study employs the scientometric method, that is the sub-field of bibliometric analysis that is concerned with analysis and measuring of scientific literature. Bibliometric analysis can be defined as quantitative and statistical analysis of research data like journal publications, articles, and their patterns to identify the impact of those publications as well as to identify further research trends or patterns (Iftikhar et. al., 2019). The concept of bibliometric review was said to be introduced by Pritchard in 1969, who argued that this form of analysis had the potential to provide comprehensive insights into the research literature. (Pritchard, 1969). Fig. 1 outlines what would the scientometric analysis and mapping process would entail at each stage of the implementation. It illustrates what would be included at each step of this research project.

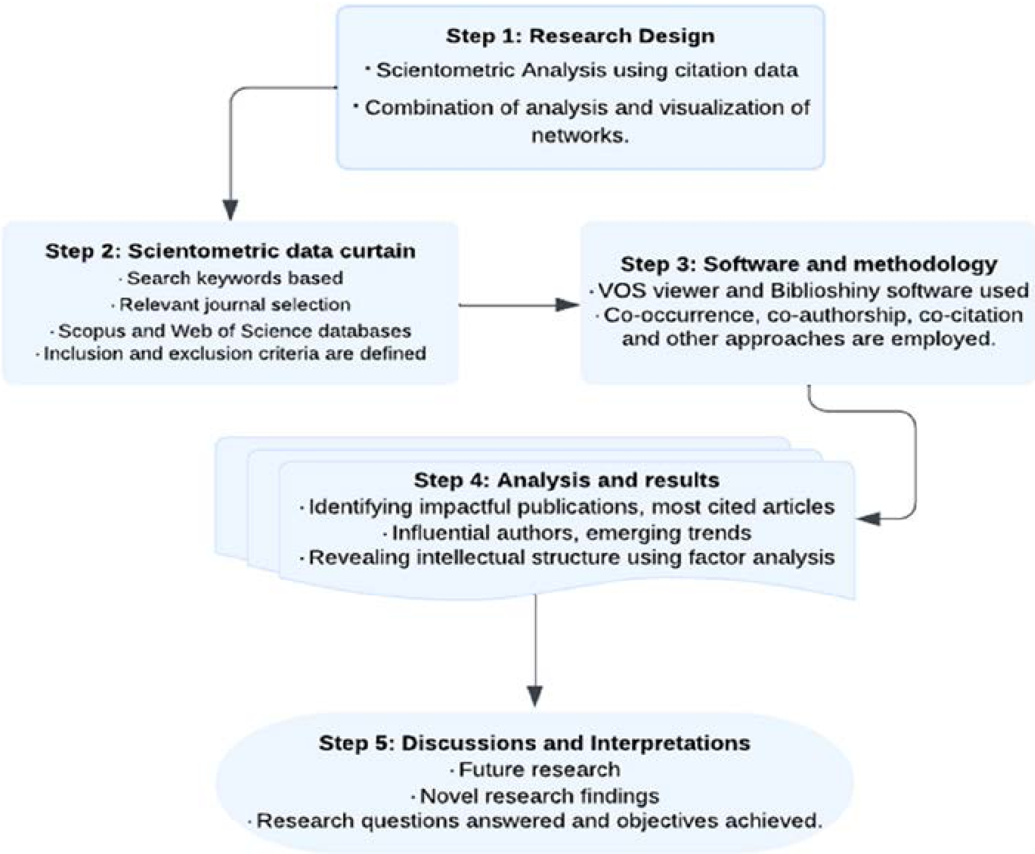

Fig. 1: Scientometric analysis and research mapping process

4. RESULTS AND DISCUSSION

Scientometric analysis was analyzed using several software as discussed and explained in research methods. The first analysis will revolve around outlining analytics related to Co-Authorship (type of analysis) and Authors (unit of analysis). The visualization results of 176 scientific documents retrieved from 'Web of Science' database, which were fed to VOS viewer. Hence, a visualization of co-authorship network was developed to analyze authors that had accounted for scientific research related to Building Information Modelling's role in procurement of construction projects, amelioration of construction supply chain and playing part in supply chain's management.

4.1 Visualisation Using VOSviewer

The VOS viewer was set to ignore publications which had large number of authors (maximum level set at 25 authors). The author's threshold with minimum number of documents was set at 2, whereas the minimum number of citations of an author were set to 1 citation. After applying the analytical functions, out of 464 authors, 46 authors met the threshold. These 46 authors had accounted for the most documents and citations in this respective research area. The table below outlines the data regarding these authors. The analysis reflects the most productive authors who had made significant research contributions to Building Information Modelling's role in AEC industry, especially, the areas related to supply chain management and procurement. As shown in Table 1, the 3 most productive researchers were found to be Chong, Heap-yih (7 documents,146 citations), Wang, Xiangyu (6 documents,142 citations) and Love, Peter (4 documents,124 citations). This was followed by authors Grilo, Antonio (3 documents, 95 citations), Jardim-goncalves, Ricardo (3 documents,95 citations) and Lee, cen-ying (3 documents, 94 documents).

Table 1: Publications and citations per author

No	Author	Documents	Citations
1	chong, heap-yih	7	146

4.2 Network Visualisation

The network visualisation is shown in Figure 2 Network Visualization Co-authorship, that illustrates the total link strength of 60 with 32 links and 25 clusters. The co-authorship link strength refers to the collaboration strength of the authors. The nodes represent the author whereas thickness or size of nodes represent the documents. The edges or links refer to co-authorship collaboration between the authors, the thicker the lines, the stronger the collaborations. As mentioned previously, there are a total of 25 clusters, but we will analyse only top 3 clusters as they are indicative of strong collaborative research authorship between them. Fig. 2 shows the biggest cluster, cluster 1, is denoted by red colour and comprises of 5 top productive others; Chong, heap-yih being the most productive of the lot with total link strength of 12, 7 documents and 4 links (1 link with each other author in the cluster 1). Following Chong is Wang, Xiangyu with 3 links with Chong, Lee and Cin-Yeng. Wang had co-authored total of 6 documents with a total link strength of 10.

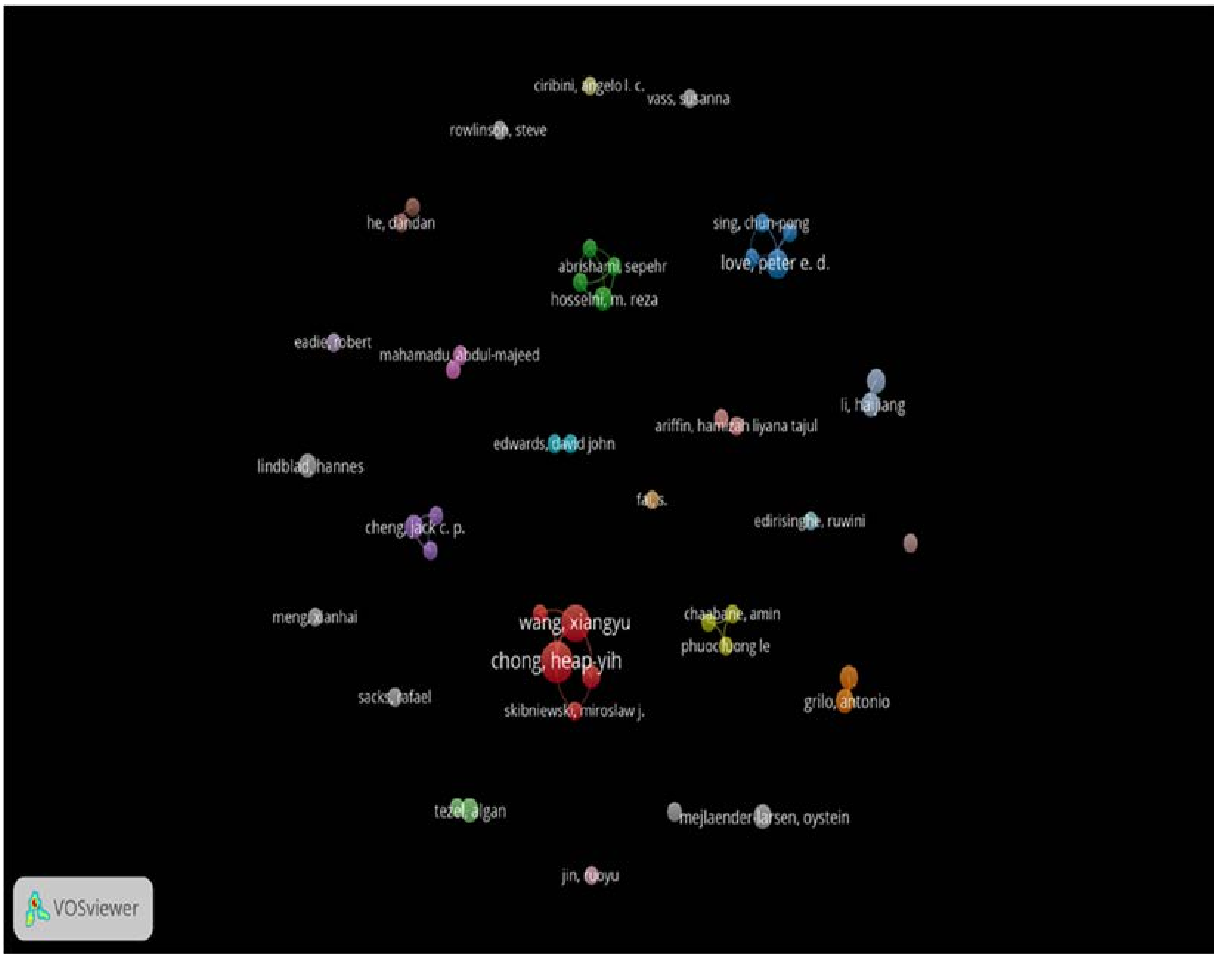

Fig. 2: Network visualization co-authorship

The cluster 2 consisted of 4 authors, 2 of these authors, Abrishami. and Abu-samra had strong collaboration links between them in terms of co-authorship of publications as both had published 2 documents but their total link strength was 5 each and had links with each other as well as 2 other authors in the cluster. The other author Husseini had the same total link strength of 5, however, he had authored 3 publications only with each of the fellow authors in its cluster. However, in blue colored cluster 3, author Love, Peter's node and edges were indicative of very strong collaborative effort with rest of the authors in the cluster. Love had total of 4 documents with total link strength of 6 and 4 documents thus depicting significant co-authorship whereas rest of the 3 authors namely Sing, Chun-pong, Matthews, Jane and Zhou, Jingyang had each collaborated 2 documents and had link strength of 4.

4.3 Co-occurrence keyword analysis

Over the past couple of years there has been increased involvement and information about Building Information Modelling in every aspect of Built environment and AEC Industry at large. This has led to evolvement of numerous themes and topics in research related to BIM's involvement in the construction industry. In this section we'll be discussing analytics surrounding co-occurring keywords in our results' dataset. Keywords play an important role by serving as reference point, aiding the contents' description and conceptual understanding in research literature. (Akinlolu, et al., 2020). Hence to perform co-occurring analysis of keywords, data from Web of Science was imported into VOS viewer. After feeding the said data into VOS viewer, the threshold for minimum occurrence of a keyword was set to 5 keywords. Hence, out of 781 keywords, 34 met the threshold. Table 2 tabulated the most recurring or co-occurring keywords in decreasing order of occurrence.

Table 2: Keyword occurrences

No	Keyword	Occurences	Total link strength
1	bim	57	150
2	building information modelling	33	100
3	management	29	108
4	procurement	28	80
5	construction	24	66
6	performance	23	89
7	design	22	86
8	framework	22	90
9	implementation	21	94
10	model	21	84
11	collaboration	17	53
12	building information modelling	15	29
13	building information modelling (bim)	15	36
14	building information modelling (bim)	15	37
15	information	15	51
16	innovation	13	65
17	project management	13	52
18	system	13	53
19	projects	12	57
20	industry	10	57
21	technology	9	42
22	sustainability	8	27
23	adoption	7	34
24	construction industry	7	27
25	construction supply chain	7	14
26	information modelling bim	7	39
27	construction projects	6	27
28	interoperability	6	20
29	systems	6	25
30	infrastructure	5	14

31	ipd	5	14
32	lean construction	5	19
33	prefabrication	5	18
34	simulation	5	27

The degree of co-occurrence is determined by similarity of keywords as well as their proximity to one another. The 34 top productive and repetitive keywords from 176 research publications produced total of 4 clusters as shown in the figure below. The biggest cluster of all was cluster 1 with 13 keywords and is denoted by red color. The intertwining of links and proximity of nodes reinforces the point that the various aspects of construction industry and built environment are directly proportional and related to Building Information Modelling.

4.3.1 Cluster 1

The first and strongest cluster had various keywords with strong and highly imperative correlation and literature's scientific structure thus helping in anticipating trends and establishing firm research base for future. As shown in Fig. 3, the first cluster had several keywords like building information model/modelling, project management, construction industry, lean construction, prefabrication, sustainability, and interoperability.

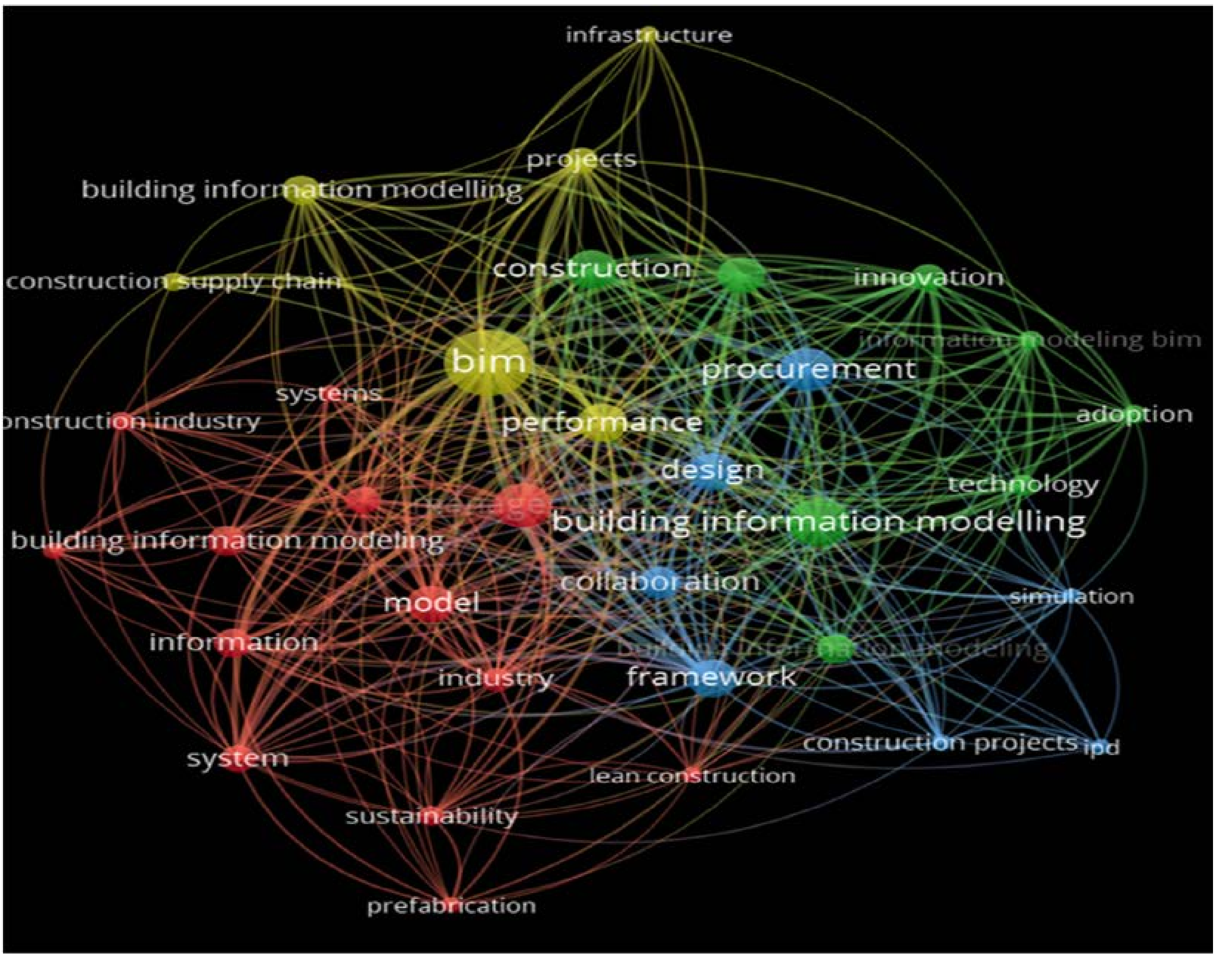

Fig. 3: Keyword co-occurrence network visualization

This cluster's keywords had most relatedness thus depicting that these areas of research in relation to BIM were most comprehensive. We'll also look at the overlay visualization of these clusters as well in the figure below. The cluster 1 had research conducted on its keywords from 2015 to 2017.38 average year. The keywords like 'lean construction' and 'prefabrication' were the latest with average year 2017 moreover both keywords had 5 occurrences each. This is indicative of the fact that although BIM's involvement with sustainability and industry is couple of years old, but still witch each passing year we are seeing innovative concepts being researched about in BIM's context.

4.3.2 Cluster 2

This cluster had some interesting terminologies like technology, innovation, implementation, and adoption along with the other repetitive keywords like "BIM", "construction" etc. As opposed to the cluster 1, this cluster had more recent research trends averaging between year 2017 to 2018. The keywords like "innovation" had strong links with "BIM adoption" and "construction collaboration". Thus, it is pertinent to note that there has been increased inclusion of innovation and adoption in hot areas of global subject literature around BIM and the strong edges in "overlay visualization" are indicative of increased research trends.

4.3.3 Cluster 3

The third cluster as shown in Fig. 4 revolved around keywords like "collaboration" (17 occurrences, 22 links and avg. pub. Year 2016.4), "construction projects" (6 occurrences, 16 links, avg. pub. year 2017.5), "design" (22 occurrences, 27 links, average year of publication 2016.80), "framework" (22 occurrences, 28 links and average year 2017), "procurement" (28 occurrences, 26 links, average pub. year 2016.19) whereas '"IPD or integrated project delivery" and "simulation" had 5 occurrences each with 14 and 19 links, and avg. pub. years. 2015.25 and 2016.5 respectively. Keywords like "framework", "procurement" and "simulation" were seen to be the most recent ones in this cluster, however, one common thing among all clusters is the strong link strength and proximity with the words 'BIM'. Based on centrality of nodes and strength of links, an inference could be made that these keywords play an important role in diversifying the BIM's research literature.

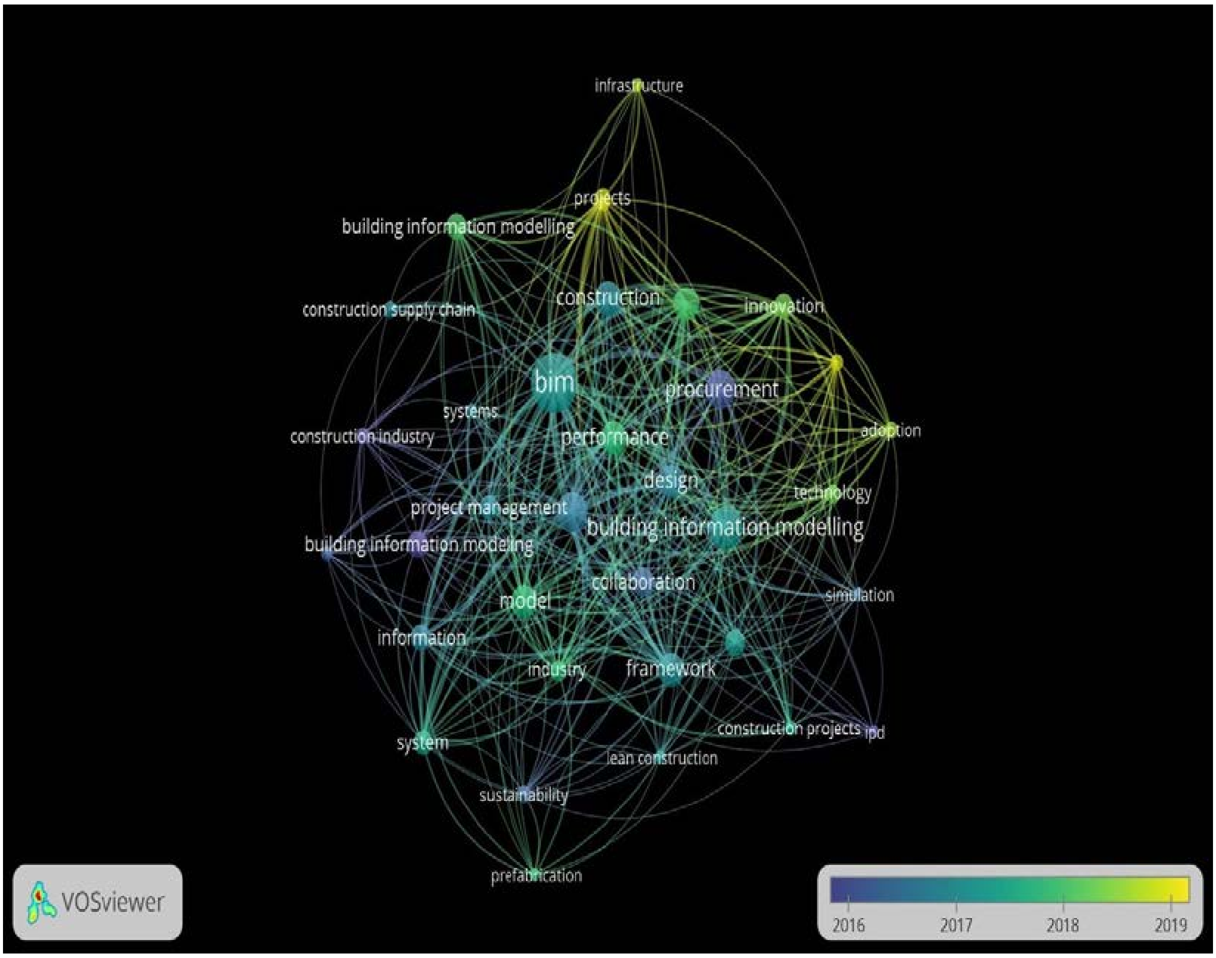

Fig. 4: Keyword cluster overlay visualization

4.3.4 Cluster 4

The last cluster had total of 6 keywords that included BIM, building information modelling, construction supply chain, infrastructure, performance, and projects. The green and yellow nodes (representing year 2017 and 2018) of these keywords reflect the latest research developments and collaboration in these respective fields. If we look at the item density visualization in Figure 5, item density visualization it tells us about the keywords density at a particular point and is represented by a color. The colors vary from blue to green to yellow. The closer the proximity of the keyword to the large number of other keywords and the larger the weight of those items, the more the color of that point is yellow. Hence, if we analyze the density visualization, it is self-evident that keyword "BIM" has bright yellow color and has proximity and relatedness with keywords like "performance", "procurement", "management", "design", "collaboration" and "construction". Since the word "BIM or Building information modelling" has been repetitive in each cluster thus not all same keywords have same density. For example, item density visualization in Figure. 5 illustrates "construction supply chain" in proximity with 'building information modelling' in top left corner thus reiterating the connection between the two.

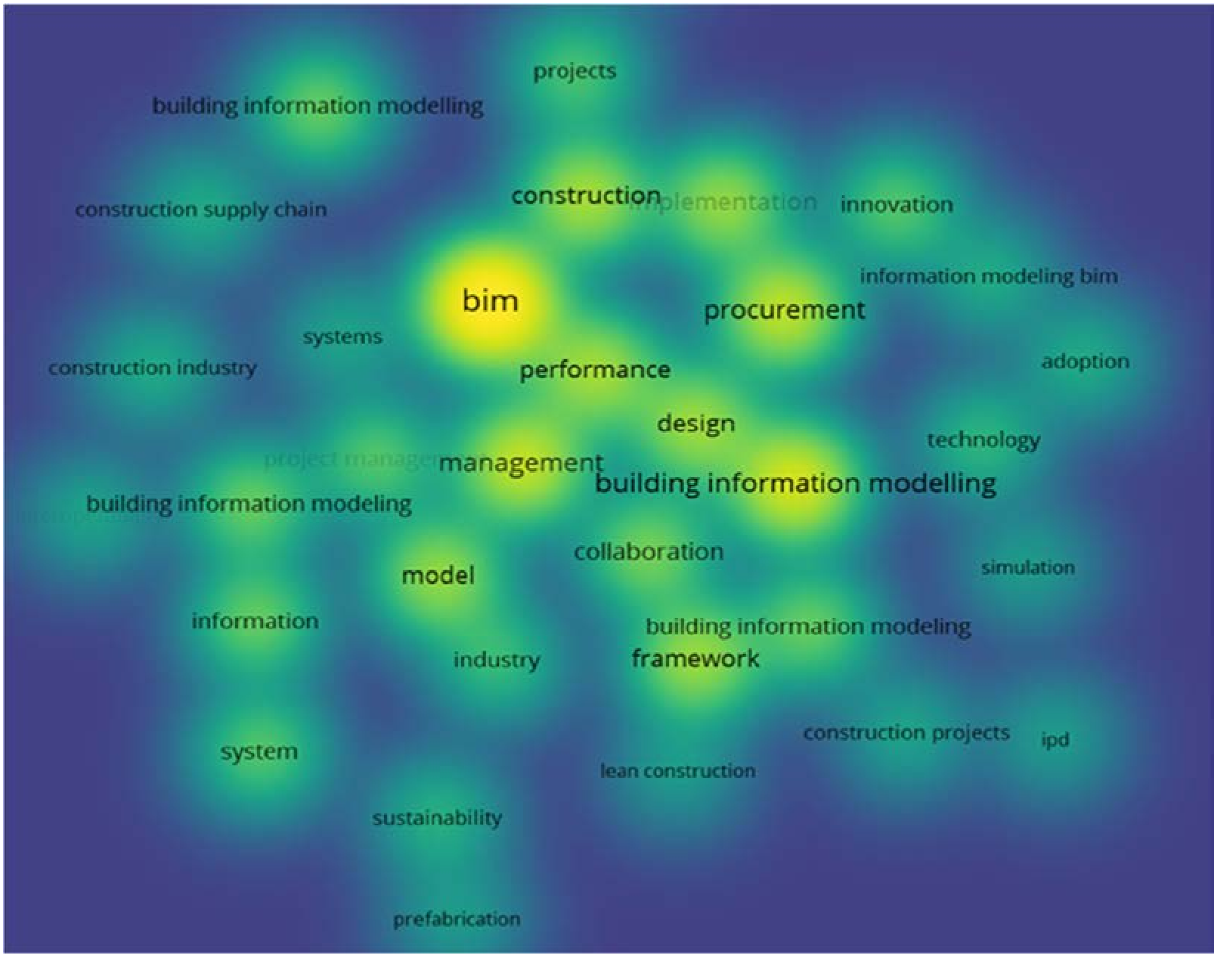

Fig. 5: Item density visualization

4.4 Collaboration network of countries

Consequently, the dataset produced comprehensive scientific mapping for us to analyze. The collaboration network of countries was pulled out and examined, as shown in Figure 7: Collaboration Network of Countries. The figure illustrates the biggest collaboration node being represented by UK having the strongest cross collaboration link with Australia. UK was seen to have a collaboration network with Australia, Luxembourg, Canada, South Africa, Ireland, China, Hong Kong, and Ireland. Whereas, after removing the isolated nodes several collaboration trios were identified. These trios included USA, China, and Israel. Moreover, to have a clear picture of social structure, a country collaboration map was prepared as shown in Fig. 6, that showed intercontinental collaboration on BIM usage in supply chain and construction industry.

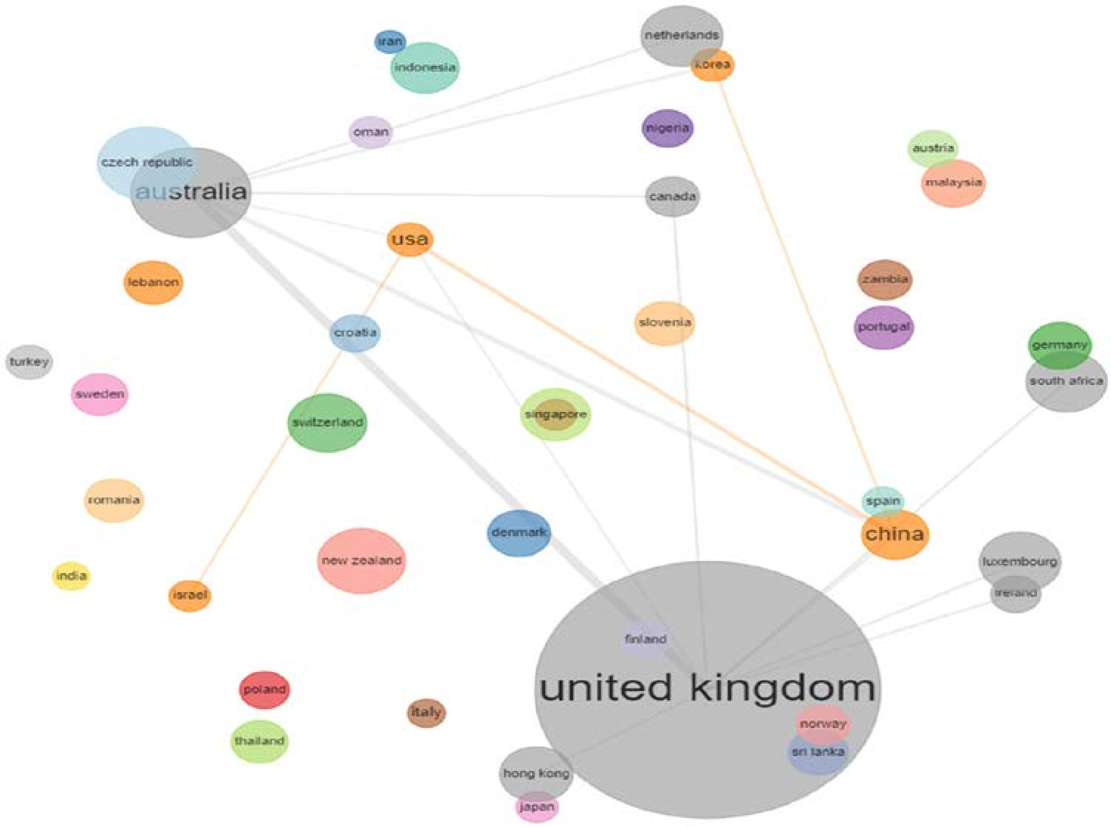

Fig. 6: Collaboration network of countries

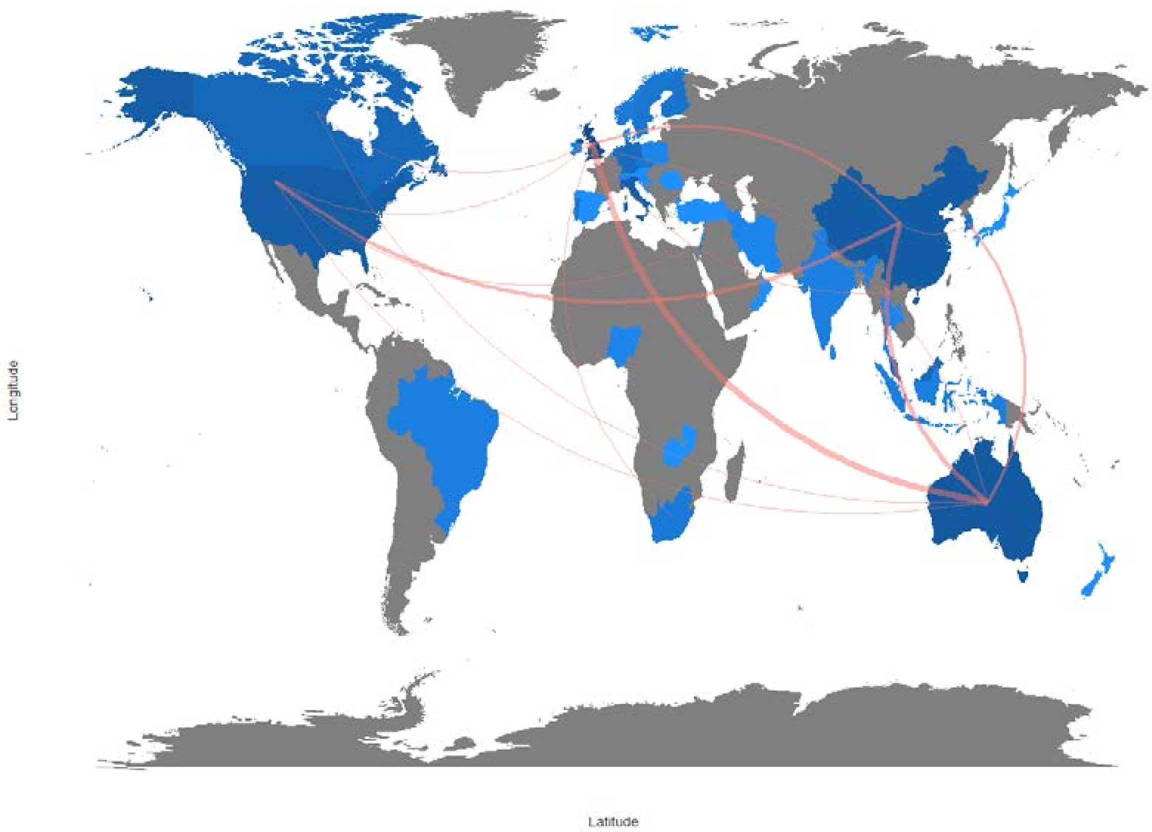

Fig. 7: Countries of collaboration

Fig. 7 shows there are three shades of blue clearly seen in the map. The darkest shade of blue seen between China, Australia, UK, and USA represent most productive contribution, whereas the thicker pink linkages depict the strength of collaboration. The lighter shade of blue comes second in production of scientific literature on BIM, construction supply chain and procurement.

4.5 Conclusions

The Web of Science database helped discover 176 relevant publications which were imported into VOS viewer and as per research objectives the co-authorship analysis were performed initially. The co-occurrence authorship analysis depicted various patterns. The strongest partnership cluster between authors comprised of 5 authors denoted by red color and had thickest edges thus had biggest impact. We can see the biggest cluster of 5 authors although had the strongest links and collaboration but still the average publication years were between 2014-2015. This explains that the only strong collaborations on BIM's relation with construction supply chain were done couple of years ago and are not recent. Whereas the yellow-colored clusters which are not only small in link strength and only consist of 2 or 3 authors, but also have less collaboration and occur isolated in the cluster, are the most recent ones. There is no robust or exponential growth in scientific research literature when it comes to BIM adoption into supply chain management, logistic and/or procurement. Thus, the future BIM research must be driven and molded towards these areas.

The second scientometric analysis was Co-occurrence of keyword analysis, which consisted of 4 keyword clusters, with Cluster 1 being biggest containing 13 keywords, followed by 8,7 and 6 keywords respectively. It was pertinent to observe that the word "Construction Supply Chain" only appeared once in a cluster, with 7 occurrences in cluster 4, with average publication year of 2017. The most recent or latest keyword cluster was seen to be 'adoption' (denoted by yellow) with strong links to other keywords like "technology", "information", "infrastructure", "management", "design", "framework" etc. Thus, a clear pattern can be observed here that the already existing research regarding BIM's adoption into infrastructure management and other fields is being explored but at the same time key area like supply chain is somewhat lagging. On the other hand, 280 publications from Scopus were exported to Biblioshiny for scientometric mapping purposes and collaboration network between the countries was analyzed. This was done to examine the global research patterns which would further help in identifying the parts of the world where lack of collaboration is significant. Hence paving the way for future researchers, belonging from those countries, to comprehensively explore into otherwise ignored BIM's associated aspects, particularly in construction supply chain.

The innovative contribution of this study is pertinent with the integration of BIM and CSC are still quite theoretical and conceptual, lagging in substantiated research. Only after extensive research and observing BIM's impact on the construction supply chain and its management, its contributions are clear to the CSC. Study gaps in previous research highlighted BIM's role on multi-dimensional aspects to supply chain. This study is highly imperative as it compliments the existing knowledge in context of BIM's at large and particularly in relation to construction procurement. Current challenge includes the creation of a consistent information flow that hasn't addressed BIM cooperation process among all construction stakeholders. Therefore, this study contributes towards addressing these practical issues by outlining a framework for the integration of BIM and CSC. An example of successful application of the relationship is when BIM acts as an information integrator while CSC is a secure environment for collaboration in real-world construction project. The BIM-based CSC multi-model integration framework is therefore crucial in identifying, analyzing, and making full use of the organisational, operational, and technical complexity. Additional real-world cases can be used to calibrate the model in the future to establish successful application of the relationship between BIM and the construction supply chain.

E-PROCUREMENT IN THE AUSTRALIAN CONSTRUCTION INDUSTRY: BENEFITS, BARRIERS AND ADOPTION

Eleanor Hayden, Melissa Chan & David van Kan
Victoria University, Australia

Victor Arowoiya
Monash University, Australia

Mohd. Amizan Mohamed @ Ariffin
Universiti Teknologi Mara, Malaysia

ABSTRACT: *A clear benefit of e-procurement technology in the construction sector is its capacity for in reducing waste and costs. Despite its successful adoption in other major industries, the take-up of e-procurement in the construction industry has generally been slow. A variety of barriers to adoption have been identified in literature, predominantly at an international level. Whilst the benefits of e-procurement are well-known and the challenges and barriers to the adoption of these systems in the construction industry has been well-documented, research into actual outcomes following the adoption of e-procurement systems through a case study analysis is limited. Tracking and measurement of adoption rates in the Australian construction industry is particularly scarce. To build upon and add to the existing body of contemporary literature, this study seeks to examine the adoption of e-procurement technologies in the Australian construction industry. As the Australian construction sector enters a period of high inflation, technologies such as e-procurement have a critical role in mitigating these price escalations. Understanding the barriers and opportunities for wider adoption of e-procurement in the Australian construction industry is also a clear benefit with its capacity for digital transformation in the construction sector.*

KEYWORDS: *E-procurement, technologies, digital transformation, construction, Australia.*

1. INTRODUCTION

The construction industry is one of the largest sectors in the Australian economy, employing some 1.03 million workers across 395,000 individual businesses (IBISWorld, 2021). The industry accounts for 9% of Australian Gross Domestic Product (GDP) with the total value of construction work done over the 12-months to December 2021 in the order of $214 billion (ABS, 2022). Procurement management is a well-established technique utilised by firms to drive sustainable competitive advantages during periods of economic turbulence (Hong and Kwon, 2012). Since emerging more than two decades ago, e-procurement technologies have increased significantly across many sectors (e.g., manufacturing, wholesaling) as both government and private firms have realised the benefits of e-procurement platforms, including, inter alia, increased transparency and accountability, improved sustainability, and cost savings (Deraman et al., 2019). The evolution of e-procurement platforms has evolved greatly over this period, growing from simple electronic-based systems to fully integrated, web-based platforms. Despites its successful adoption in other major industries, the take-up of e-procurement in the construction industry has generally been slow and low (Afolabi et al., 2019).

A clear benefit of e-procurement technology in the construction sector is its capacity to reduce waste and costs. For instance, e-procurement enables building and construction firms to more accurately review and cost projects at the procurement stage and enables more efficient management processes on-site. Furthermore, e-procurement enables clients to achieve more competitive pricing through contacting more potential suppliers without increasing overheads. Technologies such as e- procurement systems have a critical role in mitigating price escalations and while the challenges to the adoption of these systems in the construction industry has been well-documented, research into actual outcomes following the adoption of e-procurement systems is limited. Tracking adoption rates in the Australian construction industry is particularly scarce. To build upon and add to the existing body of contemporary literature, this study applied the science mapping approach into the area of e-procurement in construction. It aims to provide insight into the existing challenges, benefits, and adoptions rates of e-procurement in the Australian construction industry and seeks to provide recommendations for future adoption.

2. LITERATURE REVIEW

E-procurement is the use of the Internet to support the delivery of procurement tasks. More specifically, it is an aspect of e-Commerce that incorporates web-based applications and communication technologies to carry out

Referee List (DOI: 10.36253/fup_referee_list)
FUP Best Practice in Scholarly Publishing (DOI 10.36253/fup_best_practice)

Eleanor Hayden, Melissa Chan, David van Kan, Victor Arowoiya, Mohd. Amizan Mohamed, *E-Procurement in the Australian Construction Industry: Benefits, Barriers, and Adoption,* pp. 489-498, DOI 10.36253/979-12-215-0289-3.47

procurement activities such as sending and receiving tender information, submission of tenders, acquisition of materials, equipment and services, and payment of goods and services (Ibem and Laryea, 2015). A study conducted in the United Kingdom by Eadie et al., (2010) sort to identify the leading barriers and benefits in e-procurement. A survey of 775 construction organizations was conducted and revealed that the leading benefits were 'Process, transaction and administration cost savings', 'Convenience of archiving completed work', and 'Increased quality through increased accuracy'. These benefits support the findings of Brandon-Jones (2017) who suggests that the use of e-procurement can deliver significant operational benefits, including improved delivery accuracy, reduced transaction costs and greater control over organization procurement. Furthermore, Yevu and Yu (2019) found that drivers of e-procurement can be broken into seven categories: external drivers, project-level drivers, technological and process-level drivers, company-level drivers, individual-level drivers, service satisfaction drivers and sustainability concept drivers. Interestingly, they note that modern construction concepts such as sustainability and client satisfaction are influencing the adoption of e-procurement. Conversely, Eadie et al., (2010) identified the dominate barriers to e-procurement as 'Prevention of tampering with documents', 'Confidentiality of information', and 'Resistance to change'. Another study by Yevu et al., (2021b) categorized barriers into six groups: technological usability and evolution, security and unsupportive environment, culture, infrastructure, unethical practices, and financial and skills related.

A wide range of international studies has been undertaken, (Zunk et al., 2014; Ibem and Laryea, 2015; Afolabi et al., 2017, 2019; Tran et al., 2021) and found that whilst e-procurement is not a new concept in the varying industrial sectors, the construction industry has been slow in adoption compared to other industries such as manufacturing and retail business (Ibem and Laryea, 2015). These studies indicated the varying barriers and drivers e-procurement has on developing and developed economies. It has been discovered that the high cost and low access of Internet services in developing countries combined with lack of industry experience and training has had an adverse effect on initial uptake of e-procurement (Ibem et at., 2021; Tran et al., 2021). A common barrier found both in developing and developed countries was the lack of expertise and promotion of e-procurement (Yevu et al., 2021b; Zunk et al., 2014). Zunk et al., (2014) reports that some construction firms in Austria didn't know what e-procurement was let alone the benefits. Afolabi et al., (2017) states that the benefits of e-procurement platforms should not be overlooked. They note it is a viable tool for increasing productivity and empowering construction professionals to exercise greater control of the construction process. Aghimien et al., (2021) added that digitalisation offers solutions to consistent challenges of delivering projects over budget, beyond the expected timeframes and not to specification. It is evident that a large volume of international research exists relating to e-procurement within the construction sector.

Enterprise Resource Planning (ERP) systems have become commonplace applications in significant sectors. According to industry rankings and turnover, the top suppliers include SAP, ORACLE, Microsoft. ABAS, IFS and Step Ahead. Implementing BIM enables better project management, process efficiency, increased transparency, cost control, and real-time communication, just like with ERP systems. Additionally, the system may retain all technical information, drawings, and construction methods, and users can simultaneously work on different project phases throughout the course of the project's lifespan. BIM may be used to manage the technical elements of a building project as well as help with strategic procurement choices like choosing a contractor. There are many advantages of adopting ERP systems in the construction industry including automating procedures in client assistance, project management, cost predictions, employee management and procurement management through operational automation. Project management needs to be optimized since it is vital to the success of any construction company. Without good project management, the company would lose Clients and money. With all operational activities are automated by the ERP system, project management supervision is improved. ERP is a useful tool for cost estimation since it considers all important cost aspects, including materials, design, contracts, and transportation. Budgets for specific cost centres can be estimated and allocated to include overhead liabilities and even potential delays.

In the construction sector, successful project execution depends on efficient communication, in which ERP systems are enhancing communication. One issue that construction businesses frequently struggle with is maintaining strong departmental communication. Project schedules may be impacted by departmental disconnections that slow down operations and business processors. Employees may rapidly tell executives and management on projects on their mobile devices thanks to mobile features. It is possible to handle external communication and updates using stakeholder and customer relationship management software that is integrated with the ERP system. Another key benefit of ERP in construction is it enables remote access to all pertinent files and data. ERP systems assist in the efficient and speedy centralisation of huge amounts of data. Cloud applications can be used by the latest technology, which eliminates the need for big, expensive servers. ERP and BIM technologies provide more efficient project management and improved cost accuracy. All project data may be kept in a single repository, and numerous users can access it at once. Computing aided design applications can be integrated with BIM as a solution to improve efficiency in procurement in the construction industry.

3. METHODOLOGY

This review-based study applied the science mapping approach into the area of e-procurement in construction. It aims to provide insight into the existing challenges, benefits, and adoptions rates of e-procurement in the Australian construction industry and seeks to provide recommendations for future adoption. To achieve these objectives, a three-stage review process will be adopted.

3.1 Bibliometric search

The initial step of the review was the preliminary literature search using academic research database, Scopus. Scopus database has been used as the main source of information as it is considered a reliable source of scientific publications by academics (Baas et al., 2020). A comprehensive search was undertaken using a search string of keywords consisting of “e- procurement” or “procurement” or “sustainable procurement” or “digital procurement” and “construction” or “building”. Initially, 654 publications were found. These publications were further screened by only including publications dated between 2012 – 2022, journal articles exclusively and in English. This screening reduced the available literature samples to 492. Further screening of the remaining articles was conducted through the review of publication titles, abstracts, and keywords. Publications that were not closely related to this study were removed. This exercise highlighted that Automation in Construction, Construction Innovation and International Journal of Procurement Management had at least three papers each. A total of 82 papers from 45 journals were selected as the literature sample for the scientometric analysis.

3.2 Scientometric analysis

The second step of the review involved a scientometric analysis method by adopting the bibliometric mapping software VOSviewer (Van Eck and Waltman, 2010). Scientometrics can be described as the quantitative approach applied in text mining of scientific publications (Hawkins, cited in Aghimien et al., 2021). Scientometrics are useful in facilitating a visual perspective of structural and dynamic aspects of scientific research and analysis outlined within existing literature (Olawumi and Chan, cited in Aghimien et al., 2021). Thus, it has allowed researchers to discover existing systematic literature-related findings by connecting literature theories that may have been missed in manual review studies. VOSviewer generates, visualises, and analyses bibliometric networks (Van Eck and Waltman, 2010). Specifically, its text mining capabilities can construct network maps of journal sources, co-citations, co-authorship, country of origin and co-occurring keywords sourced from abstracts and bodies of research articles (Van Eck and Waltman, 2011). The literature sample sourced from Step 1 was imported into VOSviewer to create a network of co-occurrence keywords, along with lead journal authors and sources, and country of origin. The co-occurrence network assisted in identifying the primary area of interest of e-procurement.

4. RESULTS

A total of 30 countries was identified from the literature sample. Australia has the highest number of publications (15), with 82 citations. This is followed by United Kingdom with 9 publications and 86 citations, and China with 8 publications and 42 citations. Countries which closely followed included Malaysia, Hong Kong, and Nigeria. Interestingly, 14 out of the 30 countries only published one article between 2012 and 2022. The potential for further research within these countries to gain a greater understanding of e-procurement in construction could be beneficial for future researchers.

4.1 Publications per author

An authorship network map is used to identify the influential researchers in the e-procurement sector of construction research (Marzouk et al., 2022). A minimum of two published articles and five citations was set as the criteria of the authors. Tunji-Olayeni P., Yevu S.K., and Yu A.T.W. are the most productive scholars in this research domain based on the number of published articles. Additionally, Eadie, R., Perera, S., and Heaney, G., are in the same cluster, indicating their mutual relationship by citing one another’s work. The distance and connection lines between clusters can also be used to determine the authors linkage strength (Van Eck and Waltman, 2014). The quantitative measurements of the most prominent authors are explored in Table 1. The affiliation column shows the author’s institution at the time of publication and reveals that Ibem E.O. has the highest number of citations 79 for their three extracted documents. However, Yevu S.K., Yu A.T.W., and Tunji-Olayeni P. have the highest number of publications of four extracted documents with 14, 14 and 53 citations, respectively.

Table 1: Number of publications per author

Author	Affiliation	Nos	Citations
Tunji-Olayeni P.	Department of Building Technology, Covenant University, Nigeria	4	53
Yevu S.K.	Department of Building and Real Estate, The Hong Kong Polytechnic University, Kowloon, Hong Kong	4	14
Yu A.T.W.	Department of Building and Real Estate, The Hong Kong Polytechnic University, Kowloon, Hong Kong	4	14
Ibem E.O.	Department of Architecture, Covenant University, Nigeria	3	79
Layryea S.	School of Construction Economics and Management, University of Witwatersrand, South Africa	2	60
Grilo A.	UNIDEMI, Faculdade de Ciências e Tecnologia da, Universidade Nova de Lisboa, Monte de Caparica, Portugal	2	58
Costa A.A.	CIST/Instituto Superior Técnico, University of Lisbon, Portugal	2	37
Tavares L.V.	CESUR/Instituto Superior Técnico, University of Lisbon, Portugal	2	37

4.2 Publications per source

Publications within the literature sample originated from 49 sources. Table 2 depicts five sources with at least three publications focusing on e-procurement in construction. Engineering, Construction and Architectural Management and Construction Innovation have the highest number of extractions with four articles each and interestingly, 14 citations each. The most cited source is Automation in Construction, with three articles and 42 citations.

Table 2: Number of publications per source

Source	Nos	Citations
Engineering, Construction and Architectural Management	4	14
Construction Innovation	4	14
Automation in Construction	3	42
International Journal of Procurement Management	3	34
International Journal of Construction Management	3	22

4.3 Pattern of keywords

Through analysing keyword co-occurrences, knowledge advancements can be mapped to assist in understanding the knowledge structure of study (Su and Lee, 2010). To formulate such map, VOSviewer's co-occurrence analysis of keywords was used. The assessed articles produced a total of 459 keywords. VOSviewer groups the keywords into clusters using a set criterion for co-occurrences (Aghimien et al., 2021). The clusters identify common areas of research in past studies. The threshold of minimum number of occurrences of keywords in automatically set to five. According to Aghimien et at. (2021) there is no joint agreement regarding the ideal number of minimum co-occurrences to be applied in the body of knowledge. To ensure an optimal representation of keywords was identified in this study, the minimum number of occurrences was set to three. A total of 37 keywords met this threshold with a total link strength (TLS) of 460. General keywords such as "construction", "construction industry', "construction project", etc, were removed. Additionally, keywords with the same meaning, such as block-chain and blockchain were blended. Finally, 32 keywords were generated as illustrated in Fig. 1.

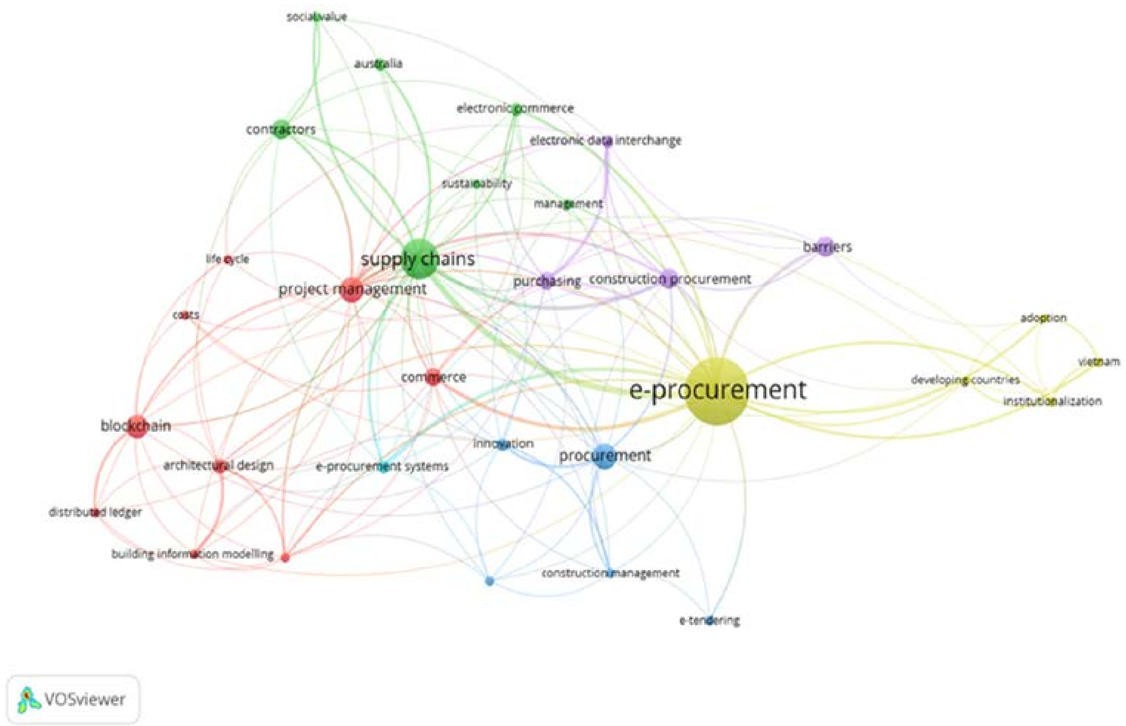

Fig. 1: Keyword co-occurrence network

The size of the nodes shows the frequency of occurrence and the lines between the nodes represent their co-occurrence in the same publication (Van Eck and Waltman, 2018). The closer the two nodes are, the greater the number of co-occurrences of the two keywords. For example, architectural design is found with close relationship with blockchain, information management and building information modelling design. It has been identified that, e-procurement, supply chains and project management were the most frequently entered keywords in the context of e- procurement in construction. It is unsurprising that e-procurement is at the centre of this network given it was the main search keyword to which other keywords are linked. Table 3 shows the occurrence and TLS of each keyword. Furthermore, the analysis categorised keywords that appeared multiple times into six clusters.

Table 3: List of clusters and co-occurring keywords

Cluster 1 (Red)	Occ.	TLS	***Cluster 3 (Blue)***	Occ.	TLS
Architectural design	5	16	Construction management	3	11
Blockchain	8	14	E-tendering	3	4
Building Information Modelling	3	11	Innovation	4	14
Commerce	6	18	Procurement	9	19
Costs	3	5	Public procurement	3	8
Life cycle	3	7	***Cluster 4 (Yellow)***		
Project management	9	34	Adoption	3	8
Cluster 2 (Green)			Developing countries	3	10
Australia	4	7	E-procurement	27	58
Contractors	7	15	Institutionalisation	3	9
Electronic commerce	4	13	Vietnam	3	8
Management	3	9	***Cluster 5 (Purple)***		
Social value	3	8	Barriers	7	10
Supply chains	15	47	Construction procurement	7	24
Sustainability	3	5	Electronic data interchange	4	15
			Purchasing	6	21
Occ. = Occurrence			***Cluster 6 (Teal)***		
TLS = Total Link Strength			E-procurement systems	4	16

4.4 Pattern of keywords

In addition to the network map, an overlay visualisation map is produced in VOSviewer. This map shows the keywords based on their year of publication during the period of 2016 to 2021. A coloured bar, identifying the years with a correlating colour is displayed in the bottom right- hand corner of the map (Van Eck and Waltman, 2018). For example, keywords coloured blue were published between 2016–2017 and focused on e-procurement areas relating to developing countries, adoption, institutionalisation, e-commerce, and information management. Publications between 2017–2019 seemed to shift focus slightly to areas such as supply chains, costs, barriers, purchasing, e-tendering, and e-procurement systems. These keywords are displayed in dark green/blue on the visualisation map. The latest years on the map which include 2020 – 2021 see a wide range of topics be introduced, including, electronic data exchange, social value, blockchain, building information modelling (BIM), innovation, sustainability, construction management and life cycle. These keywords are represented in bright green/yellow. Fig. 2 illustrates the overlay visualisation map. Examining the overlay visualisation map in conjunction with the

TLS results in Table 3 (cluster table) suggests that future research of e-procurement in construction could explore areas relating to e- tendering, costs, life cycle, sustainability, adoption, and social value. These areas have been identified to have low TLS results from past research studies. Despite their importance, these research areas have received little attention.

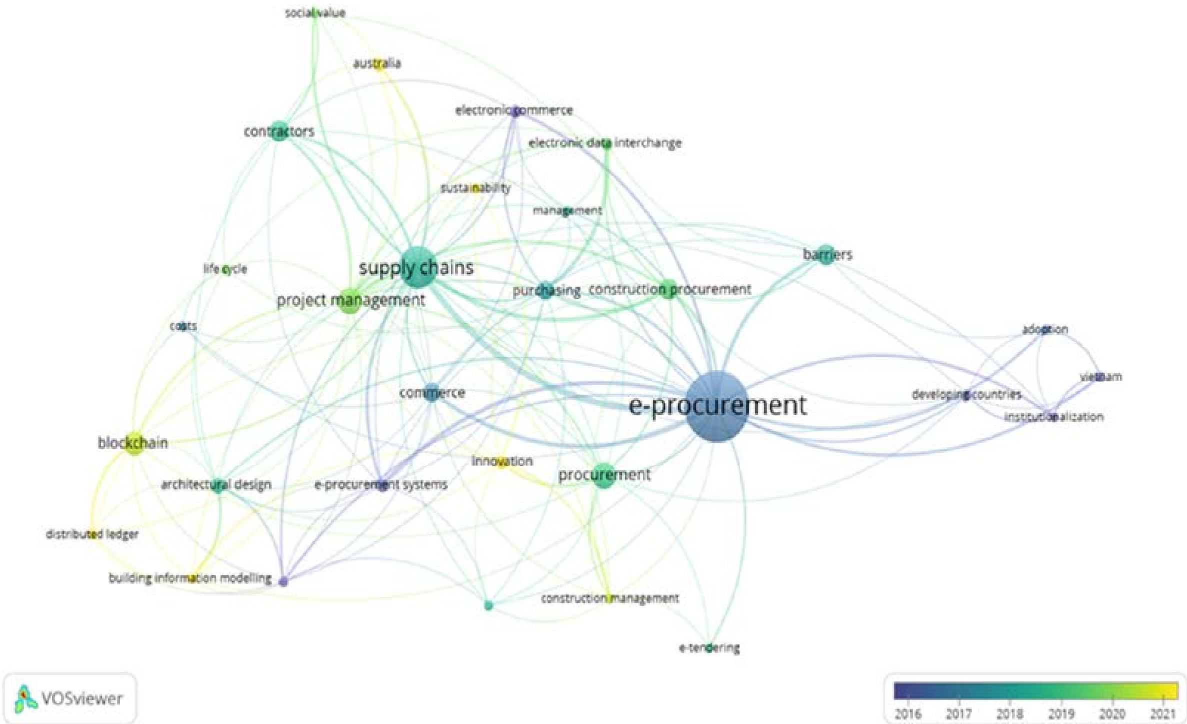

Fig. 2: Overlay visualization map.

5. DISCUSSION

From the foregoing review and bibliometric analysis, the following four key areas have been identified as the main categories of this research.

5.1 Adoption rates in other countries

Whilst several global studies into the barriers of e-procurement have been carried out (Yevu et al., 2022), analysis into the actual adoption levels of e-procurement practices globally is not heavily featured in the literature reviewed. Instead, analysis on adoption rates is often country specific. Several in-depth studies into a broad mix of developed and developing countries has been identified, such as Austria (Zunk et al., 2014), South Africa (Ibem and Laryea, 2015), Nigeria (Afolabi et al., 2019) and Vietnam (Tran et al., 2021). Whilst there has been some investigation into e-procurement practices in the Australian construction industry (Lin et al., 2022; Loosemore and Reid, 2019), there is very little contemporary literature into the adoption rates in the Australian context and how this compares globally. This Study will seek to partially address this gap in existing literature.

5.2 Benefits and enablers of e-procurement

There is a significant volume of research and analysis into the benefits and enablers of e- procurement practices. The drivers and barriers of e-procurement in the construction sector was comprehensively examined in Eadie et al. (2010), with the key drivers identified including (1) Process, transaction and administration cost savings; (2) Convenience of archiving completed work; (3) Increased quality, efficiency and accuracy; and (4) Shortened internal and external communication cycle times. The literature into drivers and benefits has continually strengthened over the past decade, with key contributions from Yevu et al., (2021), Khahro et al., (2021), Pattanayak and Punyatoya (2021) and Wimalasena and Gunatilake (2018), amongst others.

Despite the significant volume of literature, there are few examples of 'firm-level' studies which validate the perceived benefits of e-procurement from a construction organisation perspective. The need for more firm-level studies to measure the link between productivity and digitization in the context of the Australian construction industry was identified by Leviakangas et al., (2017). There is also a clear lack of Australian-focused literature which examines the potential benefits of e-procurement based on the local industry environment.

5.3 Barriers to e-procurement adoption and challenges upon implementation

As observed with benefits and enablers, there is an extensive volume of existing literature and research into the barriers to e-procurement adoption in the construction industry. Eadie et al. (2010, 2012) was one of the first to examine these barriers in significant detail, though extensive primary research has been carried out across multiple countries since that time, with prominent examples being Yevu et al., (2021), Yevu and Yu (2019), Nawi et al., (2017) and Afolabi et al., (2017). Yevu et. al (2021) categorised some 21 individual barriers to e-procurement adoption into six barrier groups based on an extensive review of existing literature and primary research. These barrier groups include:

i. Technological Usability and Evolution-Related Barriers

ii. Security and Unsupportive Environment-Related Barriers

iii. Culture-Related Barriers

iv. Infrastructure-Related Barriers

v. Unethical Practices–Related Barriers.

vi. Financial and Skill-Related Barriers

There is more limited research into the challenges of e-procurement usage in the construction industry upon implementation. Primary research through direct interviews with construction industry professionals in Ibem et al. (2021), Isikdag (2019) Nawi et al. (2017) and Brandon- Jones (2017) provide useful insights into the first-hand challenges of industry participants upon implementation of e-procurement systems. Whilst there is an excellent base of research from which the Study can leverage, it is evident from the literature review that there is a lack of Australian-focused studies which have identified (if any) Australian-specific barriers and challenges of e-procurement practices in the construction sector. The Study will seek to examine this in detail and further build upon the strong evidence base of research into the barriers of e-procurement adoption and the challenges identified by industry participants upon implementation of e-procurement systems.

5.4 Conclusions

Existing literature has carried out extensive engagement with industry stakeholders to identify the barriers to adopting e-procurement practices and the challenges upon their implementation as observed in Ibem et al., (2021), Isikdag (2019) Nawi et al. (2017) and Brandon-Jones (2017). It is noted that none of these studies have focused specifically on the Australian construction industry. Whilst there is an excellent base of research from which this study can leverage, it is evident from the literature review that there is a lack of Australian-focused studies on specific barriers and challenges of e-procurement practices in the construction sector. The scope of this review focusses on the implementation of e-procurement in facilitating towards digital transformation in the construction sector. The study examines this in detail in the next phase of study and further build upon the strong evidence base of research into the barriers of e-procurement adoption and the challenges identified by industry participants upon implementation of e-procurement systems. Study findings may be used to guide construction companies' investment choices in digitally modernising the procurement function. Through their procurement processes, organisations may boost their digital transformation objectives.

A PRELIMINARY INVESTIGATION OF KNOWLEDGE MANAGEMENT TOOLS FOR THE CONSTRUCTION SECTOR

Bartu Kologlu & Deniz Artan

Istanbul Technical University

ABSTRACT: *Knowledge management (KM) is used by construction firms to establish organizational memory (OM) and consequently improve their performance by learning from past mistakes and best practices. Knowledge is the input to innovation; thus, the industry must adopt better ways of managing knowledge for advancement in the construction processes. Knowledge management consists of locating, modifying, and sharing knowledge to meet the needs of the current fast-paced sector. Various tools have been developed to support KM and OM in construction companies, however, it is very important to adequately address the needs of the sector for successful implementations. The aim of this study is to analyze the existing KM tools and evaluate their compatibility with the necessities of today's sector. First, knowledge types in the construction industry were outlined, and existing KM tools were evaluated. Then, expert interviews were performed with two representatives from a prominent construction and a prominent consulting firm to delineate the contemporaneous KM practices as well as the KM needs in the construction industry. Finally, current practice in KM in the construction sector is evaluated, and a vision is developed for a more effective KM approach that could support OM in construction firms.*

KEYWORDS: *Knowledge Management, Organizational Memory, Construction Firms, Software Tools*

1. INTRODUCTION

Intellectual assets are the primary capital in knowledge-intensive industries. For companies looking to thrive in knowledge-based work environments, in-house procedures should be created to accumulate, explore, and exploit corporate and individual knowledge. The term "knowledge management (KM)" was used in Western countries for the first time during the late 20th century in books, academic research, consulting, and organizational adaptation processes. Nevertheless, the management of organizational knowledge did not truly start until the mid-1990s. Implementations of KM mechanisms were somehow present in companies long before these concepts emerged, such as knowledge-sharing activities. In the early 1990s, sector leaders such as BP, Shell, and Chevron used KM initiatives before any academic publication (Quintas, 2005). This shows that KM techniques were naturally used as a part of cooperative incentives to gain a competitive advantage and improve business performance. Today, KM is at the center of any modern business as rapid developments in information and communication technologies influence a profound shift from tangible assets to intangible assets focusing on people and knowledge. Even though many sectors with such needs have adapted ways of managing knowledge today, it is only in the last ten years that companies in the construction sector have started familiarizing themselves with the KM concept (Rezgui & Miles, 2011).

In order to benefit from KM as a pursuit of enriching organizational memory (OM) and achieving productivity, the types of knowledge encountered must be analyzed. There is a popular attempt to categorize types of knowledge in order to ease comprehending, storing, and sharing it. Each categorization considers different aspects of knowledge that guide the analysis in the specific field. The most applicable and renowned categorization for the knowledge management field belongs to Polanyi (Polanyi, 1966), which divides knowledge into tacit and explicit knowledge. Explicit knowledge is the recordable or documented information that can be written, coded, or saved with the intention to transmit knowledge. Tacit knowledge is the knowledge an individual owns, gathered from their insights, personal experience, and observations.

The construction sector is a knowledge-based industry comprising different project participants such as designers, engineers, contractors, and clients that generate overwhelming amounts of data in each project. Effective KM is crucial to organize and benefit from this data overflow. In the past decade, much research has focused on KM for various other sectors, such as consulting, finance, or computer science. Despite the evident need, the construction sector is still lacking effective KM tools to foster organizational memory in a project-based environment. The aim of this study is to explore the KM tools used for gathering, sharing, and storing tacit and explicit knowledge in construction companies. Since KM is effectively used in only a few initiator companies, the authors investigated the steps taken by these pioneers to delineate KM best practices for the construction sector.

This paper reports the results of the two pilot interviews done with the senior managers of two multinational firms.

The first firm is a consulting firm operating in 50 countries with more than 55 years of experience in the consulting sector. The interview was performed with a senior project director who has 10 years of experience in the sector. The second firm was chosen among the few contractors that use KM effectively, which operates in 50 countries with 107 years of experience in the construction sector. They are among the sector leaders with more than 80,000 employees. The interview was performed with a country manager who has 20 years of experience in the sector. Both experts were asked the same set of 12 questions under three main categories, which were: Data Collection, Data Accessibility and Usage, and Knowledge Management (See Appendix for the Questionnaire Form). The interviews with the company representatives took approximately one and a half hours each, during which the experts were guided by the questions and expressed their views on the topics driven from, but not limited to, the questionnaire.

2. EXPLICIT & TACIT KNOWLEDGE

Resources and competencies are critical factors for companies to survive in an evolving and fiercely competitive atmosphere in the knowledge-based economy (Subramaniam & Youndt, 2005). Thus, one of the biggest challenges is to be able to distinguish characteristics of knowledge from information. Knowledge can be either explicit or tacit. It is also important to distinguish tacit and explicit knowledge in order to comprehend the notion of organizational knowledge

Explicit knowledge is founded on widely recognized and objective standards. It is archived in the form of written procedures or documents. Therefore, it can be codified and communicated with relative ease. It encompasses the majority of knowledge exchange inside companies. Since explicit knowledge can be easily documented, formalized, and expressed, processes of sharing knowledge tend to be more widely used in the workplace. Several management tools are used to increase the willingness of employees to share their explicit knowledge, such as handbooks and information technology systems (Coakes, 2006). Since this knowledge can be codified, it may be reused repeatedly and is, hence, simpler to convey. Design codes of practice, performance requirements, paper-based or electronic drawings, and building methods are a few examples of explicit knowledge in the construction industry (Charles & Robinson, 2011). Other instances of explicit information include design sketches and photographs, 3-D models, and textbooks. Explicit knowledge is the data that can be interpreted by others once it has been codified. People with supplementary knowledge who are able to understand the "codes" and derive meaning from them may be able to understand the presented knowledge. Even this process of comprehending or deriving meaning from knowledge requires the application of implicit interpretational, evaluative, and generalizing skills.

The foundation of tacit knowledge sharing is human experience (Nonaka & Takeuchi, 1995). Polanyi (1966) described tacit knowledge as instinctive knowledge that cannot be expressed coherently by means of words; it is acquired via collective involvement and can be challenging to describe, systematize, and transmit. The informal adoption of taught behavior and methods obtains the uncodified and disembodied know-how. Furthermore, tacit knowledge cannot be directly conveyed to someone since knowledge and task performance have distinctive personal qualities, requiring the acquirer to adjust their mindset. Hence, the degree to which it is conveyed varies. Tacit knowledge can be maintained by individuals or as a team in the form of collective experiences and assessments of events. Employee objectives, capabilities, routines, and intangible information are sources of individual tacit knowledge. On the other hand, collective tacit knowledge may arise from various notions, including top management strategies, organizational agreement on previous shared experiences, company procedures, company culture, and professional customs (Lyles & Schwenk, 1992). Tacit knowledge can also be described as knowledge that has been converted into a habit and possesses a personal quality, as well as being very context-specific. The reality of tacit knowledge is that the less clear and codified the tacit know-how, the more difficult it is for individuals and businesses to internalize. Academics and managers have overlooked the notion of tacit knowledge until recently, although it now plays a major role in corporate growth and economic competitiveness (Howells, 1996). Transmitting tacit knowledge is frequently done primarily through direct conversation. Some tacit knowledge transfers are official as a result of training programs or seminars, while others are more informal as a consequence of interdepartmental work teams, unofficial social networks, and personnel interactions. The desire and ability of individuals to share their knowledge and apply it in practice are crucial to the formal and informal transmission of tacit knowledge (Holste & Fields, 2010). On the other hand, explicit knowledge is able to be formalized and communicated through structured and methodical means, such as in the form of rules and procedures (Nonaka & Takeuchi, 1995).

The difference between individual and collective explicit knowledge is that individual explicit knowledge consists of expertise and abilities that are easily teachable or writable, whereas collective explicit knowledge lies in standard operating procedures, record keeping, IT systems, and policies (Brown & Duguid, 1991). Regarding innovation speed and financial success, tacit knowledge sharing is more influential than explicit knowledge sharing, whereas innovation quality and operational efficiency are influenced more by explicit knowledge sharing (Wang &Wang, 2012). Thus, companies must learn to share and store both knowledge practices to unlock their potential benefits fully. The following statement explains the criticality of harmonizing explicit knowledge with tacit knowledge; *"If Nasa wanted to go to the moon again, it would have to start from scratch, having lost not the data, but the human expertise that took it there last time"* (Brown & Duguid, 2000,p.122).

3. KNOWLEDGE MANAGEMENT

In a knowledge economy, conducting business has opportunities as well as drawbacks. The opportunities include the potential for expanding market share, enhancing productivity, and increasing profitability through innovation and efficient knowledge asset management. The key difficulties are dealing with rising global competitiveness, shifting levels and patterns of client, customer, and societal demands, and the speed as well as effects of change in information and communication technologies (ICT) (Charles & Robinson, 2011). In order to gain a competitive edge, one must be able to use knowledge efficiently. A common question is whether organizations store knowledge in memory similarly to how people do. The answer is that there is a rising notion that organizations do have frameworks, practices, structures, and other tangible artifacts that demonstrate the existence of knowledge encoded in the organizational culture.

The formation of an organizational memory (OM) within an organization is a critical knowledge management activity that promotes the organizational learning (OL) processes (Ozorhon, Dikmen & Birgonul, 2005). OM can be defined as the means by which knowledge from the past is brought to bear on present activities; thus, it helps to learn from previous experiences (Stein & Zwass, 1995). OM becomes a corporate asset by sharing, organizing, storing, and reusing the knowledge created previously. The knowledge management activities within organizations should aim to enhance the OM.

OM requires continuous improvement and growth of organizational knowledge, which means that both the organizations and the individuals within them must be constant learners. One important aspect of KM is its need to reinvent your organization through learning constantly. Experience-based knowledge is incorporated into procedures and is embedded in technologies and systems. Organizational routines and a culture that encourages the creation, assimilation, and abandonment of outdated information and practices must be developed in order to promote continuous change. Organizations must accomplish two goals that may be in conflict with one another: first, they must build their knowledge bases over time and draw lessons from their past experiences; second, they must make sure that they are learning outside of their core competencies and develop the capacity to assimilate new knowledge in order to be able to respond to change (Quintas, 2005). The generation of knowledge is frequently seen as somehow more significant than knowledge reuse, more challenging to manage, and less dependent on information technology support. However, perhaps a more common organizational concern—and one that is unmistakably tied to organizational effectiveness—is the efficient reuse of knowledge (Markus, 2001). The reuse of knowledge in various decision-making mechanisms and circumstances is expected to result in the generation of new remarks that automatically update the organizational memory when stored back into the system. A cycle should be made where organizational memory is referred to on knowledge transactions, and outcomes are reflected back to enhance the organizational memory.

Construction companies must implement knowledge management mechanisms in their daily routines to improve effectiveness and thrive in an overly competitive sector. In order to meet this objective, first, the sources of knowledge generation need to be analyzed, as well as the type of knowledge they generate. As explained in the previous section, the possible tools for regulating and sharing tacit and explicit knowledge differ due to the nature of the knowledge.

4. KNOWLEDGE MANAGEMENT TOOLS

There are a variety of knowledge management tools available to choose from thus, it is vital to select the appropriate tool that addresses the goals of the organization adequately. The KM tools can be categorized as IT and non-IT-based tools that are used to support the essential aspects of KM such as sharing, reusing, and locating knowledge. In order to distinguish between the two categories, experts suggest naming IT-based tools as KM technologies and non-IT-based as KM techniques (Al-Ghassani, Anumba, Carrillo, & Robinson, 2005).

KM techniques do not require IT tools to execute the sub-processes of KM, such as knowledge sharing. It is clear that the scope and nature of human knowledge are much broader than what can be encoded by IT tools. Some of these tools are; seminars, post-project reviews, communes of practice, project feedback mechanisms, mentor programs, and training programs. Knowledge has a social aspect thus, seminars, communes of practice (where different professions meet to interact), and training programs are great opportunities for employees from different backgrounds to meet and share knowledge. Whereas post-project reviews, project feedback mechanisms, and mentor programs promise a similar scenario to a master-apprentice model where junior individuals get to be criticized and influenced directly by a senior colleague, which is an extremely effective knowledge-sharing mechanism. These tools may seem simpler to implement when compared to IT-based KM tools, however, they hold a much greater value for the initialization of tacit knowledge when compared to IT-based tools. Often the highly skilled members of the working environment are unaware of their tacit knowledge, such as their problem-solving skills or the resources they use. For this reason, knowledge sharing becomes highly dependent on communication within the working environment. Tacit knowledge is personal, linked to experience and learning, and cannot be coded. This results in tacit knowledge being shared within groups with common learning experiences and understandings rooted in common practice via non-codified pathways (Brown & Duguid, 1998).

The IT-based KM tools mainly focus on capturing codifiable knowledge. These tools act as a great OM archive that eases how organizations create an organizational learning and knowledge management culture. The data stored in software and hardware systems can be referred to and reused whenever necessary, making monitoring the data much simpler. Today, there is a variety of software-based programs on the market that offer diversified approaches to KM.

Using Artificial Intelligence (AI) and Machine Learning (ML) based software for KM is one of the leading trends in the knowledge industry. The classification, labeling, and retrieval of data are only a few examples of knowledge management tasks that can automated with the help of AI. Large volumes of unstructured data may be analyzed by these technologies, making it simpler to find insightful patterns and trends in a company's knowledge base. According to Forrester Consulting's principal analyst, Gualtieri (2016), between 60% to 73% of all the collected data within an enterprise goes unused for analytics. With the help of AI-driven KM tools, advanced data structuring could be done for an insight-driven data presentation for the knowledge seeker. The outcome is similar to a personal intelligent assistant that can revolutionize how knowledge workers consume meaningful information and increase their cognitive capacity by providing them with more efficient tools for processing, filtering, sorting, and navigating information sources (Jarrahi, Askay, Eshraghi & Smith, 2022). Thus, organizations can improve their search capabilities, use time more efficiently for knowledge management operations, and provide employees with more individualized content suggestions by implementing AI-powered algorithms.

Another current KM-IT tool is the ontology-based KM system and its application. A knowledge management system based on an ontology is more capable of encouraging the integration of linked resources, identifying precise knowledge rapidly, and steering away a significant amount of unnecessary knowledge. The procedure transforms disorganized knowledge data into structured knowledge by transferring all the necessary information. Storage of knowledge is the process by which the metadata is extracted from the knowledge sources acquired, and knowledge objects are marked in the implication of ontology and metadata standards, with the aim of transforming semi-structured and unstructured knowledge into structured knowledge and storing it in the knowledge base (Zhang, Zhao, Wie & Chen, 2015).

Whether it is a more futuristic approach to KM, such as AI-based tools or more simple cloud-based archive programs, these IT tools share distinct key functions to cover the majority of the needs of KM. Firstly, a "Document Management" function must be present to act as an archive with a correct taxonomy for material and track document changes when they occur. The second one is a "Knowledge Archive". Knowledge bases store structured and unstructured information in the system. These could be not only documents but also tutorials, videos, etc. The third key functionality is the "Security System". This feature limits accessibility for predetermined employees that determines which data is available to obtain. The fourth feature is a strong "Search Function". This function aims to save time when searching for past documents. The final feature should be "Communication Tools". Communication channels can make the systems much more efficient, especially when one has further questions on the uploaded material and can directly reach the author.

5. CONSTRUCTION SECTOR & KM

The activities of today's construction industry demand an increased level of knowledge, skills, and learning, as the sector is a multilayered knowledge-based environment that has knowledge input from different project parties

(Ferrada, Núñez, Neyem, Serpell, & Sepúlveda, 2016). Explicit and tacit knowledge come together to form organizational knowledge. In every individual's thought lies an accumulation of tacit knowledge. It is a collection of experiences, observations, and intuition that can be either cognitive or technical. Examples of tacit knowledge in the context of construction may include estimating and tendering prices that have been prepared over time through practical experience in preparing bids, encountering the construction processes, interaction with clients/customers and project team members in the construction supply chain, as well as an understanding of markets. Experience-based, judgmental, and context-specific knowledge makes it challenging to codify and share this type of knowledge.

Explicit knowledge in construction is generally the data obtained from site activities. This could be man-hours, machine hours, periodical reports, unit prices, and anything generated from real-life implementations. As a result, better ways of knowledge management should be the primary target to comprehend the overflow of data in the construction sector. However, this might be unfavorable at first for some managers due to the general nature of the lack of human resources or timely pressure on on-site activities. Thus, the general outcome and long-term benefits of adopting such an ideology must be made clear to decision-makers for the right resource allocation. Every employee in a construction organization must embrace a culture that values knowledge capture and sharing of knowledge.

However, there are a set of socio-technical barriers defined by Rezgui & Miles (2011) that limit the progress of KM in the construction industry. Firstly, employees do not perceive any immediate benefits from sharing knowledge and experiences. In fact, this is seen as a possible threat to their status as "experts" since there is usually no encouragement for a supportive knowledge-sharing culture focused on all employees. (e.g., by implementing creative ways for rewards and recognition). Next, shelf solutions do not work, and there is a weak culture of software adoption. In order to perform their duties and access software, employees are frequently limited to a specific place, which is usually their office. However, access to information from construction sites is frequently constrained by network availability. Another obstacle is that the industry is divided and organized into numerous disciplines, each of which has its own rules and specialized terminology. There is not a particular language that captures a shared comprehension of construction principles utilized across disciplines. All these aforementioned challenges limit effective communication and the sharing of experiences.

By actively participating in projects over an extended length of time, one can gain valuable construction knowledge. However, this is usually not the case, as employee turnover is radically high. The specific needs of the employees who will use the project data may not always be understood by those in charge of gathering and archiving it. Furthermore, data is gathered and archived at the end of the construction phase rather than being handled while it is being created. By now, it is likely that those who were aware of the project have moved on to other projects. Again, due to high turnover, many businesses keep archives projects however, it is challenging to get in touch with the original report authors. These projects should be available to be used with little (or no) consultation, this past data should have a rich representation of the data context. Lastly, decision-making objectives are frequently not noted or documented. The millions of spontaneous messages, phone calls, emails, and discussions that comprise much project-related information require complex methods to track and document.

In order to understand the reflections of these limitations on current construction sector knowledge management practices, two interviews were conducted. The first interview is held with the country manager of a 100-year-old multi-national construction firm, which is among the top 20 highest-grossing international contractors according to ENR magazine 2023. The second interview is made with a senior consultant in one of the top global strategy consultancy firms by revenue, who has one of her expertise in KM. The reason for the second interview being made with a representative from the consultancy sector is due to the factor that they were one of the earliest adaptors of KM tools in their organizations. From the early stages of the introduction of the KM concept, the major consulting firms took advantage of the immense potential of information technology as the driving force in the business world. The ideology has always been similar to the one today, which combines well-known IT tools like databases to make it easier to gather, share, store, retrieve, and use knowledge (Easterby-Smith & Lyles, 2015). For this reason, comparing the approaches to KM of a successful construction firm to one of the best knowledge-managing sectors in business would outline the necessities to be implemented by the construction industry, which is the aim of this study.

6. FINDINGS OF THE EXPERT INTERVIEWS

The interview questions were categorized under three headlines: Data Collection, Data Accessibility/ Usage and Updates, and Knowledge Management. The results are explained with the participants being referred to as

"Consultancy (Firm) Representative" and "Construction (Firm) Representative". On the first question of the Data Collection section, participants were asked if there is a department in their organization dedicated to collecting and storing data from past projects. It was revealed by the construction representative that there was no such dedicated department, but all the departments in the headquarters (such as Procurement, Legal Matters, HR, etc.) would collect their own data from the sites. The consultancy representative revealed that they did have a special team dedicated to knowledge management for every specific field of activity. Next, participants were asked if their organizations had a digital database and a predetermined taxonomy for storing this data and what type of data was chosen to be stored in this system. The construction representative explained that they do have a digital database to store this knowledge, but only the specific departments have a taxonomy to obtain worldwide uniformity, such as the finance department, cost control department, and HSEQ department. It was added that they try and store most of the explicit data generated from the site, such as the man-hours, machine hours, accident rates, etc. Similarly, the consultancy representative stated that they do have a company-wide digital database to store project data. It was revealed that the uploaded material usually is in project analysis reports that have some identifiers that make it easy to find it in the future, such as keywords, date, location of the project, project team, a summary page, etc.

The next section was about Data Accessibility/Usage and Updates, where the first question inquired if the stored data from the previous projects could be accessible anytime when needed and who could access this data. The construction representative stated that this data is only accessible to the related departments at the headquarters, and site employees could only access it via headquarters. On the other hand, the consultant representative made clear that this data could be accessible to anyone at any time. The second question on this topic examined if the ongoing projects referred to the stored data, how often they referred to it, and what type of data was most frequently requested. The answers to this question were quite different, as the construction representative stated that even though there are times when the site refers to the stored data, it is not too regularly requested. He added that the most requested data from the headquarters is the sub-contractor-related data (such as their prices, if they have worked with them before, and their references). On the contrary, the consultant representative stated that it is referred to at the beginning of each project. The last question was asked to determine how frequently the system was updated with the knowledge currently produced. The construction representative stated that it was every month unless there was a special reason to make it more frequent, and the consultancy representative stated that the sanitized version (a version that prevents the disclosure of the client) was uploaded at the end of each project.

The final section consisted of questions regarding the KM policies. The first question of this section was to determine the explicit knowledge-sharing methods used in their company. The construction representative stated that they have an e-learning platform for employees to work on themselves and that some of the end project reports and analyses are available for every employee to view. The major explicit knowledge sharing on the consulting firm is stated to be their online tool, where the majority of the project data is imported into. The last question was about the knowledge-sharing mechanisms of tacit knowledge. The construction representative stated that there are regular voluntary webinars and seminars made, but most employees are expected to obtain this knowledge from working with one another, similar to the master-apprentice model. The consultant representative stated that they too, have seminars on general business matters and seminars on expertise fields. However, it was explained that although these seminars are voluntary, they have a reward system, such as being awarded a certificate or conference invitation. Additionally, it was explained that they, too aim to convey the tacit knowledge by the mater-apprentice model but in a more structured way. Firstly, a pairing system is used within project groups where seniors and juniors are matched. Next, throughout a project, the juniors get to work with their seniors to understand the business approaches they take in action. Then, after the end of the project, there is a feedback mechanism that monitors the desired performance of individuals, which is a great way to restructure the knowledge learned from the project.

7. DISCUSSION AND CONCLUSION

The review performed on the requirements of the construction sector revealed that knowledge management tools need to (1) collect the contextual details in a structured, continuous and real-time manner, (2) overcome difficulties in the extraction of knowledge from text-based data, (3) encourage a knowledge sharing culture, (4) combat the limits of the fragmented industry in effective communication and the sharing of experiences, (5) meet the specific needs of the employees who will use the project data, not those in charge of gathering and archiving it, and (6) facilitate efficient reuse of knowledge and learning outside of core competencies.

The findings from the expert interview show similarities as well as major differences. For example, even though each department is set to collect data from the site in the construction firm, it is ambiguous how much the employees are involved in the real site activity when compared to knowledge management teams in consulting firms who act as part of the project for a period of time. Another major difference is seen with the KM software these companies use. The accessibility and usability of the KM tool of the construction firm seem considerably constrained in terms of creating a knowledge-sharing culture compared to the KM tool used in the consulting firm. Even though the diversity of data is richer in construction, due to a lack of accessibility from key players and site personnel, there are significant limits to embracing the concept as a company culture. Finally, the biggest gap between their KM ideologies is related to their approach to sharing tacit knowledge. We can see a clear company culture inside the consultancy firm that motivates and provokes both the knowledge owner and knowledge seeker to interact in a knowledge-sharing activity. This is either done by rewarding systems for participation in seminars or compulsory feedback mechanisms post-project. On the other hand, an environment is set for this knowledge-sharing interaction in the construction firm, however, it is left to the employee will and enthusiasm to engage in it.

The interview results reveal that most of the determined KM requirements of the construction industry have not been incorporated into the current tools and practices. Whether it is due to the natural barriers of the construction firms, which is explained in the previous section, or being the latecomer to the KM concept, one thing is for sure; which is that are many areas of improvement for enhancing the engagement in KM within the construction firms. The sector has a huge advantage in generating enormous amounts of knowledge, which, if and when interpreted correctly, could result in a much more efficient, resilient, and technologically advanced sector.

These challenges faced by construction companies can only be overcome by establishing and maintaining a knowledge culture where knowledge is valued and generated, shared, and utilized as an instinctive aspect of corporate activities. Organizations and the individuals within them must be constant learners, and this demands a clear vision, strong leadership, and solid processes from the corporation. If the construction industry is to build and maintain the capability in a knowledge economy, it must shift its adversarial culture to a sharing culture. Furthermore, it has to learn from each project and then transfer knowledge from projects to organizational bases to improve OM. A cycle should be made where organizational memory is referred to on knowledge transactions, and outcomes are reflected back to enhance the organizational memory. For future studies, this research that acts as a pilot study will be broadened with more interviews from the construction sector to understand the in-depth usage of KM tools within organizations.

8. APPENDIX: QUESTIONNAIRE FORM

This questionnaire form is part of the MSc thesis study of Bartu Kologlu at Istanbul Technical University Construction Management Program. The aim of the thesis is to understand the current knowledge management practices and the tools that construction companies use to maintain and enhance their organizational memory. The answers will only be used for academic purposes, and the answers will be evaluated anonymously without the identity of the participant/organization.

1) Data Collection: One of the main capital of knowledge-intensive sectors such as construction/consulting is intellectual assets. Most of the processes are generated toward exploration, accumulation, and exploitation of individual and firm knowledge. Your company has been in the construction/consulting sector for many years and has completed many projects.
   1.1) Is there a department/process in your company that collects and stores the knowledge data acquired from

the projects?

1.2) What kind of data is collected/stored from the previous projects (financials, man-hours, machine hours, financials, reports, etc.)?

1.3) How often is this data collected?

1.4) How is this data stored? Is there a digital database for this purpose? If yes, is there a predetermined taxonomy or a uniform filing system that is used to store the data?

2) Data Accessibility and Usage

2.1) Is the stored data from the previous projects accessible when needed?

2.2) If yes, do the ongoing projects use this data? How often is the previous data used for ongoing projects?

2.3) What type of data is used? Please list the specific information/data items used most frequently.

2.4) Is there an IT program to access this data? If yes, what is the most critical aspect of this program to operate correctly?

3) Knowledge Management: We can divide knowledge into two categories: Explicit and Tacit. Explicit Knowledge is the documented or recorded information that is written or saved. Tacit knowledge is the knowledge that an individual owns that is gathered from their personal experience, insights, and observations.

3.1) What are the knowledge-sharing methods in your company for explicit knowledge (seminars, shared monthly reports, etc.)?

3.2) Skilled members of a community of practitioners are often unaware of the tacit knowledge they possess, e.g., their problem recognition and problem-solving behavior, the rules that they follow, and the knowledge sources that they draw on. What are the methods in your company that convey tacit knowledge transactions?

3.3) The sector operates in a project-based environment. How can you ensure that individual knowledge becomes a company asset and does not disappear when that person is no longer part of the company?

3.4) Are there any other Organizational Learning practices your company performs?

IMPROVING BIM AUTHORING PROCESS REPRODUCIBILITY WITH ENHANCED BIM LOGGING

Suhyung Jang
Building Informatics Group, Dept. of Architecture and Architectural Engineering, Yonsei University, Republic of Korea

Ghang Lee
Professor, Department of Architecture and Architectural Engineering, Yonsei University, Republic of Korea

ABSTRACT: *This paper presents an enhanced BIM logger designed to capture both geometry and attribute changes of building element geometries, thereby offering a transparent source of representation of the BIM authoring process. The authors developed the logger and reproduction algorithm using the Revit C# API based on the analysis of information required to define building elements and associated attributes. The enhanced BIM log was evaluated through a case study of Villa Savoye designed by Le Corbusier. Despite negligible discrepancies, the results show that the enhanced BIM log can accurately represent the BIM authoring process capturing and reproducing 92.45% of the building elements from the original BIM model. Future research can focus on expanding the scope of logging and probing the potential of automating the BIM authoring process using these enhanced BIM logs.*

KEYWORDS: *Building information modeling (BIM), BIM log mining, BIM authoring software, Custom BIM log, Authoring process reproducibility.*

1. INTRODUCTION

The architecture, engineering, construction, and operation (AECO) industry has experienced a transformational shift with the widespread adoption of BIM technology. The shift has not only enhanced productivity but also improved informed decision-making within the sector (Sacks et al., 2018). Although BIM models—products of the BIM process—display the finalized decisions of a project, they encapsulate a wealth of insights due to the extensive decision-making endeavors underpinning their authoring. Consequently, the BIM authoring process can serve as a valuable knowledge repository for understanding the decision-making process.

BIM log mining seeks to extract these insights by examining the BIM logs in detail. BIM logs serve as invaluable data reservoirs, capturing sequential events recorded during BIM software usage (Jang et al., 2023). Previous studies have explored various aspects of the BIM authoring process, from design authoring patterns (Yarmohammadi et al., 2017), productivity (Shin, 2023; Shin et al., 2022), and collaboration patterns (Zhang & Ashuri, 2018), to the specific roles of modelers (Forcael et al., 2020).

Researchers have emphasized the significance of incorporating data attributes to elucidate the as-happened process within the log to attain reliable results from the analysis (Bose et al., 2013; Suriadi et al., 2017). Nonetheless, the BIM logs produced by prevailing BIM software overlook modifications in building elements undertaken during the BIM authoring phase because they were originally developed for maintenance operations (Autodesk, 2022). Consequently, such logs often miss the depth required to accurately capture the BIM authoring narrative (Jang et al., 2023; Yarmohammadi & Castro-Lacouture, 2018). Even though efforts have been made to enhance these logs through custom loggers (Gao et al., 2021; Jang et al., 2021; Kouhestani & Nik-Bakht, 2020; Pan & Zhang, 2021; Yarmohammadi & Castro-Lacouture, 2018), these adaptations still are not able to capture critical geometric nuances like shapes, scales, and locations—details pivotal to understanding the evolution and decision making involved in the BIM authorship.

To address the issue, this paper introduces an improved BIM logger capable of capturing comprehensive details for the precise replication of the BIM authoring process. The methodology behind this advanced logger includes analyzing the essential data needed to describe building elements in Autodesk Revit, followed by the design of a custom BIM logger to record this crucial information. In addition, a reproduction algorithm was developed to evaluate the logger's accuracy in representing the BIM authoring process. The reproducibility of the logger was further validated through a case study.

The paper is structured as follows. Section 2 reviews previous custom BIM loggers proposed in the literature, and Section 3 describes the research methodology employed in this study. Section 4 reviews the minimum information

requirements to define BIM elements in Revit, and Section 5 outlines the development of the enhanced BIM logger and reproduction algorithm. Section 6 evaluates the reproducibility of the enhanced BIM logger through a case study, and Section 7 concludes the paper.

2. LITERATURE REVIEW

BIM log mining is a data analysis approach that utilizes process mining techniques to explore BIM event logs collected during a BIM software operation. Process mining includes various techniques for automated process discovery, social network analysis, process optimization, case prediction, and history-based recommendations (Aalst et al., 2011). However, event log imperfections can lead to unreliable results, and researchers have introduced an incremental approach to evaluating event log fitness and a methodology to guide process mining execution (Bose et al., 2013; Suriadi et al., 2017).

While improving event log quality has received significant attention, several studies have focused on enhancing the information included in the BIM logs. These include custom Revit logger which extracts element identifiers and bounding boxes (Yarmohammadi & Castro-Lacouture, 2018), IFC loggers which capture snapshots and identify the changes made between different versions of BIM models (Kouhestani & Nik-Bakht, 2020; Pan & Zhang, 2021), and command-object graphs to notate the geometric modeling sequence (Gao et al., 2021) to improve the understanding on modeling patterns. However, these custom logs still grapple with reproducing the BIM authoring process due to missing information to represent the geometric shape and attributes of the building elements.

The BIM authoring process is often defined as a process in which 3D software is used to develop a BIM model based on criteria that are important to the translation of the building's design (Messner et al., 2019). Accordingly, this process includes the addition, deletion, and modification of the geometry of building elements and their associated properties (Kouhestani & Nik-Bakht, 2020; Lin & Zhou, 2020). Through BIM authoring, building elements are refined to meet the level of development (LOD)—the information necessary to depict the building elements—within the BIM model. However, the BIM model only reflects the end result of the comprehensive BIM authoring process. Concurrently, the design decisions made during this process can be a rich and invaluable reservoir of information, encapsulating real-time design decision-making. Documenting these design decisions can also aid in extracting the design knowledge of architects, especially when paired with recently emerging data-based analysis techniques (Jang et al., 2023). In this context, this study aims to develop a custom logger designed to capture essential information, enabling the reproduction of the BIM authoring process.

3. METHODOLOGY

This study developed a three-step methodology to enhance the reproducibility of BIM logs as depicted in Fig. 1. The methodology involved developing a customized BIM authoring logger, implementing a BIM authoring process reproducer, and evaluating the reproducibility of the enhanced BIM log through a case study.

Fig. 1: Research flowchart.

To capture sufficient information in the BIM log to reproduce the BIM authoring process, the authors analyzed the minimum inputs required to represent building elements in Revit. As building elements are represented using classes in an object-oriented programming model, the information required for each class corresponding to a specific category of elements was analyzed. The log captures the geometric shape and attribute values to represent the building elements in a comma-separated value (CSV) format. The reproduction algorithm developed in this study iterates through the events recorded in the BIM log, identifies the command type (i.e., "ADDED," "MODIFIED," or "DELETED"), and executes them with reference to the "Comments" property (i.e., copied "ElementID") of the building elements.

The evaluation phase of this study involved modeling Villa Savoye designed by Le Corbusier for the case study, during which the BIM authoring logger recorded the authoring process (Fig. 2). The events recorded in the enhanced BIM log were iterated using the BIM authoring process reproducer, and the reproducibility of the developed model was evaluated based on the volumetric center distances and volume differences between elements, as well as visual analysis of plans, elevations, sections, and 3D views.

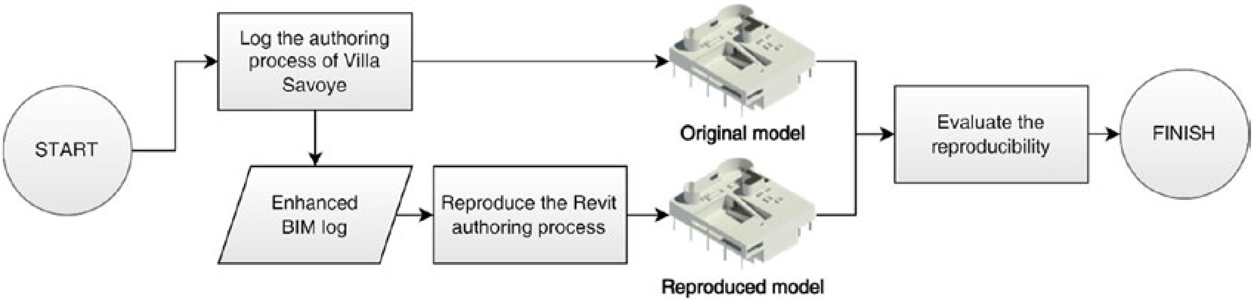

Fig. 2: Evaluation of BIM authoring logger and BIM authoring log reproducer.

4. ENHANCED BIM LOGS

This section provides a detailed overview of how building elements are defined in Revit and how the enhanced BIM log captures the necessary information to accurately represent the BIM authoring process. The study utilized Autodesk Revit 2023 and Revit C# API for the implementation of the enhanced BIM log. Building elements in Revit are represented using classes in an object-oriented programming model that has a hierarchical structure that reflects the physical structure of the building. Each class corresponds to a specific type of building element, such as walls, floors, roofs, doors, and windows. Fig. 3 illustrates the geometric shape and attribute values recorded for each building element category.

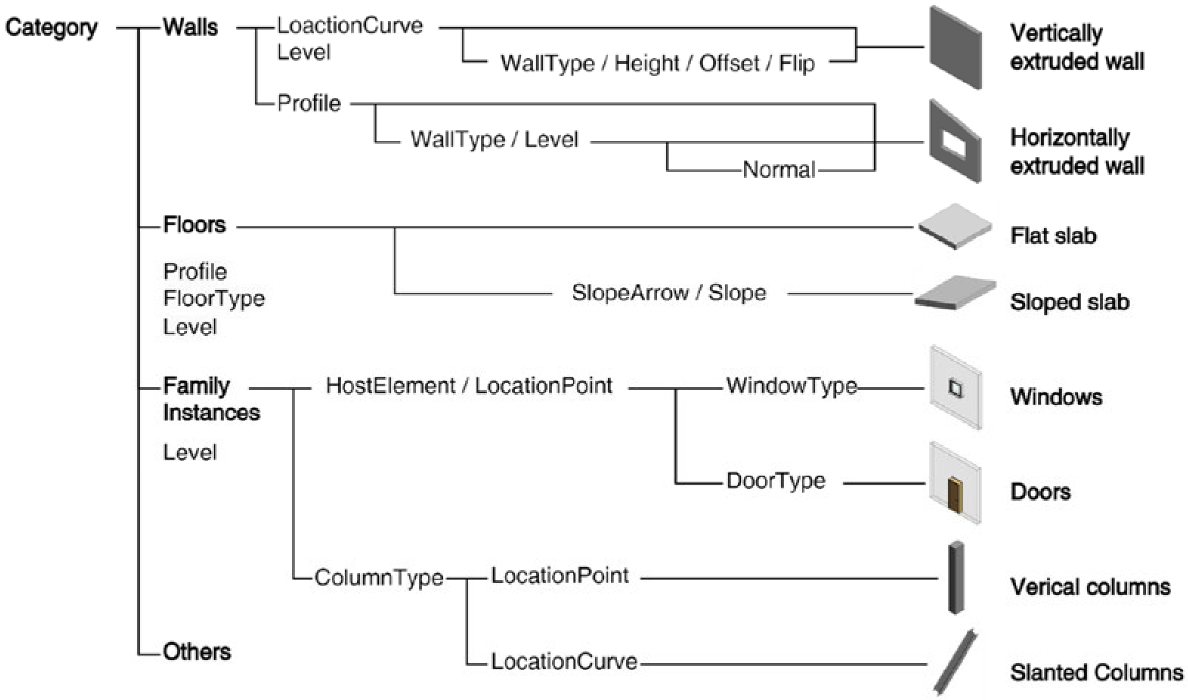

Fig. 3: Geometric shape and attribute values recorded within the enhanced BIM log.

Wall elements in Revit are classified into two categories—rectangular profile walls and nonrectangular profile walls—following the different creation methods for each type. Floor elements are classified into two types, flat floors, and sloped floors, and are created using different attributes depending on the type. Windows, doors, and columns are classified as "FamilyInstances," and their representation is based on the placement of predefined instances on the selected base geometry. "FamilyInstances" have different categories based on the "FamilySymbol" used, such as "WindowType," "DoorType," and "ColumnType." Windows and doors require a "LocationPoint" and "HostElement," while columns can be placed without a "HostElement," depending on whether the representation of the slope is required.

In addition to recording other required information items as string formats, the enhanced BIM log captures geometric bases, such as "LocationPoint," "LocationCurve," and "Profile," and their respective subclasses, such as "Line," "Arc," "CylindricalHelix," "Ellipse," "HermiteSpline," and "NurbsSpline." The information required for each geometric base and its string format representation is presented in Table 1. The enhanced BIM logger records the geometric bases of the building elements represented during the BIM authoring process in the described format.

Table 1: Definition of geometric classes.

Classes	Subclasses	Input Requirements	String Formats
Location Point	XYZ	(X coordinate, Y coordinate, Z coordinate)	(double, double, double)
Location Curve	Line	(endPoint1, endPoint2)	[Line, XYZ, XYZ]
	Arc	(plane, radius, startAngle, endAngle)	[Arc, XYZ, double, double, double]
	CylindricalHelix	(basePoint, radius, xVector, zVector, pitch, startAngle, endAngle)	[CylindricalHelix, XYZ, double, XYZ, XYZ, double, double, double]
	Ellipse	(center, xRadius, yRadius, xAxis, yAxis, startParameter, endParameter)	[Ellipse, XYZ, double, double, XYZ, XYZ, double, double]
	NurbsSpline	(degree, knots, controlPoints, weights)	[NurbsSpline, int, IList<double>, Ilist<XYZ>, Ilist<double>]
	HermiteSpline	(controlPoints,periodic,tangents)	[HermiteSpline, Ilist<XYZ>, bool, HermiteSplineTangents]
CurveLoop	CurveLoop	(LocationCurve_1, …, LocationCurve_n)	{CurveLoop, LocationCurve_1, …, LocationCurve_n}
Profile	Profile	(CurveLoop_1, … ,CurveLoop_n)	Profile, CurveLoop_1, … ,CurveLoop_n

Furthermore, multiple attribute values in Revit can be modified to better represent each building element. For instance, recording whether it was flipped was important in representing vertically extruded walls because the sequence of the wall layer can be positioned opposite. Meanwhile, a normal vector that the wall is facing is critical in the horizontally extruded walls. The initial values and modifications of the attributes are also recorded in the enhanced log, providing information on how the building elements were defined and developed during the BIM authoring process.

5. REPRODUCTION ALGORITHM

The authors implemented a reproduction algorithm to iterate through the events in the enhanced BIM log and repeat them, as illustrated in Fig. 4. The algorithm begins by identifying the command type of events. If the command type is "ADDED," the algorithm adds an element of the recorded category and applies the recorded attribute values, while adding the "ElementID" of the event to the "Comments" attribute of the newly created BIM element. If the command type is "MODIFIED," the algorithm queries the element with the "ElementID" recorded in the Comments value and applies the corresponding modification. If the command type is "DELETED," the algorithm queries the elements with the "ElementID" recorded in the "Comments" value and deletes the element.

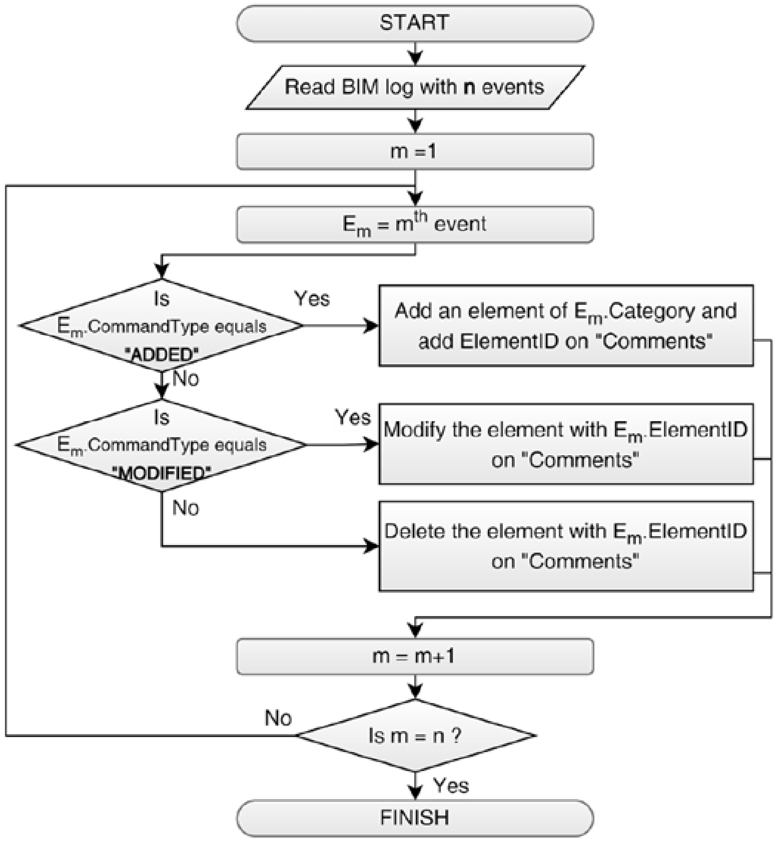

Fig. 4: Reproduction algorithm.

6. EVALUATION OF REPRODUCIBILITY

To assess the enhanced log and its ability to be reproduced, the authors of this study carried out a case study of Villa Savoye, designed by Le Corbusier. Using the BIM log from the authoring process, a reproduced BIM model was generated using the reproduction algorithm, as depicted in part (a) of Fig. 5.

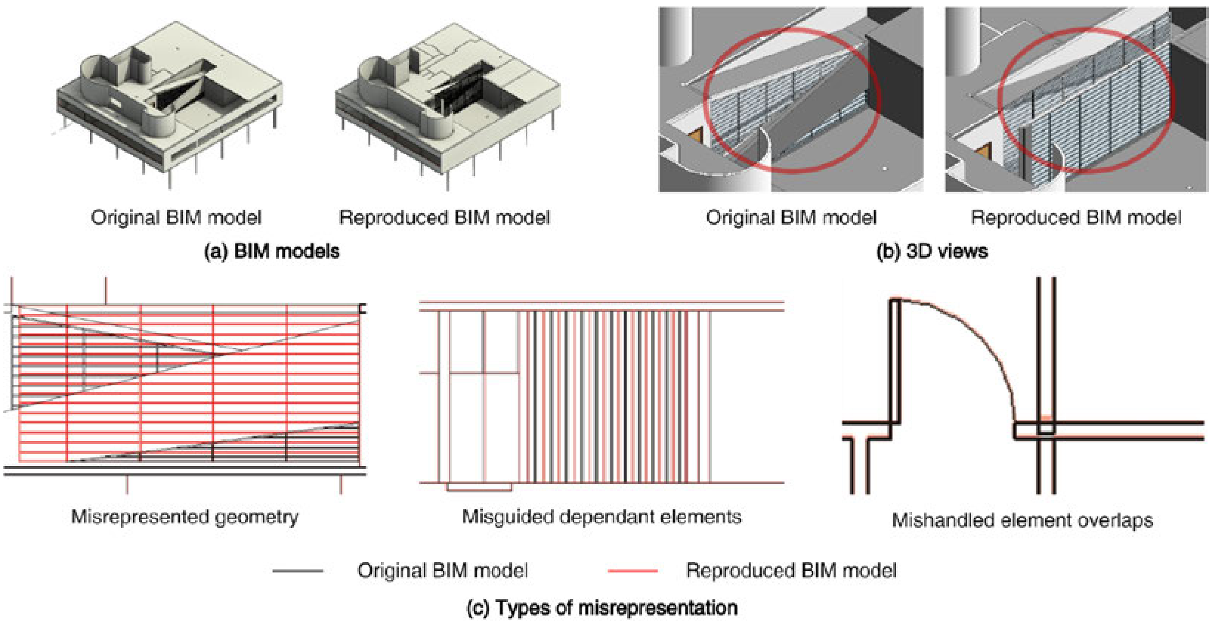

Fig. 5: Comparison between the original BIM model and reproduced BIM model.

The BIM model comprised 158 elements, which included 97 walls, 8 slabs, 8 windows, 19 doors, and 27 columns, with 2,836 events logged during the process. The reproduced model captured every element present in the original. A comparison revealed minimal average distances between the volumetric centers of the elements: 3.6440E-07 for walls, 2.1470E-07 for floors, 1.4760E-07 for windows, 1.6139E-07 for doors, and 1.4380E-07 for columns. Volume differences were also analyzed, with disparities noted as 0.1876% for walls, 0.0198% for floors, and 0.0433% for columns, with no discrepancies for windows and doors. The variations in distance and volume displayed a near-perfect reproduction. It is postulated that such differences may arise from metric and imperial unit conversions.

The models were contrasted visually in 3D, along with elevation, section, and plan views. The manual analysis allowed the authors to pinpoint inaccuracies in the reproduced model. As highlighted by the red ellipses in part (b) of Fig. 5, the curtain wall profiles were inaccurately depicted. Part (c) of Fig. 5 overlays drawings from the original and reproduced BIM models, delineated by black and red lines respectively. The comparison revealed three main types of inaccuracies:

Custom attributes: In this version of the implementation, custom attributes, such as distances between vertical mullions, were not supported. This omission led to mullions in the reproduced model being placed with default values. The issue was observed in four curtain wall elements.

Automatically connected elements: In instances where building elements overlapped, their placements varied occasionally. The function in Revit that automatically joins closely placed elements generates minor discrepancies in the lengths of the automatically joined elements, depending on how far apart the joined elements were initially. The issue was observed in two interior wall elements.

Unknown reasons: There were instances where the wall elements with specific profiles did not align precisely with the original design. These discrepancies may be attributed to limitations within the logging and reproduction algorithm. This issue was observed in six profile wall elements.

In summary, 12 of the 159 elements (or 92.45%) in the reproduced BIM models were inaccurately represented–all being wall elements. Despite these discrepancies, the enhanced BIM logger effectively logged most of the necessary information to recreate the BIM authoring process.

7. CONCLUSION

This study developed an enhanced BIM logger that captures the necessary information to reproduce the BIM authoring process. By analyzing the information requirements of five representative building elements in Revit, the authors developed a custom logger that records geometric shapes and attribute values. The study also developed a reproduction algorithm to repeat the BIM authoring process. The effectiveness of the enhanced log was evaluated in a case study of Villa Savoye designed by Le Corbusier, which showed that the enhanced BIM logger provides a valuable tool for capturing and reproducing 92.45% of the building elements generated and modified within the BIM authoring process. While minor discrepancies and misrepresentations were observed, the results of the case study demonstrated the potential of the enhanced BIM logger.

Looking ahead, avenues for improvement lie in broadening the spectrum of building element categories or attribute values to augment reproducibility. Additionally, the applications of enhanced BIM logs beckon exploration, as does the prospect of analyzing the as-happened BIM authoring process (Shin et al., 2022; Yarmohammadi & Castro-Lacouture, 2018) and automating the BIM authoring process using such logs (Pan & Zhang, 2020). Overall, the enhanced BIM logger presented in this study can contribute to elevating the transparency and efficiency of the BIM authoring process, serving as an invaluable data source for its enhancement.

TOWARDS CONSTRUCTION SAFETY MANAGEMENT MATURITY MODEL IN THE INDUSTRY 4.0 ERA: A STATE-OF-THE-ART REVIEW

Nazi Soltanmohammadlou, Sara Rashidian, Carol K.H. Hon, Robin Drogemuller & Sara Omrani
Building 4.0 CRC, Caulfield East, Victoria, Australia and School of Architecture and Built Environment, Queensland University of Technology (QUT), Brisbane, QLD 4001, Australia

ABSTRACT: *While the advantages of leveraging advanced technologies and Industry 4.0 for effective safety management have been extensively recognized, the journey towards a more mature integration of Industry 4.0 technologies into safety management practices often lacks a well-defined and systematic guidance map. This research is a step towards providing organizations with a structured approach to navigate and achieve successful safety management transformation, enabling them to fully harness the potential of industry 4.0 technologies in the workplace. Two rounds of systematic literature reviews (SLRs) are conducted to narrow down the number of articles based on the PRISMA method, which are then subjected to further content analysis. The study highlights the integration of Industry 4.0 technologies within the domains of People, Process, and Policy and their significance in advancing safety maturity. This research uncovered key themes, providing valuable insights that will shape the conceptual maturity model structure of safety management based on the innovative nature of Industry 4.0 to enhance their safety culture to align with. The results provide a fertile ground for a Smart Safety Maturity Model, to integrate technologies to elevate safety drivers in construction safety management.*

KEYWORDS: *Industry 4.0, Maturity model, safety management, construction industry*

1. INTRODUCTION

The fourth industrial revolution, also known as Industry 4.0, in the construction industry, has been conceptualized as the application of innovative technologies and processes to improve the deliverance of tangible and intangible services within construction companies (Kumar et al., 2019). Construction contractors are adopting various technologies including robotics, advanced data analysis, immersive technologies, additive manufacturing, autonomous systems, cloud computing, cybersecurity, and the Internet of Things (Nnaji et al., 2019; Rüßmann et al., 2015; Smallwood & Allen, 2023). Although the construction sector increasingly adopts innovative technologies that go beyond conventional practices to address occupational Safety and health (OSH) constraints, there is no paved avenue for measuring their progress, benchmarking against standards and regulations, and pinpointing areas where efforts should be focused to achieve effective outcomes.

Maturity models (MMs) offer a structured transformational roadmap for organizations adopting new strategies like Industry 4.0 technologies for safety objectives and evaluate the current maturity level and plan for improved future performance (Alankarage et al., 2022; Paulk, 1995; Wendler, 2012). The structure of MMs is commonly organized into five stages or levels: initial, repeatable, defined, managed, and optimizing (Das et al., 2023; Rashidian, Drogemuller, Omrani, et al., 2023). The MMs also have a series of attributes and sub-attributes, mainly covering hard (technology-related aspects) and soft (human-related aspects) attributes (Rashidian, Drogemuller, & Omrani, 2023). However, their application has since expanded to various disciplines, including the construction industry (Rashidian et al., 2022). The current study heavily relies on using established Safety MMs available in the literature to understand the digital readiness in the existing safety MMs. The review of the MMs in the construction field by Rashidian et al. (2022) revealed that safety maturity is one of the key focus areas, covering two major themes safety culture and safety climate (Wilson & Koehn, 2000). Safety culture refers to the underlying beliefs and values that influence organizational behavior, while safety climate pertains to the attitudes and views of the workforce at a particular moment Griffin and Curcuruto (2016). While safety maturity models offer a structured approach for evaluating organizational safety progression, there exists a gap in understanding how the integration of technologies can effectively elevate safety maturity within construction processes. This gap raises the question of how technology can be strategically employed to benchmark and enhance safety practices. By addressing this research problem, organizations can better understand the synergistic relationship between technology adoption and safety progression, leading to optimized safety practices, improved risk mitigation, and ultimately safer working environments. The overarching aim of this study is to comprehensively analyze the correlation between Industry 4.0 technologies and the attributes of a construction safety maturity model. This involves a dual focus: firstly, to pinpoint the precise Industry 4.0 technologies that play a role in enhancing construction safety; and secondly, to conduct an exhaustive investigation into how these technologies are integrated within the existing Safety Maturity Models (MMs). By delving into the intricate relationship between Industry 4.0 technologies and construction safety maturity attributes, this study enhances the knowledge base surrounding the potential benefits and challenges of adopting Industry 4.0 technologies. It provides organizations with valuable insights into the

ways in which technology can be harnessed to benchmark and enhance safety practices, ultimately leading to more effective risk mitigation strategies.

2. RESEARCH METHODOLOGY

A systematic literature search was conducted. Title, abstract, and keywords of peer-reviewed articles published from 2013 onwards. Our search was conducted exclusively within the cross-disciplinary database Scopus, which is recognized as the largest archive of peer-reviewed publications, including scientific reviews, collections of academic works, and conference proceedings (Hijazi et al., 2021). The identification phase of the PRISMA model was used as a framework for extracting relevant publications (Moher et al., 2009). The primary criteria for the initial filtering stage were defined, encompassing factors such as English language, academic relevance, and full-text accessibility. Subsequently, a preliminary assessment of content was carried out to ensure the presence of the required keywords within the titles and abstracts of the publications. Additionally, a reverse search approach was employed during this phase of searching and screening. Baker et al. (2023) mention to the approach as the "snowballing" technique which allows the acquisition of papers utilizing cross-references from the selected publications to minimize the impact of missing relevant resources. The systematic literature reviews (SLRs) were conducted through a two-phase approach, which is detailed in the subsequent subsections.

2.1 phase 1

We aimed to identify the utilization of maturity models in the realm of construction safety management. Following the removal of irrelevant articles, the total count of articles has been reduced to 11. Table 1 demonstrates how the connection between Boolean operators and the result of the search is represented in order to locate pertinent scientific articles.

Table 1*:* The PRISMA Identification stage results from searching the database (SCOPUS)

Search 1 Boolean operators (Searches done in July 2023)	Search Results Scopus
((“maturity model" OR "maturity framework") AND ("safety" OR "safety management" OR "risk" OR "risk management" OR "hazard" OR "accident" OR "accident prediction" OR "accident prevention") AND ("Construction site" OR "construction jobsite" OR "construction work zone" OR "construction industry" OR "construction workplace" OR "construction work*" OR "construction professional*" OR "construction labo*" OR "construction workforce*" OR "construction staff" OR "construction personnel*" OR "construction activit*"))	29

2.2 phase 2

Phase 2 is dedicated to retrieving papers associated with Industry 4.0 and safety management. The Scopus database yielded a total of 48 papers as shown in Table 2. Following a thorough evaluation of extracted papers, 26 papers were excluded based on the content of abstracts, as they were identified as irrelevant to the scope of the research. Then, a content analysis approach was employed to categorize highly interconnected terms, relying on researchers' semantic comprehension, to identify the various dimensions associated with them (Das et al., 2022). Due to the absence of a universally accepted definition of Industry 4.0, there is often a reliance on related terms to describe this paradigm (Das et al., 2022). Incorporating the keywords associated with each Industry 4.0 technology in the search led to a significant increase in the number of articles retrieved. Furthermore, a considerable portion of the papers examined did not propose dimensions that could be compared to existing safety maturity models. To ensure important references were not missed, manual searches of the references in the included studies and review articles were performed in addition to the electronic searches. Ultimately, through the process of reference tracking, an additional seven review papers were identified which covered the different applications of technologies in construction safety management, resulting in a total of 29 articles included in the review.

Table 2: The PRISMA Identification stage results from searching the database (SCOPUS)

Search 2 Boolean operators (Searches done in July 2023)	Search Results
	Scopus
(("industry 4.0" OR "4ir" OR "fourth industrial revolution") AND ("safety" OR "safety management" OR "risk" OR "risk management" OR "hazard" OR "accident" OR "accident prediction" OR "accident prevention") AND ("Construction site" OR "construction jobsite" OR "construction work zone" OR "construction industry" OR "construction workplace" OR "construction work*" OR "construction professional*" OR "construction labo*" OR "construction workforce*" OR "construction staff" OR "construction personnel*" OR "construction activit*"))	48

As can be seen in Fig 1., by combining the findings from Search 1 and Search 2, the findings and discussion were conducted to encompass the specific requirements of construction safety management while also addressing the essential elements needed to effectively navigate the challenges and opportunities presented by Industry 4.0. A total of 11 maturity models and 29 papers were curated from the outcomes of Search 1 and Search 2, correspondingly. Subsequently, each phase was independently analyzed to identify shared elements between them and how Industry 4.0 technologies improve the maturity of construction safety.

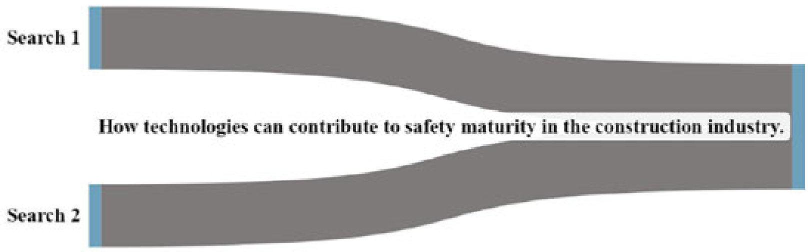

Fig 1. The goal of combining the findings from two-phase searches

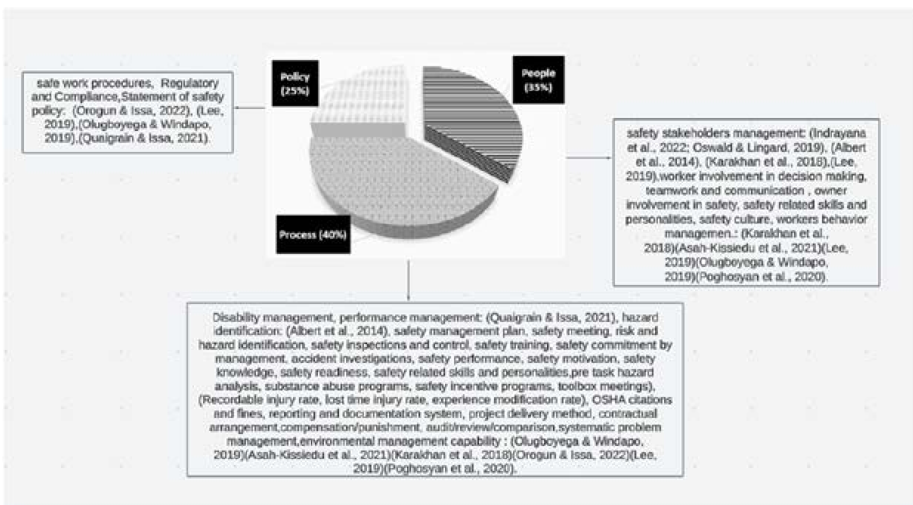
3. CONTENT ANALYSIS

3.1 Publication distribution by safety maturity model attrinutes

Fig 2. has illustrated the distribution of publications based on their viewpoint on maturity models focusing on components. A total of 11 construction safety maturity models were extracted from phase one, each with distinct areas of emphasis classified under three main categories: people, process, and policy. The level of emphasis placed on regulation and standards maturity within models had the lowest hit when compared to other components. The apportionment of maturity models focus proximately reveals that the majority of maturity models' elements in the construction sector predominantly concentrate on managing various processes, while the second most prominent focus pertains to people as a foundational area in safety maturity models.



3.2 Publication distribution by industry 4.0 technologies application

The allocation of focus in Industry 4.0 technologies in Fig 3. which is extracted from phas two of search indicates that an equal proportion of attention, 39% each, is dedicated to both people and processes in the construction sector. These two areas are considered equally significant in the application of advanced technologies in construction safety management. The level of emphasis on improving regulation and standards through technologies was relatively limited comprising only 22% of the overall focus.

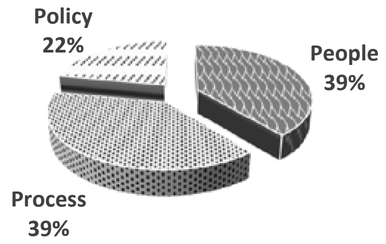


Fig 3. Publication distribution by industry 4.0 technologies applications

3.3 Publication distribution by industry 4.0 technologies type

Fig 4. in the literature encompasses a representation of the terminologies associated with various technologies. Among these, Artificial Intelligence (AI) and Industry 4.0 technologies have emerged as the most prominent and frequently referenced terms. The application of these technologies to aid safety challenges related to people, processes, and policy promote safety maturity in the construction process.

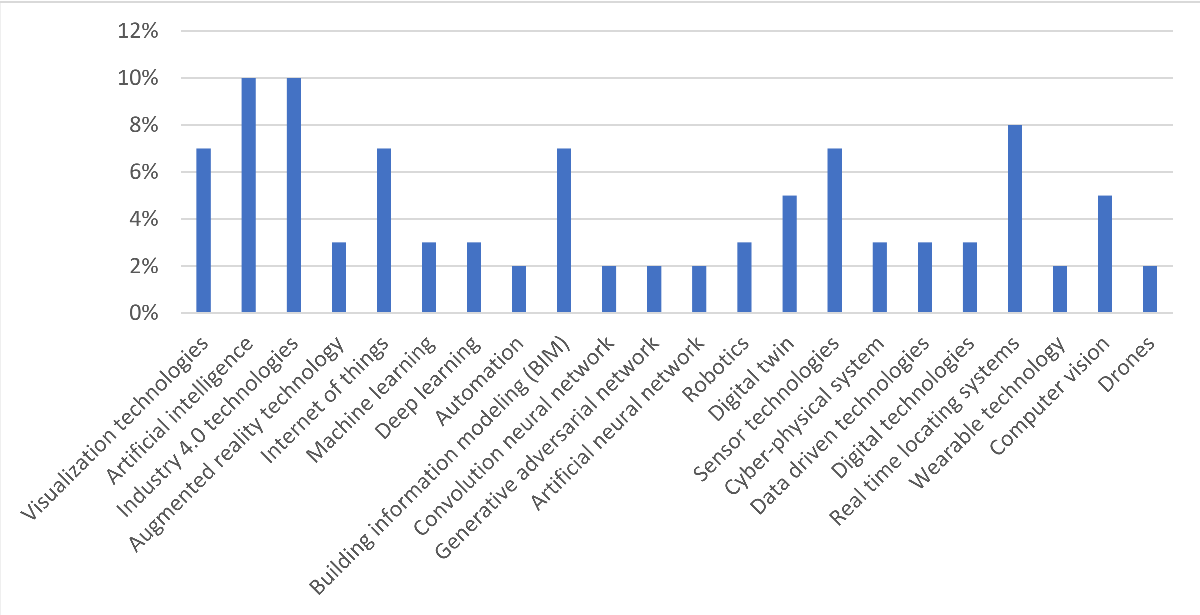

Fig 1. Publication distribution by industry 4.0 technologies type

3.4 Keywords co-occurrence in safety maturity models: insights from phase one search

A keyword network provides a visual representation and showcases the interconnectedness and intellectual organization of various research themes (Van Eck & Waltman, 2014). There are no universally defined guidelines for determining the frequency at which keywords should occur (Wuni et al., 2019). The frequency of the occurrence of the keywords as can be seen in Fig 5., among 28 keywords, the most important topics in the domain of construction safety maturity models extracted from phase one of search are related to cluster 1 labeled in red on the map had 8 members with keywords such as lagging indicators (e.g., job site safety audits, safety training, pre-task hazard analysis, and safety incentive program), leading indicators (e.g., recordable injury rate, lost time injury rate, and OSHA citations and fines), contractor selection, and decision making. Cluster 2 in the green region of the map had 7 items with keywords such as hazard awareness, hazard identification, safety accident, construction industry, occupation safety, safety management, labor, and personnel issues. Safety culture is the most important topic which has 18 links with other clusters.

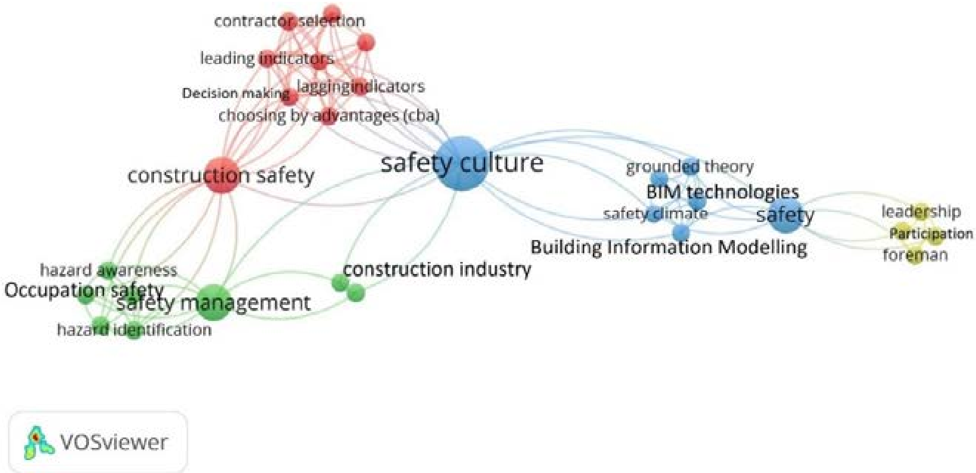

Fig 2. Co-occurrence of keywords of safety maturity models extracted from phase one of the search

3.5 Keywords co-occurrence in application of industry 4.0 technologies in construction safety: insights from phase two search

In Fig 6., the first cluster, indicated by the color red, represents the relevant technologies in the field of construction safety management such as artificial intelligence, automation, big data, digital twin, internet of things, machine learning, etc. The second cluster green shows links between Safety, technologies, and the construction industry, and cluster 3 dark blue shows keywords related to Industry 4.0 terms and their relationship to other clusters. The purple color cluster demonstrates how safety management has links with specific technologies such as sensor technologies, real-time locating systems, and visualization technologies. The last health and Safety, depicted in yellow, illustrates the opportunities and challenges arising from the adoption of technologies in the construction safety management domain after the fourth industrial revolution.

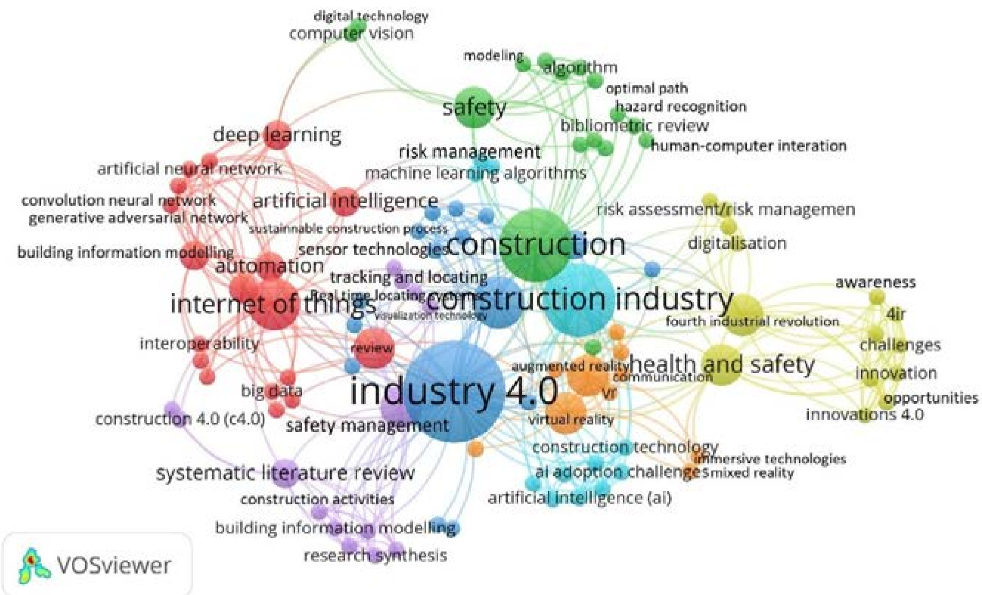

Fig 3. Co-occurrence of keywords of application of industry 4.0 technologies in construction safety extracted from phase two search

4. DISCUSSION

The thematic analysis of the drivers in the studied MMs revealed three major themes: Process, People, and Policy. This categorization aligns with other related literature, although slight variations exist. For instance, Succar (2010) utilized a BIM MM model and classified the drivers into three primary themes: People, Processes, and Technologies. Another context, as presented by Orogun and Issa (2022), involved categorizing the drivers in the health and safety assessment tool for Sustainable building projects, with the major themes being Building, Process and People. These findings emphasised the recurring significance of the Process and People themes in driving success in various domains while also highlighting the role of other drivers, such as technology or Buildings, in certain contexts.

4.1 Identification of safety drivers of maturity models in construction safety management

A body of literature focused on maturity models for Occupational Health and Safety (OHS) within the construction sector emphasizes the critical significance of leadership, commitment, engagement, effective communication, competence, and well-defined procedures as crucial elements in attaining maturity in this domain (Musonda et al., 2021). Assessing the maturity of Occupational Health and Safety (OHS) in construction projects also relies on the indispensable use of information and technology resources, along with facilitated collaboration made possible by technology (Poghosyan et al., 2020). Safety maturity also serves as a basis for evaluating safety performance (Karakhan et al., 2018; Oswald & Lingard, 2019) as well as disability management (Quaigrain & Issa, 2021). Construction frontline leaders play a crucial intermediaries role in transmitting messages between top-level management and workers, as well as bridging the gap between office-based and site-based people (Oswald & Lingard, 2019). safety leadership is a key factor in assessing causative incident factors and without supporting of leaders, workers are unable to effectively advocate for and implement safety behaviors (Indrayana et al., 2022). To establish a framework for evaluation and improving such practices, Oswald and Lingard (2019) developed a three-stage maturity model for revealing the relationships between foremen and subcontractor supervisors, the leadership styles of foremen and supervisors, the relationship between foremen and workers, the interaction between subcontractor supervisors, effective workgroup communication, and the relationship between frontline leaders and H&S advisors. Karakhan et al. (2018) also suggested a decision-making framework to assess the safety maturity of construction contractors which has seven main factors including safety leading and lagging indicators, Safety and supervisory personnel, system maturity and resiliency, preconstruction services, technology and innovation, and safety culture. Albert et al. (2014) suggested a maturity model for hazard recognition of workers to assist unanticipated hazardous conditions. A comprehensive framework in the work of Asah-Kissiedu et al. (2021) shed light on the various aspects of Safety, health, and environmental (SHE) management in construction operations. Table 3 illustrates the coverage of construction safety maturity research, showcasing components from different stages of construction safety management.

Table 3. Safety Drivers of maturity models in construction safety management

Reference	Maturity model	Safety drivers	Evaluation scope	Evaluation style
(Indrayana et al., 2022; Oswald & Lingard, 2019)	Frontline H&S leadership maturity model	People	Organization	Self-assessment

4.2 Application of industry 4.0 technologies in construction safety management

Numerous investigations have explored the application of technologies in the domain of construction safety management (Asadzadeh et al., 2020; Babalola et al., 2023; Fargnoli & Lombardi, 2020; Sadeghi et al., 2021; Soltanmohammadlou et al., 2019). These investigations delve into various facets of the safety management process such as visualizing construction activities and hazards, data gathering, integrating health and Safety into construction activities, monitoring noncompliance, determining accident costs, linking requirements to construction activities, integrating health and Safety into the construction process, connecting information to construction activities, mitigating worker hazards, assessing health and safety costs, and monitoring health and Safety in construction processes and activities (Smallwood & Allen, 2023). According to Khodabakhshian et al. (2023), the correlation of big data, digital technologies, and artificial intelligence paves the road for covering various aspects of construction safety management. Based on extracted data in the content analysis section, there are three key focal areas of studies about the application of Industry 4.0 technologies in construction safety management.

4.3 Industry 4.0 technological solutions for process-related safety challenges

The integration of various technologies has forged paths toward embracing the safety challenges in the construction process (Statsenko, Samaraweera, Bakhshi, & Chileshe, 2022). The prevailing technology-driven solutions encompass a range of methods, including automating safety planning (such as job hazard analysis, safe work method statements, plan and design review, and organisational safety performance) through visualization technologies. Sensor-based location technologies play a significant role, as does on-site safety management (including optimizing safety processes, proactively preventing accidents, and enhancing the repository of safety knowledge), achieved, for example, through the integration of Big Data with Building Information modeling (BIM) or semantic web technology. Additionally, safety training, safety outcomes assessment, safety monitoring, safety program costs, and real-time hazard identification are facilitated through the utilization of technologies such as real-time location tracking, augmented reality (AR), and virtual reality (VR)(Pedro, Pham-Hang, Nguyen, & Pham, 2022)(Akanmu et al., 2021; Asadzadeh et al., 2020; Babalola et al., 2023; Fargnoli & Lombardi, 2020; Franco et al., 2022; Guo et al., 2017; Li et al., 2018; Malomane et al., 2022; Oke & Arowoiya, 2022; Perrier et al., 2020; Regona et al., 2022; Smallwood & Allen, 2023; Soltanmohammadlou et al., 2019; Statsenko et al., 2022; Wen & Gheisari, 2020).

4.4 Industry 4.0 technological solutions for people-related safety challenges

Industry 4.0 technologies find application in various domains of safety maturity elements, aiding in multiple areas. These include recognizing unsafe behavior, detecting worker hazardous motions, monitoring physiological indicators, capturing worker responses, facilitating communication-based safety, assessing worker capabilities, providing operator aids, enhancing the safety management system of main contractors, qualifying manufacturers, supervising main contractor site activities, nurturing workers' safety values, fostering safety culture, evaluating safety climate, and managing worker job stress. These domains benefit from the integration of Industry 4.0 technologies, including real-time locating systems, visualization technology, Internet of Things (IoT), wearable technology, and etc. (Awolusi et al., 2018; Fang et al., 2020; Franco et al., 2022; Guo et al., 2017; Malomane et al., 2022; Panteli et al., 2020; Sadeghi et al., 2021; Soltanmohammadlou et al., 2019; Statsenko et al., 2022).

4.5 Industry 4.0 technological solutions for policy-related safety challenges

Health and safety noncompliance, safety standards requirements, adherence to site safety rules, evaluation of equipment operators' compliance, and compliance with safety regulations form key areas of Industry 4.0 integration. This integration is facilitated through diverse technologies like digital twins, 4D models, real-time locating systems, Internet of Things (IoT) and etc within the framework of safety policies (Fargnoli & Lombardi, 2020; Franco et al., 2022; Malomane et al., 2022; Oke & Arowoiya, 2022; Panteli et al., 2020; Patrucco et al., 2020; Sadeghi et al., 2021).

4.6 Conclusion and future work

This research aims to determine how the identified Industry 4.0 technologies currently contribute to safety maturity models in the construction industry. The key findings of this research reveal a structured approach to advancing safety maturity within the construction industry in the context of Industry 4.0. Our findings highlight the paramount importance of integrating Industry 4.0 technologies within the realms of Process,People, and Policy to advance safety maturity. Additionally, it is essential to explore how these technologies offer solutions for challenges associated with processes, people, and policies in safety management.This categorization is mirrored in the classification of Industry 4.0 technology implementation, illustrating a direct alignment between safety progression and the adoption of Industry 4.0 technologies. The aim is to systematically organize the transformation of construction safety maturity models within the context of Industry 4.0 by identifying critical aspects of the contribution of technologies. Furthermore, the research underlines the pivotal role of technology, emphasizing its multifaceted contribution to enhancing safety practices and overall maturity within the construction sector.
In the existence of construction safety maturity model, there is no structured way to measure the contribution of technologies to attributes of safety maturity. The utilization of technology in contributing to the maturity level of safety in the construction process can also indirectly provide advantages to policymakers and government bodies to present the state of safety management in the construction industry in their region and establish specific goals and regulations accordingly. However, most Industry 4.0 technologies in the domain of construction safety management are immature and have not yet been comprehensively developed. This study paved the way for developing a Smart Safety Maturity Model which integrates technologies for improving safety in the construction process.

ABSTRACT: *The development of methods for building permit issuing supported by digital tools could improve the current mostly manual procedures for processing regulatory information and related compliance processes. Several studies are currently addressing the challenge of building permit digitalisation, mostly considering building information models as the source data for automating the regulations checks. However, many of the main checks, that usually represent the major bottlenecks of the compliance checking process, need a joint representation of the new proposed construction and its context, which could be effectively represented in a (3D) geographical information system. This study aims at supporting the automation of building permitting by addressing the rule interpretation as an input to model preparation and code checking. In particular, the regulations interpretation in this case is functional to the definition of data requirements and checking rules referring to a joint GIS and BIM (GeoBIM) framework. The approach is developed and tested in the case of an Italian municipality of 45.000 inhabitants. This paper describes the interpretation of distance-related regulations by adopting a semantic mark-up and sentence-centric approach. The resulting level of information need has been represented in conceptual models (object, attributes, relationships) as an essential input to city and building model preparation. While the case study is specific in location and regulations, the type of issues encountered are a generally applicable example for the building permit use case. Future works will extend the methodology to additional three European municipalities between 45.000 and 1.000.000 inhabitants, in three European countries, to address the need for a flexible and scalable approach.*

KEYWORDS: *Digital building permit; Rule interpretation; GeoBIM; Information requirements; Building-urban interaction.*

1. INTRODUCTION

A building permit is an authorisation required to start the construction phase of a building and it is granted by public authorities after verifying that the design proposal complies with construction regulations at building and urban levels (Noardo, *et al.* 2022). Building permit checks are traditionally a time-consuming and manual procedure for municipalities and the process is recognised as poorly effective due to multiple factors including, but not limited to, the technical knowledge of public officers in the assessment and the high demand for building permits to be inspected, troubled by the lack of adequate personnel (Fauth & Soibelman, 2022). Also, procedures for the issuance of the permit tend to be complex because of having to adapt to frequent legislative updates (Malsane, *et al.* 2015).

The development and connection of methods for building permit issuing supported by digital tools could improve the current as-is manual procedures for processing regulatory information and related compliance processes. With the increased adoption of Building Information Models (BIM) in building design processes, several municipalities are investing in automating these checks both by using BIM methods and tools, but also by increasingly integrating them with the geographic datasets at their disposal (Hobeika, *et al.* 2022). Research in the adoption of BIM to design verification for regulatory compliance is not recent - think of the discussion on BIM-based rule checking proposed by Eastman, *et al.* (2009). However, until a few years ago, research works were mainly focused on analysing building data, including their conversion in building-related neutral data schema as Industry Foundation Classes (IFC), rather than integrating BIM and Geographic Information System (GIS) (i.e., GeoBIM) (Hobeika, *et al.* 2022).

It is clear how important checks for the issuing of building permits require constant interaction between data on

Silvia Mastrolembo Ventura, Sara Comai, Francesca Noardo, Kavita Raj, Angelo L.C. Ciribini, *Integrated GeBIM Requirements Definition for Digital Building Permit,* pp. 526-537, DOI 10.36253/979-12-215-0289-3.51

the building for which permission to proceed with the construction phase is sought – to be retrieved in the building information model - and information about the urban context in which it is located – to be retrieved in geo-data sets or 3D city models. This means that without adopting a GeoBIM approach some checks would require users to manually add information that should be instead automatically extracted from geo-data sets. For example, many urban parameters depend on urban zones, a new building must comply with minimum distance criteria from existing ones, interaction with existing public or private facilities must be considered, as well as public transport, parking standards and so on (Hobeika, *et al.* 2022). For this reason, according to recent studies on digital building permit (DBP), the automation of the checking of those kinds of regulations can only be effective if both geo-data and building data are considered. At present, the adoption of a GeoBIM approach represents a significant challenge of the DBP use case (Arroyo Ohori, *et al.* 2018). Recent literature, especially from 2016 (Noardo, *et al.* 2022), investigate the management of geo-data by available standards (e.g., CityGML) (Guler & Yomralioglu, 2021) and GeoBIM interoperability (e.g., conversion of 3D city models to BIM) (Nebras, *et al.* 2020) as essential steps for allowing designers to consider geoinformation as a suitable reference (Noardo, *et al.* 2022).

This paper focuses on rule interpretation, the process of conversion of the natural language of city and building regulations into computable parameters and constraints. Within the broader research framework, the methodology adopted for the interpretation of *distance-related* regulatory requirements and their formalisation is described in Section 2. Distance-related checks are one of the examples of regulatory checks that need the adoption of an integrated GeoBIM approach to be automated. Results from the interpretation of regulatory requirements from a specific case study are described in Section 3, including the formalisation of the relevant level of information need as a preliminary input to city and building model preparation and code checking (Section 4). Finally, limitations of the study, which is currently ongoing, are discussed along with future contributions (Section 5).

2. RESEARCH FRAMEWORK AND METHODOLOGY

The research considers the digitisation of the building permit use case for an Italian municipality of 45.000 inhabitants (i.e., Municipality of Ascoli Piceno). It has been explored in close collaboration with the municipality, and it is based on the field experience of its own officers. First, the list of checks to be digitised for effectively supporting the building permit process has been defined. Then, regulations among the ones that were deemed likely to have the best advantage from GeoBIM have been considered as a priority by municipality officers. They include: maximum buildable urban volume, buildability index, covered area, coverage ratio, maximum building height, building protrusions on public streets and squares, parcel's fence height, distance from other buildings (i.e., building-building distance), distance from the parcel boundaries (i.e., building-parcel boundaries distance), building-road distance, parking standards (dimensions/area and n. of parking spaces).

In this paper the results regarding *distance-related* regulations are described. Those regulations were selected, in consultation with municipality experts, because these were judged to be among the most important ones to be implemented. Distance-related regulations have been classified as follows: building-building distance, building-parcel boundaries distance and building-building distance if a road is interposed. The specific text of the regulation has been analysed with the aim of translating it into a set of information requirements for the DBP use case and, on the other hand, into a machine-readable format. The former objective lies within the scope of this paper, while the development of a pseudocode, developed based on this initial discussion, will be a future work of this research which is still ongoing.

2.1 Rule interpretation

Rule interpretation represents the first step of the DBP workflow (Figure 1) but it is also one of the main challenges in such a use case. The relevant information in documents such as public laws, codes and regulative standards should be captured in a time and cost-effective way to be able to adopt rule checking effectively (Noardo, *et al.* 2022). However, the complexity of the natural language used for regulatory requirements and its interpretation into data sets for supporting the adoption of a digital approach represents an open issue for automating and digitising design compliance checking and, specifically, building permitting. Malsane, *et al.* (2015) describe how knowledge formalisation of building codes could provide "suitable, significant and required data for the development of the building regulation-specific object modelling". They claimed how the formalisation of building regulations should include the classification of regulation clauses into "those which are computer-interpretable (declarative) and those which are not (informative)". The former provides a direct meaning to be interpreted (e.g., simple geometrical rules which when applied to an element can return true or false), while the latter contain data only partially suitable for interpretation into computer rules that can be processed (e.g., information is not obvious as checkable, needs human interpretation to understand the exact content and meaning). Finally, a remaining category of clauses exist that can be considered as unsuitable for automated compliance checking.

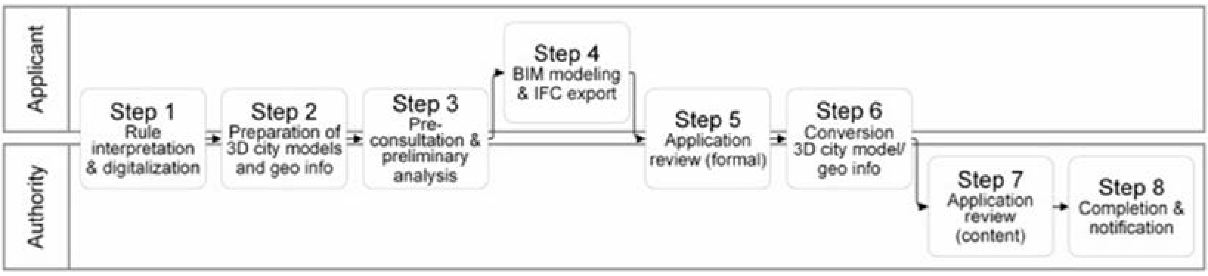

Fig. 1: Overview of considered DBP workflow steps assigned to involved parties (Noardo, *et al.* 2022)

Several rule interpretation processes are described in literature, both manual-based and automatically enabled, to create computable representations of normative data (Dimyadi, *et al.* 2017). Studies exist that propose methods to automatically interpret the natural language of regulations transforming them to code to check the proposed building design, as represented in building information models (e.g., Song, *et al.* 2018; Zhang & El-Gohary, 2017). However, challenges appear long before the conversion of this information from natural language to any formal language since even for human beings the interpretation of the text, tables and graphical contents of regulations can be open to different interpretations (Noardo, *et al.* 2020). According to Zhang, *et al.* (2023), the ambiguity of building requirements is one of the main issues since it could prevent their accurate interpretation and automated checking. They discussed how some ambiguous clauses in building requirements "reflect regulators' intention while others are unintentional, resulting from the use of language or tacit knowledge". Even if the rule interpretation process could rely on the programmer's interpretation and translation of the written rules into computer code (Eastman, *et al.* 2009), in most cases the logic of the human language statements is first formally interpreted and then translated. In fact, because of the complexity and subjectivity in nature of building regulations, as just mentioned, building regulation experts (e.g., municipality officers) need to be involved in their conversion to computer interpretable rules to ensure the correct interpretations (Malsane, *et al.* 2015).

In this study, a sentence-centric approach and a semantic mark-up procedure have been adopted for rule interpretation. Each regulatory article that municipality officers considered as significant for distance-related checks was interpreted (i.e., sentence-centric approach). To this end the *Requirement, Applicability, Selection, and Exception* (RASE) methodology has been adopted for deconstructing rule sentences and to extract semantics from building regulations for compliance checking (Hjelseth & Nisbet, 2011; Nisbet, *et al.* 2022). The content of regulatory requirements has been interpreted by dividing each sentence into these four basic components to support formalisation (i.e., semantic mark-up procedure). Such an approach to rule interpretation can be seen as a pre-processing step as in this case the result cannot be directly interpreted by the computer (Preidel & Borrmann, 2018).

Moreover, a relevant step to solve ambiguities has been performed by the organisation of a specific meeting with the involvement of municipality officers who usually check and then release or deny the building permits themselves. The details and meanings of the distance-related regulations were explained and agreed upon and specific questions were asked about ambiguous statements. Moreover, some more details arising during the following work towards implementation were asked later. That was the only way to have ambiguities about the regulation solved. This issue already showed how little the current state of regulations lends itself to automation (Noardo, *et al.* 2020).

After that, the regulation was formalised step by step. A table containing the metric phrases identified through the RASE labelling has been compiled and the following data set has been provided (Hjelseth & Nisbet, 2011; Tomczak, *et al.* 2022): the object to which the rule refers, the type of information to be verified (i.e., property), the data type (e.g., text, number, boolean) of the required properties, the comparison (e.g., ≤, ≥, contains), the value to be compared (i.e., target value), the unit of measurement that the value should have (i.e., for numerical values) and, if necessary, dependencies and application conditions. Plain text description could be added to support unambiguous definitions and information requirements could also demand a particular level of detailedness to support building and city model preparation, meaning what needs to be modelled and to what precision (i.e., geometrical data) (Tomczak, *et al.* 2022).

2.2 Information conceptual models

Based on the results from rule interpretation, information requirements have been identified and formalised in terms of information conceptual models (object, attributes, relationships) as an essential input to city and building model preparation (Zhang, *et al.* 2023). Both building and city models are sources of information involved in automated compliance audit processes if a GeoBIM approach is adopted. They respectively represent the building design to be audit - usually developed by the professional responsible for applying for a building permit on behalf of the applicant - and the urban context in which it is located. Another source in the automated compliance checking process is represented by normative clauses structured in machine-readable formats, which is not within the scope of this paper.

Conceptual models, in the practice of database design, are intended to formally represent the information to be stored in a database. The database design methodology defined by the ANSI/X3/SPARC standard defines four levels of data modelling: external model, representing a simple narration of requirements for information representation of the database; conceptual model, abstracting and formalising the information requirements in the external model into objects (i.e., entities or classes), the respective properties or characteristics (attributes) and reciprocal relationships; logical model, converting the conceptual model into rules more computing oriented; and finally the internal, or physical model, corresponding to the actual implementation format of the database (Laurini & Thompson, 1992).

In this study, the information about requirements was collected from the regulations, and the mark-up phase through the RASE methodology facilitating the formalisation of the regulatory contents was one intermediate step supporting the definition of data requirements as conceptual models, which were represented following the Unified Modelling Language (UML) (OMG, 2023). Objects and related attributes needed for distance-related checks in the DBP use case for the considered municipality have been identified. The representation includes data types and specifies if data are directly extractable from the model (e.g., the height of the object) or whether they need to be entered manually by the designer. For numerical value the type is specified (e.g., integer, real, float), while for textual data allowed classifications are specified from which data values can be chosen (e.g., the list of actual intended uses for the municipality's urban zone from which a designer has to choose before submitting its design to the building permit procedure. Depending on the type of intended use of the urban zone, in fact, some regulatory constraints will apply over others). The conceptual model representation also allows the type of relationship (aggregation relationship, composition relationship, etc.) to be specified.

Finally, the development of the conceptual models supports an easier comparison and harmonisation of the information requirements according to the same type of check (e.g., distance-related check) applied in different municipalities or according to different types of checks applied by the same municipality. This will facilitate the mapping to standards for representing BIM and GIS-related information consistently in future steps. To this end, as a preliminary step, for the objects in the conceptual model proposed in this paper it is specified whether they should belong to the BIM or GIS information representation.

3. RESULTS FROM THE INTERPRETATION OF REGULATORY REQUIREMENTS

The regulation considered here is the *Regolamento edilizio comunale (i.e., Building code) of the Municipality of Ascoli Piceno.* Municipality officers pointed out Article 61 of the text, reported here in paragraphs 2, 3, 4 and 6, as important for distance-related checks. The text translated into the English language is available in Table 1.

When considering this Article for formalisation, several examples of the complexity of the natural language of regulatory requirements emerges. For example, paragraph 2 refers to another regulatory text whose requirements, in relation to the one under analysis, are not made explicit. A reference to the "*urban planning instrument",* which could contain additional requirements, is also mentioned in the paragraph. The prescribed minimum distance between two buildings is implicit in the text – referring to the *"height of the tallest building"* - and refers to another regulatory aspect concerning the maximum building height, for the explication of which it is necessary to refer to further definitions or regulatory articles. The same happens for the distance of the building from the boundaries of the parcel in which it is located (i.e., "*the distance of a building from the parcel boundaries shall be equal to the half of the maximum permitted height"*). Paragraph 4 also refers to additional definitions, such as the one of the distances of a building from a road: what does the road should contain as an object in city or building information models?

It is therefore essential to interpret not only the regulatory requirements but also definitions contained in building regulations and other regulatory texts that are relevant to the inspection in question. In 2016, an agreement was reached between the Italian state, Regions and the National Association of Italian Municipalities to adopt the so-called Standardized Building Regulations to simplify and unify actions in building matters. To this end, a set of forty-two uniform building-urban definitions was also developed, which represents the common glossary valid throughout the country. However, the process of transposing the Standard Building Regulations and their homogeneous definitions is still in progress and it is currently not possible to proceed with an unambiguous interpretation of them that has generalised validity. In this case, the regulation considered here is the *Regolamento edilizio comunale of the Municipality of Ascoli Piceno – art. 13 (o, p, q).* The text of these definitions translated into the English language is contained in Table 2, which also contains the graphical interpretation of the definitions as proposed by the authors and validated by municipality officers. The definition of building height (art. 13, paragraph m and n) had to be considered as well and it is contained in Table 3.

Table 1: *Building code of the Municipality of Ascoli Piceno. Art. 61 (i.e., distance-related checks)*

Paragraph	Text of Normative Article
2	In (c) areas of expansion referred to in Article 2 of Ministerial Decree No 1444 of 2 April 1968, published in the Official Gazette of 16 April 1968, No 97 between windowed walls of facing buildings, a minimum distance is prescribed, equal to the height of the tallest building and no lower than 10 m; if the facing facades overlap for more than 12 meters, the rule applies also when only one of them has windows. In the same urban zones, the distance of a building from the parcel boundaries shall be equal to the half of the maximum permitted height and in any case not less than 5 m. Construction on parcel boundaries is allowed, where permitted by the urban planning instrument, by agreement between the neighboring owners
3	For all construction operations in other areas, the following minimum distances are prescribed: (building-building distance) (1) between windowed walls and walls of buildings in front of which at least one window: ml. 10; (building-parcel boundaries distance) (2) from the boundaries: ml.5 and unless otherwise prescribed by the general urban planning instrument.
4	Minimum distance between buildings with roads in-between, excluding cul-de-sac roads serving single buildings or settlements, must be equal to the road width plus: (1) 5.00 m per side, in case of streets width lower than 7.00 m, (2) 7.50 m per side, in case of streets width between 7.00 and 15.00 m, (3) 10.00 m per side, in case of streets width higher than 15.00 m
6	It will not be taken into account for the purposes of determining distances, overhang structures such as steps and open external stairs (maximum height 4), (1) gutter frames, open balconies and canopies, provided that the relative outline remains spaced from the boundaries at least by 1.50 m; (2) While account shall be taken of anybody closed in protrusion whatever is the adjective and at whatever height of the building it begins.

Several ambiguities and uncertainties also arise for human interpretation. Those were mainly solved with the help of municipality officers in a meeting organised on the 17th of May 2023. Later, further ambiguities have been solved thanks to the continuous collaboration with the municipality, which was critical for the success of this initial phase. For example, the *building-building distance* can be considered radially or perpendicularly to the new building. Through discussions with municipality officers, it was defined that the segment defining the distance is perpendicular to the line of the building (see Table 2, paragraph o). Considering the building-road distance check, doubts emerged in relation to the “road furniture areas”. Talking with the municipality officers it was possible to define the entity of “flowerbed” to which the normative text refers (see Table 2, paragraph q).

Results from rule interpretation have been formalised in a table containing the metric phrases identified through the RASE labelling as described in Section 2 (Figure 2). In Figure 2, the identified values for distances only apply to one urban zone, namely the c) areas of expansion. The first part of the article identifies the distance between two buildings with external windowed walls (art. 61(2) – case a), while in the second part, the overlap factor intervenes (x >12 m) (art. 61(2) – case b) and the distance is calculated between two walls of which at least one is windowed, so we have two cases, the existing building with a wall containing a window and the new building without windows or vice versa, the new building with a window and the existing building without (Figure 3).

Table 2: Distances-related definitions as defined in the *Building code of the Municipality of Ascoli Piceno, Art. 13*

Regulatory requirement	Graphical interpretation
Paragraph o – Building-building distance. Is the distance (minimum) between the walls in front of the buildings, or buildings of the same, except for the walls on the interior spaces referred to in point (r) below, measured at the points of maximum protrusion. Two walls are considered to be facing when the angle formed by the extension of the same is less than 70 degrees sexagesimal and the overlap is greater than 1/4 of the minimum distance of the walls themselves. For graded buildings, the distance is measured at each setback.	Paragraph p – Building-parcel boundaries distance. It is the distance between the vertical projection of the wall of the building and the boundary line, measured at the point of maximum protrusion. It is understood as a border beyond the separation line of the different existing properties or the line defining the different lots or compartments of the implementation plans, as well as the line of delimitation of public areas for services or equipment identified in urban planning instruments.	Paragraph q - Building-building distance if a road is interposed. It is the distance between the vertical projection of the wall of the building and the edge of the road, including sidewalk and public parking and road furniture areas.	
Table 3: Building-height definitions as defined in the *Building code of the Municipality of Ascoli Piceno, Art. 13*

Regulatory requirement	Graphical interpretation
Paragraph m - Front height (H) - This is the height of any part of the elevation into which the building can be broken down, measured from the ground line to the roof line, taking into account the setback bodies if not included. The ground line is defined by the intersection of the wall of the elevation with the street level or the plane of the pavement or the plane of the ground at final settlement. The roof line is defined, in the case of a flat roof, by the intersection of the elevation wall with the plane corresponding to the extrados of the roof slab; in the case of a pitched roof, by the intersection of the elevation wall with the plane corresponding to the extrados of the roof pitch. Unless otherwise specifically prescribed by the individual town-planning instruments, the height measurement does not take into account stairwells, lifts and flues, nor the increases corresponding to basement window wells or external accesses, both vehicular and pedestrian, provided that the accesses themselves, built in a trench with respect to the ground line, are not more than 3 m wide.	Paragraph n - Maximum height of buildings (HMAX) This is the maximum between the heights of the different parts of the elevation into which the building can be divided, measured as in letter m) above. In the	

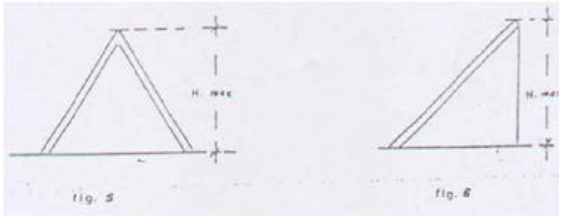
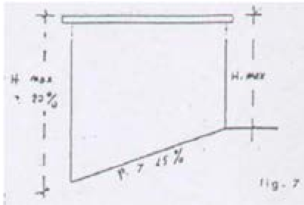
case of elevations in which there are inclined roof pitches (gabled, staggered or single-pitched), the maximum height is considered to be that corresponding to the intersection of the elevation walls with the plane corresponding to the extrados of the roof pitch (1) as long as the ridge does not exceed the height measured in this way by more than 1.80 m, otherwise the maximum height is measured at the ridge line (see Figures 1,2,3 and 4). (2) If the roof slopes coincide with the sloping walls of the elevations, the maximum height must always be measured to the ridge line (see Figures 5 and 6). (3) For buildings on land with a natural slope of more than 15%, the maximum height permitted by the town planning instruments, unless more restrictive prescriptions of the same, may be exceeded by 20% in the downstream parts of the elevations, with an absolute maximum of 2.00 (see Figure 7).





Normative clause (*Regolamento edilizio comunale* – Art. 61.2)	Metric phrase	Mark-Up (RASE)	Object needed (building/city model)	Property	Data type	Comparison	Target	Unit	Dependency

Fig. 2: Resulting interpretation of Art. 61.2 based on a semantic mark-up and sentence-centric approach.

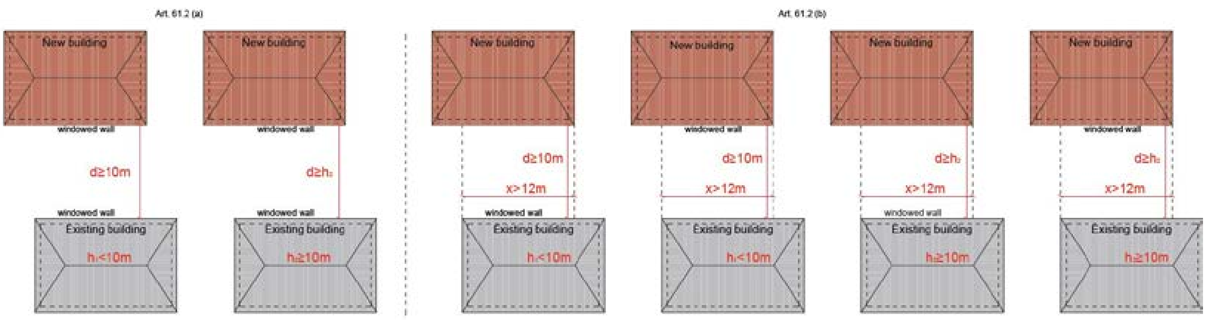

Fig. 3: Graphic Interpretation of Articles 61.2(a) (on the left) and 61.2(b) (on the right).

In the analysis of Article 61.3 shown in Figure 4, there are the values of the distances to be observed in '*other areas*'. This concept was the subject of discussion with the municipality as it does not specify in detail in which Urban Zones it applies. Unlike the previous article, the rule to be respected in this case is that the 3 areas emerged from the comparison: *Historic centre*, *Areas of completion* and *Areas of expansion*.

Normative clause (*Regolamento edilizio comunale* – Art. 61.3)	Metric phrase	Mark-Up (RASE)	Object needed (building/city model)	Property	Data type	Comparison	Target	Unit	Dependency
For all construction operations in other areas, the following minimum distances are prescribed: (1) between windowed walls and walls of buildings in front of which at least one window: ml. 10; (2) from the boundaries: ml.5 and unless otherwise prescribed by the general urban planning instrument.	minimum distance	Applicability	- New building - Existing building(s)			Exist			
	For all construction operations in other areas	Selection	Urban zone	Intended Use	Text	≠	- Historic centre - Areas of completion - Areas of expansion		
	between windowed walls and walls of buildings in front of which at least one window:	Selection	- New building			Contains	Wall: (which contains) window		If facing walls
			- Existing buidling(s)			Contains	Wall: (which contains) window		
	ml. 10	Requirement	- New building - Existing building(s)	Distance	Number	≥	10	m	
	minimum distance	Applicability	- New building - Existing building(s) - Parcel						
	from the boundaries	Selection	- Parcel			Contains	parcel boundaries		
	ml.5	Requirement	- New building - Parcel boundaries	Distance	Number	≥	5	m	
	unless otherwise prescribed by the general urban planning instrument	Exception							

Fig. 4: Resulting interpretation of Art. 61.3 based on a semantic mark-up and sentence-centric approach.

Article 61.4 (Figure 5) deals with the distance that must be between the building and the road. First of all, it is necessary to identify the width of the road. In fact, the article refers to 3 brackets: less than 7 m (1), between 7 m and 15 m (2) and greater than 15 m (3). For these 3 cases it identifies the distance as the sum of the road width increased by a specific value: 5 m for the first case, 7.50 m for the second case and 10 m for the third case. Article 61.6 (Figure 6) deals with the distance between the projecting parts of the building and the parcel boundaries. A requirement emerges that has been identified by the authors as an '*implicit piece of the regulation*'. For the previous articles, the building line from which to calculate the distance referred to the external elevation understood as the external wall that must contain a window (Art.61.2a). In this article, the reference building line is moved from the outer wall to the reference overhang if the latter is less than 1.50 m away from the parcel boundaries. The projections referred to are precisely eaves cornices, open balconies and canopies.

Normative clause (*Regolamento edilizio comunale* – Art. 61.4)	Metric phrase	Mark-Up (RASE)	Object needed (building/city model)	Property	Data type	Comparison	Target	Unit	Dependency
Minimum distance between buildings with roads in-between, excluding cul-de-sac roads serving single buildings or settlements, must be equal to the road width plus: (1) 5.00 m per side, in case of streets width lower than 7.00 m, (2) 7.50 m per side, in case of streets width between 7.00 and 15.00 m, (3) 10.00 m per side, in case of streets width higher than 15.00 m	minimum distance	Applicability	- New building - Existing building(s)			Exist			
	between buildings with roads in-between	Selection	- Road			Exist			If the roads is interposed between New building and Existing building(s)
	excluding cul-de-sac roads serving single buildings or settlements	Exception	- Road	Type	Text	=	Cul-de-sac roads serving individual buildings or settlements		
	in case of streets width lower than 7.00 m	Selection	- Road	Width	Number	<	7	m	
	must be equal to the road width plus 5.00 m per side	Requirement	- New building - Existing building(s)	Distance	Number	≥	Road's width + buffer 5,00 m	m	
	in case of streets width between 7.00 and 15.00 m	Selection	- Road	Width	Number	≥ ≤	7 15	m	
	must be equal to the road width plus 7.50 m per side	Requirement	- New building - Existing building(s)	Distance	Number	≥	Road's width + buffer 7,5 m	m	
	in case of streets width higher than 15.00 m	Selection	- Road	Width	Number	>	15	m	
	must be equal to the road width plus 10.00 m per side	Requirement	- New building - Existing building(s)	Distance	Number	≥	Road's width + buffer 10.00 m	m	

Fig. 5: Resulting interpretation of Art. 61.4 based on a semantic mark-up and sentence-centric approach.

Normative clause (*Regolamento edilizio comunale* – Art. 61.6)	Metric phrase	Mark-Up (RASE)	Object needed (building/city model)	Property	Data type	Comparison	Target	Unit	Dependency
It will not be taken into account for the purposes of determining distances, overhang structures such as steps and open external stairs (maximum height 4). (1) gutter frames, open balconies and canopies, provided that the relative outline remains spaced from the boundaries at least by 1.50 m; (2) While account shall be taken of any body closed in protrusion whatever is the adjective and at whatever height of the building it begins.	distances	Applicability	- New building

4. INFORMATION REQUIREMENTS DEFINITION

As already mentioned in Section 2.2, Figure 7 shows the representation of the data required to verify the constraints specified in the *Regolamento edilizio comunale* of Ascoli Piceno. Each box represents an entity of building information models or city models, with its specific attributes. To facilitate the identification of entities belonging to the different models, colours were used, assigning a different colour depending on whether the entity should come from a BIM or city model. In particular, *green* was used to identify elements belonging to the building model (BIM) and *blue* to identify elements belonging to the city model (GIS). This distinction allows to have an immediate view of where the data should come from and highlights the necessary correlation between the data of the building and the geospatial data of the urban context in which it is located. This example makes it clear that the need to integrate BIM with GIS, and GIS with BIM, is increasingly essential. A grain size and tolerance must be defined to integrate these two types of data.

Building information models and city models for checking distance-related requirements in a digital building permit use case should contain:

- *urban zones* with an absolute location and for which the *intended use* (e.g., area of expansion; historic centre) is specified;
- *cadastral parcels* with an absolute location and for which *parcel boundaries* are modelled as well;
- *existing buildings*, meaning those that are already located in the urban context of the *buildings* for which the building permit is required. Existing buildings could be detailed with a simplified geometry that allows the extrapolation of the *building height* according to the relevant definition (e.g., a cube for a house with a flat roof that is not accessible). Existing buildings have to contain *windows* to allow building-building distance checks to be executed. Existing buildings have to be identified with their absolute location;
- *buildings*, meaning the ones for which the building permit is required. Buildings need to be detailed with their actual shape and size to identify the building outline. For this reason, buildings need to be modelled including overhangs as *balconies*, *canopies, roofs' eave cornices* and *closed building extrusions*. Appearance is not to be considered for this type of check. Moreover, *external walls* have to include *windows*. The *type of construction* could be a property to assign to buildings (e.g., new construction, renovation) for compliance checking;

- *roads* will have to be modelled including *streets, sidewalks*, *parking spaces* and *flowerbeds*. In fact, according to the definition in Table 2 (see paragraph q), the road is considered as the sum of several elements. The information content of *road* elements has to contain properties as *type of road* (e.g., cul-de-sac) and *width*.

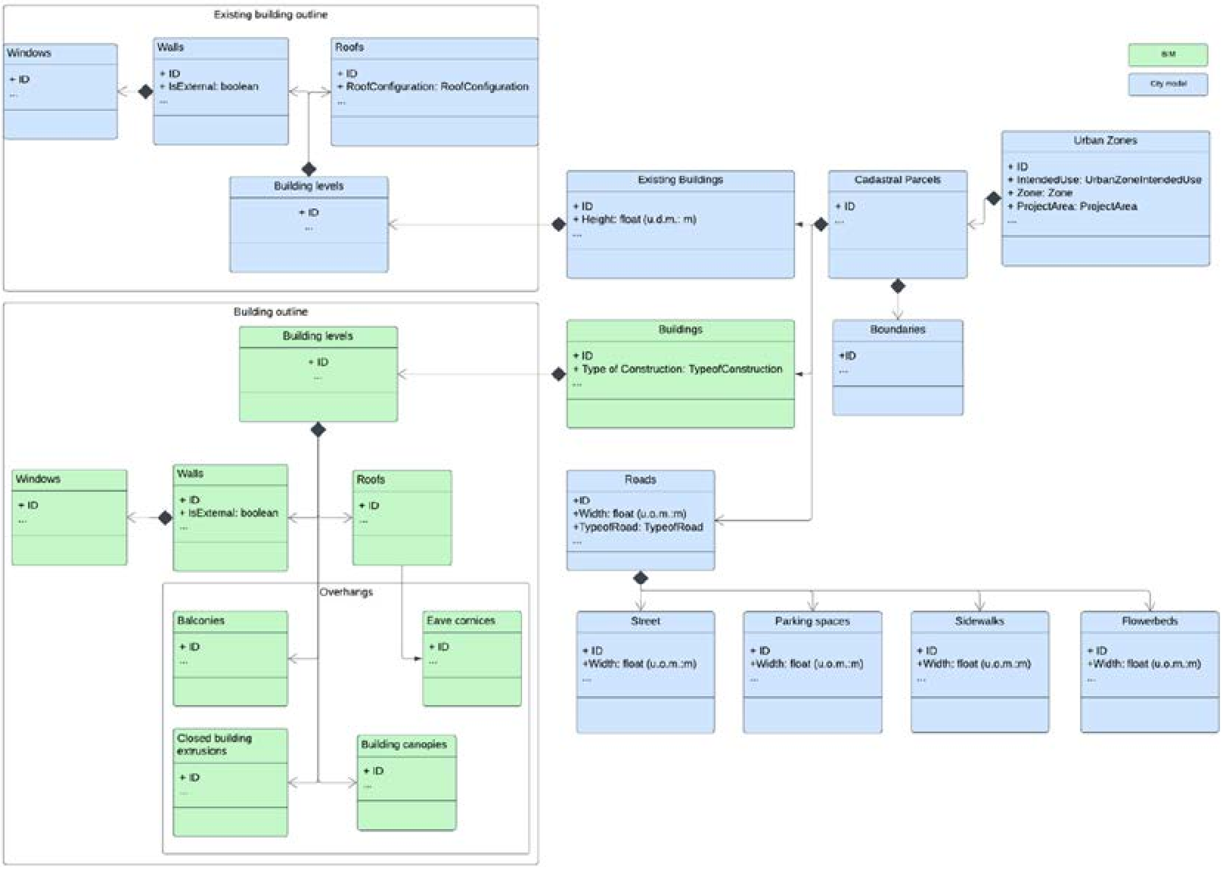

Fig. 7: Conceptual model representing the entities, attributes and relationships that must be present in the model to apply for a digital building permit.

5. CONCLUSIONS

5.1 Discussion of results

This paper describes the interpretation of distance-related regulations for the digitisation of the building permit use case for an Italian municipality of 45.000 inhabitants. Those regulations were selected as a priority by municipality officers, and they check the compliance of design proposal with regulatory requirements related to: building-building distance, building-parcel boundaries distance and building-building distance if a road is interposed. A semantic mark-up and sentence-centric approach has been adopted to extract normative constraints from the natural language of the regulatory text with the aim of translating it into a set of information requirements for the DBP use case. Information requirements have been defined as an essential input to city and building model preparation and they have been formalised in terms of information conceptual models. Domain-specific object types have been associated with required properties properly detailed. Moreover, object types have been matched with a preliminary categorisation into building-related and city-related objects. This could be the basis for the development of standard-oriented specifications for building and city information models.

The rule interpretation step revealed several difficulties, proving to be, as already described in the existing literature, probably the most critical phase in digitising design compliance checking and, specifically, building permitting. First, despite the fact that the municipality officers initially indicated only one regulatory article as necessary for distance verification based on urban zones (i.e., Art. 61 from *Regolamento edilizio comunale*), it was needed to add further regulatory references to this explicit request, either from the same regulatory text or from others normative codes. In addition, it was necessary to interpret not only the regulatory requirements but also the definitions to which they refer (e.g., the actual meaning of building-road distances and maximum building height). Moreover, to validate the extrapolated data and to remove ambiguities related to the complex regulatory textual form, a comparison with municipality officers was essential, which underlines, again confirming the literature, the interpretative subjectivity of building regulations that hardly fits with their digitisation.

5.2 Limitations and future works

Current outcomes show how, despite any fascinating narrative about the automated technical solutions, the hurdles to be tackled with and overcome imply to definitely understand a lot of multi-faceted meanings, unless a whole re-writing of the regulations might be figured out. While the case study is specific in location and regulations, the type of issues encountered are a generally applicable example for the building permit use case. Future works will extend the methodology to the analysis of distance-related regulations from additional three municipalities between 45.000 and 1.000.000 inhabitants, in other two European countries. The resultant level of information need will be formalised in terms of information conceptual models for the complete set of four municipalities and compared to point out the need for a flexible and scalable approach. To this end, the generated data set will be shared with professionals from municipalities, city modellers, and designers to allow the comparison and subsequent validation of the identified and analysed requirements.

Moreover, what is proposed in this article is a first step to proceed, in future works, with deeper analysis in relation to semantics, level of details, geometric representations and GeoBIM interoperability. As a future work, the representation of design and context information according to BIM and geospatial standards will be considered as well as standard definitions for the level of information need as the one proposed by the EN Standard 17412, to be soon re-shaped as a EN ISO Standard.

A SYSTEMATIC REVIEW OF THE IMPACTS OF DIGITALIZATION ON PROJECT MANAGEMENT

Ailin Zerafat, Emmanuel Daniel & Louis Gyoh
School of Architecture and Built Environment, University of Wolverhampton, UK

ABSTRACT: *This article systematically reviews digitalization's impacts on project management in the construction industry. The article discusses the challenges the construction industry in successfully applying digitalization during the construction phase, including high costs, subpar performance, low productivity, and sustainability issues. The article then outlines the research questions and methodology used to conduct the systematic review, including selecting acceptable research questions, selecting acceptable research questions, using a qualitative approach, and the content review approach. The study analyzed 21 papers and identified the primary research themes regarding the effects of digitalization on project management. The study found that digital technologies, such as smart building technology, digital twins, reality capture, and laser scanning, have positively impacted project management by increasing efficiency, accuracy, value, and safety. The study concludes that the construction industry must embrace digitalization to address its challenges and improve project management.*

KEYWORDS: *Digitalization, Systematic review, Project Management, BIM, Construction Industry,* Automation, Innovation, *Construction Sector*, *Innovation*, *AI*, *Remote, Architect, Engineering*

1. INTRODUCTION

Digitalization is changing the way construction projects are managed and impacting not only the design and construction phases but also facility management (Bazán *et al.,* 2021). It is challenging to successfully apply digitalization during the most time-consuming, expensive, and collaborative period of a project—the construction phase (Qais K. Jahanger *et al.,* 2021). With digitalization being the most promising option to address these difficulties, the construction industry faces a number of hurdles, including high costs, subpar performance, low productivity, and sustainability issues (Nikmehr *et al.,* 2021).

The implementation of Building Information Modelling (BIM) is one of how the construction industry is being digitalized, and its adoption is increasing globally, requiring the conversion of conventional building life cycle phases into BIM-integrated project deliveries (Yilmaz, Akcamete and Demirors, 2023). Strong relationships between frequently encountered independent BIM uses are a requirement for the Total BIM approach, where the principal contractual and legally binding construction document should be production-oriented BIM. Other key success elements include cloud-based model administration, user-friendly on-site mobile BIM software, and strong leadership (Disney *et al.,* 2022). However, BIM deployment frequently has limitations, such as parallel 2D drawing production, which results in wasteful effort, and the need for structural engineers on-site to develop POVs for construction because collecting measurements using the software was not supported. Additionally, Tekla, which supports a 3D model-based approach for rebar and steel structures, is used in the examples, which largely focus on infrastructure projects (Disney *et al.,* 2022).

To fully utilize BIM and digitalization in project management, it is necessary to develop tools for documentation, registration, and data management that allow for effective information sharing among all stakeholders (Bazán *et al*., 2021). Moreover, the cost of construction expert's services, including BIM services, which are now determined by established rates based on construction and equipment prices, can be more accurately predicted with the help of historical data (Nguyen, Dang and Nguyen, 2022). Using BIM-Facility Management with three-dimensional information models created during construction, BIM-based solutions offer the opportunity for collaborative, multidisciplinary workflows and full life cycle consideration (Bazán *et al*., 2021).

Apart from BIM, the construction industry is also moving towards Construction Automation and Robotics (CAR) (Pons-Valladares *et al*., 2023). This is because the upkeep and building of conventional structures account for roughly 30-40% of global energy usage and greenhouse gas emissions into the built environment, posing a threat to the environment due to the significant amount of resources and energy required in these buildings (Ejidike and Mewomo, 2023). According to the UN, the construction industry is responsible for around 40% of global energy use, nearly 40% of waste production, and roughly 30% of greenhouse gas emissions related to energy (Reinbold *et al.*, 2022).

FUP Best Practice in Scholarly Publishing (DOI 10.36253/fup_best_practice)
Ailin Zerafat, Emmanuel Daniel, Louis Gyoh, *A Systematic Review of the Impacts of Digitalization on Project Management,* pp. 538-544, DOI 10.36253/979-12-215-0289-3.52

As part of industrial digitalization, the manufacturing sector makes use of digital technologies like AI, cloud processing, and IoT. This speaks of initiatives taken to increase output using digital technology, which can have an effect on all areas of an organization and alter current business procedures (Carlsson, 2023). Effective strategizing of organizational capabilities relies on managers' capacity to elucidate the socio-cognitive factors, and it contributes to management practice by highlighting the divergent opinions among managers concerning digital technology's influence on efforts to improve the organization (Carlsson, 2023). Additionally, a potential solution to the lack of focus on workers in digitalization research for the construction industry is digital visual management (DVM), which aims to provide real-time visual information that can be easily accessed and utilized during production activities to increase transparency and communication. However, understanding the various actors' information needs is crucial to effectively implement DVM (Reinbold *et al.*, 2022).

The growth of digital methods is transforming the design and construction business, impacting not only how the sector operates but also the range of output; yet, there is a dearth of critical analysis because the majority of research mainly concentrate on creating the approaches (Brooks, Zantinge and Elghaish, 2022). The lack of comprehensive analysis of this disaggregated knowledge on the application of digital technology in project management informed the current systematic literature review. This study aimed to comprehend how digitalization has affected project management. The study objectives are;

• To examine the project management literature currently available on digitalization.

• To determine how project management is currently using digitalization.

• To identify the obstacles preventing the use of digitization in project management

The building industry faces the challenge of creating comprehensively built infrastructures that meet the demands of a growing population, urban sprawl, and globalization. This includes implementing efficient energy management, ensuring proper water supply, providing indoor comfort for occupants, and managing construction waste (Ejidike and Mewomo, 2023). The substantial financial burden of maintaining and repairing deteriorating facilities is highlighted by the necessity for improved management and inspection systems given the size of some countries' infrastructure (Bazán *et al*., 2021). The successful use of digital technology by a construction company depends on having sufficient knowledge of the organization, including its structure, nature of work, and human resource characteristics (Nikmehr *et al.,* 2021).

2. RESEARCH METHOD

The basis for increasing knowledge in a certain discipline, such as architecture and construction, among others, is a thorough review of the scientific literature. The study employed a systematic review methodology, in accordance with the strategy described by Denyer and Tranfield, to thoroughly assess the body of literature and arrange knowledge into a trustworthy manner that can influence practices (Ejidike and Mewomo, 2023).

This literature review with a qualitative approach aims to explore the advantages of digitalization in project management in the construction industry. The review employs the Scopus search engine to locate pertinent papers. Due to Scopus's high data recovery accuracy and precision, the researcher chose to use it for their literature search. The investigation considers papers published between 2015 and 2022, using the following search strategy: (TITLE-ABS-KEY ("Digitalization" AND Construction AND Management)).

The initial search resulted in 129 articles that met the criteria. Inclusion and exclusion criteria were applied to ensure that only relevant papers were selected. The criteria stipulated that the articles must be in English and deal with engineering. Any papers that did not meet these criteria were discarded. The review specifically focused on digitalization in project management, analyzing pertinent academic journals and conference papers. Despite the thorough search, not all of the articles that were found appeared to be pertinent to the study's specific focus. Therefore, the researcher used a content review approach to further filter and select the most relevant papers for the investigation.

The content review approach involved a three-step process. First, the researcher examined the article's topical relevance to the study. Second, the researcher analyzed the abstract to determine whether the article provided sufficient information related to the study's focus. Finally, the researcher reviewed the article's findings as they were reported in the literature. After applying the content review approach, a total of 21 papers were selected for examination. These papers were analyzed in detail, and their findings were synthesized to develop a comprehensive understanding of the advantages of digitalization in project management in the construction industry.

To ensure the reliability of the literature review, the researcher used a systematic approach to the search, screening, and selection of articles(citation). The inclusion and exclusion criteria were clearly defined and consistently applied throughout the study. The content review approach provided a structured and transparent method for selecting the most relevant papers for the investigation.

The primary research themes regarding the effects of digitalization on project management were identified and categorised in this study, with the hopes that the findings will help other researchers better understand current events, trends, and potential areas for research and innovation in the AEC industry.

3. RESULT AND DISCUSSION

3.1 Qualitative Analysis and Discussion

3.1.1 The state-of-art of Digitalization in project management

Digitalization in project management is a growing trend that is transforming the Architecture, Engineering, Construction, and Facility Management (AEC-FM) sector in many ways. Digital technologies, such as IoT, UAVs, 3D printing, AR, VR, MR, BIM, AI, and DSS, are increasingly being used to solve problems with cost, rework, efficiency, safety, quality, and productivity (Nikmehr et al., 2021). Web-based project systems, digital meetings, and BIM have been available for some time, but they are not always fully utilized. However, the right digitalization approach can reverse productivity declines, and European Directives for Procurement are pushing for more radical digital transformations with support for R&D and training (Prebanić and Vukomanović, 2021).

Project managers are responsible for determining how to use ICT tools to involve project stakeholders effectively, and there is extensive research on the digitalization of construction project management practices (Prebanić and Vukomanović, 2021). Digital technology has been used in the construction industry in the past, but its scope was limited due to technological constraints. However, advancements in processing power have given construction organizations the opportunity to combine their skills and enhance their processes using digital technology (Lundberg, Nylén and Sandberg, 2022).

Digital twins, which are virtual replicas of physical things that faithfully reproduce all of their properties, including how they behave under actual use-case scenarios, can aid in the integration of various information technologies into a single digital platform and twin for construction projects (Ryzhakova *et al.,* 2022). Reality Capture (RC), a valuable tool for construction project management, can increase project efficiency, correctness, value, and safety by incorporating building geometry, build typology, and material amounts in 3D models (Fobiri, Musonda and Muleya, 2022). Similarly, laser scanning, which is safe and non-invasive and efficiently and precisely organizes space, is gaining popularity in the fields of design, engineering, and construction, all of which contribute to the achievement of sustainable development goals (Fobiri, Musonda and Muleya, 2022). Digital technologies are having an increasingly negative impact on the AEC-FM sector in two ways: the monitoring of sensor network data and the easy management of automation systems (Hosamo *et al.,* 2022).

Both industrialized and developing countries have adopted sustainable construction techniques, such as green roofs and structures, modular construction, information modeling, and smart building technology (SBT), to improve their processes (Ejidike and Mewomo, 2023).

3.1.2 The impacts of Digitalization in project management

As technology has advanced, building experts have increasingly used it to improve energy management, environmental protection, economic efficiency, and human comfort (Ejidike and Mewomo, 2023). By encouraging sustainable construction methods that limit waste output, maximize resource consumption, and minimize environmental effect, smart building technology adoption benefits professionals, clients, and the nation as a whole in developing countries (Ejidike and Mewomo, 2023). For the purpose of enhancing and facilitating a specific activity, new digital technologies like computer modeling, digitalization, and creative business processes are being developed (Brooks, Zantinge and Elghaish, 2022).

Digitalization has the ability to improve project management and delivery through the use of construction or document software solutions, which includes contractor, document management, process management, and activity monitoring and oversight (Qais K. Jahanger *et al.,* 2021). A construction company must have a strong commitment to change in order to achieve real digital transformation, as opposed to running analogue and digital systems in parallel. It also needs to develop and implement a defined digitalization transition strategy (Nikmehr *et* *al.,* 2021). BIM and other digital technologies have been utilized successfully in construction projects all around the world, showcasing their capacity to manage multidisciplinary teams, spot conflicts, and minimize rework in significant projects (Nikmehr *et al.,* 2021).

The development of 3D models made possible by the application of RC technologies in construction management provides clients, consultants, and contractors with a singular learning chance to interact with and define faults, structural analyses, constructability challenges, risks, and costs in real-time, in a secure, hazard-free environment (Fobiri, Musonda and Muleya, 2022). Although Big Data technology can assist with analysis and processing of the large and complex datasets created by construction projects, it is still difficult to integrate data from various automated systems to create a digital twin (Ryzhakova *et al.,* 2022). The Digital Twin can interact with other simulators and programs by incorporating data and information from throughout an asset's existence, making it a crucial decision-making tool for the duration of the asset (Hosamo *et al.,* 2022).

In order to meet market demand and improve their value offer, the UK's changing construction agenda is encouraging construction companies to adopt new business models that make use of digital technology and manufacturing processes to develop and deliver whole life value (Çıdık and Boyd, 2022). The construction industry's methods for generating and capturing value change as a result of digitalization, which causes a transition from project-based logic to production-based logic (Çıdık and Boyd, 2022). The construction industry's interdisciplinary, dispersed, and temporary project organizations, as well as the interdependencies between stakeholders, add complexity and make it difficult to meet project requirements for cost, time, and productivity. This calls for improved integration, cooperation, interaction, and coordination (Prebanić and Vukomanović, 2021).

3.1.3 How Digitalization impacts on Project Management

The push for digitization in construction highlights the need for change in the way construction is planned and carried out (Brooks, Zantinge and Elghaish, 2022). Digitalization in construction practices uses digital technologies to create new organizational practices (Lundberg, Nylén and Sandberg, 2022). A digital representation of the real world can be made using Reality Capture (RC) technology, making it easier to plan, oversee, and evaluate construction, engineering, and architectural projects (Fobiri, Musonda and Muleya, 2022). The use of digital models of buildings and planned project activities can support tasks at different levels, such as transaction conclusion, securing investment support, and thorough assessments of capital construction objects (Ekaterina Tereshko, 2021). Building assets must be managed, and facility management (FM) calls for handling a lot of data, which is currently kept in paper documents that are prone to theft (Siccardi and Villa, 2023).

Through the seamless integration of information using information-based systems like Building Information Modeling (BIM), AEC-FM operations can be improved, projects can be more efficiently completed, and their efficacy over their whole lifespan can be increased (Hosamo *et al.,* 2022). Throughout the entire building construction process, risk prevention and safety planning have advanced significantly thanks to the use of BIM methods and digital twins, which enable accurate data collection and 3D visualization (Torrecilla-García, J., Pardo-Ferreira, M., Rubio-Romero,J., 2021). A technology was created to build and analyse models of control processes as well as create strategies and tactics to apply the findings to real-world demands (Ereshko *et al.,* 2022). Digital construction-phase information management (DCIM) systems can be an effective solution for reversing the fall in productivity in the construction industry, however certain governmental agencies have not yet completely adopted this technology (Qais K. Jahanger *et al.,* 2021). An information system with an intuitive design and standardized methods for data extraction, transformation, and loading can guarantee the long-term archiving, updating, and synchronization of metadata and data from different information systems while also safeguarding it from unauthorized access by other project participants (Ryzhakova *et al.,* 2022).

Convenience, cost savings, a wider range of options, greater information, improved sustainability, higher communication quality, increased customer satisfaction, and success of economic models and investments are just a few of the advantages that digitalization brings to industries (Nikmehr *et al.,* 2021). The construction industry's interdisciplinary, dispersed, and temporary project organizations, as well as the interdependencies between stakeholders, add complexity and make it difficult to meet project requirements for cost, time, and productivity. This calls for improved integration, cooperation, interaction, and coordination (Prebanić and Vukomanović, 2021). Because of the intricate nature of projects and the involvement of several contracting parties with potentially competing interests, stakeholder management, which includes stakeholder analysis and engagement, is essential in the construction industry (Prebanić and Vukomanović, 2021).

To ensure the adoption of smart building technology in underdeveloped countries, it is essential to fully comprehend its benefits, make the concept more familiar to building experts, and promote its successful use in those areas (Ejidike and Mewomo, 2023). The current emphasis on digitization in the agenda for transforming construction assumes that integrated digital technologies can identify coordination issues and enable better inter-organizational cooperation, but this perspective poorly articulates how value is formed and ignores the practical difficulties of digitization (Çıdık and Boyd, 2022).

4. RECOMMENDATIONS AND DIRECTIONS FOR FUTURE RESEARCH

Digital technologies have disrupted many industries, and project management is no exception. Digitalization has enabled project managers to leverage new tools and techniques to improve project outcomes and collaboration, but it has also brought new challenges related to data privacy, security, and governance. To address these challenges and leverage the benefits of digitalization, there is a need for further research in the impacts of digitalization in project management. This article provides recommendations and directions for future research in this field.

The first recommendation is to investigate the adoption rate of digital technologies in project management and identify factors influencing its adoption. This research can provide insights into the current state-of-art of digitalization in project management and help project managers understand the factors that drive or hinder its adoption. For example, research could explore the impact of organizational culture, leadership support, and digital competencies on adopting digital technologies in project management.

The second recommendation is to examine the role of digital technologies in enabling remote project management and explore the impact on team collaboration and communication. With the rise of remote work, project managers need to adapt to new ways of working and leverage digital technologies to collaborate effectively with team members who are geographically dispersed. Research could explore the impact of digital tools such as video conferencing, instant messaging, and collaboration platforms on team communication, collaboration, and performance.

The third recommendation is to analyze the impact of digitalization on project outcomes, including project completion time, cost, quality, and scope. Digital technologies can potentially improve project outcomes by enabling more efficient and effective project planning, execution, monitoring, and control. However, research is needed to understand the specific impact of digital technologies on different project outcomes and to identify best practices for leveraging digital technologies to improve project outcomes.

The fourth recommendation is to investigate the impact of digital technologies on project risk management, including identifying, assessing, and mitigating risks. Digital technologies can enable more effective risk management by providing project managers with real-time data and insights into project risks. Research could explore the impact of digital tools such as risk management software, predictive analytics, and machine learning on project risk management and identify best practices for leveraging these tools to mitigate project risks.

The fifth recommendation is to explore the impact of digitalization on project management processes, including project planning, execution, monitoring, and control. Digital technologies can enable more efficient and effective project management processes by automating tasks, providing real-time data, and enabling more effective collaboration. Research could explore the impact of digital tools such as project management software, project management dashboards, and agile methodologies on project management processes and identify best practices for leveraging these tools to improve project management processes.

5. CONCLUSION

In this systematic review, the aim was to investigate the impacts of digitalization on project management in the construction industry. The study revealed both the challenges faced during the implementation of digitalization, such as high costs and sustainability issues, and the positive outcomes resulting from the adoption of digital technologies. Through a comprehensive analysis of 21 papers, the study identified key research themes highlighting the transformative potential of digital tools like smart building technology, digital twins, reality capture, and laser scanning. These technologies have proven to enhance project management by increasing efficiency, accuracy, value, and safety.

The findings emphasize the need for the construction industry to fully embrace digitalization. Integrating Building Information Modelling (BIM) and other digital tools facilitates effective information sharing, enabling collaborative and multidisciplinary workflows throughout the construction lifecycle. Additionally, Construction Automation and Robotics (CAR) are emerging as essential components in sustainable construction practices. To successfully leverage digitalization, organizations must adopt a defined digitalization transition strategy and genuinely commit to a digital transformation, considering the organization's structure, nature of work, and human resource characteristics.

Looking ahead, further research is recommended to explore the adoption rate of digital technologies in project management and the factors influencing their successful implementation. Understanding the role of digital technologies in enabling remote project management and their impact on team collaboration and communication is crucial in adapting to evolving work practices. Moreover, in-depth analysis of the impact of digitalization on project outcomes, risk management, and project management processes will provide valuable insights and best practices for the industry. Ultimately, embracing digitalization presents not only a necessity but also an opportunity for the construction industry to thrive in an increasingly digital world, delivering successful projects that meet the demands of a growing population and sustainability requirements.

EVALUATING THE COMPREHENSION OF CONSTRUCTION SCHEDULES OF AN ARTIFICIAL INTELLIGENCE

Tulio Sulbaran, Ph.D.

The University of Texas at San Antonio, Texas, United States.

ABSTRACT: *Construction schedules are an important tool to communicate with the project stakeholders and are critical for the project management team to plan, coordinate, and manage construction projects. Each construction project has a unique schedule that is created based on the construction drawings, specifications, contracting requirements, construction methods, and the judgment of the project management team. Therefore, each construction schedule is unique in many aspects such as the number of activities, the names of the activities, the duration of those activities, and the relationship between the activities. The names of the activities are of particular interest as they are the critical core unit to creating the schedule. Furthermore, the activities are the ones that bring together all other aspects of the schedule. Unfortunately, there is no standard naming conversion for those activities and they vary from project to project as well as from project management team to project management team. This inconsistency of the activity name makes it extremely challenging for both humans and machines to understand the meaning and scope of the activities. Thus, the problem that this paper addresses is the challenge faced by machines to comprehend the activities of a construction schedule. Therefore, the objective of this paper is to evaluate the ability of an Artificial Intelligence (AI) implementation to comprehend activities in a construction schedule. This research was conducted following a mixed research method. The AI implementation training was done by providing the Construction Specifications Institute (CSI) Master Format activity list to a Sentence Transformer. Then the AI was given the task of interpreting the activities of a construction schedule according to the 50 Divisions of the CSI Master Format. A group of senior construction students was also given the same interpretation task. The evaluation was done by comparing the results of the AI vs the humans for each of the activities in the construction schedule. The result was that the AI has 0.56 accuracy, 0.50 precision, 0.85 recall and, 0.64 F1 Score. This result is very promising and it supports further research to refine the AI to increase its ability to comprehend construction schedule activities. Upon achieving a higher level of comprehension an AI could be used to assist humans in the preparation of construction schedules or perhaps prepare drafts of the construction schedules for the human to review.*

KEYWORDS: *Construction Scheduling, Decision Support, Artificial Intelligence, Comprehension*

1. BACKGROUND
